Note that this may raise NotImplementedError on Unix platforms like Mac OS X where sem_getvalue() is not implemented.

empty()
Return True if the queue is empty, False otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

full()
Return True if the queue is full, False otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

put(item[, block[, timeout]])
Put item into the queue. If the optional argument block is True
(the default) and $timeout$ is None (the default), block if necessary until a free slot is available. If $timeout$ is a positive number, it blocks at most $timeout$ seconds and raises the Queue.Full exception if no free slot was available within that time. Otherwise ($block$ is False), put an item on the queue if a free slot is immediately available, else raise the Queue.Full exception ($timeout$ is ignored in that case).

**put_nowait(item)**
Equivalent to put(item, False).

**get([block[ , timeout]])**
Remove and return an item from the queue. If optional args $block$ is True (the default) and $timeout$ is None (the default), block if necessary until an item is available. If $timeout$ is a positive number, it blocks at most $timeout$ seconds and raises the Queue.Empty exception if no item was available within that time. Otherwise ($block$ is False), return an item if one is immediately available, else raise the Queue.Empty exception ($timeout$ is ignored in that case).

**get_nowait()**
**get_no_wait()**
Equivalent to get(False).

**multiprocessing.Queue** has a few additional methods not found in Queue.Queue. These methods are usually unnecessary for most code:

**close()**
Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.
join_thread()
Join the background thread. This can only be used after close() has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue’s background thread. The process can call cancel_join_thread() to make join_thread() do nothing.

cancel_join_thread()
Prevent join_thread() from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see join_thread().

class multiprocessing. JoinableQueue([maxsize])
JoinableQueue, a Queue subclass, is a queue which additionally has task_done() and join() methods.

task_done()
Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each get() used to fetch a task, a subsequent call to task_done() tells the queue that the processing on the task is complete.

If a join() is currently blocking, it will resume when all items have been processed (meaning that a task_done() call was received for every item that had been put() into the queue).

Raises a ValueError if called more times than there were items placed in the queue.
join()
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

**Miscellaneous**

`multiprocessing.active_children()`
Return list of all live children of the current process.

Calling this has the side affect of “joining” any processes which have already finished.

`multiprocessing.cpu_count()`
Return the number of CPUs in the system. May raise `NotImplementedError`.

`multiprocessing.current_process()`
Return the `Process` object corresponding to the current process.

An analogue of `threading.current_thread()`.

`multiprocessing.freeze_support()`
Add support for when a program which uses `multiprocessing` has been frozen to produce a Windows executable. (Has been tested with `py2exe`, `PyInstaller` and `cx_Freeze`).

One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:
```python
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is missed out then trying to run the frozen executable will raise `RuntimeError`.

If the module is being run normally by the Python interpreter then `freeze_support()` has no effect.

`multiprocessing.set_executable()`

Sets the path of the python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```python
setExecutable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes. (Windows only)

**Note:** `multiprocessing` contains no analogues of `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, or `threading.local`.

**Connection Objects**

Connection objects allow the sending and receiving of picklable
objects or strings. They can be thought of as message oriented connected sockets.

Connection objects usually created using `Pipe()` – see also *Listeners and Clients*.

class `multiprocessing.Connection`

    `send(obj)`
    Send an object to the other end of the connection which should be read using `recv()`.

    The object must be picklable.

    `recv()`
    Return an object sent from the other end of the connection using `send()`. Raises `EOFError` if there is nothing left to receive and the other end was closed.

    `fileno()`
    Returns the file descriptor or handle used by the connection.

    `close()`
    Close the connection.

    This is called automatically when the connection is garbage collected.

    `poll([timeout])`
    Return whether there is any data available to be read.

    If `timeout` is not specified then it will return immediately. If `timeout` is a number then this specifies the maximum time in seconds to block. If `timeout` is `None` then an infinite timeout is used.
**send_bytes**(buffer[, offset[, size]])

Send byte data from an object supporting the buffer interface as a complete message.

If offset is given then data is read from that position in buffer. If size is given then that many bytes will be read from buffer.

**recv_bytes**(maxlength)

Return a complete message of byte data sent from the other end of the connection as a string. Raises `EOFError` if there is nothing left to receive and the other end has closed.

If maxlength is specified and the message is longer than maxlength then `IOError` is raised and the connection will no longer be readable.

**recv_bytes_into**(buffer[, offset])

Read into buffer a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Raises `EOFError` if there is nothing left to receive and the other end was closed.

buffer must be an object satisfying the writable buffer interface. If offset is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the *length of *buffer (in bytes).

If the buffer is too short then a `BufferTooShort` exception is raised and the complete message is available as `e.args[0]` where `e` is the exception instance.

For example:

```python
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
```
```python
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes('thank you')
>>> a.recv_bytes()
'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

**Warning:** The `Connection.recv()` method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message. Therefore, unless the connection object was produced using `Pipe()` you should only use the `recv()` and `send()` methods after performing some sort of authentication. See *Authentication keys*.

**Warning:** If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

**Synchronization primitives**

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for `threading` module.

Note that one can also create synchronization primitives by using a manager object – see *Managers*.

class multiprocessing.BoundedSemaphore([value])

A bounded semaphore object: a clone of
threading.BoundedSemaphore.

(On Mac OS X this is indistinguishable from Semaphore because sem_getvalue() is not implemented on that platform).

class multiprocessing.

**Condition**([lock])

If lock is specified then it should be a Lock or RLock object from multiprocessing.

class multiprocessing.

**Event**

A clone of threading.Event.

class multiprocessing.

**Lock**

A non-recursive lock object: a clone of threading.Lock.

class multiprocessing.

**RLock**

A recursive lock object: a clone of threading.RLock.

class multiprocessing.

**Semaphore**([value])

A bounded semaphore object: a clone of threading.Semaphore.

**Note:** The acquire() method of BoundedSemaphore, Lock, RLock and Semaphore has a timeout parameter not supported by the equivalents in threading. The signature is acquire(block=True, timeout=None) with keyword parameters being acceptable. If block is True and timeout is not None then it specifies a timeout in seconds. If block is False then timeout is ignored.

**Note:** If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to BoundedSemaphore.acquire(), Lock.acquire(), RLock.acquire(), Semaphore.acquire(),
Condition.acquire() or Condition.wait() then the call will be immediately interrupted and KeyboardInterrupt will be raised. This differs from the behaviour of threading where SIGINT will be ignored while the equivalent blocking calls are in progress.

### Shared ctypes Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

**Value(typecode_or_type[, *args, lock])**

Return a ctypes object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object.

*typecode_or_type* determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the array module. *args* is passed on to the constructor for the type.

If lock is True (the default) then a new lock object is created to synchronize access to the value. If lock is a Lock or RLock object then that will be used to synchronize access to the value. If lock is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that lock is a keyword-only argument.

**multiprocessing.Array(typecode_or_type, size_or_initializer, *, lock=True)**

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

*typecode_or_type* determines the type of the elements of the
returned array: it is either a ctypes type or a one character
typecode of the kind used by the array module. If
size_or_initializer is an integer, then it determines the length of
the array, and the array will be initially zeroed. Otherwise,
size_or_initializer is a sequence which is used to initialize the
array and whose length determines the length of the array.

If lock is True (the default) then a new lock object is created to
synchronize access to the value. If lock is a Lock or RLock object
then that will be used to synchronize access to the value. If lock
is False then access to the returned object will not be
automatically protected by a lock, so it will not necessarily be
“process-safe”.

Note that lock is a keyword only argument.

Note that an array of ctypes.c_char has value and rawvalue
attributes which allow one to use it to store and retrieve strings.

The multiprocessing.sharedctypes module

The multiprocessing.sharedctypes module provides functions for
allocating ctypes objects from shared memory which can be
inherited by child processes.

Note: Although it is possible to store a pointer in shared memory
remember that this will refer to a location in the address space of a
specific process. However, the pointer is quite likely to be invalid in
the context of a second process and trying to dereference the
pointer from the second process may cause a crash.

multiprocessing.sharedctypes.RawArray(typecode_or_type,
size_or_initializer)

Return a ctypes array allocated from shared memory.
`typecode_or_type` determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If `size_or_initializer` is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise `size_or_initializer` is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

```python
def RawValue(typecode_or_type, *args):
    return multiprocessing.sharedctypes.RawValue(typecode_or_type, *args)
```

Return a ctypes object allocated from shared memory. `typecode_or_type` determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the `array` module. `*args` is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `rawvalue` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

```python
def Array(typecode_or_type,
         size_or_initializer[, *args[, lock]]))
```

The same as `RawArray()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes array.
If `lock` is True (the default) then a new lock object is created to synchronize access to the value. If `lock` is a Lock or RLock object then that will be used to synchronize access to the value. If `lock` is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```python
multiprocessing.sharedctypes.Value(typecode_or_type, *args[, lock])
```

The same as RawValue() except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If `lock` is True (the default) then a new lock object is created to synchronize access to the value. If `lock` is a Lock or RLock object then that will be used to synchronize access to the value. If `lock` is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```python
multiprocessing.sharedctypes.copy(obj)
```

Return a ctypes object allocated from shared memory which is a copy of the ctypes object `obj`.

```python
multiprocessing.sharedctypes.synchronized(obj[, lock])
```

Return a process-safe wrapper object for a ctypes object which uses `lock` to synchronize access. If `lock` is None (the default) then a multiprocessing.RLock object is created automatically.

A synchronized wrapper will have two methods in addition to
those of the object it wraps: \texttt{get\_obj()} returns the wrapped object and \texttt{get\_lock()} returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table \texttt{MyStruct} is some subclass of \texttt{ctypes.Structure}.)

<table>
<thead>
<tr>
<th>ctypes</th>
<th>sharedctypes using type</th>
<th>sharedctypes using typecode</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_double(2.4)</td>
<td>\texttt{RawValue(c_double, 2.4)}</td>
<td>\texttt{RawValue('d', 2.4)}</td>
</tr>
<tr>
<td>MyStruct(4, 6)</td>
<td>\texttt{RawValue(MyStruct, 4, 6)}</td>
<td></td>
</tr>
<tr>
<td>(c_short * 7)()</td>
<td>\texttt{RawArray(c_short, 7)}</td>
<td>\texttt{RawArray('h', 7)}</td>
</tr>
<tr>
<td>(c_int * 3)(9, 2, 8)</td>
<td>\texttt{RawArray(c_int, (9, 2, 8))}</td>
<td>\texttt{RawArray('i', (9, 2, 8))}</td>
</tr>
</tbody>
</table>

Below is an example where a number of ctypes objects are modified by a child process:

```python
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()
```
Managers

Managers provide a way to create data which can be shared between different processes. A manager object controls a server process which manages shared objects. Other processes can access the shared objects by using proxies.

multiprocessing.Manager()

Returns a started SyncManager object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the multiprocessing.managers module:
class multiprocessing.managers.BaseManager([address[, authkey]])

Create a BaseManager object.

Once created one should call start() or serve_forever() to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If address is None then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If authkey is None then current_process().authkey is used and it must be a string.

start()
    Start a subprocess to start the manager.

serve_forever()
    Run the server in the current process.

from_address(address, authkey)
    A class method which creates a manager object referring to a pre-existing server process which is using the given address and authentication key.

shutdown()
    Stop the process used by the manager. This is only available if start() has been used to start the server process.

    This can be called multiple times.

register(typeid[, callable[, proxytype[, exposed[, target, protocol]]]])
A classmethod which can be used for registering a type or callable with the manager class.

`typeid` is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

`callable` is a callable used for creating objects for this type identifier. If a manager instance will be created using the `from_address()` classmethod or if the `create_method` argument is `False` then this can be left as `None`.

`proxytype` is a subclass of `BaseProxy` which is used to create proxies for shared objects with this `typeid`. If `None` then a proxy class is created automatically.

`exposed` is used to specify a sequence of method names which proxies for this typeid should be allowed to access using `BaseProxy._callMethod()`. (If `exposed` is `None` then `proxytype._exposed_` is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a `__call__()` method and whose name does not begin with `_`.)

`method_to_typeid` is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If `method_to_typeid` is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method’s name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

`create_method` determines whether a method should be
created with name typeid which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is True.

BaseManager instances also have one read-only property:

dcld

address

The address used by the manager.

class multiprocessing.managers. SyncManager

A subclass of BaseManager which can be used for the synchronization of processes. Objects of this type are returned by multiprocessing.Manager().

It also supports creation of shared lists and dictionaries.

BoundedSemaphore([value])

Create a shared threading.BoundedSemaphore object and return a proxy for it.

Condition([lock])

Create a shared threading.Condition object and return a proxy for it.

    If lock is supplied then it should be a proxy for a threading.Lock or threading.RLock object.

Event()

Create a shared threading.Event object and return a proxy for it.

Lock()

Create a shared threading.Lock object and return a proxy for it.
**Namespace()**
Create a shared `Namespace` object and return a proxy for it.

**Queue([maxsize])**
Create a shared `queue.Queue` object and return a proxy for it.

**RLock()**
Create a shared `threading.RLock` object and return a proxy for it.

**Semaphore([value])**
Create a shared `threading.Semaphore` object and return a proxy for it.

**Array(typecode, sequence)**
Create an array and return a proxy for it.

**Value(typecode, value)**
Create an object with a writable `value` attribute and return a proxy for it.

**dict()**
**dict(mapping)**
**dict(sequence)**
Create a shared `dict` object and return a proxy for it.

**list()**
**list(sequence)**
Create a shared `list` object and return a proxy for it.

### Namespace objects

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.
However, when using a proxy for a namespace object, an attribute beginning with `'_'_` will be an attribute of the proxy and not an attribute of the referent:

```python
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3  # this is an attribute of the proxy
>>> print Global
Namespace(x=10, y='hello')
```

### Customized managers

To create one's own manager, one creates a subclass of `BaseManager` and use the `register()` classmethod to register new types or callables with the manager class. For example:

```python
from multiprocessing.managers import BaseManager

class MathsClass(object):
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    manager = MyManager()
    manager.start()
    maths = manager.Maths()
    print maths.add(4, 3)  # prints 7
    print maths.mul(7, 8)  # prints 56
```

### Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls
involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```plaintext
>>> from multiprocessing.managers import BaseManager
>>> import Queue
>>> class QueueManager(BaseManager): pass
...>>> QueueManager.register('getQueue', callable=lambda:queue)
>>> m = QueueManager(address=('', 50000), authkey='abracadabra')
>>> m.serveForever()
```

One client can access the server as follows:

```plaintext
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
...>>> QueueManager.register('getQueue')
>>> m = QueueManager.from_address(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> queue = m.getQueue()
>>> queue.put('hello')
```

Another client can also use it:

```plaintext
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
...>>> QueueManager.register('getQueue')
>>> m = QueueManager.from_address(address=('foo.bar.org', 50000), authkey='abracadabra')
>>> queue = m.getQueue()
>>> queue.get()
'hello'
```

Proxy Objects

A proxy is an object which refers to a shared object which lives (presumably) in a different process. The shared object is said to be
the referent of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). A proxy can usually be used in most of the same ways that its referent can:

```python
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0xb799974c>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying str() to a proxy will return the representation of the referent, whereas applying repr() will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. Note, however, that if a proxy is sent to the corresponding manager’s process then unpickling it will produce the referent itself. This means, for example, that one shared object can contain a second:

```python
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)  # referent of a now contains referent of b
>>> print(a, b)
[[[]]] [[]]
>>> b.append('hello')
>>> print(a, b)
[['hello']] ['hello']
```
Note: The proxy types in multiprocessing do nothing to support comparisons by value. So, for instance,

```python
manager.list([1,2,3]) == [1,2,3]
```

will return False. One should just use a copy of the referent instead when making comparisons.

class multiprocessing.managers.BaseProxy

Proxy objects are instances of subclasses of BaseProxy.

```python
__call_method__(methodname[, args[, kwds]])
```

Call and return the result of a method of the proxy's referent.

If proxy is a proxy whose referent is obj then the expression

```python
proxy.__call_method__(methodname, args, kwds)
```

will evaluate the expression

```python
getattr(obj, methodname)(*args, **kwds)
```

in the manager’s process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the method_to_typeid argument of BaseManager.register().

If an exception is raised by the call, then then is re-raised by __call_method__. If some other exception is raised in the manager's process then this is converted into a RemoteError exception and is raised by __call_method__.

Note in particular that an exception will be raised if
methodname has not been exposed

An example of the usage of _call_method():

```python
>>> l = manager.list(range(10))
>>> l._call_method('__len__')
10
>>> l._call_method('__getslice__', (2, 7))  # equiv to l[2:7]  
[2, 3, 4, 5, 6]
>>> l._call_method('__getitem__', (20,))  # equiv to l[20]  
...
IndexError: list index out of range
```

__get_value__

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

__repr__

Return a representation of the proxy object.

__str__

Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

Process Pools
One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

```python
class multiprocessing.Pool([processes[, initializer[, initargs]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

`processes` is the number of worker processes to use. If `processes` is `None` then the number returned by `cpu_count()` is used. If `initializer` is not `None` then each worker process will call `initializer(*initargs)` when it starts.

```python
apply(func[, args[, kwds]])
```
Equivalent of the `apply()` builtin function. It blocks till the result is ready.

```python
apply_async(func[, args[, kwds[, callback]]])
```
A variant of the `apply()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it (unless the call failed). `callback` should complete immediately since otherwise the thread which handles the results will get blocked.

```python
map(func, iterable[, chunksize])
```
A parallel equivalent of the `map()` builtin function. It blocks till the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by
setting `chunksize` to a positive integer.

```python
map_async(func, iterable[, chunksize[, callback]])
```

A variant of the `map()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it (unless the call failed). `callback` should complete immediately since otherwise the thread which handles the results will get blocked.

```python
imap(func, iterable[, chunksize])
```

An equivalent of `itertools.imap()`.

The `chunksize` argument is the same as the one used by the `map()` method. For very long iterables using a large value for `chunksize` can make make the job complete much faster than using the default value of 1.

Also if `chunksize` is 1 then the `next()` method of the iterator returned by the `imap()` method has an optional `timeout` parameter: `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within `timeout` seconds.

```python
imap_unordered(func, iterable[, chunksize])
```

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

```python
close()
```

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker
processes will exit.

terminate()
   Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected terminate() will be called immediately.

join()
   Wait for the worker processes to exit. One must call close() or terminate() before using join().

class multiprocessing.pool.AsyncResult
   The class of the result returned by Pool.apply_async() and Pool.map_async().

get([timeout])
   Return the result when it arrives. If timeout is not None and the result does not arrive within timeout seconds then multiprocessing.TimeoutError is raised. If the remote call raised an exception then that exception will be reraised by get().

wait([timeout])
   Wait until the result is available or until timeout seconds pass.

ready()
   Return whether the call has completed.

successful()
   Return whether the call completed without raising an exception. Will raise AssertionError if the result is not ready.

The following example demonstrates the use of a pool:

```python
from multiprocessing import Pool
```
def f(x):
    return x**x

if __name__ == '__main__':
    pool = Pool(processes=4)  # start 4 worker processes
    result = pool.applyAsync(f, (10,))  # evaluate "f(10)" asynchronously
    print(result.get(timeout=1))  # prints "100" unless your computer is *very* slow

    print(pool.map(f, range(10)))  # prints "[0, 1, 4,...

    it = pool.imap(f, range(10))
    print(it.next())  # prints "0"
    print(it.next())  # prints "1"
    print(it.next(timeout=1))  # prints "4" unless your computer is *very* slow

import time
result = pool.applyAsync(time.sleep, (10,))
print(result.get(timeout=1))  # raises TimeoutError

Listeners and Clients

Usually message passing between processes is done using queues or by using Connection objects returned by Pipe().

However, the multiprocessing.connection module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes, and also has support for digest authentication using the hmac module.

multiprocessing.connection.deliver_challenge(connection, authkey)

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using authkey as the key then a welcome message is sent to the other end of the connection. Otherwise AuthenticationError is raised.
multiprocessing.connection.\texttt{answerChallenge}(\texttt{connection}, \texttt{authkey})

Receive a message, calculate the digest of the message using \texttt{authkey} as the key, and then send the digest back.

If a welcome message is not received, then \texttt{AuthenticationError} is raised.

multiprocessing.connection.\texttt{Client}(\texttt{address}[, \texttt{family}[, \texttt{authenticate}[, \texttt{authkey}]])

Attempt to set up a connection to the listener which is using address \texttt{address}, returning a \texttt{Connection}.

The type of the connection is determined by \texttt{family} argument, but this can generally be omitted since it can usually be inferred from the format of \texttt{address}. (See \texttt{Address Formats})

If \texttt{authentication} is \texttt{True} or \texttt{authkey} is a string then digest authentication is used. The key used for authentication will be either \texttt{authkey} or \texttt{current_process().authkey} if \texttt{authkey} is \texttt{None}. If authentication fails then \texttt{AuthenticationError} is raised. See \texttt{Authentication keys}.

class multiprocessing.connection.\texttt{Listener}([\texttt{address}[, \texttt{family}[[, \texttt{backlog}[[, \texttt{authenticate}[[, \texttt{authkey}]]]]]])

A wrapper for a bound socket or Windows named pipe which is ‘listening’ for connections.

\texttt{address} is the address to be used by the bound socket or named pipe of the listener object.

\texttt{family} is the type of socket (or named pipe) to use. This can be one of the strings \texttt{'AF_INET'} (for a TCP socket), \texttt{'AF_UNIX'} (for a
Unix domain socket) or 'AF_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If family is `None` then the family is inferred from the format of address. If address is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if family is 'AF_UNIX' and address is `None` then the socket will be created in a private temporary directory created using `tempfile.mkstemp()`.

If the listener object uses a socket then backlog (1 by default) is passed to the `listen()` method of the socket once it has been bound.

If `authenticate` is `True` (False by default) or `authkey` is not `None` then digest authentication is used.

If `authkey` is a string then it will be used as the authentication key; otherwise it must be `None`.

If `authkey` is `None` and `authenticate` is `True` then `current_process().authkey` is used as the authentication key. If `authkey` is `None` and `authentication` is `False` then no authentication is done. If authentication fails then `AuthenticationError` is raised. See *Authentication keys*.

**accept()**

Accept a connection on the bound socket or named pipe of the listener object and return a `Connection` object. If authentication is attempted and fails, then `AuthenticationError` is raised.

**close()**

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage
collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

**address**

The address which is being used by the Listener object.

**last_accepted**

The address from which the last accepted connection came. If this is unavailable then it is None.

The module defines two exceptions:

**exception** multiprocessing.connection.**AuthenticationError**

Exception raised when there is an authentication error.

**Examples**

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client:

```python
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)  # family is deduced to be 'AF
listener = Listener(address, authkey='secret password')

conn = listener.accept()
print 'connection accepted from', listener.last_accepted

conn.send([2.25, None, 'junk', float])
conn.send_bytes('hello')
conn.send_bytes(array('i', [42, 1729]))
conn.close()
listener.close()
```

The following code connects to the server and receives some data
from the server:

```python
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)
conn = Client(address, authkey='secret password')

print conn.recv()  # => [2.25, None, 'junk', float]
print conn.recv_bytes()  # => 'hello'

arr = array('i', [0, 0, 0, 0, 0])
print conn.recv_bytes_into(arr)  # => 8
print arr  # => array('i', [42, 1729, 0, 0, 0])

conn.close()
```

### Address Formats

- An 'AF_INET' address is a tuple of the form `(hostname, port)` where `hostname` is a string and `port` is an integer.

- An 'AF_UNIX' address is a string representing a filename on the filesystem.

- An 'AF_PIPE' address is a string of the form `r'\\\pipe\PipeName'`. To use `Client()` to connect to a named pipe on a remote computer called `ServerName*` one should use an address of the form `r'\\\ServerName\pipe\PipeName'` instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

### Authentication keys
When one uses `Connection.recv()`, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore `Listener` and `Client()` use the `hmac` module to provide digest authentication.

An authentication key is a string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but do authentication key is specified then the return value of `current_process().authkey` is used (see `Process`). This value will automatically inherited by any `Process` object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between the themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

### Logging

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and has a
handler which sends output to `sys.stderr` using format `{levelname}/%(processName)s: %(message)s`. (The logger allows use of the non-standard `%(processName)s` format.) Message sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process’s logger – any other customization of the logger will not be inherited.

Below is an example session with logging turned on:

```python
>>> import processing, logging
>>> logger = processing.getLogger()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = processing.Manager()
[INFO/SyncManager-1] child process calling self.run()
[INFO/SyncManager-1] manager bound to '\\.\\pipe\pyc-2776-0-
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-1] manager exiting with exitcode 0
```

The `multiprocessing.dummy` module

`multiprocessing.dummy` replicates the API of `multiprocessing` but is no more than a wrapper around the `threading` module.
Programming guidelines

There are certain guidelines and idioms which should be adhered to when using `multiprocessing`.

All platforms

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives from the `threading` module.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the same proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be
joined. Also calling a finished process’s `Process.is_alive()` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

On Windows many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which need access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the `Process.terminate()` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate()` on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread()` method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the
queue will terminate. Remember also that non-daemonic processes will be automatically be joined.

An example which will deadlock is the following:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()  # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines round (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```python
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...
```
should be rewritten as

```python
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

**Windows**

Since Windows lacks `os.fork()` it has a few extra restrictions:

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. This means, in particular, that bound or unbound methods cannot be used directly as the `target` argument on Windows — just define a function and use that instead.

Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start()` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start()` was called.

However, global variables which are just module level constants
cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, under Windows running the following module would fail with a `RuntimeError`:

```python
from multiprocessing import Process

def foo():
    print 'hello'

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```python
from multiprocessing import Process, freeze_support

def foo():
    print 'hello'

if __name__ == '__main__':
    freeze_support()
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module’s `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.
Demonstration of how to create and use customized managers and proxies:

```python
# This module shows how to use arbitrary callables with a subclass of `BaseManager`.
#
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##
class Foo(object):
    def f(self):
        print 'you called Foo.f()'
    def g(self):
        print 'you called Foo.g()'
    def _h(self):
        print 'you called Foo._h()'

    # A simple generator function
    def baz():
        for i in xrange(10):
            yield i*i

    # Proxy type for generator objects
    class GeneratorProxy(BaseProxy):
        _exposed_ = ('next', '__next__')
        def __iter__(self):
            return self
        def next(self):
            return self._callmethod('next')
        def __next__(self):
            return self._callmethod('__next__')

    # Function to return the operator module
    def get_operator_module():
        return operator

##
```
class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print '-' * 20
    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

An example of how a pool of worker processes can each run a `SimpleHTTPServer.HttpServer` instance while sharing a single listening socket.

```python
import os
import sys
from multiprocessing import Process, current_process, freeze_support
from BaseHTTPServer import HTTPServer
from SimpleHTTPServer import SimpleHTTPRequestHandler

if sys.platform == 'win32':
    import multiprocessing.reduction  # make sockets pickable/inheritable

def note(format, *args):
    sys.stderr.write('[%s]	%s
' % (current_process().name, format%args))

class RequestHandler(SimpleHTTPRequestHandler):
    # we override log_message() to show which process is handling request
    def log_message(self, format, *args):
        note(format, *args)

def serve_forever(server):
    note('starting server')
    try:
        server.serve_forever()
    except KeyboardInterrupt:
        pass

def runpool(address, number_of_processes):
    # create a single server object -- children will each inherit
    server = HTTPServer(address, RequestHandler)

    # create child processes to act as workers
```

# Example where a pool of http servers share a single listening
# On Windows this module depends on the ability to pickle a socket
# object so that the worker processes can inherit a copy of the
# object. (We import `multiprocessing.reduction` to enable this)
# Not sure if we should synchronize access to `socket.accept()`
# using a process-shared lock -- does not seem to be necessary.

import os
import sys
from multiprocessing import Process, current_process, freeze_support
from BaseHTTPServer import HTTPServer
from SimpleHTTPServer import SimpleHTTPRequestHandler

if sys.platform == 'win32':
    import multiprocessing.reduction  # make sockets pickable/inheritable

def note(format, *args):
    sys.stderr.write('[%s]	%s
' % (current_process().name, format%args))

```
mmap — Memory-mapped file support

Memory-mapped file objects behave like both strings and like file objects. Unlike normal string objects, however, these are mutable. You can use mmap objects in most places where strings are expected; for example, you can use the re module to search through a memory-mapped file. Since they're mutable, you can change a single character by doing `obj[index] = 'a'`, or change a substring by assigning to a slice: `obj[i1:i2] = '...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

For both the Unix and Windows versions of the constructor, access may be specified as an optional keyword parameter. `access` accepts one of three values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively. `access` can be used on both Unix and Windows. If `access` is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a `TypeError` exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but
does not update the underlying file.

*Changed in version 2.5:* To map anonymous memory, -1 should be passed as the fileno along with the length.

*Changed in version 2.6:* mmap.mmap has formerly been a factory function creating mmap objects. Now mmap.mmap is the class itself.

class mmap.mmap(fileno, length[, tagname[, access[, offset]])

*(Windows version)* Maps length bytes from the file specified by the file handle fileno, and creates a mmap object. If length is larger than the current size of the file, the file is extended to contain length bytes. If length is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. offset defaults to 0. offset must be a multiple of the ALLOCATIONGRANULARITY.

class mmap.mmap(fileno, length[, flags[, prot[, access[, offset]]]])

*(Unix version)* Maps length bytes from the file specified by the file descriptor fileno, and returns a mmap object. If length is 0, the
maximum length of the map will be the current size of the file when `mmap` is called.

`flags` specifies the nature of the mapping. `MAP_PRIVATE` creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and `MAP_SHARED` creates a mapping that’s shared with all other processes mapping the same areas of the file. The default value is `MAP_SHARED`.

`prot`, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. `prot` defaults to `PROT_READ | PROT_WRITE`.

`access` may be specified in lieu of `flags` and `prot` as an optional keyword parameter. It is an error to specify both `flags`, `prot` and `access`. See the description of `access` above for information on how to use this parameter.

`offset` may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. `offset` defaults to 0. `offset` must be a multiple of the PAGESIZE or ALLOCATIONGRANULARITY.

This example shows a simple way of using `mmap`:

```python
import mmap

# write a simple example file
with open("hello.txt", "w") as f:
    f.write("Hello Python!\n")

with open("hello.txt", "r+") as f:
```
The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```python
import mmap
import os

map = mmap.mmap(-1, 13)
map.write("Hello world!")

pid = os.fork()

if pid == 0:  # In a child process
    map.seek(0)
    print(map.readline())

map.close()
```

Memory-mapped file objects support the following methods:

```python
mmap.close()
```
Close the file. Subsequent calls to other methods of the object will result in an exception being raised.

**mmap. find**(`string[, start[, end]]`)  
Returns the lowest index in the object where the substring `string` is found, such that `string` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns `-1` on failure.

**mmap. flush**([`offset`, `size`])  
Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If `offset` and `size` are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

**(Windows version)** A nonzero value returned indicates success; zero indicates failure.

**(Unix version)** A zero value is returned to indicate success. An exception is raised when the call failed.

**mmap. move**(`dest`, `src`, `count`)  
Copy the `count` bytes starting at offset `src` to the destination index `dest`. If the mmap was created with `ACCESS_READ`, then calls to move will throw a `TypeError` exception.

**mmap. read**(`num`)  
Return a string containing up to `num` bytes starting from the current file position; the file position is updated to point after the bytes that were returned.

**mmap. read_byte**()
Returns a string of length 1 containing the character at the current file position, and advances the file position by 1.

```python
mmap.readline()
```
Returns a single line, starting at the current file position and up to the next newline.

```python
mmap.resize(newsize)
```
Resizes the map and the underlying file, if any. If the mmap was created with `ACCESS_READ` or `ACCESS_COPY`, resizing the map will throw a `TypeError` exception.

```python
mmap.rfind(string[, start[, end]])
```
Returns the highest index in the object where the substring `string` is found, such that `string` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns `-1` on failure.

```python
mmap.seek(pos[, whence])
```
Set the file's current position. `whence` argument is optional and defaults to `os.SEEK_SET` or `0` (absolute file positioning); other values are `os.SEEK_CUR` or `1` (seek relative to the current position) and `os.SEEK_END` or `2` (seek relative to the file's end).

```python
mmap.size()
```
Return the length of the file, which can be larger than the size of the memory-mapped area.

```python
mmap.tell()
```
Returns the current position of the file pointer.

```python
mmap.write(string)
```
Write the bytes in `string` into memory at the current position of the file pointer; the file position is updated to point after the
bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will throw a `TypeError` exception.

```python
mmap.write_byte(byte)
```

Write the single-character string `byte` into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with `ACCESS_READ`, then writing to it will throw a `TypeError` exception.
The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly or via the `rlcompleter` module. Settings made using this module affect the behaviour of both the interpreter’s interactive prompt and the prompts offered by the `raw_input()` and `input()` built-in functions.

The `readline` module defines the following functions:

- `readline.parse_and_bind(string)`
  - Parse and execute single line of a readline init file.

- `readline.get_line_buffer()`
  - Return the current contents of the line buffer.

- `readline.insert_text(string)`
  - Insert text into the command line.

- `readline.read_init_file([filename])`
  - Parse a readline initialization file. The default filename is the last filename used.

- `readline.read_history_file([filename])`
  - Load a readline history file. The default filename is `~/.history`.

- `readline.write_history_file([filename])`
  - Save a readline history file. The default filename is `~/.history`.

- `readline.clear_history()`
Clear the current history. (Note: this function is not available if the installed version of GNU readline doesn't support it.)

*New in version 2.4.*

**readline.**`get_history_length()`  
Return the desired length of the history file. Negative values imply unlimited history file size.

**readline.**`set_history_length(length)`  
Set the number of lines to save in the history file. **write_history_file()** uses this value to truncate the history file when saving. Negative values imply unlimited history file size.

**readline.**`get_current_history_length()`  
Return the number of lines currently in the history. (This is different from **get_history_length()**, which returns the maximum number of lines that will be written to a history file.)

*New in version 2.3.*

**readline.**`get_history_item(index)`  
Return the current contents of history item at `index`.

*New in version 2.3.*

**readline.**`remove_history_item(pos)`  
Remove history item specified by its position from the history.

*New in version 2.4.*

**readline.**`replace_history_item(pos, line)`  
Replace history item specified by its position with the given line.

*New in version 2.4.*
readline.\texttt{redisplay()}

Change what's displayed on the screen to reflect the current contents of the line buffer.

\textit{New in version 2.3.}

readline.\texttt{set\_startup\_hook([function])}

Set or remove the startup\_hook function. If \texttt{function} is specified, it will be used as the new startup\_hook function; if omitted or \texttt{None}, any hook function already installed is removed. The startup\_hook function is called with no arguments just before readline prints the first prompt.

readline.\texttt{set\_pre\_input\_hook([function])}

Set or remove the pre\_input\_hook function. If \texttt{function} is specified, it will be used as the new pre\_input\_hook function; if omitted or \texttt{None}, any hook function already installed is removed. The pre\_input\_hook function is called with no arguments after the first prompt has been printed and just before readline starts reading input characters.

readline.\texttt{set\_completer([function])}

Set or remove the completer function. If \texttt{function} is specified, it will be used as the new completer function; if omitted or \texttt{None}, any completer function already installed is removed. The completer function is called as \texttt{function(text, state)}, for \texttt{state} in \texttt{\phi, 1, 2, ...}, until it returns a non-string value. It should return the next possible completion starting with \texttt{text}.

readline.\texttt{get\_completer()}

Get the completer function, or \texttt{None} if no completer function has been set.
New in version 2.3.

```python
readline.get_completion_type()
```
Get the type of completion being attempted.

New in version 2.6.

```python
readline.get_begidx()
```
Get the beginning index of the readline tab-completion scope.

```python
readline.get_endidx()
```
Get the ending index of the readline tab-completion scope.

```python
readline.set_completer_delims(string)
```
Set the readline word delimiters for tab-completion.

```python
readline.get_completer_delims()
```
Get the readline word delimiters for tab-completion.

```python
readline.set_completion_display_matches_hook([function])
```
Set or remove the completion display function. If function is specified, it will be used as the new completion display function; if omitted or None, any completion display function already installed is removed. The completion display function is called as function(substitution, matches, longest_match_length) once each time matches need to be displayed.

New in version 2.6.

```python
readline.add_history(line)
```
Append a line to the history buffer, as if it was the last line typed.

See also:

Module `rlcompleter`
Completion of Python identifiers at the interactive prompt.
Example

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.pyhist` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```python
import os
histfile = os.path.join(os.environ["HOME"], ".pyhist")
try:
    readline.read_history_file(histfile)
except IOError:
    pass
import atexit
atexit.register(readline.write_history_file, histfile)
del os, histfile
```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```python
import code
import readline
import atexit
import os

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/.console-history"),
                 locals=locals or {}):
        code.InteractiveConsole.__init__(self)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except IOError:
                pass
        atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
```
readline.write_history_file(histfile)
The `rlcompleter` module defines a completion function suitable for the `readline` module by completing valid Python identifiers and keywords.

When this module is imported on a Unix platform with the `readline` module available, an instance of the `Completer` class is automatically created and its `complete()` method is set as the `readline` completer.

Example:

```python
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline.completer
readline.__doc__
readline.get_line_buffer(
readline.insert_text(
readline.set_completer(
readline.parse_and_bind(
```

The `rlcompleter` module is designed for use with Python's interactive mode. A user can add the following lines to his or her initialization file (identified by the `PYTHONSTARTUP` environment variable) to get automatic Tab completion:

```python
try:
    import readline
except ImportError:
    print "Module readline not available."
else:
    import rlcompleter
    readline.parse_and_bind("tab: complete")
```

On platforms without `readline`, the `Completer` class defined by this
module can still be used for custom purposes.
Completer Objects

Completer objects have the following method:

Completer.complete(text, state)

Return the state*th completion for *text.

If called for text that doesn't include a period character ('.'), it will complete from names currently defined in __main__, __builtin__ and keywords (as defined by the keyword module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to __getattr__() up to the last part, and find matches for the rest via the dir() function. Any exception raised during the evaluation of the expression is caught, silenced and None is returned.
Interprocess Communication and Networking

The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. `signal` and `subprocess`. Other modules support networking protocols that two or more processes can used to communicate across machines.

The list of modules described in this chapter is:

- **subprocess** — Subprocess management
  - Using the subprocess Module
    - Convenience Functions
    - Exceptions
    - Security
  - Popen Objects
  - Replacing Older Functions with the subprocess Module
    - Replacing `/bin/sh` shell backquote
    - Replacing shell pipe line
    - Replacing `os.system()`
    - Replacing `os.spawn*`
    - Replacing `os.popen*`
    - Replacing `popen2.*`

- **socket** — Low-level networking interface
  - Socket Objects
  - Example

- **ssl** — SSL wrapper for socket objects
  - Functions, Constants, and Exceptions
- SSLSocket Objects
- Certificates
- Examples
  - Testing for SSL support
  - Client-side operation
  - Server-side operation

- **signal** — Set handlers for asynchronous events
  - Example

- **popen2** — Subprocesses with accessible I/O streams
  - Popen3 and Popen4 Objects
  - Flow Control Issues

- **asyncore** — Asynchronous socket handler
  - asyncore Example basic HTTP client

- **asynchat** — Asynchronous socket command/response handler
  - asynchat - Auxiliary Classes and Functions
  - asynchat Example
subprocess — Subprocess management

New in version 2.4.

The subprocess module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several other, older modules and functions, such as:

```python
os.system
os.spawn*
os.popen*
popen2.*
commands.*
```

Information about how the subprocess module can be used to replace these modules and functions can be found in the following sections.

See also:  PEP 324 – PEP proposing the subprocess module
Using the subprocess Module

This module defines one class called `Popen`:

```python
class subprocess.Popen(args, bufsize=0, executable=None, stdin=None, stdout=None, stderr=None, preexec_fn=None, close_fds=False, shell=False, cwd=None, env=None, universal_newlines=False, startupinfo=None, creationflags=0)
```

Arguments are:

- `args` should be a string, or a sequence of program arguments. The program to execute is normally the first item in the `args` sequence or the string if a string is given, but can be explicitly set by using the `executable` argument.

On Unix, with `shell=False` (default): In this case, the Popen class uses `os.execvp()` to execute the child program. `args` should normally be a sequence. A string will be treated as a sequence with the string as the only item (the program to execute).

On Unix, with `shell=True`: If `args` is a string, it specifies the command string to execute through the shell. If `args` is a sequence, the first item specifies the command string, and any additional items will be treated as additional shell arguments.

On Windows: the `Popen` class uses `CreateProcess()` to execute the child program, which operates on strings. If `args` is a sequence, it will be converted to a string using the `list2cmdline()` method. Please note that not all MS Windows applications interpret the command line the same way: `list2cmdline()` is designed for applications using the same rules as the MS C runtime.

`bufsize`, if given, has the same meaning as the corresponding
argument to the built-in open() function: 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size. A negative bufsize means to use the system default, which usually means fully buffered. The default value for bufsize is 0 (unbuffered).

The executable argument specifies the program to execute. It is very seldom needed: Usually, the program to execute is defined by the args argument. If shell=True, the executable argument specifies which shell to use. On Unix, the default shell is /bin/sh. On Windows, the default shell is specified by the COMSPEC environment variable.

stdin, stdout and stderr specify the executed programs’ standard input, standard output and standard error file handles, respectively. Valid values are PIPE, an existing file descriptor (a positive integer), an existing file object, and None. PIPE indicates that a new pipe to the child should be created. With None, no redirection will occur; the child’s file handles will be inherited from the parent. Additionally, stderr can be STDOUT, which indicates that the stderr data from the applications should be captured into the same file handle as for stdout.

If preexec_fn is set to a callable object, this object will be called in the child process just before the child is executed. (Unix only)

If close_fds is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (Unix only). Or, on Windows, if close_fds is true then no handles will be inherited by the child process. Note that on Windows, you cannot set close_fds to true and also redirect the standard handles by setting stdin, stdout or stderr.

If shell is True, the specified command will be executed through
the shell.

If `cwd` is not `None`, the child’s current directory will be changed to `cwd` before it is executed. Note that this directory is not considered when searching the executable, so you can’t specify the program’s path relative to `cwd`.

If `env` is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of inheriting the current process’ environment, which is the default behavior.

If `universal_newlines` is `True`, the file objects `stdout` and `stderr` are opened as text files, but lines may be terminated by any of `\n`, the Unix end-of-line convention, `\r`, the old Macintosh convention or `\r\n`, the Windows convention. All of these external representations are seen as `\n` by the Python program.

```
Note: This feature is only available if Python is built with universal newline support (the default). Also, the newlines attribute of the file objects `stdout`, `stdin` and `stderr` are not updated by the `communicate()` method.
```

The `startupinfo` and `creationflags`, if given, will be passed to the underlying `CreateProcess()` function. They can specify things such as appearance of the main window and priority for the new process. (Windows only)

### Convenience Functions

This module also defines two shortcut functions:

```
subprocess.call(*popenargs, **kwargs)
```
Run command with arguments. Wait for command to complete, then return the `returncode` attribute.

The arguments are the same as for the Popen constructor. Example:

```python
retcode = call(['ls', '-l'])
```

`subprocess.check_call(*popenargs, **kwargs)`

Run command with arguments. Wait for command to complete. If the exit code was zero then return, otherwise raise `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute.

The arguments are the same as for the Popen constructor. Example:

```python
check_call(['ls', '-l'])
```

*New in version 2.5.*

## Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called `child_traceback`, which is a string containing traceback information from the childs point of view.

The most common exception raised is `OSError`. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for `OSError` exceptions.

A `ValueError` will be raised if `Popen` is called with invalid arguments.
check_call() will raise `CalledProcessError`, if the called process returns a non-zero return code.

**Security**

Unlike some other popen functions, this implementation will never call `/bin/sh` implicitly. This means that all characters, including shell metacharacters, can safely be passed to child processes.
Popen Objects

Instances of the `Popen` class have the following methods:

`Popen.poll()`  
Check if child process has terminated. Set and return `returncode` attribute.

`Popen.wait()`  
Wait for child process to terminate. Set and return `returncode` attribute.

**Warning:** This will deadlock if the child process generates enough output to a stdout or stderr pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use `communicate()` to avoid that.

`Popen.communicate(input=None)`  
Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional `input` argument should be a string to be sent to the child process, or `None`, if no data should be sent to the child.

`communicate()` returns a tuple `(stdout, stderr)`.

Note that if you want to send data to the process’s stdin, you need to create the Popen object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

**Note:** The data read is buffered in memory, so do not use this
method if the data size is large or unlimited.

Popen. `send_signal(signal)`
Sends the signal `signal` to the child.

**Note:** On Windows only SIGTERM is supported so far. It’s an alias for `terminate()`.

*New in version 2.6.*

Popen. `terminate()`
Stop the child. On Posix OSs the method sends SIGTERM to the child. On Windows the Win32 API function `TerminateProcess` is called to stop the child.

*New in version 2.6.*

Popen. `kill()`
Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

*New in version 2.6.*

The following attributes are also available:

**Warning:** Use `communicate()` rather than `stdin.write()`, `stdout.read()` or `stderr.read()` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

Popen. `stdin`
If the `stdin` argument is `PIPE`, this attribute is a file object that provides input to the child process. Otherwise, it is `None`.

Popen. `stdout`
If the `stdout` argument is `PIPE`, this attribute is a file object that provides output from the child process. Otherwise, it is `None`.

Popen. **stderr**

If the `stderr` argument is `PIPE`, this attribute is file object that provides error output from the child process. Otherwise, it is `None`.

Popen. **pid**

The process ID of the child process.

Popen. **returncode**

The child return code, set by `poll()` and `wait()` (and indirectly by `communicate()`). A `None` value indicates that the process hasn’t terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).
Replacing Older Functions with the subprocess Module

In this section, “a ==> b” means that b can be used as a replacement for a.

**Note:** All functions in this section fail (more or less) silently if the executed program cannot be found; this module raises an `OSError` exception.

In the following examples, we assume that the subprocess module is imported with “from subprocess import *”.

### Replacing `/bin/sh` shell backquote

```python
output=`mycmd myarg`
==> output = Popen(['mycmd', 'myarg'], stdout=PIPE).communicate()[0]
```

### Replacing shell pipe line

```python
output=`dmesg | grep hda`
==> p1 = Popen(['dmesg'], stdout=PIPE)
p2 = Popen(['grep', 'hda'], stdin=p1.stdout, stdout=PIPE)
output = p2.communicate()[0]
```

### Replacing `os.system()`

```python
sts = os.system('mycmd "myarg"
==> p = Popen('mycmd "myarg", shell=True)
sts = os.waitpid(p.pid, 0)
```
Notes:

- Calling the program through the shell is usually not required.
- It’s easier to look at the returncode attribute than the exit status.

A more realistic example would look like this:

```python
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print >>sys.stderr, "Child was terminated by signal", -retcode
    else:
        print >>sys.stderr, "Child returned", retcode
except OSError, e:
    print >>sys.stderr, "Execution failed:", e
```

Replacing os.spawn*

P_NOWAIT example:

```python
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==> pid = Popen(["/bin/mycmd", "myarg"]).pid
```

P_WAIT example:

```python
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==> retcode = call(["/bin/mycmd", "myarg"])
```

Vector example:

```python
os.spawnvp(os.P_NOWAIT, path, args)
==> Popen([path] + args[1:])
```

Environment example:
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==> Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})

Replacing os.popen*

pipe = os.popen(cmd, 'r', bufsize)
==> pipe = Popen(cmd, shell=True, bufsize=bufsize, stdout=PIPE).stdout

pipe = os.popen(cmd, 'w', bufsize)
==> pipe = Popen(cmd, shell=True, bufsize=bufsize, stdin=PIPE).stdin

(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize)
==> p = Popen(cmd, shell=True, bufsize=bufsize,
           stdin=PIPE, stdout=PIPE, close_fds=True)
   (child_stdin, child_stdout) = (p.stdin, p.stdout)

(child_stdin, child_stdout, child_stderr) = os.popen3(cmd, mode, bufsize)
==> p = Popen(cmd, shell=True, bufsize=bufsize,
            stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
   (child_stdin, child_stdout, child_stderr) = (p.stdin, p.stdout, p.stderr)

(child_stdin, child_stdout_and_stderr) = os.popen4(cmd, mode, bufsize)
==> p = Popen(cmd, shell=True, bufsize=bufsize,
            stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
   (child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)

Replacing popen2.*

Note: If the cmd argument to popen2 functions is a string, the
command is executed through /bin/sh. If it is a list, the command is
directly executed.

```python
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize, child_stdout, child_stdin) = popen2.popen2(['"mycmd", "myarg"'], bufsize, stdin=PIPE, stdout=PIPE, close_fds=True)
```

The popen2.Popen3 and popen2.Popen4 basically works as subprocess.Popen, except that:

- subprocess.Popen raises an exception if the execution fails
- the capturestderr argument is replaced with the stderr argument.
- stdin=PIPE and stdout=PIPE must be specified.
- popen2 closes all file descriptors by default, but you have to specify close_fds=True with subprocess.Popen.
socket — Low-level networking interface

This module provides access to the BSD socket interface. It is available on all modern Unix systems, Windows, Mac OS X, BeOS, OS/2, and probably additional platforms.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

For an introduction to socket programming (in C), see the following papers: An Introductory 4.3BSD Interprocess Communication Tutorial, by Stuart Sechrest and An Advanced 4.3BSD Interprocess Communication Tutorial, by Samuel J. Leffler et al, both in the UNIX Programmer’s Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to RFC 3493 titled Basic Socket Interface Extensions for IPv6.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python’s object-oriented style: the `socket()` function returns a `socket object` whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

Socket addresses are represented as follows: A single string is used
for the `AF_UNIX` address family. A pair `(host, port)` is used for the `AF_INET` address family, where `host` is a string representing either a hostname in Internet domain notation like `daring.cwi.nl` or an IPv4 address like `'100.50.200.5'`, and `port` is an integral port number. For `AF_INET6` address family, a four-tuple `(host, port, flowinfo, scopeid)` is used, where `flowinfo` and `scopeid` represents `sin6_flowinfo` and `sin6_scope_id` member in `struct sockaddr_in6` in C. For `socket` module methods, `flowinfo` and `scopeid` can be omitted just for backward compatibility. Note, however, omission of `scopeid` can cause problems in manipulating scoped IPv6 addresses. Other address families are currently not supported. The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents `INADDR_ANY`, and the string `'<broadcast>'` represents `INADDR_BROADCAST`. The behavior is not available for IPv6 for backward compatibility, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the `host` portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in `host` portion.

New in version 2.5: AF_NETLINK sockets are represented as pairs `pid, groups`.

New in version 2.6: Linux-only support for TIPC is also available using the `AF_TIPC` address family. TIPC is an open, non-IP based
networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is \((addr\_type, v1, v2, v3 [, scope])\), where:

- \(addr\_type\) is one of TIPC_ADDR_NAMESEQ, TIPC_ADDR_NAME, or TIPC_ADDR_ID.

- \(scope\) is one of TIPC_ZONE_SCOPE, TIPC_CLUSTER_SCOPE, and TIPC_NODE_SCOPE.

- If \(addr\_type\) is TIPC_ADDR_NAME, then \(v1\) is the server type, \(v2\) is the port identifier, and \(v3\) should be 0.

  If \(addr\_type\) is TIPC_ADDR_NAMESEQ, then \(v1\) is the server type, \(v2\) is the lower port number, and \(v3\) is the upper port number.

  If \(addr\_type\) is TIPC_ADDR_ID, then \(v1\) is the node, \(v2\) is the reference, and \(v3\) should be set to 0.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; errors related to socket or address semantics raise the error \(\text{socket.error}\).

Non-blocking mode is supported through \(\text{setblocking}()\). A generalization of this based on timeouts is supported through \(\text{settimeout}()\).

The module \texttt{socket} exports the following constants and functions:

- \texttt{exception socket.error}
  This exception is raised for socket-related errors. The accompanying value is either a string telling what went wrong or a pair \((errno, string)\) representing an error returned by a
system call, similar to the value accompanying `os.error`. See the module `errno`, which contains names for the error codes defined by the underlying operating system.

*Changed in version 2.6:* `socket.error` is now a child class of `IOError`.

**exception socket.herror**

This exception is raised for address-related errors, i.e. for functions that use `h_errno` in the C API, including `gethostbyname_ex()` and `gethostbyaddr()`.

The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. `string` represents the description of `h_errno`, as returned by the `hstrerror` C function.

**exception socket.gaierror**

This exception is raised for address-related errors, for `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair `(error, string)` representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror` C function. The `error` value will match one of the `EAI_*` constants defined in this module.

**exception socket.timeout**

This exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()`. The accompanying value is a string whose value is currently always “timed out”.

*New in version 2.3.*

`socket.AF_UNIX`

`socket.AF_INET`
socket. **AF_INET6**

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the **AF_UNIX** constant is not defined then this protocol is unsupported.

socket. **SOCK_STREAM**
socket. **SOCK_DGRAM**
socket. **SOCK_RAW**
socket. **SOCK_RDM**
socket. **SOCK_SEQPACKET**

These constants represent the socket types, used for the second argument to `socket()`. (Only **SOCK_STREAM** and **SOCK_DGRAM** appear to be generally useful.)

**SO_**
socket. **SOMAXCONN**

**MSG_**

**SOL_**

**IPPROTO_**

**IPPORT_**

**INADDR_**

**IP_**

**IPV6_**

**EAI_**

**AI_**

**NI_**

**TCP_**

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

**SIO_**

**RCVALL_**

Constants for Windows' `WSAIoctl()`. The constants are used as
arguments to the `ioctl()` method of socket objects.

*New in version 2.6.*

**TIPC_***

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

*New in version 2.6.*

**socket.** has_ipv6

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

*New in version 2.3.*

**socket.** `create_connection` *(address[, timeout])*

Convenience function. Connect to `address` (a 2-tuple `(host, port)`), and return the socket object. Passing the optional `timeout` parameter will set the timeout on the socket instance before attempting to connect. If no `timeout` is supplied, the global default timeout setting returned by `getdefaulttimeout()` is used.

*New in version 2.6.*

**socket.** `getaddrinfo` *(host, port[, family[, socktype[, proto[, flags]]]]*)

Resolves the `host/port` argument, into a sequence of 5-tuples that contain all the necessary arguments for creating the corresponding socket. `host` is a domain name, a string representation of an IPv4/IPv6 address or `None`. `port` is a string service name such as `'http'`, a numeric port number or `None`. The rest of the arguments are optional and must be numeric if specified. By passing `None` as the value of `host` and `port`, , you
can pass `NULL` to the C API.

The `getaddrinfo()` function returns a list of 5-tuples with the following structure:

```
(family, socktype, proto, canonname, sockaddr)
```

`family`, `socktype`, `proto` are all integers and are meant to be passed to the `socket()` function. `canonname` is a string representing the canonical name of the `host`. It can be a numeric IPv4/v6 address when `AI_CANONNAME` is specified for a numeric `host`. `sockaddr` is a tuple describing a socket address, as described above. See the source for `socket` and other library modules for a typical usage of the function.

*New in version 2.2.*

```
socket.getfqdn([name])
```

Return a fully qualified domain name for `name`. If `name` is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by `gethostbyaddr()` is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by `gethostname()` is returned.

*New in version 2.0.*

```
socket.gethostbyname(hostname)
```

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and
getaddrinfo() should be used instead for IPv4/v6 dual stack support.

socket.gethostbyname_ex(hostname)
Translate a host name to IPv4 address format, extended interface. Return a triple (hostname, aliaslist, ipaddrlist) where hostname is the primary host name responding to the given ip_address, aliaslist is a (possibly empty) list of alternative host names for the same address, and ipaddrlist is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). gethostbyname_ex() does not support IPv6 name resolution, and getaddrinfo() should be used instead for IPv4/v6 dual stack support.

socket.gethostname()
Return a string containing the hostname of the machine where the Python interpreter is currently executing. If you want to know the current machine's IP address, you may want to use gethostbyname(gethostname()). This operation assumes that there is a valid address-to-host mapping for the host, and the assumption does not always hold. Note: gethostname() doesn't always return the fully qualified domain name; use getfqdn() (see above).

socket.gethostbyaddr(ip_address)
Return a triple (hostname, aliaslist, ipaddrlist) where hostname is the primary host name responding to the given ip_address, aliaslist is a (possibly empty) list of alternative host names for the same address, and ipaddrlist is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function getfqdn(). gethostbyaddr() supports both IPv4 and IPv6.
socket. `getnameinfo(sockaddr, flags)`

Translate a socket address `sockaddr` into a 2-tuple `(host, port)`. Depending on the settings of `flags`, the result can contain a fully-qualified domain name or numeric address representation in `host`. Similarly, `port` can contain a string port name or a numeric port number.

*New in version 2.2.*

socket. `getprotobynumber(protocolname)`

Translate an Internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

socket. `getservbyname(servicename[, protocolname])`

Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

socket. `getservbyport(port[, protocolname])`

Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

socket. `socket([family[, type[, proto]]])`

Create a new socket using the given address family, socket type and protocol number. The address family should be `AF_INET` (the default), `AF_INET6` or `AF_UNIX`. The socket type should be `SOCK_STREAM` (the default), `SOCK_DGRAM` or perhaps one of the other `sock_` constants. The protocol number is usually zero and may be
omitted in that case.

socket. **socketpair**([*family[, type[, proto]]]*)

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the **socket()** function above. The default family is `AF_UNIX` if defined on the platform; otherwise, the default is `AF_INET`. Availability: Unix.

*New in version 2.4.*

socket. **fromfd**(*fd, family, type[, proto]*)

Duplicate the file descriptor *fd* (an integer as returned by a file object's **fileno()** method) and build a socket object from the result. Address family, socket type and protocol number are as for the **socket()** function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode. Availability: Unix.

socket. **ntohl**(*x*)

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket. **ntohs**(*x*)

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.
socket.\texttt{htonl}(x)
Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.\texttt{htons}(x)
Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

socket.\texttt{inet\_aton}(ip\_string)
Convert an IPv4 address from dotted-quad string format (for example, ‘123.45.67.89’) to 32-bit packed binary format, as a string four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type \texttt{struct in\_addr}, which is the C type for the 32-bit packed binary this function returns.

If the IPv4 address string passed to this function is invalid, \texttt{socket.error} will be raised. Note that exactly what is valid depends on the underlying C implementation of \texttt{inet\_aton}.

\texttt{inet\_aton()} does not support IPv6, and \texttt{getnameinfo()} should be used instead for IPv4/v6 dual stack support.

socket.\texttt{inet\_ntoa}(packed\_ip)
Convert a 32-bit packed IPv4 address (a string four characters in length) to its standard dotted-quad string representation (for example, ‘123.45.67.89’). This is useful when conversing with a program that uses the standard C library and needs objects of type \texttt{struct in\_addr}, which is the C type for the 32-bit packed binary data this function takes as an argument.
If the string passed to this function is not exactly 4 bytes in length, `socket.error` will be raised. `inet_ntoa()` does not support IPv6, and `getnameinfo()` should be used instead for IPv4/v6 dual stack support.

```python
socket.inet_pton(address_family, ip_string)
```

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to `inet_aton()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the IP address string `ip_string` is invalid, `socket.error` will be raised. Note that exactly what is valid depends on both the value of `address_family` and the underlying implementation of `inet_pton`.

Availability: Unix (maybe not all platforms).

*New in version 2.3.*

```python
socket.inet_ntop(address_family, packed_ip)
```

Convert a packed IP address (a string of some number of characters) to its standard, family-specific string representation (for example, `'7.10.0.5'` or `'5ae:2b::8'`) `inet_ntop()` is useful when a library or network protocol returns an object of type `struct in_addr` (similar to `inet_ntoa()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the string `packed_ip` is not the correct length for the specified address family, `ValueError` will be raised. A `socket.error` is raised for errors from the call to `inet_ntop()`.

Availability: Unix (maybe not all platforms).
New in version 2.3.

socket. **getdefaulttimeout()**

Return the default timeout in floating seconds for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

New in version 2.3.

socket. **setdefaulttimeout(timeout)**

Set the default timeout in floating seconds for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

New in version 2.3.

socket. **SocketType**

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

**See also:**

**Module** `SocketServer`

Classes that simplify writing network servers.
Socket Objects

Socket objects have the following methods. Except for `makefile()` these correspond to Unix system calls applicable to sockets.

**socket.**`accept()`
Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection.

**socket.**`bind(address)`
Bind the socket to `address`. The socket must not already be bound. (The format of `address` depends on the address family — see above.)

**Note:** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

**socket.**`close()`
Close the socket. All future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

**socket.**`connect(address)`
Connect to a remote socket at `address`. (The format of `address` depends on the address family — see above.)
**Note:** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

`socket.connect_ex(address)`

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect` call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

**Note:** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

`socket.fileno()`

Return the socket’s file descriptor (a small integer). This is useful with `select.select()`.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as `os.fdopen()`). Unix does not have this limitation.

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.
socket.**getsockname()**

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

socket.**getsockopt**(level, optname[, buflen])

Return the value of the given socket option (see the Unix man page `getsockopt(2)`). The needed symbolic constants (so_* etc.) are defined in this module. If buflen is absent, an integer option is assumed and its integer value is returned by the function. If buflen is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a string. It is up to the caller to decode the contents of the buffer (see the optional built-in module **struct** for a way to decode C structures encoded as strings).

socket.**ioctl**(control, option)

Platform: Windows

The ioctl() method is a limited interface to the WSAIoctl system interface. Please refer to the MSDN documentation for more information.

New in version 2.6.

socket.**listen**(backlog)

Listen for connections made to the socket. The backlog argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

socket.**makefile**([mode[, bufsize]])

Return a file object associated with the socket. (File objects are described in File Objects.) The file object references a dupped
version of the socket file descriptor, so the file object and socket object may be closed or garbage-collected independently. The socket must be in blocking mode (it can not have a timeout). The optional mode and bufsize arguments are interpreted the same way as by the built-in file() function.

socket.recv(bufsize[, flags])

Receive data from the socket. The return value is a string representing the data received. The maximum amount of data to be received at once is specified by bufsize. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero.

**Note:** For best match with hardware and network realities, the value of bufsize should be a relatively small power of 2, for example, 4096.

socket.recvfrom(bufsize[, flags])

Receive data from the socket. The return value is a pair (string, address) where string is a string representing the data received and address is the address of the socket sending the data. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero. (The format of address depends on the address family — see above.)

socket.recvfrom_into(buffer[, nbytes[, flags]])

Receive data from the socket, writing it into buffer instead of creating a new string. The return value is a pair (nbytes, address) where nbytes is the number of bytes received and address is the address of the socket sending the data. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero. (The format of address depends on the address family — see above.)
socket.recv_into(buffer[, nbytes[, flags]])

Receive up to nbytes bytes from the socket, storing the data into a buffer rather than creating a new string. If nbytes is not specified (or 0), receive up to the size available in the given buffer. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero.

socket.send(string[, flags])

Send data to the socket. The socket must be connected to a remote socket. The optional flags argument has the same meaning as for recv() above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data.

socket.sendall(string[, flags])

Send data to the socket. The socket must be connected to a remote socket. The optional flags argument has the same meaning as for recv() above. Unlike send(), this method continues to send data from string until either all data has been sent or an error occurs. None is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

socket.sendto(string[, flags], address)

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by address. The optional flags argument has the same meaning as for recv() above. Return the number of bytes sent. (The format
of address depends on the address family — see above.)

socket.\texttt{setblocking}(flag)
Set blocking or non-blocking mode of the socket: if \textit{flag} is 0, the socket is set to non-blocking, else to blocking mode. Initially all sockets are in blocking mode. In non-blocking mode, if a \texttt{recv()} call doesn’t find any data, or if a \texttt{send()} call can’t immediately dispose of the data, a \textit{error} exception is raised; in blocking mode, the calls block until they can proceed. \texttt{s.setblocking(0)} is equivalent to \texttt{s.settimeout(0)}; \texttt{s.setblocking(1)} is equivalent to \texttt{s.settimeout(None)}.

socket.\texttt{settimeout}(value)
Set a timeout on blocking socket operations. The \textit{value} argument can be a nonnegative float expressing seconds, or \texttt{None}. If a float is given, subsequent socket operations will raise an \textit{timeout} exception if the timeout period \textit{value} has elapsed before the operation has completed. Setting a timeout of \texttt{None} disables timeouts on socket operations. \texttt{s.settimeout(0.0)} is equivalent to \texttt{s.setblocking(0)}; \texttt{s.settimeout(None)} is equivalent to \texttt{s.setblocking(1)}.

\textit{New in version 2.3.}

socket.\texttt{gettimeout}()
Return the timeout in floating seconds associated with socket operations, or \texttt{None} if no timeout is set. This reflects the last call to \texttt{setblocking()} or \texttt{settimeout()}.

\textit{New in version 2.3.}

Some notes on socket blocking and timeouts: A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets
are always created in blocking mode. In blocking mode, operations block until complete. In non-blocking mode, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately. In timeout mode, operations fail if they cannot be completed within the timeout specified for the socket. The `setblocking()` method is simply a shorthand for certain `settimeout()` calls.

Timeout mode internally sets the socket in non-blocking mode. The blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. A consequence of this is that file objects returned by the `makefile()` method must only be used when the socket is in blocking mode; in timeout or non-blocking mode file operations that cannot be completed immediately will fail.

Note that the `connect()` operation is subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()`.

`socket.setsockopt(level, optname, value)`
Set the value of the given socket option (see the Unix manual page `setsockopt(2)`). The needed symbolic constants are defined in the `socket` module (so_* etc.). The value can be an integer or a string representing a buffer. In the latter case it is up to the caller to ensure that the string contains the proper bits (see the optional built-in module `struct` for a way to encode C structures as strings).

`socket.shutdown(how)`
Shut down one or both halves of the connection. If `how` is `SHUT_RD`, further receives are disallowed. If `how` is `SHUT_WR`, further sends are disallowed. If `how` is `SHUT_RDWR`, further sends and receives are disallowed.
Note that there are no methods `read()` or `write()`; use `recv()` and `send()` without `flags` argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

```python
socket.family
    The socket family.
    
    New in version 2.5.
```

```python
socket.type
    The socket type.
    
    New in version 2.5.
```

```python
socket.proto
    The socket protocol.
    
    New in version 2.5.
```
Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `send()`/`recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```python
# Echo server program
import socket
HOST = ''  # Symbolic name meaning all available interfaces
PORT = 50007  # Arbitrary non-privileged port
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.bind(((HOST, PORT)))
s.listen(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()

# Echo client program
import socket
HOST = 'daring.cwi.nl'  # The remote host
PORT = 50007  # The same port as used by the server
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.connect((HOST, PORT))
s.send('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)
```
The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```python
# Echo server program
import socket
import sys

HOST = None  # Symbolic name meaning all available
PORT = 50007  # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error, msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except socket.error, msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()
```

```python
# Echo client program
import socket
```
import sys

HOST = 'daring.cwi.nl'  # The remote host
PORT = 50007  # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error, msg:
        s = None
        continue
    try:
        s.connect(sa)
    except socket.error, msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
s.send('Hello, world')
data = s.recv(1024)
s.close()
print 'Received', repr(data)

The last example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)
# receive a package
print s.recvfrom(65565)

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
SSL wrapper for socket objects

New in version 2.6.

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

Note: Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior.

This section documents the objects and functions in the ssl module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, ssl.SSLSocket, which is derived from the socket.socket type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional read() and write() methods, along with a method, getpeercert(), to retrieve the certificate of the other side of the connection, and a method, cipher(), to retrieve the cipher being used for the secure connection.
exception ssl.SSLError

Raised to signal an error from the underlying SSL implementation. This signifies some problem in the higher-level encryption and authentication layer that's superimposed on the underlying network connection. This error is a subtype of socket.error, which in turn is a subtype of IOError.

ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True)

Takes an instance sock of socket.socket, and returns an instance of ssl.SSLSocket, a subtype of socket.socket, which wraps the underlying socket in an SSL context. For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after connect() is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the accept() method. wrap_socket() may raise SSLError.

The keyfile and certfile parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of Certificates for more information on how the certificate is stored in the certfile.

Often the private key is stored in the same file as the certificate; in this case, only the certfile parameter need be passed. If the private key is stored in a separate file, both parameters must be
used. If the private key is stored in the `certfile`, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values `CERT_NONE` (certificates ignored), `CERT_OPTIONAL` (not required, but validated if provided), or `CERT_REQUIRED` (required and validated). If the value of this parameter is not `CERT_NONE`, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of `Certificates` for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server’s choice. Most of the versions are not interoperable with the other versions. If not specified, for client-side operation, the default SSL version is SSLv3; for server-side operation, SSLv23. These version selections provide the most compatibility with other versions.
Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

<table>
<thead>
<tr>
<th>client / server</th>
<th>SSLv2</th>
<th>SSLv3</th>
<th>SSLv23</th>
<th>TLSv1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLv2</td>
<td>yes</td>
<td>no</td>
<td>yes*</td>
<td>no</td>
</tr>
<tr>
<td>SSLv3</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>SSLv23</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>TLSv1</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>yes</td>
</tr>
</tbody>
</table>

In some older versions of OpenSSL (for instance, 0.9.7l on OS X 10.4), an SSLv2 client could not connect to an SSLv23 server.

The parameter `do_handshake_on_connect` specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the `SSLSocket.do_handshake()` method. Calling `SSLSocket.do_handshake()` explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the `SSLSocket.read()` method should signal unexpected EOF from the other end of the connection. If specified as `True` (the default), it returns a normal EOF in response to unexpected EOF errors raised from the underlying socket; if `False`, it will raise the exceptions back to the caller.

`ssl.RAND_status()`

Returns True if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and False otherwise. You can use `ssl.RAND_egd()` and `ssl.RAND_add()` to increase the randomness of the pseudo-random number generator.

`ssl.RAND_egd(path)`
If you are running an entropy-gathering daemon (EGD) somewhere, and `path` is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

```python
ssl.RAND_add(bytes, entropy)
```

Mixes the given `bytes` into the SSL pseudo-random number generator. The parameter `entropy` (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See RFC 1750 for more information on sources of entropy.

```python
ssl.cert_time_to_seconds(timestring)
```

Returns a floating-point value containing a normal seconds-after-the-epoch time value, given the time-string representing the “notBefore” or “notAfter” date from a certificate.

Here’s an example:

```python
>>> import ssl
>>> ssl.cert_time_to_seconds("May  9 00:00:00 2007 GMT")
1178694000.0

>>> import time
>>> time.ctime(ssl.cert_time_to_seconds("May  9 00:00:00 2007 GMT"))
'Wed May 9 00:00:00 2007'
```

```python
ssl.get_server_certificate(addr, ssl_version=PROTOCOL_SSLv3, ca_certs=None)
```
Given the address addr of an SSL-protected server, as a (hostname, port-number) pair, fetches the server’s certificate, and returns it as a PEM-encoded string. If ssl_version is specified, uses that version of the SSL protocol to attempt to connect to the server. If ca_certs is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in wrap_socket(). The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

ssl.DER_cert_to_PEM_cert(DER_cert_bytes)
Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

ssl.PEM_cert_to_DER_cert(PEM_cert_string)
Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

ssl.CERT_NONE
Value to pass to the cert_reqs parameter to sslobj() when no certificates will be required or validated from the other side of the socket connection.

ssl.CERT_OPTIONAL
Value to pass to the cert_reqs parameter to sslobj() when no certificates will be required from the other side of the socket connection, but if they are provided, will be validated. Note that use of this setting requires a valid certificate validation file also be passed as a value of the ca_certs parameter.

ssl.CERT_REQUIRED
Value to pass to the cert_reqs parameter to sslobj() when certificates will be required from the other side of the socket connection. Note that use of this setting requires a valid
certificate validation file also be passed as a value of the `ca_certs` parameter.

ssl. **PROTOCOL_SSLv2**
Selects SSL version 2 as the channel encryption protocol.

ssl. **PROTOCOL_SSLv23**
Selects SSL version 2 or 3 as the channel encryption protocol. This is a setting to use with servers for maximum compatibility with the other end of an SSL connection, but it may cause the specific ciphers chosen for the encryption to be of fairly low quality.

ssl. **PROTOCOL_SSLv3**
Selects SSL version 3 as the channel encryption protocol. For clients, this is the maximally compatible SSL variant.

ssl. **PROTOCOL_TLSv1**
Selects TLS version 1 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it.
SSL Socket Objects

SSL Socket. **read**([`nbytes=1024`])
Reads up to `nbytes` bytes from the SSL-encrypted channel and returns them.

SSL Socket. **write**(`data`)
Writes the `data` to the other side of the connection, using the SSL channel to encrypt. Returns the number of bytes written.

SSL Socket. **getpeercert**(`binary_form=False`) If there is no certificate for the peer on the other end of the connection, returns **None**.

If the the parameter `binary_form` is **False**, and a certificate was received from the peer, this method returns a **dict** instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with the keys **subject** (the principal for which the certificate was issued), and **notAfter** (the time after which the certificate should not be trusted). The certificate was already validated, so the **notBefore** and **issuer** fields are not returned. If a certificate contains an instance of the **Subject Alternative Name** extension (see **RFC 3280**), there will also be a **subjectAltName** key in the dictionary.

The “subject” field is a tuple containing the sequence of relative distinguished names (RDNs) given in the certificate’s data structure for the principal, and each RDN is a sequence of name-value pairs:

```python
{'notAfter': 'Feb 16 16:54:50 2013 GMT',
'subject': (((('countryName', u'US'),)),
```
If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. This return value is independent of validation; if validation was required (`CERT_OPTIONAL` or `CERT_REQUIRED`), it will have been validated, but if `CERT_NONE` was used to establish the connection, the certificate, if present, will not have been validated.

**SSLSocket.cipher()**

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

**SSLSocket.do_handshake()**

Perform a TLS/SSL handshake. If this is used with a non-blocking socket, it may raise `SSLError` with an `arg[0]` of `SSL_ERROR_WANT_READ` or `SSL_ERROR_WANT_WRITE`, in which case it must be called again until it completes successfully. For example, to simulate the behavior of a blocking socket, one might write:

```python
while True:
    try:
        s.do_handshake()
    break
except ssl.SSLError, err:
```
if err.args[0] == ssl.SSL_ERROR_WANT_READ:
    select.select([s], [], [])
elif err.args[0] == ssl.SSL_ERROR_WANT_WRITE:
    select.select([], [s], [])
else:
    raise

SSLSocket.unwrap()

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The socket instance returned should always be used for further communication with the other side of the connection, rather than the original socket instance (which may not function properly after the unwrap).
Certificates

Certificates in general are part of a public-key / private-key system. In this system, each principal, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the public key; the other part is kept secret, and is called the private key. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and only with the other part.

A certificate contains information about two principals. It contains the name of a subject, and the subject's public key. It also contains a statement by a second principal, the issuer, that the subject is who he claims to be, and that this is indeed the subject’s public key. The issuer’s statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer’s statement by finding the issuer’s public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called “notBefore” and “notAfter”.

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as
“PEM” (see RFC 1422), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
...(certificate in base64 PEM encoding)...
-----END CERTIFICATE-----
```

The Python files which contain certificates can contain a sequence of certificates, sometimes called a certificate chain. This chain should start with the specific certificate for the principal who “is” the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of that certificate, and so on up the chain till you get to a certificate which is self-signed, that is, a certificate which has the same subject and issuer, sometimes called a root certificate. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
...(certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
...(the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
...(the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

If you are going to require validation of the other side of the connection's certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches.
Some “standard” root certificates are available from various certification authorities: CACert.org, Thawte, Verisign, Positive SSL (used by python.org), Equifax and GeoTrust.

In general, if you are using SSL3 or TLS1, you don’t need to put the full chain in your “CA certs” file; you only need the root certificates, and the remote peer is supposed to furnish the other certificates necessary to chain from its certificate to a root certificate. See RFC 4158 for more discussion of the way in which certification chains can be built.

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
........+++++
.............................+++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name (DN)
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My O
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
%```
The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.
Examples

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    [ do something that requires SSL support ]
```

Client-side operation

This example connects to an SSL server, prints the server’s address and certificate, sends some bytes, and reads part of the response:

```
import socket, ssl, pprint

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

# require a certificate from the server
ssl_sock = ssl.wrap_socket(s,
                           ca_certs="/etc/ca_certs_file",
                           cert_reqs=ssl.CERT_REQUIRED)

ssl_sock.connect(('www.verisign.com', 443))

print repr(ssl_sock.getpeername())
print ssl_sock.cipher()
print pprint.pformat(ssl_sock.getpeercert())

# Set a simple HTTP request -- use httplib in actual code.
ssl_sock.write("""GET / HTTP/1.0\r
Host: www.verisign.com\r\n\n""")

# Read a chunk of data. Will not necessarily
# read all the data returned by the server.
data = ssl_sock.read()
```
# note that closing the SSLSocket will also close the underlying socket

close()

As of September 6, 2007, the certificate printed by this program looked like this:

```json
{"notAfter": "May 8 23:59:59 2009 GMT,
'subject": ["serialNumber", u'2497886'],
["1.3.6.1.4.1.311.60.2.1.3", u'US'],
["1.3.6.1.4.1.311.60.2.1.2", u'Delaware'],
["countryName", u'US'],
["postalCode", u'94043'],
["stateOrProvinceName", u'California'],
["localityName", u'Mountain View'],
["streetAddress", u'487 East Middlefield Road'],
["organizationName", u'VeriSign, Inc.'],
["organizationalUnitName",
  u'Production Security Services'],
["organizationalUnitName",
  u'Terms of use at www.verisign.com/rpa (c)06'],
["commonName", u'www.verisign.com']}
```

which is a fairly poorly-formed subject field.

## Server-side operation

For server operation, typically you’d need to have a server certificate, and private key, each in a file. You’d open a socket, bind it to a port, call `listen()` on it, then start waiting for clients to connect:

```python
import socket, ssl

bindsocket = socket.socket()
bindsocket.bind(('[myaddr.mydomain.com', 10023])
bindsocket.listen(5)
```

When one did, you’d call `accept()` on the socket to get the new socket from the other end, and use `wrap_socket()` to create a server-
side SSL context for it:

```python
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = ssl.wrap_socket(newsocket,
                               server_side=True,
                               certfile="mycertfile",
                               keyfile="mykeyfile",
                               ssl_version=ssl.PROTOCOL_TLSv1)
    deal_with_client(connstream)
```

Then you’d read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```python
def deal_with_client(connstream):
    data = connstream.read()
    # null data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.read()
    # finished with client
    connstream.close()
```

And go back to listening for new client connections.

RFC 1750: Randomness Recommendations for Security
This module provides mechanisms to use signal handlers in Python. Some general rules for working with signals and their handlers:

- A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for **SIGCHLD**, which follows the underlying implementation.
- There is no way to “block” signals temporarily from critical sections (since this is not supported by all Unix flavors).
- Although Python signal handlers are called asynchronously as far as the Python user is concerned, they can only occur between the “atomic” instructions of the Python interpreter. This means that signals arriving during long calculations implemented purely in C (such as regular expression matches on large bodies of text) may be delayed for an arbitrary amount of time.
- When a signal arrives during an I/O operation, it is possible that the I/O operation raises an exception after the signal handler returns. This is dependent on the underlying Unix system’s semantics regarding interrupted system calls.
- Because the C signal handler always returns, it makes little sense to catch synchronous errors like **SIGFPE** or **SIGSEGV**.
- Python installs a small number of signal handlers by default: **SIGPIPE** is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and **SIGINT** is translated into a **KeyboardInterrupt** exception. All of these can be overridden.
- Some care must be taken if both signals and threads are used
in the same program. The fundamental thing to remember in using signals and threads simultaneously is: always perform `signal()` operations in the main thread of execution. Any thread can perform an `alarm()`, `getsignal()`, `pause()`, `setitimer()` or `getitimer();` only the main thread can set a new signal handler, and the main thread will be the only one to receive signals (this is enforced by the Python `signal` module, even if the underlying thread implementation supports sending signals to individual threads). This means that signals can't be used as a means of inter-thread communication. Use locks instead.

The variables defined in the `signal` module are:

`signal.SIG_DFL`
This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for `SIGQUIT` is to dump core and exit, while the default action for `SIGCLD` is to simply ignore it.

`signal.SIG_IGN`
This is another standard signal handler, which will simply ignore the given signal.

`SIG*`
All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for `signal` lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

`signal.NSIG`
One more than the number of the highest signal number.
signal. **ITIMER_REAL**

Decrement interval timer in real time, and delivers `SIGALRM` upon expiration.

signal. **ITIMER_VIRTUAL**

Decrement interval timer only when the process is executing, and delivers `SIGVTALRM` upon expiration.

signal. **ITIMER_PROF**

Decrement interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with **ITIMER_VIRTUAL**, this timer is usually used to profile the time spent by the application in user and kernel space. `SIGPROF` is delivered upon expiration.

The **signal** module defines one exception:

exception **signal. ItimerError**

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of **IOError**.

The **signal** module defines the following functions:

**signal. alarm(time)**

If `time` is non-zero, this function requests that a `SIGALRM` signal be sent to the process in `time` seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If `time` is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page `alarm(2)`.) Availability: Unix.
signal.getsignal(signalnum)

Return the current signal handler for the signal signalnum. The returned value may be a callable Python object, or one of the special values signal.SIG_IGN, signal.SIG_DFL or None. Here, signal.SIG_IGN means that the signal was previously ignored, signal.SIG_DFL means that the default way of handling the signal was previously in use, and None means that the previous signal handler was not installed from Python.

signal.pause()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page signal(2).)

signal.setitimer(which, seconds[, interval])

Sets given interval timer (one of signal.ITIMER_REAL, signal.ITIMER_VIRTUAL or signal.ITIMER_PROF) specified by which to fire after seconds (float is accepted, different from alarm()) and after that every interval seconds. The interval timer specified by which can be cleared by setting seconds to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; signal.ITIMER_REAL will deliver SIGALRM, signal.ITIMER_VIRTUAL sends SIGVTALRM, and signal.ITIMER_PROF will deliver SIGPROF.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause a ItimerError.

New in version 2.6.

signal.getitimer(which)
Returns current value of a given interval timer specified by which.

*New in version 2.6.*

**signal. set_wakeup_fd(fd)**

Set the wakeup fd to *fd*. When a signal is received, a `
\0`
byte is written to the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned. *fd* must be non-blocking. It is up to the library to remove any bytes before calling poll or select again.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a **ValueError** exception to be raised.

**signal. siginterrupt(signalnum, flag)**

Change system call restart behaviour: if *flag* is **False**, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page *siginterrupt*(3) for further information).

Note that installing a signal handler with **signal()** will reset the restart behaviour to interruptible by implicitly calling **siginterrupt** with a true *flag* value for the given signal.

*New in version 2.6.*

**signal. signal(signalnum, handler)**

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values **signal.SIG_IGN** or **signal.SIG_DFL**. The previous signal handler will be returned (see the description of **getsignal()** above). (See the Unix man page
signal(2).)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The handler is called with two arguments: the signal number and the current stack frame (None or a frame object; for a description of frame objects, see the reference manual section on the standard type hierarchy or see the attribute descriptions in the `inspect` module).
Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```python
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise IOError, "Couldn't open device!"

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)  # Disable the alarm
```
Interprocess Communication and Networking
popen2 — Subprocesses with accessible I/O streams

*Deprecated since version 2.6:* This module is obsolete. Use the subprocess module. Check especially the *Replacing Older Functions with the subprocess Module* section.

This module allows you to spawn processes and connect to their input/output/error pipes and obtain their return codes under Unix and Windows.

The subprocess module provides more powerful facilities for spawning new processes and retrieving their results. Using the subprocess module is preferable to using the popen2 module.

The primary interface offered by this module is a trio of factory functions. For each of these, if bufsize is specified, it specifies the buffer size for the I/O pipes. mode, if provided, should be the string 'b' or 't'; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for mode is 't'.

On Unix, cmd may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with os.spawnv()). If cmd is a string it will be passed to the shell (as with os.system()).

The only way to retrieve the return codes for the child processes is by using the poll() or wait() methods on the Popen3 and Popen4 classes; these are only available on Unix. This information is not available when using the popen2(), popen3(), and popen4() functions, or the equivalent functions in the os module. (Note that the
tuples returned by the os module's functions are in a different order from the ones returned by the open2 module.)

popen2. open2([cmd[, bufsize[, mode]]])
Executes cmd as a sub-process. Returns the file objects (child_stdout, child_stdin).

popen2. open3([cmd[, bufsize[, mode]]])
Executes cmd as a sub-process. Returns the file objects (child_stdout, child_stdin, child_stderr).

popen2. open4([cmd[, bufsize[, mode]]])
Executes cmd as a sub-process. Returns the file objects (child_stdout_and_stderr, child_stdin).

New in version 2.0.

On Unix, a class defining the objects returned by the factory functions is also available. These are not used for the Windows implementation, and are not available on that platform.

class open2. Popen3([cmd[, capturestderr[, bufsize]]])
This class represents a child process. Normally, Popen3 instances are created using the open2() and open3() factory functions described above.

If not using one of the helper functions to create Popen3 objects, the parameter cmd is the shell command to execute in a sub-process. The capturestderr flag, if true, specifies that the object should capture standard error output of the child process. The default is false. If the bufsize parameter is specified, it specifies the size of the I/O buffers to/from the child process.
class popen2. \texttt{Popen4(cmd[, bufsize])}

Similar to \texttt{Popen3}, but always captures standard error into the same file object as standard output. These are typically created using \texttt{popen4()}.

\textit{New in version 2.0.}
Popen3 and Popen4 Objects

Instances of the `Popen3` and `Popen4` classes have the following methods:

**Popen3.** `poll()`

Returns `-1` if child process hasn’t completed yet, or its status code (see `wait()`) otherwise.

**Popen3.** `wait()`

Waits for and returns the status code of the child process. The status code encodes both the return code of the process and information about whether it exited using the `exit` system call or died due to a signal. Functions to help interpret the status code are defined in the `os` module; see section *Process Management* for the `W*( )` family of functions.

The following attributes are also available:

**Popen3.** `fromchild`

A file object that provides output from the child process. For `Popen4` instances, this will provide both the standard output and standard error streams.

**Popen3.** `tochild`

A file object that provides input to the child process.

**Popen3.** `childerr`

A file object that provides error output from the child process, if `capturestderr` was true for the constructor, otherwise `None`. This will always be `None` for `Popen4` instances.

**Popen3.** `pid`
The process ID of the child process.
Flow Control Issues

Any time you are working with any form of inter-process communication, control flow needs to be carefully thought out. This remains the case with the file objects provided by this module (or the `os` module equivalents).

When reading output from a child process that writes a lot of data to standard error while the parent is reading from the child's standard output, a deadlock can occur. A similar situation can occur with other combinations of reads and writes. The essential factors are that more than `_PC_PIPE_BUF` bytes are being written by one process in a blocking fashion, while the other process is reading from the first process, also in a blocking fashion.

There are several ways to deal with this situation.

The simplest application change, in many cases, will be to follow this model in the parent process:

```python
import popen2
r, w, e = popen2.popen3('python slave.py')
e.readlines()
r.readlines()
r.close()
e.close()
w.close()
```

with code like this in the child:

```python
import os
import sys

# note that each of these print statements
# writes a single long string

print >>sys.stderr, 400 * 'this is a test\n'
```
In particular, note that `sys.stderr` must be closed after writing all data, or `readlines()` won’t return. Also note that `os.close()` must be used, as `sys.stderr.close()` won’t close `stderr` (otherwise assigning to `sys.stderr` will silently close it, so no further errors can be printed).

Applications which need to support a more general approach should integrate I/O over pipes with their `select()` loops, or use separate threads to read each of the individual files provided by whichever `popen*()` function or `Popen*` class was used.

**See also:**

**Module subprocess**
Module for spawning and managing subprocesses.
This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do “more than one thing at a time.” Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It’s really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the “background.” Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The `asyncore` module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For “conversational” applications and protocols the companion `asynchat` module is invaluable.

The basic idea behind both modules is to create one or more network channels, instances of class `asyncore.dispatcher` and `asynchat.async_chat`. Creating the channels adds them to a global map, used by the `loop()` function if you do not provide it with your own map.
Once the initial channel(s) is(are) created, calling the `loop()` function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

```
asyncore.loop([timeout[, use_poll[, map[, count]]]])
```

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The `count` parameter defaults to None, resulting in the loop terminating only when all channels have been closed. The `timeout` argument sets the timeout parameter for the appropriate `select()` or `poll()` call, measured in seconds; the default is 30 seconds. The `use_poll` parameter, if true, indicates that `poll()` should be used in preference to `select()` (the default is `False`).

The `map` parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If `map` is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `async_chat.async_chat` and subclasses thereof) can freely be mixed in the map.

```
class asyncore.dispatcher
```

The `dispatcher` class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the
expectation of success). The implied higher-level events are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle_connect()</td>
<td>Implied by the first write event</td>
</tr>
<tr>
<td>handle_close()</td>
<td>Implied by a read event with no data available</td>
</tr>
<tr>
<td>handle_accept()</td>
<td>Implied by a read event on a listening socket</td>
</tr>
</tbody>
</table>

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels selected or polled for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

**handle_read()**

Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

**handle_write()**

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```python
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

**handle_expt()**

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.
handle_connect()
Called when the active opener’s socket actually makes a connection. Might send a “welcome” banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()
Called when the socket is closed.

handle_error()
Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()
Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a connect() call for the local endpoint.

readable()
Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns True, indicating that by default, all channels will be interested in read events.

writable()
Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns True, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(family, type)
This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the socket documentation for information on creating sockets.

`connect(address)`
As with the normal socket object, `address` is a tuple with the first element the host to connect to, and the second the port number.

`send(data)`
Send `data` to the remote end-point of the socket.

`recv(buffer_size)`
Read at most `buffer_size` bytes from the socket's remote end-point. An empty string implies that the channel has been closed from the other end.

`listen(backlog)`
Listen for connections made to the socket. The `backlog` argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

`bind(address)`
Bind the socket to `address`. The socket must not already be bound. (The format of `address` depends on the address family — see above.) To mark the socket as re-usable (setting the `SO_REUSEADDR` option), call the `dispatcher` object's `set_reuse_addr()` method.

`accept()`
Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and
address is the address bound to the socket on the other end of the connection.

close()
Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class asyncore.file_dispatcher
A file_dispatcher takes a file descriptor or file object along with an optional map argument and wraps it for use with the poll or loop functions. If provided a file object or anything with a fileno method, that method will be called and passed to the file_wrapper constructor. Availability: UNIX.

class asyncore.file_wrapper
A file_wrapper takes an integer file descriptor and calls os.dup() to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the file_dispatcher class. Availability: UNIX.
Here is a very basic HTTP client that uses the `dispatcher` class to implement its socket handling:

```python
import asyncore, socket

class http_client(asyncore.dispatcher):
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.connect((host, 80))
        self.buffer = 'GET %s HTTP/1.0\r\n\n' % path

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print self.recv(8192)

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

c = http_client('www.python.org', '/')
asyncore.loop()
```
This module builds on the `asyncore` infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. `asynchat` defines the abstract class `async_chat` that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as `asyncore`, and the two types of channel, `asyncore.dispatcher` and `asynchat.async_chat`, can freely be mixed in the channel map. Typically an `asyncore.dispatcher` server channel generates new `asynchat.async_chat` channel objects as it receives incoming connection requests.

```python
class asynchat.async_chat
    This class is an abstract subclass of `asyncore.dispatcher`. To make practical use of the code you must subclass `async_chat`, providing meaningful `collect_incoming_data()` and `found_terminator()` methods. The `asyncore.dispatcher` methods can be used, although not all make sense in a message/response context.

    Like `asyncore.dispatcher`, `async_chat` defines a set of events that are generated by an analysis of socket conditions after a `select` call. Once the polling loop has been started the `async_chat` object's methods are called by the event-processing framework with no action on the part of the programmer.

    Two class attributes can be modified, to improve performance, or possibly even to conserve memory.
```
**ac_in_buffer_size**

The asynchronous input buffer size (default 4096).

**ac_out_buffer_size**

The asynchronous output buffer size (default 4096).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a first-in-first-out queue (fifo) of producers. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (i.e. that it contains no more data) by having its `more()` method return the empty string. At this point the `async_chat` object removes the producer from the fifo and starts using the next producer, if any. When the producer fifo is empty the `handle_write()` method does nothing. You use the channel object’s `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The methods are described below.

```python
async_chat.close_when_done()
```

Pushes a `None` on to the producer fifo. When this producer is popped off the fifo it causes the channel to be closed.

```python
async_chat.collect_incoming_data(data)
```

Called with `data` holding an arbitrary amount of received data. The default method, which must be overridden, raises a `NotImplementedError` exception.

```python
async_chat._collect_incoming_data(data)
```
Sample implementation of a data collection routine to be used in conjunction with \_get\_data() in a user-specified found_terminator().

async_chat.discard_buffers()
In emergencies this method will discard any data held in the input and/or output buffers and the producer fifo.

async_chat.found_terminator()
Called when the incoming data stream matches the termination condition set by set_terminator(). The default method, which must be overridden, raises a NotImplemented exception. The buffered input data should be available via an instance attribute.

async_chat._get_data()
Will return and clear the data received with the sample \_collect\_incoming\_data() implementation.

async_chat.get_terminator()
Returns the current terminator for the channel.

async_chat.handle_close()
Called when the channel is closed. The default method silently closes the channel’s socket.

async_chat.handle_read()
Called when a read event fires on the channel's socket in the asynchronous loop. The default method checks for the termination condition established by set_terminator(), which can be either the appearance of a particular string in the input stream or the receipt of a particular number of characters. When the terminator is found, handle_read() calls the found_terminator() method after calling collect_incoming_data() with any data preceding the terminating condition.
async_chat.handle_write()
    Called when the application may write data to the channel. The
default method calls the initiate_send() method, which in turn
will call refill_buffer() to collect data from the producer fifo
associated with the channel.

async_chat.push(data)
Creates a simple_producer object (see below) containing the
data and pushes it on to the channel's producer_fifo to ensure
its transmission. This is all you need to do to have the channel
write the data out to the network, although it is possible to use
your own producers in more complex schemes to implement
encryption and chunking, for example.

async_chat.push_with_producer(producer)
Takes a producer object and adds it to the producer fifo
associated with the channel. When all currently-pushed
producers have been exhausted the channel will consume this
producer's data by calling its more() method and send the data to
the remote endpoint.

async_chat.readable()
    Should return True for the channel to be included in the set of
channels tested by the select loop for readability.

async_chat.refill_buffer()
    Refills the output buffer by calling the more() method of the
producer at the head of the fifo. If it is exhausted then the
producer is popped off the fifo and the next producer is activated.
If the current producer is, or becomes, None then the channel is
closed.

async_chat.set_terminator(term)
Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

<table>
<thead>
<tr>
<th>term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Will call <code>found_terminator()</code> when the string is found in the input stream</td>
</tr>
<tr>
<td>integer</td>
<td>Will call <code>found_terminator()</code> when the indicated number of characters have been received</td>
</tr>
<tr>
<td>None</td>
<td>The channel continues to collect data forever</td>
</tr>
</tbody>
</table>

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.

`async_chat.writable()`  
Should return `True` as long as items remain on the producer fifo, or the channel is connected and the channel's output buffer is non-empty.
asynchat - Auxiliary Classes and Functions

class asynchat.simple_producer(data[, buffer_size=512])
A simple_producer takes a chunk of data and an optional buffer size. Repeated calls to its more() method yield successive chunks of the data no larger than buffer_size.

more()
Produces the next chunk of information from the producer, or returns the empty string.

class asynchat.fifo([list=None])
Each channel maintains a fifo holding data which has been pushed by the application but not yet popped for writing to the channel. A fifo is a list used to hold data and/or producers until they are required. If the list argument is provided then it should contain producers or data items to be written to the channel.

is_empty()
Returns True if and only if the fifo is empty.

first()
Returns the least-recently push()ed item from the fifo.

push(data)
Adds the given data (which may be a string or a producer object) to the producer fifo.

pop()
If the fifo is not empty, returns True, first(), deleting the popped item. Returns False, None for an empty fifo.
The `asynchat` module also defines one utility function, which may be of use in network and textual analysis operations.

`asynchat.find_prefix_at_end(haystack, needle)`

Returns `True` if string `haystack` ends with any non-empty prefix of string `needle`.
The following partial example shows how HTTP requests can be read with async_chat. A web server might create an http_request_handler object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the Content-Length: header is used to set a numeric terminator to read the right amount of data from the channel.

The handle_request() method is called once all relevant input has been marshalled, after setting the channel terminator to None to ensure that any extraneous data sent by the web client are ignored.

```python
class http_request_handler(asynchat.async_chat):
    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = ''
        self.set_terminator("\r\n\r\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log

    def collect_incoming_data(self, data):
        """Buffer the data""
        self.ibuffer.append(data)

    def found_terminator(self):
        if self.reading_headers:
            self.reading_headers = False
```
self.parse_headers("".join(self.ibuffer))
self.ibuffer = []
if self.op.upper() == "POST":
    clen = self.headers.getheader("content-length")
    self.set_terminator(int(clen))
else:
    self.handling = True
    self.set_terminator(None)
    self.handle_request()
else:
    self.set_terminator(None)  # browsers sometimes over
self.cgi_data = parse(self.headers, "".join(self.ib
self.handling = True
self.ibuffer = []
self.handle_request()
Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the Internet.

- **email** — An email and MIME handling package
  - email: Representing an email message
  - email: Parsing email messages
    - FeedParser API
    - Parser class API
    - Additional notes
  - email: Generating MIME documents
  - email: Creating email and MIME objects from scratch
  - email: Internationalized headers
  - email: Representing character sets
  - email: Encoders
  - email: Exception and Defect classes
  - email: Miscellaneous utilities
  - email: Iterators
  - email: Examples
  - Package History
  - Differences from mimelib

- **json** — JSON encoder and decoder
  - Basic Usage
  - Encoders and decoders

- **mailcap** — Mailcap file handling

- **mailbox** — Manipulate mailboxes in various formats
  - Mailbox objects
    - Maildir
- mbox
- MH
- Babyl
- MMDF
  - Message objects
    - MaildirMessage
    - mboxMessage
    - MHMessage
    - BabylMessage
    - MMDFMessage
  - Exceptions
  - Deprecated classes and methods
  - Examples

- **mhlib** — Access to MH mailboxes
  - MH Objects
  - Folder Objects
  - Message Objects

- **mimetypes** — Tools for parsing MIME messages
  - Additional Methods of Message Objects

- **mimetools** — Tools for parsing MIME messages
  - Additional Methods of Message Objects

- **MimeWriter** — Generic MIME file writer
  - MimeWriter Objects

- **mimify** — MIME processing of mail messages

- **multifile** — Support for files containing distinct parts
  - MultiFile Objects
  - MultiFile Example
- **rfc822** — Parse RFC 2822 mail headers
  - Message Objects
  - AddressList Objects
- **base64** — RFC 3548: Base16, Base32, Base64 Data Encodings
- **binhex** — Encode and decode binhex4 files
  - Notes
- **binascii** — Convert between binary and ASCII
- **quopri** — Encode and decode MIME quoted-printable data
- **uu** — Encode and decode uuencode files
email — An email and MIME handling package

New in version 2.2.

The email package is a library for managing email messages, including MIME and other RFC 2822-based message documents. It subsumes most of the functionality in several older standard modules such as rfc822, mimetools, multifile, and other non-standard packages such as mimecntl. It is specifically not designed to do any sending of email messages to SMTP (RFC 2821), NNTP, or other servers; those are functions of modules such as smtplib and nntplib. The email package attempts to be as RFC-compliant as possible, supporting in addition to RFC 2822, such MIME-related RFCs as RFC 2045, RFC 2046, RFC 2047, and RFC 2231.

The primary distinguishing feature of the email package is that it splits the parsing and generating of email messages from the internal object model representation of email. Applications using the email package deal primarily with objects; you can add sub-objects to messages, remove sub-objects from messages, completely re-arrange the contents, etc. There is a separate parser and a separate generator which handles the transformation from flat text to the object model, and then back to flat text again. There are also handy subclasses for some common MIME object types, and a few miscellaneous utilities that help with such common tasks as extracting and parsing message field values, creating RFC-compliant dates, etc.

The following sections describe the functionality of the email package. The ordering follows a progression that should be common in applications: an email message is read as flat text from a file or
other source, the text is parsed to produce the object structure of the email message, this structure is manipulated, and finally, the object tree is rendered back into flat text.

It is perfectly feasible to create the object structure out of whole cloth — i.e. completely from scratch. From there, a similar progression can be taken as above.

Also included are detailed specifications of all the classes and modules that the email package provides, the exception classes you might encounter while using the email package, some auxiliary utilities, and a few examples. For users of the older mimelib package, or previous versions of the email package, a section on differences and porting is provided.

Contents of the email package documentation:

- **email**: Representing an email message
- **email**: Parsing email messages  
  - FeedParser API  
  - Parser class API  
  - Additional notes
- **email**: Generating MIME documents
- **email**: Creating email and MIME objects from scratch
- **email**: Internationalized headers
- **email**: Representing character sets
- **email**: Encoders
- **email**: Exception and Defect classes
- **email**: Miscellaneous utilities

- **email**: Iterators

- **email**: Examples

**See also:**

- SMTP protocol client

**Module nntplib**
- NNTP protocol client
Package History

This table describes the release history of the email package, corresponding to the version of Python that the package was released with. For purposes of this document, when you see a note about change or added versions, these refer to the Python version the change was made in, not the email package version. This table also describes the Python compatibility of each version of the package.

<table>
<thead>

</tr>
</tbody>
</table>

Here are the major differences between email version 4 and version 3:

- All modules have been renamed according to PEP 8 standards. For example, the version 3 module `email.Message` was renamed to `email.message` in version 4.

- A new subpackage `email.mime` was added and all the version 3 `email.MIME*` modules were renamed and situated into the `email.mime` subpackage. For example, the version 3 module `email.MIMEText` was renamed to `email.mime.text`.

Note that the version 3 names will continue to work until Python 2.6.
• The email.mime.application module was added, which contains the MIMEApplication class.

• Methods that were deprecated in version 3 have been removed. These include Generator.__call__(), Message.get_type(), Message.get_main_type(), Message.get_subtype().

• Fixes have been added for RFC 2231 support which can change some of the return types for Message.get_param() and friends. Under some circumstances, values which used to return a 3-tuple now return simple strings (specifically, if all extended parameter segments were unencoded, there is no language and charset designation expected, so the return type is now a simple string). Also, %-decoding used to be done for both encoded and unencoded segments; this decoding is now done only for encoded segments.

Here are the major differences between email version 3 and version 2:

• The FeedParser class was introduced, and the Parser class was implemented in terms of the FeedParser. All parsing therefore is non-strict, and parsing will make a best effort never to raise an exception. Problems found while parsing messages are stored in the message's defect attribute.

• All aspects of the API which raised DeprecationWarningS in version 2 have been removed. These include the _encoder argument to the MIMEText constructor, the Message.add_payload() method, the Utils.dump_address_pair() function, and the functions Utils.decode() and Utils.encode().

• New DeprecationWarnings have been added to: Generator.__call__(), Message.get_type(), Message.get_main_type(), Message.get_subtype(), and the strict
argument to the `Parser` class. These are expected to be removed in future versions.

- Support for Pythons earlier than 2.3 has been removed.

Here are the differences between `email` version 2 and version 1:

- The `email.Header` and `email.Charset` modules have been added.

- The pickle format for `Message` instances has changed. Since this was never (and still isn't) formally defined, this isn't considered a backward incompatibility. However if your application pickles and unpickles `Message` instances, be aware that in `email` version 2, `Message` instances now have private variables `_charset` and `_default_type`.

- Several methods in the `Message` class have been deprecated, or their signatures changed. Also, many new methods have been added. See the documentation for the `Message` class for details. The changes should be completely backward compatible.

- The object structure has changed in the face of `message/rfc822` content types. In `email` version 1, such a type would be represented by a scalar payload, i.e. the container message's `is_multipart()` returned false, `get_payload()` was not a list object, but a single `Message` instance.

   This structure was inconsistent with the rest of the package, so the object representation for `message/rfc822` content types was changed. In `email` version 2, the container does return `True` from `is_multipart()`, and `get_payload()` returns a list containing a single `Message` item.

   Note that this is one place that backward compatibility could not
be completely maintained. However, if you’re already testing the return type of `get_payload()`, you should be fine. You just need to make sure your code doesn’t do a `set_payload()` with a `Message` instance on a container with a content type of `message/rfc822`.

- The `Parser` constructor’s `strict` argument was added, and its `parse()` and `parsestr()` methods grew a `headersonly` argument. The `strict` flag was also added to functions `email.message_from_file()` and `email.message_from_string()`.

- `Generator.__call__()` is deprecated; use `Generator.flatten()` instead. The `Generator` class has also grown the `clone()` method.

- The `DecodedGenerator` class in the `email.Generator` module was added.

- The intermediate base classes `MIMENonMultipart` and `MIME-Multipart` have been added, and interposed in the class hierarchy for most of the other MIME-related derived classes.

- The `_encoder` argument to the `MIMEText` constructor has been deprecated. Encoding now happens implicitly based on the `_charset` argument.

- The following functions in the `email.Utils` module have been deprecated: `dump_address_pairs()`, `decode()`, and `encode()`. The following functions have been added to the module: `make_msgid()`, `decode_rfc2231()`, `encode_rfc2231()`, and `decode_params()`.

- The non-public function `email.Iterators._structure()` was added.
Differences from `mimelib`

The `email` package was originally prototyped as a separate library called `mimelib`. Changes have been made so that method names are more consistent, and some methods or modules have either been added or removed. The semantics of some of the methods have also changed. For the most part, any functionality available in `mimelib` is still available in the `email` package, albeit often in a different way. Backward compatibility between the `mimelib` package and the `email` package was not a priority.

Here is a brief description of the differences between the `mimelib` and the `email` packages, along with hints on how to port your applications.

Of course, the most visible difference between the two packages is that the package name has been changed to `email`. In addition, the top-level package has the following differences:

- `messageFromString()` has been renamed to `message_from_string()`.
- `messageFromFile()` has been renamed to `message_from_file()`.

The `Message` class has the following differences:

- The method `asString()` was renamed to `as_string()`.
- The method `ismultipart()` was renamed to `is_multipart()`.
- The `get_payload()` method has grown a `decode` optional argument.
- The method `getall()` was renamed to `get_all()`.
- The method `addheader()` was renamed to `add_header()`.
- The method `gettype()` was renamed to `get_type()`.
• The method `getmaintype()` was renamed to `get_main_type()`.
• The method `getsubtype()` was renamed to `get_subtype()`.
• The method `getparams()` was renamed to `get_params()`. Also, whereas `getparams()` returned a list of strings, `get_params()` returns a list of 2-tuples, effectively the key/value pairs of the parameters, split on the `'='` sign.
• The method `getparam()` was renamed to `get_param()`.
• The method `getcharsets()` was renamed to `get_charsets()`.
• The method `getfilename()` was renamed to `get_filename()`.
• The method `getboundary()` was renamed to `get_boundary()`.
• The method `setboundary()` was renamed to `set_boundary()`.
• The method `getdecodedpayload()` was removed. To get similar functionality, pass the value 1 to the `decode` flag of the `get_payload()` method.
• The method `getpayloadastext()` was removed. Similar functionality is supported by the `DecodedGenerator` class in the `email.generator` module.
• The method `getbodyastext()` was removed. You can get similar functionality by creating an iterator with `typed_subpart_iterator()` in the `email.iterators` module.

The `Parser` class has no differences in its public interface. It does have some additional smarts to recognize `message/delivery-status` type messages, which it represents as a `Message` instance containing separate `Message` subparts for each header block in the delivery status notification [1].

The `Generator` class has no differences in its public interface. There is a new class in the `email.generator` module though, called `DecodedGenerator` which provides most of the functionality previously available in the `Message.getpayloadastext()` method.
The following modules and classes have been changed:

- The **MIMEBase** class constructor arguments `_major` and `_minor` have changed to `_maintype` and `_subtype` respectively.

- The **Image** class/module has been renamed to **MIMEImage**. The `_minor` argument has been renamed to `_subtype`.

- The **Text** class/module has been renamed to **MIMEText**. The `_minor` argument has been renamed to `_subtype`.

- The **MessageRFC822** class/module has been renamed to **MIMEMessage**. Note that an earlier version of **mimelib** called this class/module **RFC822**, but that clashed with the Python standard library module **rfc822** on some case-insensitive file systems.

  Also, the **MIMEMessage** class now represents any kind of MIME message with main type `message`. It takes an optional argument `_subtype` which is used to set the MIME subtype. `_subtype` defaults to `rfc822`.

**mimelib** provided some utility functions in its `address` and `date` modules. All of these functions have been moved to the `email.utils` module.

The **MsgReader** class/module has been removed. Its functionality is most closely supported in the `body_line_iterator()` function in the `email.iterators` module.

**Footnotes**

[1] Delivery Status Notifications (DSN) are defined in **RFC 1894**.
email: Representing an email message

The central class in the `email` package is the `Message` class, imported from the `email.message` module. It is the base class for the `email` object model. `Message` provides the core functionality for setting and querying header fields, and for accessing message bodies.

Conceptually, a `Message` object consists of `headers` and `payloads`. Headers are `RFC 2822` style field names and values where the field name and value are separated by a colon. The colon is not part of either the field name or the field value.

Headers are stored and returned in case-preserving form but are matched case-insensitively. There may also be a single envelope header, also known as the `Unix-From` header or the `From_` header. The payload is either a string in the case of simple message objects or a list of `Message` objects for MIME container documents (e.g. `multipart/*` and `message/rfc822`).

`Message` objects provide a mapping style interface for accessing the message headers, and an explicit interface for accessing both the headers and the payload. It provides convenience methods for generating a flat text representation of the message object tree, for accessing commonly used header parameters, and for recursively walking over the object tree.

Here are the methods of the `Message` class:

```python
class email.message.Message
    The constructor takes no arguments.

    as_string([unixfrom])
```
Return the entire message flattened as a string. When optional *unixfrom* is *True*, the envelope header is included in the returned string. *unixfrom* defaults to *False*.

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it mangles lines that begin with *From*. For more flexibility, instantiate a *Generator* instance and use its *flatten()* method directly. For example:

```python
from cStringIO import StringIO
from email.generator import Generator

fp = StringIO()
g = Generator(fp, mangle_from_=False, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

__str__()
Equivalent to *as_string(unixfrom=True)*.

is_multipart()
Return *True* if the message’s payload is a list of sub-*Message* objects, otherwise return *False*. When *is_multipart()* returns False, the payload should be a string object.

set_unixfrom(*unixfrom*)
Set the message’s envelope header to *unixfrom*, which should be a string.

get_unixfrom()
Return the message’s envelope header. Defaults to *None* if the envelope header was never set.

attach(*payload*)
Add the given `payload` to the current payload, which must be `None` or a list of `Message` objects before the call. After the call, the payload will always be a list of `Message` objects. If you want to set the payload to a scalar object (e.g. a string), use `set_payload()` instead.

`get_payload([i[, decode]])`

Return the current payload, which will be a list of `Message` objects when `is_multipart()` is `True`, or a string when `is_multipart()` is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument `i`, `get_payload()` will return the `i`-th element of the payload, counting from zero, if `is_multipart()` is `True`. An `IndexError` will be raised if `i` is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. `is_multipart()` is `False`) and `i` is given, a `TypeError` is raised.

Optional `decode` is a flag indicating whether the payload should be decoded or not, according to the `Content-Transfer-Encoding` header. When `True` and the message is not a multipart, the payload will be decoded if this header's value is `quoted-printable` or `base64`. If some other encoding is used, or `Content-Transfer-Encoding` header is missing, or if the payload has bogus base64 data, the payload is returned as-is (undecoded). If the message is a multipart and the `decode` flag is `True`, then `None` is returned. The default for `decode` is `False`.

`set_payload(payload[, charset])`

Set the entire message object’s payload to `payload`. It is the
client’s responsibility to ensure the payload invariants. Optional `charset` sets the message’s default character set; see `set_charset()` for details.

*Changed in version 2.2.2: charset argument added.*

**set_charset(charset)**

Set the character set of the payload to `charset`, which can either be a `Charset` instance (see `email.charset`), a string naming a character set, or `None`. If it is a string, it will be converted to a `Charset` instance. If `charset` is `None`, the `charset` parameter will be removed from the `Content-Type` header. Anything else will generate a `TypeError`.

The message will be assumed to be of type `text/*` encoded with `charset.input_charset`. It will be converted to `charset.output_charset` and encoded properly, if needed, when generating the plain text representation of the message. MIME headers (`MIME-Version`, `Content-Type`, `Content-Transfer-Encoding`) will be added as needed.

*New in version 2.2.2.*

**get_charset()**

Return the `Charset` instance associated with the message’s payload.

*New in version 2.2.2.*

The following methods implement a mapping-like interface for accessing the message’s RFC 2822 headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed
order to the keys returned by `keys()`, but in a `Message` object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

```python
__len__()  
Return the total number of headers, including duplicates.

__contains__(name)  
Return true if the message object has a field named `name`. Matching is done case-insensitively and `name` should not include the trailing colon. Used for the `in` operator, e.g.:

```python
if 'message-id' in myMessage:
    print 'Message-ID:', myMessage['message-id']
```

```python
__getitem__(name)  
Return the value of the named header field. `name` should not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message’s headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant named headers.

```python
__setitem__(name, val)  
Add a header to the message with field name `name` and value
val. The field is appended to the end of the message’s existing fields.

Note that this does not overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name name, delete the field first, e.g.:

```python
del msg['subject']
msg['subject'] = 'Python roolz!
```

__delitem__(name)
Delete all occurrences of the field with name name from the message’s headers. No exception is raised if the named field isn’t present in the headers.

has_key(name)
Return true if the message contains a header field named name, otherwise return false.

keys()
Return a list of all the message’s header field names.

values()
Return a list of all the message’s field values.

items()
Return a list of 2-tuples containing all the message’s field headers and values.

get(name[, failobj])
Return the value of the named header field. This is identical to __getitem__() except that optional failobj is returned if the named header is missing (defaults to None).

Here are some additional useful methods:
get_all(name[, failobj])
Return a list of all the values for the field named name. If there are no such named headers in the message, failobj is returned (defaults to None).

add_header(_name, _value, **_params)
Extended header setting. This method is similar to __setitem__() except that additional header parameters can be provided as keyword arguments. _name is the header field to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the key will be added.

Here's an example:

msg.add_header('Content-Disposition', 'attachment', filename="bud.gif")

This will add a header that looks like

Content-Disposition: attachment; filename="bud.gif"

replace_header(_name, _value)
Replace a header. Replace the first header found in the message that matches _name, retaining header order and field name case. If no matching header was found, a KeyError is raised.

New in version 2.2.2.
get_content_type()

Return the message's content type. The returned string is coerced to lower case of the form maintype/subtype. If there was no Content-Type header in the message the default type as given by get_default_type() will be returned. Since according to RFC 2045, messages always have a default type, get_content_type() will always return a value.

RFC 2045 defines a message's default type to be text/plain unless it appears inside a multipart/digest container, in which case it would be message/rfc822. If the Content-Type header has an invalid type specification, RFC 2045 mandates that the default type be text/plain.

New in version 2.2.2.

get_content_maintype()

Return the message's main content type. This is the maintype part of the string returned by get_content_type().

New in version 2.2.2.

get_content_subtype()

Return the message's sub-content type. This is the subtype part of the string returned by get_content_type().

New in version 2.2.2.

get_default_type()

Return the default content type. Most messages have a default content type of text/plain, except for messages that are subparts of multipart/digest containers. Such subparts have a default content type of message/rfc822.

New in version 2.2.2.
**set_default_type(ctype)**

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

*New in version 2.2.2.*

**get_params([failobj[, header[, unquote]]])**

Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '=' sign. The left hand side of the '=' is the key, while the right hand side is the value. If there is no '=' sign in the parameter the value is the empty string, otherwise the value is as described in *get_param()* and is unquoted if optional *unquote* is *True* (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

*Changed in version 2.2.2: unquote argument added.*

**get_param(param[, failobj[, header[, unquote]]])**

Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to *None*).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was *RFC 2231* encoded. When it's a 3-tuple, the
elements of the value are of the form (CHARSET, LANGUAGE, VALUE). Note that both CHARSET and LANGUAGE can be None, in which case you should consider VALUE to be encoded in the us-ascii charset. You can usually ignore LANGUAGE.

If your application doesn’t care whether the parameter was encoded as in RFC 2231, you can collapse the parameter value by calling email.Utils.collapse_rfc2231_value(), passing in the return value from get_param(). This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn’t. For example:

```python
rawparam = msg.get_param('foo')
param = email.Utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the VALUE item in the 3-tuple) is always unquoted, unless unquote is set to False.

*Changed in version 2.2.2: unquote argument added, and 3-tuple return value possible.*

```python
set_param(param, value[, header[, requote[, charset[, language]]]])
```

Set a parameter in the Content-Type header. If the parameter already exists in the header, its value will be replaced with value. If the Content-Type header has not yet been defined for this message, it will be set to text/plain and the new parameter value will be appended as per RFC 2045.

Optional header specifies an alternative header to Content-Type, and all parameters will be quoted as necessary unless optional requote is False (the default is True).
If optional charset is specified, the parameter will be encoded according to RFC 2231. Optional language specifies the RFC 2231 language, defaulting to the empty string. Both charset and language should be strings.

New in version 2.2.2.

def del_param(param[, header[, requote]])
Remove the given parameter completely from the Content-Type header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless requote is False (the default is True). Optional header specifies an alternative to Content-Type.

New in version 2.2.2.

def set_type(type[, header][, requote])
Set the main type and subtype for the Content-Type header. type must be a string in the form maintype/subtype, otherwise a ValueError is raised.

This method replaces the Content-Type header, keeping all the parameters in place. If requote is False, this leaves the existing header’s quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the header argument. When the Content-Type header is set a MIME-Version header is also added.

New in version 2.2.2.

def get_filename([failobj])
Return the value of the filename parameter of the Content-
Disposition header of the message. If the header does not have a filename parameter, this method falls back to looking for the name parameter. If neither is found, or the header is missing, then failobj is returned. The returned string will always be unquoted as per Utils.unquote().

get_boundary(\[failobj\])
Return the value of the boundary parameter of the Content-Type header of the message, or failobj if either the header is missing, or has no boundary parameter. The returned string will always be unquoted as per Utils.unquote().

set_boundary(boundary)
Set the boundary parameter of the Content-Type header to boundary. set_boundary() will always quote boundary if necessary. A HeaderParseError is raised if the message object has no Content-Type header.

Note that using this method is subtly different than deleting the old Content-Type header and adding a new one with the new boundary via add_header(), because set_boundary() preserves the order of the Content-Type header in the list of headers. However, it does not preserve any continuation lines which may have been present in the original Content-Type header.

get_content_charset(\[failobj\])
Return the charset parameter of the Content-Type header, coerced to lower case. If there is no Content-Type header, or if that header has no charset parameter, failobj is returned.

Note that this method differs from get_charset() which returns the Charset instance for the default encoding of the
message body.

*New in version 2.2.2.*

**get_charsets([failobj])**

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the *charset* parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no *charset* parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

**walk()**

The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a *for* loop; each iteration returns the next subpart.

Here’s an example that prints the MIME type of every part of a multipart message structure:

```python
>>> for part in msg.walk():
...   print part.get_content_type()
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
```
Changed in version 2.5: The previously deprecated methods `get_type()`, `get_main_type()`, and `get_subtype()` were removed.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the **Parser** discovers some text after the headers but before the first boundary string, it assigns this text to the message’s *preamble* attribute. When the **Generator** is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See `email.parser` and `email.generator` for details.

Note that if the message object has no preamble, the *preamble* attribute will be **None**.

**epilogue**

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

Changed in version 2.5: You do not need to set the epilogue
to the empty string in order for the Generator to print a newline at the end of the file.

**defects**

The *defects* attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.

*New in version 2.4.*
email: Parsing email messages

Message object structures can be created in one of two ways: they can be created from whole cloth by instantiating `Message` objects and stringing them together via `attach()` and `set_payload()` calls, or they can be created by parsing a flat text representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a string or a file object, and the parser will return to you the root `Message` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the `get_payload()` and `walk()` methods.

There are actually two parser interfaces available for use, the classic `Parser` API and the incremental `FeedParser` API. The classic `Parser` API is fine if you have the entire text of the message in memory as a string, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate for when you’re reading the message from a stream which might block waiting for more input (e.g. reading an email message from a socket). The `FeedParser` can consume and parse the message incrementally, and only returns the root object when you close the parser [1].

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. There is no magical connection between the `email` package’s bundled parser and the `Message` class, so your custom parser can create message object trees any way it finds necessary.
FeedParser API

New in version 2.4.

The FeedParser, imported from the email.feedparser module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (e.g. a socket). The FeedParser can of course be used to parse an email message fully contained in a string or a file, but the classic Parser API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The FeedParser's API is simple; you create an instance, feed it a bunch of text until there's no more to feed it, then close the parser to retrieve the root message object. The FeedParser is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's defects attribute with a list of any problems it found in a message. See the email.errors module for the list of defects that it can find.

Here is the API for the FeedParser:

class email.parser.FeedParser(_factory)

    Create a FeedParser instance. Optional _factory is a no-argument callable that will be called whenever a new message object is needed. It defaults to the email.message.Message class.

    feed(data)
    
    Feed the FeedParser some more data. data should be a string
containing one or more lines. The lines can be partial and the
FeedParser will stitch such partial lines together properly. The
lines in the string can have any of the common three line
endings, carriage return, newline, or carriage return and
newline (they can even be mixed).

close()
Closing a FeedParser completes the parsing of all previously
fed data, and returns the root message object. It is undefined
what happens if you feed more data to a closed FeedParser.
The `Parser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a string or file. The `email.parser` module also provides a second class, called `HeaderParser` which can be used if you're only interested in the headers of the message. `HeaderParser` can be much faster in these situations, since it does not attempt to parse the message body, instead setting the payload to the raw body as a string. `HeaderParser` has the same API as the `Parser` class.

```python
class email.parser.Parser(_class)
```

The constructor for the `Parser` class takes an optional argument `_class`. This must be a callable factory (such as a function or a class), and it is used whenever a sub-message object needs to be created. It defaults to `Message` (see `email.message`). The factory will be called without arguments.

The optional `strict` flag is ignored.

*Deprecated since version 2.4:* Because the `Parser` class is a backward compatible API wrapper around the new-in-Python 2.4 `FeedParser`, all parsing is effectively non-strict. You should simply stop passing a `strict` flag to the `Parser` constructor.

*Changed in version 2.2.2:* The `strict` flag was added.

*Changed in version 2.4:* The `strict` flag was deprecated.

The other public `Parser` methods are:
parse(fp[, headersonly])

Read all the data from the file-like object fp, parse the resulting text, and return the root message object. fp must support both the readline() and the read() methods on file-like objects.

The text contained in fp must be formatted as a block of RFC 2822 style headers and header continuation lines, optionally preceded by a envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts).

Optional headersonly is as with the parse() method.

Changed in version 2.2.2: The headersonly flag was added.

parsestr(text[, headersonly])

Similar to the parse() method, except it takes a string object instead of a file-like object. Calling this method on a string is exactly equivalent to wrapping text in a StringIO instance first and calling parse().

Optional headersonly is a flag specifying whether to stop parsing after reading the headers or not. The default is False, meaning it parses the entire contents of the file.

Changed in version 2.2.2: The headersonly flag was added.

Since creating a message object structure from a string or a file object is such a common task, two functions are provided as a convenience. They are available in the top-level email package namespace.
email.parser.message_from_string(s[, _class[, strict]])

Return a message object structure from a string. This is exactly equivalent to Parser().parsestr(s). Optional _class and strict are interpreted as with the Parser class constructor.

*Changed in version 2.2.2:* The strict flag was added.

email.parser.message_from_file(fp[, _class[, strict]])

Return a message object structure tree from an open file object. This is exactly equivalent to Parser().parse(fp). Optional _class and strict are interpreted as with the Parser class constructor.

*Changed in version 2.2.2:* The strict flag was added.

Here’s an example of how you might use this at an interactive Python prompt:

```python
>>> import email
>>> msg = email.message_from_string(myString)
```
Here are some notes on the parsing semantics:

- Most non-`multipart` type messages are parsed as a single message object with a string payload. These objects will return `False` for `is_multipart()`. Their `get_payload()` method will return a string object.
- All `multipart` type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for `is_multipart()` and their `get_payload()` method will return the list of `Message` subparts.
- Most messages with a content type of `message/*` (e.g. `message/delivery-status` and `message/rfc822`) will also be parsed as container object containing a list payload of length 1. Their `is_multipart()` method will return `True`. The single element in the list payload will be a sub-message object.
- Some non-standards compliant messages may not be internally consistent about their `multipart`-edness. Such messages may have a `Content-Type` header of type `multipart`, but their `is_multipart()` method may return `False`. If such messages were parsed with the `FeedParser`, they will have an instance of the `MultipartInvariantViolationDefect` class in their `defects` attribute list. See `email.errors` for details.

Footnotes

As of email package version 3.0, introduced in Python 2.4, the classic `Parser` was re-implemented in terms of the `FeedParser`, so the semantics and results are identical between the two parsers.
The Python Standard Library » Internet Data Handling » email — An email and MIME handling package
email: Generating MIME documents

One of the most common tasks is to generate the flat text of the email message represented by a message object structure. You will need to do this if you want to send your message via the `smtplib` module or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a flat text document is the job of the `Generator` class.

Again, as with the `email.parser` module, you aren’t limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the transformation from flat text, to a message structure via the `Parser` class, and back to flat text, is idempotent (the input is identical to the output).

Here are the public methods of the `Generator` class, imported from the `email.generator` module:

```python
class email.generator.Generator(outfp[, mangle_from_[, maxheaderlen]])
```

The constructor for the `Generator` class takes a file-like object called `outfp` for an argument. `outfp` must support the `write()` method and be usable as the output file in a Python extended print statement.

Optional `mangle_from_` is a flag that, when `True`, puts a `>` character in front of any line in the body that starts exactly as `From`, i.e. `From` followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such
lines be mistaken for a Unix mailbox format envelope header separator (see WHY THE CONTENT-LENGTH FORMAT IS BAD for details). mangle_from_ defaults to True, but you might want to set this to False if you are not writing Unix mailbox format files.

Optional maxheaderlen specifies the longest length for a non-continued header. When a header line is longer than maxheaderlen (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the email.header.Header class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by RFC 2822.

The other public Generator methods are:

**flatten(msg[, unixfrom])**

Print the textual representation of the message object structure rooted at msg to the output file specified when the Generator instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded.

Optional unixfrom is a flag that forces the printing of the envelope header delimiter before the first RFC 2822 header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to False to inhibit the printing of the envelope delimiter.

Note that for subparts, no envelope header is ever printed.

*New in version 2.2.2.*

**clone(fp)**

Return an independent clone of this Generator instance with the exact same options.

*New in version 2.2.2.*
write(s)

Write the string s to the underlying file object, i.e. outfp passed to Generator’s constructor. This provides just enough file-like API for Generator instances to be used in extended print statements.

As a convenience, see the methods Message.as_string() and str(aMessage), a.k.a. Message.__str__(), which simplify the generation of a formatted string representation of a message object. For more detail, see email.message.

The email.generator module also provides a derived class, called DecodedGenerator which is like the Generator base class, except that non-text parts are substituted with a format string representing the part.

class email.generator.\:DecodedGenerator\:(outfp[, mangle_from_[, maxheaderlen[, fmt]]])

This class, derived from Generator walks through all the subparts of a message. If the subpart is of main type text, then it prints the decoded payload of the subpart. Optional _mangle_from_ and maxheaderlen are as with the Generator base class.

If the subpart is not of main type text, optional fmt is a format string that is used instead of the message payload. fmt is expanded with the following keywords, %(keyword)s format:

- type – Full MIME type of the non-text part
- maintype – Main MIME type of the non-text part
- subtype – Sub-MIME type of the non-text part
- filename – Filename of the non-text part
- description – Description associated with the non-text part
- encoding – Content transfer encoding of the non-text part
The default value for \texttt{fmt} is \texttt{None}, meaning

\[
\text{[Non-text \(\%(type)s\) part of message omitted, filename \%(filename)s]}
\]

\textit{New in version 2.2.2.}

\textit{Changed in version 2.5:} The previously deprecated method \texttt{\_\_call\_\()\) was removed.
Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual `Message` objects by hand. In fact, you can also take an existing structure and add new `Message` objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating `Message` instances, adding attachments and all the appropriate headers manually. For MIME messages though, the `email` package provides some convenient subclasses to make things easier.

Here are the classes:

```python
class email.mime.MIMEBase(_maintype, _subtype, **_params)
    Module: email.mime.base
```

This is the base class for all the MIME-specific subclasses of `Message`. Ordinarily you won’t create instances specifically of `MIMEBase`, although you could. `MIMEBase` is provided primarily as a convenient base class for more specific MIME-aware subclasses.

 `_maintype` is the `Content-Type` major type (e.g. `text` or `image`), and `_subtype` is the `Content-Type` minor type (e.g. `plain` or `gif`). `_params` is a parameter key/value dictionary and is passed directly to `Message.add_header()`.

The `MIMEBase` class always adds a `Content-Type` header (based on `_maintype`, `_subtype`, and `_params`), and a `MIME-Version`...
class email.mime.MIMENonMultipart
    Module: email.mime.nonmultipart

    A subclass of MIMEBase, this is an intermediate base class for MIME messages that are not multipart. The primary purpose of this class is to prevent the use of the attach() method, which only makes sense for multipart messages. If attach() is called, a MultipartConversionError exception is raised.

    New in version 2.2.2.

class email.mime.MIMEMultipart([subtype[, boundary[, _subparts[, _params]]]]))
    Module: email.mime.multipart

    A subclass of MIMEBase, this is an intermediate base class for MIME messages that are multipart. Optional _subtype defaults to mixed, but can be used to specify the subtype of the message. A Content-Type header of multipart/*_subtype* will be added to the message object. A :mailheader:`MIME-Version` header will also be added.

    Optional boundary is the multipart boundary string. When None (the default), the boundary is calculated when needed.

    _subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the Message.attach() method.

    Additional parameters for the Content-Type header are taken from the keyword arguments, or passed into the _params
argument, which is a keyword dictionary.

*New in version 2.2.2.*

class email.mime.MIMEApplication(_data[, _subtype[, _encoder[, **_params]]]])

Module: email.mime.application

A subclass of `MIMENonMultipart`, the `MIMEApplication` class is used to represent MIME message objects of major type `application`. `_data` is a string containing the raw byte data. Optional `_subtype` specifies the MIME subtype and defaults to `octet-stream`.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the `MIMEApplication` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

`_params` are passed straight through to the base class constructor.

*New in version 2.5.*

class email.mime.MIMEAudio(_audiodata[, _subtype[, _encoder[, **_params]]]])

Module: email.mime.audio

A subclass of `MIMENonMultipart`, the `MIMEAudio` class is used to create MIME message objects of major type `audio`. `_audiodata` is
a string containing the raw audio data. If this data can be decoded by the standard Python module `sndhdr`, then the subtype will be automatically included in the `Content-Type` header. Otherwise you can explicitly specify the audio subtype via the `_subtype` parameter. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the `MIMEAudio` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

Optional `_params` are passed straight through to the base class constructor.

```python
class email.mime.MIMEImage(_imagedata, _subtype, _encoder, **_params)]
```

Module: `email.mime.image`

A subclass of `MIMENonMultipart`, the `MIMEImage` class is used to create MIME message objects of major type `image`. `_imagedata` is a string containing the raw image data. If this data can be decoded by the standard Python module `imghdr`, then the subtype will be automatically included in the `Content-Type` header. Otherwise you can explicitly specify the image subtype via the `_subtype` parameter. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable
takes one argument, which is the `MIMEImage` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

_params are passed straight through to the `MIMEBase` constructor.

class email.mime.MIMEMessage(_msg[, _subtype])

Module: email.mime.message

A subclass of `MIMENonMultipart`, the `MIMEMessage` class is used to create MIME objects of main type `message`. `_msg` is used as the payload, and must be an instance of class `Message` (or a subclass thereof), otherwise a `TypeError` is raised.

Optional `_subtype` sets the subtype of the message; it defaults to `rfc822`.

class email.mime.MIMEText(_text[, _subtype[, _charset]])

Module: email.mime.text

A subclass of `MIMENonMultipart`, the `MIMEText` class is used to create MIME objects of major type `text`. `_text` is the string for the payload. `_subtype` is the minor type and defaults to `plain`. `_charset` is the character set of the text and is passed as a parameter to the `MIMENonMultipart` constructor; it defaults to `us-ascii`. No guessing or encoding is performed on the text data.

*Changed in version 2.4:* The previously deprecated `_encoding` argument has been removed. Encoding happens implicitly based on the `_charset` argument.
**email: Internationalized headers**

**RFC 2822** is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045, RFC 2046, RFC 2047**, and **RFC 2231**. The email package supports these standards in its **email.header** and **email.charset** modules.

If you want to include non-ASCII characters in your email headers, say in the **Subject** or **To** fields, you should use the **Header** class and assign the field in the **Message** object to an instance of **Header** instead of using a string for the header value. Import the **Header** class from the **email.header** module. For example:

```python
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> print msg.as_string()
Subject: =?iso-8859-1?q?p=F6stal=?
```

Notice here how we wanted the **Subject** field to contain a non-ASCII character? We did this by creating a **Header** instance and passing in the character set that the byte string was encoded in. When the
subsequent Message instance was flattened, the Subject field was properly RFC 2047 encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

New in version 2.2.2.

Here is the Header class description:

```python
class email.header.Header([s[, charset[, maxlinelen[, header_name[, continuation_ws[, errors]]]]]]))
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional s is the initial header value. If None (the default), the initial header value is not set. You can later append to the header with append() method calls. s may be a byte string or a Unicode string, but see the append() documentation for semantics.

Optional charset serves two purposes: it has the same meaning as the charset argument to the append() method. It also sets the default character set for all subsequent append() calls that omit the charset argument. If charset is not provided in the constructor (the default), the us-ascii character set is used both as s's initial charset and as the default for subsequent append() calls.

The maximum line length can be specified explicit via maxlinelen. For splitting the first line to a shorter value (to account for the field header which isn't included in s, e.g. Subject) pass in the name of the field in header_name. The default maxlinelen is 76, and the default value for header_name is None, meaning it is not taken into account for the first line of a long, split header.

Optional continuation_ws must be RFC 2822-compliant folding whitespace, and is usually either a space or a hard tab character.
This character will be prepended to continuation lines.

Optional errors is passed straight through to the append() method.

```
append(s[, charset[, errors]])
```

Append the string s to the MIME header.

Optional charset, if given, should be a charset instance (see email.charset) or the name of a character set, which will be converted to a Charset instance. A value of None (the default) means that the charset given in the constructor is used.

s may be a byte string or a Unicode string. If it is a byte string (i.e. isinstance(s, str) is true), then charset is the encoding of that byte string, and a UnicodeError will be raised if the string cannot be decoded with that character set.

If s is a Unicode string, then charset is a hint specifying the character set of the characters in the string. In this case, when producing an RFC 2822-compliant header using RFC 2047 rules, the Unicode string will be encoded using the following charsets in order: us-ascii, the charset hint, utf-8. The first character set to not provoke a UnicodeError is used.

Optional errors is passed through to any unicode() or ustr.encode() call, and defaults to “strict”.

```
encode([splitchars])
```

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings. Optional splitchars is a string containing characters to split long ASCII lines on, in rough support of RFC 2822's highest level
syntactic breaks. This doesn’t affect RFC 2047 encoded lines.

The `Header` class also provides a number of methods to support standard operators and built-in functions.

```python
__str__()  
A synonym for `Header.encode()`. Useful for `str(aHeader)`.

__unicode__()  
A helper for the built-in `unicode()` function. Returns the header as a Unicode string.

__eq__(other)  
This method allows you to compare two `Header` instances for equality.

__ne__(other)  
This method allows you to compare two `Header` instances for inequality.
```

The `email.header` module also provides the following convenient functions.

```python
email.header.decode_header(header)
```

Decode a message header value without converting the character set. The header value is in `header`.

This function returns a list of `(decoded_string, charset)` pairs containing each of the decoded parts of the header. `charset` is `None` for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here’s an example:
```python
from email.header import decode_header
[['p\xf6stal', 'iso-8859-1']]
```

e-mail.header.make_header(decoded_seq[, maxlinelen[, header_name[, continuation_ws]]]])

Create a `Header` instance from a sequence of pairs as returned by `decode_header()`.

decode_header() takes a header value string and returns a sequence of pairs of the format (decoded_string, charset) where charset is the name of the character set.

This function takes one of those sequence of pairs and returns a `Header` instance. Optional `maxlinelen`, `header_name`, and `continuation_ws` are as in the `Header` constructor.
email: Representing character sets

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

`New in version 2.2.2.`

```python
class email.charset.Charset([input_charset])

Map character sets to their email properties.
```

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional `input_charset` is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if `input_charset` is `iso-8859-1`, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If `input_charset` is `euc-jp`, then headers will be encoded with
base64, bodies will not be encoded, but output text will be converted from the euc-jp character set to the iso-2022-jp character set.

**Charset** instances have the following data attributes:

**input_charset**
The initial character set specified. Common aliases are converted to their official email names (e.g. latin_1 is converted to iso-8859-1). Defaults to 7-bit us-ascii.

**header_encoding**
If the character set must be encoded before it can be used in an email header, this attribute will be set to Charset.QP (for quoted-printable), Charset.BASE64 (for base64 encoding), or Charset.SHORTEST for the shortest of QP or BASE64 encoding. Otherwise, it will be None.

**body_encoding**
Same as header_encoding, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. Charset.SHORTEST is not allowed for body_encoding.

**output_charset**
Some character sets must be converted before they can be used in email headers or bodies. If the input_charset is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be None.

**input_codec**
The name of the Python codec used to convert the input_charset to Unicode. If no conversion codec is necessary, this attribute will be None.

**output_codec**
The name of the Python codec used to convert Unicode to the output charset. If no conversion codec is necessary, this attribute will have the same value as the input_codec.

Charset instances also have the following methods:

```
get_body_encoding()
Return the content transfer encoding used for body encoding.

This is either the string quoted-printable or base64 depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the Content-Transfer-Encoding header itself to whatever is appropriate.

Returns the string quoted-printable if body_encoding is QP, returns the string base64 if body_encoding is BASE64, and returns the string 7bit otherwise.

convert(s)
Convert the string s from the input_codec to the output_codec.

to_splittable(s)
Convert a possibly multibyte string to a safely splittable format. s is the string to split.

Uses the input_codec to try and convert the string to Unicode, so it can be safely split on character boundaries (even for multibyte characters).

Returns the string as-is if it isn’t known how to convert s to Unicode with the input_charset.

Characters that could not be converted to Unicode will be
replaced with the Unicode replacement character ‘U+FFFD’.

**from_splittable**(ustr[, to_output])
Convert a splittable string back into an encoded string. ustr is a Unicode string to “unsplit”.

This method uses the proper codec to try and convert the string from Unicode back into an encoded format. Return the string as-is if it is not Unicode, or if it could not be converted from Unicode.

Characters that could not be converted from Unicode will be replaced with an appropriate character (usually ‘?’).

If to_output is True (the default), uses output_codec to convert to an encoded format. If to_output is False, it uses input_codec.

**get_output_charset()**
Return the output character set.

This is the output_charset attribute if that is not None, otherwise it is input_charset.

**encoded_header_len()**
Return the length of the encoded header string, properly calculating for quoted-printable or base64 encoding.

**header_encode**(s[, convert])
Header-encode the string s.

If convert is True, the string will be converted from the input charset to the output charset automatically. This is not useful for multibyte character sets, which have line length issues (multibyte characters must be split on a character, not a byte
boundary); use the higher-level Header class to deal with these issues (see email.header). convert defaults to False.

The type of encoding (base64 or quoted-printable) will be based on the header_encoding attribute.

body_encode(s[, convert])
Body-encode the string s.

If convert is True (the default), the string will be converted from the input charset to output charset automatically. Unlike header_encode(), there are no issues with byte boundaries and multibyte charsets in email bodies, so this is usually pretty safe.

The type of encoding (base64 or quoted-printable) will be based on the body_encoding attribute.

The Charset class also provides a number of methods to support standard operations and built-in functions.

__str__() Returns input_charset as a string coerced to lower case. __repr__() is an alias for __str__().

eq__(other)
This method allows you to compare two Charset instances for equality.

eq__(other)
This method allows you to compare two Charset instances for inequality.

The email.charset module also provides the following functions for adding new entries to the global character set, alias, and codec
registries:

```python
email.charset.add_charset(charset[, header_enc[, body_enc[, output_charset]]])
```

Add character properties to the global registry.

`charset` is the input character set, and must be the canonical name of a character set.

Optional `header_enc` and `body_enc` is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for `header_enc`. The default is `None` for no encoding.

Optional `output_charset` is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `charset.convert()` is called. The default is to output in the same character set as the input.

Both `input_charset` and `output_charset` must have Unicode codec entries in the module's character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the `codecs` module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

```python
email.charset.add_alias(alias, canonical)
```

Add a character set alias. `alias` is the alias name, e.g. `latin-1`. `canonical` is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global
dictionary ALIASES.

email.charset.add_codec(charset, codecname)
Add a codec that map characters in the given character set to and from Unicode.

charset is the canonical name of a character set. codecname is the name of a Python codec, as appropriate for the second argument to the unicode() built-in, or to the encode() method of a Unicode string.
When creating Message objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for image/* and text/* type messages containing binary data.

The email package provides some convenient encodings in its encoders module. These encoders are actually used by the MIMEAudio and MIMEImage class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the Content-Transfer-Encoding header as appropriate.

Here are the encoding functions provided:

email.encoders.encode_quopri(msg)

Encodes the payload into quoted-printable form and sets the Content-Transfer-Encoding header to quoted-printable [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

email.encoders.encode_base64(msg)

Encodes the payload into base64 form and sets the Content-Transfer-Encoding header to base64. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

email.encoders.encode_7or8bit(msg)

This doesn’t actually modify the message’s payload, but it does set the Content-Transfer-Encoding header to either 7bit or 8bit
as appropriate, based on the payload data.

```
email.encoders.**encode_noop**(msg)
```

This does nothing; it doesn’t even set the `Content-Transfer-Encoding` header.

---

**Footnotes**

[1] Note that encoding with `encode_quopri()` also encodes all tabs and space characters in the data.
email: Exception and Defect classes

The following exception classes are defined in the `email.errors` module:

```python
exc(eption email.errors.MessageError
    This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

exc(eption email.errors.MessageParseError
    This is the base class for exceptions thrown by the `Parser` class. It is derived from `MessageError`.

exc(eption email.errors.HeaderParseError
    Raised under some error conditions when parsing the `RFC 2822` headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse()` or `Parser.parsestr()` methods.

    Situations where it can be raised include finding an envelope header after the first `RFC 2822` header of the message, finding a continuation line before the first `RFC 2822` header is found, or finding a line in the headers which is neither a header or a continuation line.

exc(eption email.errors.BoundaryError
    Raised under some error conditions when parsing the `RFC 2822` headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse()` or `Parser.parsestr()` methods.

    Situations where it can be raised include not being able to find
the starting or terminating boundary in a *multipart/* message when strict parsing is used.

**exception** `email.errors.MultipartConversionError`

Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message's `Content-Type` main type is not either *multipart* or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here's the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a *multipart/alternative* had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`, but this class is *not* an exception!

**New in version 2.4:** All the defect classes were added.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no *boundary* parameter.
- `StartBoundaryNotFoundDefect` – The start boundary claimed in the `Content-Type` header was never found.
- `FirstHeaderLineIsContinuationDefect` – The message had a continuation line as its first header line.
- `MisplacedEnvelopeHeaderDefect` - A “Unix From” header was
found in the middle of a header block.

- **MalformedHeaderDefect** – A header was found that was missing a colon, or was otherwise malformed.
- **MultipartInvariantViolationDefect** – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return false even though its content type claims to be *multipart*. 
There are several useful utilities provided in the email.utils module:

email.utils.quote(str)
Return a new string with backslashes in str replaced by two backslashes, and double quotes replaced by backslash-double quote.

email.utils.unquote(str)
Return a new string which is an unquoted version of str. If str ends and begins with double quotes, they are stripped off. Likewise if str ends and begins with angle brackets, they are stripped off.

email.utils.parseaddr(address)
Parse address – which should be the value of some address-containing field such as To or Cc – into its constituent realname and email address parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of (', ', ') is returned.

email.utils.formataddr(pair)
The inverse of parseaddr(), this takes a 2-tuple of the form (realname, email_address) and returns the string value suitable for a To or Cc header. If the first element of pair is false, then the second element is returned unmodified.

email.utils.getaddresses(fieldvalues)
This method returns a list of 2-tuples of the form returned by parseaddr(). fieldvalues is a sequence of header field values as might be returned by Message.get_all(). Here’s a simple example that gets all the recipients of a message:
```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

**email.utils.parsedate(date)**

Attempts to parse a date according to the rules in [RFC 2822](https://tools.ietf.org/html/rfc2822). However, some mailers don’t follow that format as specified, so parsedate() tries to guess correctly in such cases. date is a string containing an [RFC 2822](https://tools.ietf.org/html/rfc2822) date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, parsedate() returns a 9-tuple that can be passed directly to time.mktime(); otherwise None will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**email.utils.parsedate_tz(date)**

Performs the same function as parsedate(), but returns either None or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to time.mktime(), and the tenth is the offset of the date’s timezone from UTC (which is the official term for Greenwich Mean Time) [1]. If the input string has no timezone, the last element of the tuple returned is None. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**email.utils.mktime_tz(tuple)**

Turn a 10-tuple as returned by parsedate_tz() into a UTC timestamp. If the timezone item in the tuple is None, assume local time. Minor deficiency: mktime_tz() interprets the first 8 elements of tuple as a local time and then compensates for the timezone
difference. This may yield a slight error around changes in daylight savings time, though not worth worrying about for common use.

```python
e-mail.utils.formatdate([timeval[, localtime][, usegmt]])
```

Returns a date string as per RFC 2822, e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional `timeval` if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.

Optional `localtime` is a flag that when `True`, interprets `timeval`, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional `usegmt` is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when `localtime` is `False`.

*New in version 2.4.*

```python
e-mail.utils.make_msgid([idstring])
```

Returns a string suitable for an RFC 2822-compliant `Message-ID` header. Optional `idstring` if given, is a string used to strengthen the uniqueness of the message id.

```python
e-mail.utils.decode_rfc2231(s)
```

Decode the string `s` according to RFC 2231.

```python
e-mail.utils.encode_rfc2231(s[, charset[, language]])
```
Encode the string $s$ according to **RFC 2231**. Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, $s$ is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

```python
email.utils.collapse_rfc2231_value(value[, errors[, fallback_charset]])
```

When a header parameter is encoded in **RFC 2231** format, `Message.get_param()` may return a 3-tuple containing the character set, language, and value. `collapse_rfc2231_value()` turns this into a unicode string. Optional *errors* is passed to the *errors* argument of the built-in `unicode()` function; it defaults to `replace`. Optional `fallback_charset` specifies the character set to use if the one in the **RFC 2231** header is not known by Python; it defaults to `us-ascii`.

For convenience, if the *value* passed to `collapse_rfc2231_value()` is not a tuple, it should be a string and it is returned unquoted.

```python
email.utils.decode_params(params)
```

Decode parameters list according to **RFC 2231**. *params* is a sequence of 2-tuples containing elements of the form (content-type, string-value).

*Changed in version 2.4:* The `dump_address_pair()` function has been removed; use `formataddr()` instead.

*Changed in version 2.4:* The `decode()` function has been removed; use the `Header.decode_header()` method instead.

*Changed in version 2.4:* The `encode()` function has been removed;
use the `Header.encode()` method instead.

**Footnotes**

Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows *RFC 2822*. 

[1]
email — An email and MIME handling package
Iterating over a message object tree is fairly easy with the `Message.walk()` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

**email.iterators.** `body_line_iterator(msg[, decode])`

This iterates over all the payloads in all the subparts of `msg`, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn’t a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()` , skipping over all the intervening headers.

Optional `decode` is passed through to `Message.get_payload()`.

**email.iterators.** `typed_subpart_iterator(msg[, maintype[, subtype]])`

This iterates over all the subparts of `msg`, returning only those subparts that match the MIME type specified by `maintype` and `subtype`.

Note that `subtype` is optional; if omitted, then subpart MIME type matching is done only with the main type. `maintype` is optional too; it defaults to `text`.

Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`.

The following function has been added as a useful debugging tool. It should not be considered part of the supported public interface for the package.
email.iterators._structure(msg[, fp[, level]])

Prints an indented representation of the content types of the message object structure. For example:

```python
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
   text/plain
   text/plain
   multipart/digest
      message/rfc822
         text/plain
      message/rfc822
         text/plain
      message/rfc822
         text/plain
      message/rfc822
         text/plain
      message/rfc822
         text/plain
   text/plain
```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python’s extended print statement. `level` is used internally.
email — An email and MIME handling package
email: Examples

Here are a few examples of how to use the email package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message:

```python
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.mime.text import MIMEText

# Open a plain text file for reading. For this example, assume
# the text file contains only ASCII characters.
fp = open(textfile, 'rb')
# Create a text/plain message
msg = MIMEText(fp.read())
fp.close()

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server, but don't include the
# envelope header.
server = smtplib.SMTP()  # Create a mail server object
server.connect()        # Connect the server
server.sendmail(me, [you], msg.as_string())
s.close()
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```python
# Import smtplib for the actual sending function
import smtplib

# Here are the email package modules we'll need
from email.mime.image import MIMEImage
```
from email.mime.multipart import MIMEMultipart

COMMASPACE = ',', '

# Create the container (outer) email message.
msg = MIMEMultipart()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = COMMASPACE.join(family)
msg.preamble = 'Our family reunion'

# Assume we know that the image files are all in PNG format
for file in pngfiles:
    # Open the files in binary mode. Let the MIMEImage class a
    # guess the specific image type.
    fp = open(file, 'rb')
    img = MIMEImage(fp.read())
    fp.close()
    msg.attach(img)

# Send the email via our own SMTP server.
s = smtplib.SMTP()
s.connect()
s.sendmail(me, family, msg.as_string())
s.close()

---

Here's an example of how to send the entire contents of a directory as an email message: [1]

#!/usr/bin/env python

"""Send the contents of a directory as a MIME message."""

import os
import sys
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from optparse import OptionParser

from email import encoders
from email.message import Message
from email.mime.audio import MIMEAudio
from email.mime.base import MIMEBase

---
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

COMMASPACE = ', '

def main():
    parser = OptionParser(usage="""Send the contents of a directory as a MIME message.

Usage: %prog [options]"
    Unless the `-o` option is given, the email is sent by forwarding SMTP server, which then does the normal delivery process. Your local machine must be running an SMTP server.
"""
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Mail the contents of the specific directory, otherwise use the current directory. Only regular files in the directory are sent, and we don't recurse to subdirectories."""
    parser.add_option('-o', '--output',
                      type='string', action='store', metavar='FILE',
                      help="""Print the composed message to FILE instead of sending the message to the SMTP server."""
    parser.add_option('-s', '--sender',
                      type='string', action='store', metavar='SENDER',
                      help='The value of the From: header (required)
    parser.add_option('-r', '--recipient',
                      type='string', action='append', metavar='RECIPIENT',
                      default=[], dest='recipients',
                      help='A To: header value (at least one required)
    opts, args = parser.parse_args()
    if not opts.sender or not opts.recipients:

Usage: %prog [options] msgfile
"""
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Unpack the MIME message into the
directory, which will be created if it does
exist."""
    )
    opts, args = parser.parse_args()
    if not opts.directory:
        parser.print_help()
        sys.exit(1)
    try:
        msgfile = args[0]
    except IndexError:
        parser.print_help()
        sys.exit(1)
    try:
        os.mkdir(opts.directory)
    except OSError, e:
        # Ignore directory exists error
        if e.errno <> errno.EEXIST:
            raise
    fp = open(msgfile)
    msg = email.message_from_file(fp)
```
Here's an example of how to create an HTML message with an alternative plain text version: [2]

```python
#!/usr/bin/python

import smtplib

from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

# me == my email address
# you == recipient's email address
me = "my@email.com"
you = "your@email.com"

# Create message container - the correct MIME type is multipart
msg = MIMEMultipart('alternative')
msg['Subject'] = "Link"
msg['From'] = me
msg['To'] = you

# Create the body of the message (a plain-text and an HTML vers
text = "Hi!
How are you?
Here is the link you wanted:
http://www.python.org"

<html>
  <head></head>
  <body>
    <p>Hi!<br>
    How are you?<br>
    Here is the <a href="http://www.python.org">link</a> you wanted.
  </p>
</body>
</html>

# Record the MIME types of both parts - text/plain and text/html
part1 = MIMEText(text, 'plain')
part2 = MIMEText(html, 'html')

# Attach parts into message container.
# According to RFC 2046, the last part of a multipart message,
# the HTML message, is best and preferred.
msg.attach(part1)
msg.attach(part2)

# Send the message via local SMTP server.
s = smtplib.SMTP('localhost')
# sendmail function takes 3 arguments: sender's address, recipi
# and message to send - here it is sent as one string.
s.sendmail(me, you, msg.as_string())
s.close()

Footnotes

[1] Thanks to Matthew Dixon Cowles for the original inspiration and examples.
json — JSON encoder and decoder

New in version 2.6.

JSON (JavaScript Object Notation) <http://json.org> is a subset of JavaScript syntax (ECMA-262 3rd edition) used as a lightweight data interchange format.

json exposes an API familiar to users of the standard library marshal and pickle modules.

Encoding basic Python object hierarchies:

```python
>>> import json
>>> json.dumps([{'foo': {'bar': ['baz', None, 1.0, 2]}},
        {'foo': ['baz', null, 1.0, 2]}])
'[
  "foo",
  "bar"
]
```

Compact encoding:

```python
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators=(',', ':'))
'[
1, 2, 3, 
{4: 5, 6: 7}
]
```

Pretty printing:

```python
>>> import json
>>> print json.dumps({'4': 5, '6': 7}, sort_keys=True, indent=4)
```
{
"4": 5,
"6": 7
}

Decoding JSON:
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]')
[u'foo', {u'bar': [u'baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
u'"foo\x08ar'
>>> from StringIO import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
[u'streaming API']

Specializing JSON object decoding:
>>> import json
>>> def as_complex(dct):
...
if '__complex__' in dct:
...
return complex(dct['real'], dct['imag'])
...
return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}',
...
object_hook=as_complex)
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')

Extending

JSONEncoder :

>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...
def default(self, obj):
...
if isinstance(obj, complex):
...
return [obj.real, obj.imag]
...
return json.JSONEncoder.default(self, obj)
...
>>> dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)


Using json.tool from the shell to validate and pretty-print:

$ echo '{"json":"obj"}' | python -mjson.tool
{
    "json": "obj"
}
$ echo '{ 1.2:3.4}' | python -mjson.tool
Expecting property name: line 1 column 2 (char 2)

**Note:** The JSON produced by this module’s default settings is a subset of YAML, so it may be used as a serializer for that as well.
Basic Usage

```python
json.dump(obj, fp[, skipkeys[, ensure_ascii[, check_circular[, allow_nan[, cls[, indent[, separators[, encoding[, default[, **kw]]]]]]]]]])
```

Serialize `obj` as a JSON formatted stream to `fp` (a `.write()`-supporting file-like object).

If `skipkeys` is `True` (default: `False`), then dict keys that are not of a basic type (`str`, `unicode`, `int`, `long`, `float`, `bool`, `None`) will be skipped instead of raising a `TypeError`.

If `ensure_ascii` is `False` (default: `True`), then some chunks written to `fp` may be `unicode` instances, subject to normal Python `str` to `unicode` coercion rules. Unless `fp.write()` explicitly understands `unicode` (as in `codecs.getwriter()`) this is likely to cause an error.

If `check_circular` is `False` (default: `True`), then the circular reference check for container types will be skipped and a circular reference will result in an `OverflowError` (or worse).

If `allow_nan` is `False` (default: `True`), then it will be a `ValueError` to serialize out of range `float` values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification, instead of using the JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`).

If `indent` is a non-negative integer, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0 will only insert newlines. `None` (the default) selects the most compact representation.

If `separators` is an `(item_separator, dict_separator)` tuple, then
it will be used instead of the default (', ', ': ') separators. 
(', ', ': ') is the most compact JSON representation.

*encoding* is the character encoding for str instances, default is UTF-8.

*default(obj)* is a function that should return a serializable version of *obj* or raise *TypeError*. The default simply raises *TypeError*.

To use a custom *JSONEncoder* subclass (e.g. one that overrides the *default()* method to serialize additional types), specify it with the *cls* kwarg.

```python
json.dumps(obj[, skipkeys[, ensure_ascii[, check_circular[, 
allow_nan[, cls[, indent[, separators[, encoding[, default[, 
**kw]]]]]]]]]]])
```

Serialize *obj* to a JSON formatted *str*.

If *ensure_ascii* is *False*, then the return value will be a *unicode* instance. The other arguments have the same meaning as in *dump()*.
class json. **JSONDecoder**([`encoding`, `object_hook`, `parse_float`, `parse_int`, `parse_constant`, `strict`])

Simple JSON decoder.

Performs the following translations in decoding by default:

<table>
<thead>
<tr>
<th>JSON</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>dict</td>
</tr>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>string</td>
<td>unicode</td>
</tr>
<tr>
<td>number (int)</td>
<td>int, long</td>
</tr>
<tr>
<td>number (real)</td>
<td>float</td>
</tr>
<tr>
<td>true</td>
<td>True</td>
</tr>
<tr>
<td>false</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

It also understands `NaN`, `Infinity`, and `-Infinity` as their corresponding `float` values, which is outside the JSON spec.

*encoding* determines the encoding used to interpret any `str` objects decoded by this instance (UTF-8 by default). It has no effect when decoding `unicode` objects.

Note that currently only encodings that are a superset of ASCII work, strings of other encodings should be passed in as `unicode`.

*object_hook*, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given `dict`. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).
parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

parse_constant, if specified, will be called with one of the following strings: `-Infinity`, `'Infinity'`, `'NaN'`, 'null', 'true', 'false'. This can be used to raise an exception if invalid JSON numbers are encountered.

decode(s)
Return the Python representation of s (a `str` or `unicode` instance containing a JSON document)

raw_decode(s)
Decode a JSON document from s (a `str` or `unicode` beginning with a JSON document) and return a 2-tuple of the Python representation and the index in s where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

class json.JSONEncoder([
    skipkeys, ensure_ascii, check_circular, 
    allow_nan, sort_keys, indent, separators, encoding, 
    default]]))

Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:
<table>
<thead>
<tr>
<th>Python</th>
<th>JSON</th>
</tr>
</thead>
<tbody>
<tr>
<td>dict</td>
<td>object</td>
</tr>
<tr>
<td>list, tuple</td>
<td>array</td>
</tr>
<tr>
<td>str, unicode</td>
<td>string</td>
</tr>
<tr>
<td>int, long, float</td>
<td>number</td>
</tr>
<tr>
<td>True</td>
<td>true</td>
</tr>
<tr>
<td>False</td>
<td>false</td>
</tr>
<tr>
<td>None</td>
<td>null</td>
</tr>
</tbody>
</table>

To extend this to recognize other objects, subclass and implement a `default()` method with another method that returns a serializable object for it if possible, otherwise it should call the superclass implementation (to raise `TypeError`).

If `skipkeys` is `False` (the default), then it is a `TypeError` to attempt encoding of keys that are not `str`, `int`, `long`, `float` or `None`. If `skipkeys` is `True`, such items are simply skipped.

If `ensure_ascii` is `True` (the default), the output is guaranteed to be `str` objects with all incoming unicode characters escaped. If `ensure_ascii` is `False`, the output will be a unicode object.

If `check_circular` is `True` (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an `OverflowError`). Otherwise, no such check takes place.

If `allow_nan` is `True` (the default), then `NaN`, `Infinity`, and `-Infinity` will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a `ValueError` to encode such floats.

If `sort_keys` is `True` (the default), then the output of dictionaries
will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If `indent` is a non-negative integer (it is `None` by default), then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0 will only insert newlines. `None` is the most compact representation.

If specified, `separators` should be an `(item_separator, key_separator)` tuple. The default is `( ',', ':' )`. To get the most compact JSON representation, you should specify `( ',', ',', ':' )` to eliminate whitespace.

If specified, `default` is a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a `TypeError`.

If `encoding` is not `None`, then all input strings will be transformed into unicode using that encoding prior to JSON-encoding. The default is UTF-8.

`default(o)`

Implement this method in a subclass such that it returns a serializable object for `o`, or calls the base implementation (to raise a `TypeError`).

For example, to support arbitrary iterators, you could implement `default` like this:

```python
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
```

```python
else:
    return list(iterable)
return JSONEncoder.default(self, o)
```

**encode(o)**

Return a JSON string representation of a Python data structure, o. For example:

```python
>>> JSONEncoder().encode({'foo': ['bar', 'baz']})
'{"foo": ["bar", "baz"]}'
```

**iterencode(o)**

Encode the given object, o, and yield each string representation as available. For example:

```python
for chunk in JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```
Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the `xmpeg` program can be automatically started to view the file.

The mailcap format is documented in RFC 1524, “A User Agent Configuration Mechanism For Multimedia Mail Format Information,” but is not an Internet standard. However, mailcap files are supported on most Unix systems.

`mailcap.findmatch(caps, MIMEtype[, key[, filename[, plist]]])`

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`) and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

`key` is the name of the field desired, which represents the type of activity to be performed; the default value is 'view', since in the most common case you simply want to view the body of the MIME-typed data. Other possible values might be ‘compose’ and ‘edit’, if you wanted to create a new body of the given MIME type or alter the existing body data. See RFC 1524 for a complete list of these fields.

`filename` is the filename to be substituted for `%s` in the command line; the default value is `'/dev/null'` which is almost certainly not
what you want, so usually you’ll override it by specifying a filename.

*plist* can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter’s value. Mailcap entries can contain named parameters like `%{foo}`, which will be replaced by the value of the parameter named ‘foo’. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `showpartial 1 2 3`.

In a mailcap file, the “test” field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. *findmatch()* will automatically check such conditions and skip the entry if the check fails.

**mailcap.getcaps()**

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the *findmatch()* function. An entry is stored as a list of dictionaries, but it shouldn’t be necessary to know the details of this representation.

The information is derived from all of the mailcap files found on the system. Settings in the user’s mailcap file `$HOME/.mailcap` will override settings in the system mailcap files `/etc/mailcap`, `/usr/etc/mailcap`, and `/usr/local/etc/mailcap`.

An example usage:

```python
>>> import mailcap
>>> d=mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='/tmp/tmp1223')
```
This module defines two classes, `Mailbox` and `Message`, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the `email.Message` module's `Message` class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

See also:

**Module** [email](#)

Represent and manipulate messages.
**Mailbox objects**

```python
class mailbox.Mailbox
    A mailbox, which may be inspected and modified.

    The Mailbox class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from Mailbox and your code should instantiate a particular subclass.

    The Mailbox interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the Mailbox instance with which they will be used and are only meaningful to that Mailbox instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

    Messages may be added to a Mailbox instance using the set-like method `add()` and removed using a `del` statement or the set-like methods `remove()` and `discard()`.

    Mailbox interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a Message instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a Mailbox instance, the provided message representation’s contents are copied. In neither case is a reference to the message representation kept by the Mailbox instance.

    The default Mailbox iterator iterates over message representations, not keys as the default dictionary iterator does.
```
Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you’re modifying a mailbox, you must lock it by calling the `lock()` and `unlock()` methods before reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

`Mailbox` instances have the following methods:

```python
add(message)
```

Add `message` to the mailbox and return the key that has been assigned to it.

Parameter `message` may be a `Message` instance, an `email.Message.Message` instance, a string, or a file-like object (which should be open in text mode). If `message` is an instance of the appropriate format-specific `Message` subclass (e.g., if it’s an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

```python
remove(key)
_delitem_(key)
```
**discard(key)**
Delete the message corresponding to `key` from the mailbox.

If no such message exists, a `KeyError` exception is raised if the method was called as `remove()` or `__delitem__()` but no exception is raised if the method was called as `discard()`. The behavior of `discard()` may be preferred if the underlying mailbox format supports concurrent modification by other processes.

**__setitem__(key, message)**
Replace the message corresponding to `key` with `message`. Raise a `KeyError` exception if no message already corresponds to `key`.

As with `add()`, parameter `message` may be a `Message` instance, an `email.Message.Message` instance, a string, or a file-like object (which should be open in text mode). If `message` is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to `key` is left unchanged.

**iterkeys()**
**keys()**
Return an iterator over all keys if called as `iterkeys()` or return a list of keys if called as `keys()`.

**itervalues()**
**__iter__()**
**values()**
Return an iterator over representations of all messages if
called as `itervalues()` or `__iter__()` or return a list of such representations if called as `values()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**Note:** The behavior of `__iter__()` is unlike that of dictionaries, which iterate over keys.

### `iteritems()`

Return an iterator over `(key, message)` pairs, where `key` is a key and `message` is a message representation, if called as `iteritems()` or return a list of such pairs if called as `items()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

### `get(key[, default=None])`

Return a representation of the message corresponding to `key`. If no such message exists, `default` is returned if the method was called as `get()` and a `KeyError` exception is raised if the method was called as `__getitem__()`. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

### `get_message(key)`

Return a representation of the message corresponding to `key` as an instance of the appropriate format-specific `Message` subclass, or raise a `KeyError` exception if no such message
exists.

**get_string(key)**

Return a string representation of the message corresponding to `key`, or raise a `KeyError` exception if no such message exists.

**get_file(key)**

Return a file-like representation of the message corresponding to `key`, or raise a `KeyError` exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

**Note:** Unlike other representations of messages, file-like representations are not necessarily independent of the Mailbox instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

**has_key(key)**

**__contains__(key)**

Return `True` if `key` corresponds to a message, `False` otherwise.

**__len__()**

Return a count of messages in the mailbox.

**clear()**

Delete all messages from the mailbox.

**pop(key[, default])**

Return a representation of the message corresponding to `key` and delete the message. If no such message exists, return `default` if it was supplied or else raise a `KeyError` exception.
The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`popitem()`
Return an arbitrary `(key, message)` pair, where `key` is a key and `message` is a message representation, and delete the corresponding message. If the mailbox is empty, raise a `KeyError` exception. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`update(arg)`
Parameter `arg` should be a `key-to-message` mapping or an iterable of `(key, message)` pairs. Updates the mailbox so that, for each given `key` and `message`, the message corresponding to `key` is set to `message` as if by using `__setitem__()`. As with `__setitem__()`, each `key` must already correspond to a message in the mailbox or else a `KeyError` exception will be raised, so in general it is incorrect for `arg` to be a `Mailbox` instance.

**Note:** Unlike with dictionaries, keyword arguments are not supported.

`flush()`
Write any pending changes to the filesystem. For some `Mailbox` subclasses, changes are always written immediately and `flush()` does nothing, but you should still make a habit of calling this method.

`lock()`
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An `ExternalClashError` is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should always lock the mailbox before making any modifications to its contents.

`unlock()`
Release the lock on the mailbox, if any.

`close()`
Flush the mailbox, unlock it if necessary, and close any open files. For some `Mailbox` subclasses, this method does nothing.

```python
Maildir
class mailbox.Maildir(dirname[, factory=rfc822.Message[, create=True]])

A subclass of `Mailbox` for mailboxes in Maildir format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `MaildirMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

It is for historical reasons that `factory` defaults to `rfc822.Message` and that `dirname` is named as such rather than `path`. For a `Maildir` instance that behaves like instances of other `Mailbox` subclasses, set `factory` to `None`.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within
a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: `tmp`, `new`, and `cur`. Messages are created momentarily in the `tmp` subdirectory and then moved to the `new` subdirectory to finalize delivery. A mail user agent may subsequently move the message to the `cur` subdirectory and store information about the state of the message in a special “info” section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if `.` is the first character in its name. Folder names are represented by `Maildir` without the leading `.`. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using `'.'` to delimit levels, e.g., “Archived.2005.07”.

**Note:** The Maildir specification requires the use of a colon (`':'`) in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (`'!'`) is a popular choice. For example:

```python
import mailbox
mailbox.Maildir.colon = '!'  
```

The `colon` attribute may also be set on a per-instance basis.

`Maildir` instances have all of the methods of `Mailbox` in addition to the following:
list_folders()
   Return a list of the names of all folders.

.et_folder(folder)
   Return a Maildir instance representing the folder whose name is folder. A NoSuchMailboxError exception is raised if the folder does not exist.

add_folder(folder)
   Create a folder whose name is folder and return a Maildir instance representing it.

remove_folder(folder)
   Delete the folder whose name is folder. If the folder contains any messages, a NotEmptyError exception will be raised and the folder will not be deleted.

clean()
   Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some Mailbox methods implemented by Maildir deserve special remarks:

add(message)
__setitem__(key, message)
update(arg)

Warning: These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.
flush()
   All changes to Maildir mailboxes are immediately applied, so this method does nothing.

lock()
unlock()
   Maildir mailboxes do not support (or require) locking, so these methods do nothing.

close()
   Maildir instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

get_file(key)
   Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

Using maildir format
   Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on "info" semantics.

maildir man page from Courier
   Another specification of the format. Describes a common extension for supporting folders.

mbox

   class mailbox. **mbox**(path[, factory=None[, create=True]])
A subclass of `Mailbox` for mailboxes in mbox format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `mboxMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From “.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, `mbox` implements the original format, which is sometimes referred to as `mboxo`. This means that the `Content-Length` header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “>From ” when storing the message, although occurrences of “>From ” are not transformed to “From ” when reading the message.

Some `Mailbox` methods implemented by `mbox` deserve special remarks:

- `get_file(key)`
  Using the file after calling `flush()` or `close()` on the `mbox` instance may yield unpredictable results or raise an exception.

- `lock()`
- `unlock()`
  Three locking mechanisms are used—dot locking and, if available, the `flock` and `lockf` system calls.

  A specification of the format and its variations.

mbox man page from tin
  Another specification of the format, with details on locking.

Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad
  An argument for using the original mbox format rather than a variation.

“mbox” is a family of several mutually incompatible mailbox formats
  A history of mbox variations.

MH

class mailbox.MH(path[, factory=None[, create=True]])
  A subclass of Mailbox for mailboxes in MH format. Parameter
  factory is a callable object that accepts a file-like message
  representation (which behaves as if opened in binary mode) and
  returns a custom representation. If factory is None, MHMessage is
  used as the default message representation. If create is True, the
  mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH
Message Handling System, a mail user agent. Each message in
an MH mailbox resides in its own file. An MH mailbox may
contain other MH mailboxes (called folders) in addition to
messages. Folders may be nested indefinitely. MH mailboxes
also support sequences, which are named lists used to logically
group messages without moving them to sub-folders. Sequences
are defined in a file called .mh_sequences in each folder.
The **MH** class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**'s behaviors. In particular, it does not modify and is not affected by the **context** or **.mh_profile** files that are used by **mh** to store its state and configuration.

**MH** instances have all of the methods of **Mailbox** in addition to the following:

- **list_folders()**
  
  Return a list of the names of all folders.

- **get_folder(folder)**
  
  Return an **MH** instance representing the folder whose name is **folder**. A **NoSuchMailboxError** exception is raised if the folder does not exist.

- **add_folder(folder)**
  
  Create a folder whose name is **folder** and return an **MH** instance representing it.

- **remove_folder(folder)**
  
  Delete the folder whose name is **folder**. If the folder contains any messages, a **NotEmptyError** exception will be raised and the folder will not be deleted.

- **get_sequences()**
  
  Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

- **set_sequences(sequences)**
  
  Re-define the sequences that exist in the mailbox based upon **sequences**, a dictionary of names mapped to key lists, like returned by **get_sequences()**.

- **pack()**
Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

**Note:** Already-issued keys are invalidated by this operation and should not be subsequently used.

Some `Mailbox` methods implemented by `MH` deserve special remarks:

```python
remove(key)
__delitem__(key)
discard(key)
```

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

```python
lock()
unlock()
```

Three locking mechanisms are used—dot locking and, if available, the `flock` and `lockf` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

```python
get_file(key)
```

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

```python
flush()
```

All changes to MH mailboxes are immediately applied, so this method does nothing.

```python
close()
```
MH instances do not keep any open files, so this method is equivalent to `unlock()`.

A GPL-licensed book on mh and nmh, with some information on the mailbox format.

---

### Babyl

```python
class mailbox. Babyl(path[, factory=None[, create=True]])
```
A subclass of `Mailbox` for mailboxes in Babyl format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `BabylMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`\037`) and Control-L (`\014`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`\037`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a
Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

**Babyl** instances have all of the methods of *Mailbox* in addition to the following:

**get_labels()**

Return a list of the names of all user-defined labels used in the mailbox.

---

**Note:** The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some *Mailbox* methods implemented by **Babyl** deserve special remarks:

**get_file(key)**

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into a *StringIO* instance (from the *StringIO* module), which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

**lock()**

**unlock()**

Three locking mechanisms are used—dot locking and, if available, the *flock* and *lockf* system calls.

The Rmail manual, with some information on Babyl semantics.

---

**MMDF**

class mailbox.MMDF(path[, factory=None[, create=True]])

A subclass of Mailbox for mailboxes in MMDF format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, MMDFMessage is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (`\x01`) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are “From “, but additional occurrences of “From ” are not transformed to “>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some Mailbox methods implemented by MMDF deserve special remarks:

**get_file(key)**
Using the file after calling `flush()` or `close()` on the MMDF
instance may yield unpredictable results or raise an exception.

\begin{verbatim}
lock()
unlock()
\end{verbatim}

Three locking mechanisms are used—dot locking and, if available, the flock and lockf system calls.

**mmdf man page from tin**

A specification of MMDF format from the documentation of tin, a newsreader.

**MMDF**

A Wikipedia article describing the Multichannel Memorandum Distribution Facility.
class mailbox.Message([message])

If message is omitted, the new instance is created in a default, empty state. If message is an email.Message.Message instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if message is a Message instance. If message is a string or a file, it should contain an RFC 2822-compliant message, which is read and parsed.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that Message instances be used to represent messages retrieved using Mailbox instances. In some situations, the time and memory required to generate Message representations might not be acceptable. For such situations, Mailbox instances also offer string and file-like representations, and a custom message factory may be specified when a Mailbox instance is initialized.
class mailbox.MaildirMessage([message])

A message with Maildir-specific behaviors. Parameter message has the same meaning as with the Message constructor.

Typically, a mail user agent application moves all of the messages in the new subdirectory to the cur subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in cur has an "info" section added to its file name to store information about its state. (Some mail readers may also add an "info" section to messages in new.) The "info" section may take one of two forms: it may contain "2," followed by a list of standardized flags (e.g., "2,FR") or it may contain "1," followed by so-called experimental information. Standard flags for Maildir messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Draft</td>
<td>Under composition</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>P</td>
<td>Passed</td>
<td>Forwarded, resent, or bounced</td>
</tr>
<tr>
<td>R</td>
<td>Replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>S</td>
<td>Seen</td>
<td>Read</td>
</tr>
<tr>
<td>T</td>
<td>Trashed</td>
<td>Marked for subsequent deletion</td>
</tr>
</tbody>
</table>

MaildirMessage instances offer the following methods:

get_subdir()

Return either "new" (if the message should be stored in the new subdirectory) or "cur" (if the message should be stored in the cur subdirectory).

Note: A message is typically moved from new to cur after its mailbox has been accessed, whether or not the message
is has been read. A message msg has been read if "S" in msg.get_flags() is True.

**set_subdir(subdir)**
Set the subdirectory the message should be stored in. Parameter *subdir* must be either “new” or “cur”.

**get_flags()**
Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The empty string is returned if no flags are set or if “info” contains experimental semantics.

**set_flags(flags)**
Set the flags specified by *flags* and unset all others.

**add_flag(flag)**
Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character. The current “info” is overwritten whether or not it contains experimental information rather than flags.

**remove_flag(flag)**
Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If “info” contains experimental information rather than flags, the current “info” is not modified.

**get_date()**
Return the delivery date of the message as a floating-point number representing seconds since the epoch.
set_date(date)
Set the delivery date of the message to date, a floating-point number representing seconds since the epoch.

get_info()
Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

set_info(info)
Set “info” to info, which should be a string.

When a MaildirMessage instance is created based upon an mboxMessage or MMDFMessage instance, the Status and X-Status headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>O flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>R flag</td>
<td>A flag</td>
</tr>
<tr>
<td>S flag</td>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
<td>D flag</td>
</tr>
</tbody>
</table>

When a MaildirMessage instance is created based upon an MHMessage instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>R flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When a MaildirMessage instance is created based upon a BabylMessage instance, the following conversions take place:
### Resulting state

<table>
<thead>
<tr>
<th>Baby1Message state</th>
<th>Resulting state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>P flag</td>
<td>“forwarded” or “resent” label</td>
</tr>
<tr>
<td>R flag</td>
<td>“answered” label</td>
</tr>
<tr>
<td>T flag</td>
<td>“deleted” label</td>
</tr>
</tbody>
</table>

### mboxMessage

```python
class mailbox.mboxMessage([message])
```

A message with mbox-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Messages in an mbox mailbox are stored together in a single file. The sender’s envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in `Status` and `X-Status` headers.

Conventional flags for mbox messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the `Status` header, and the “D”, “F”, and “A” flags are stored in the `X-Status` header. The flags and headers typically appear in the order mentioned.
mboxMessage instances offer the following methods:

**get_from()**
Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_[, time_=None])**
Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags()**
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set_flags(flags)**
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add_flag(flag)**
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

**remove_flag(flag)**
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a
string of more than one character.

When an `mboxMessage` instance is created based upon a `MaildirMessage` instance, a “From ” line is generated based upon the `MaildirMessage` instance's delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When a `Message` instance is created based upon an `MMDFMessage`
instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>

**MHMessage**

class mailbox. **MHMessage([message])**

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard *mh* and *nmh*) use sequences in much the same way flags are used with other formats, as follows:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>flagged</td>
<td>Marked as important</td>
</tr>
</tbody>
</table>

**MHMessage** instances offer the following methods:

**get_sequences()**

Return a list of the names of sequences that include this message.

**set_sequences(sequences)**

Set the list of sequences that include this message.
add_sequence(*sequence*)

Add *sequence* to the list of sequences that include this message.

remove_sequence(*sequence*)

Remove *sequence* from the list of sequences that include this message.

When an **MHMessage** instance is created based upon a **MaildirMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no S flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>R flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an **MHMessage** instance is created based upon an **mboxMessage** or **MMDFMessage** instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no R flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>A flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an **MHMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

**BabylMessage**
class mailbox. **BabylMessage**([`message`])

A message with Babyl-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>filed</td>
<td>Copied to another file or mailbox</td>
</tr>
<tr>
<td>answered</td>
<td>Replied to</td>
</tr>
<tr>
<td>forwarded</td>
<td>Forwarded</td>
</tr>
<tr>
<td>edited</td>
<td>Modified by the user</td>
</tr>
<tr>
<td>resent</td>
<td>Resent</td>
</tr>
</tbody>
</table>

By default, Rmail displays only visible headers. The **BabylMessage** class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

**BabylMessage** instances offer the following methods:

**get_labels()**

Return a list of labels on the message.

**set_labels(labels)**

Set the list of labels on the message to `labels`.

**add_label(label)**

Add `label` to the list of labels on the message.

**remove_label(label)**

Remove `label` from the list of labels on the message.
get_visible()

Return an Message instance whose headers are the message's visible headers and whose body is empty.

set_visible(visible)

Set the message's visible headers to be the same as the headers in message. Parameter visible should be a Message instance, an email.Message.Message instance, a string, or a file-like object (which should be open in text mode).

update_visible()

When a BabylMessage instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of Date, From, Reply-To, To, CC, and Subject that are present in the original headers but not the visible headers are added to the visible headers.

When a BabylMessage instance is created based upon a MaildirMessage instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;unseen&quot; label</td>
<td>no S flag</td>
</tr>
<tr>
<td>&quot;deleted&quot; label</td>
<td>T flag</td>
</tr>
<tr>
<td>&quot;answered&quot; label</td>
<td>R flag</td>
</tr>
<tr>
<td>&quot;forwarded&quot; label</td>
<td>P flag</td>
</tr>
</tbody>
</table>

When a BabylMessage instance is created based upon an mboxMessage or MMDFMessage instance, the Status and X-Status headers are omitted and the following conversions take place:
**Resulting state**: \texttt{mboxMessage} or \texttt{MMDFMessage} state

| “unseen” label | no R flag |
| “deleted” label | D flag |
| “answered” label | A flag |

When a \texttt{BabylMessage} instance is created based upon an \texttt{MHMessage} instance, the following conversions take place:

**Resulting state**: \texttt{MHMessage} state

| “unseen” label | “unseen” sequence |
| “answered” label | “replied” sequence |

---

**MMDFMessage**

class \texttt{mailbox.MMDFMessage([message])}

A message with MMDF-specific behaviors. Parameter \texttt{message} has the same meaning as with the \texttt{Message} constructor.

As with message in an \texttt{mbox} mailbox, MMDF messages are stored with the sender’s address and the delivery date in an initial line beginning with “From “. Likewise, flags that indicate the state of the message are typically stored in \texttt{Status} and \texttt{X-Status} headers.

Conventional flags for MMDF messages are identical to those of \texttt{mbox} message and are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>
The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

**MMDFMessage** instances offer the following methods, which are identical to those offered by **mboxMessage**:

**get_from()**
Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_, time_=None)**
Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags()**
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of ‘R’, ‘O’, ‘D’, ‘F’, and ‘A’.

**set_flags(flags)**
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of ‘R’, ‘O’, ‘D’, ‘F’, and ‘A’.

**add_flag(flag)**
Set the flag(s) specified by flag without changing other flags.
To add more than one flag at a time, flag may be a string of more than one character.

\[\text{remove\_flag}(\text{flag})\]

Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an \texttt{MMDFMessage} instance is created based upon a \texttt{MaildirMessage} instance, a “From ” line is generated based upon the \texttt{MaildirMessage} instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an \texttt{MMDFMessage} instance is created based upon an \texttt{MHMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an \texttt{MMDFMessage} instance is created based upon a \texttt{BabylMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
</tbody>
</table>
When an `MMDFMessage` instance is created based upon an `mboxMessage` instance, the “From” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>O flag</th>
<th>“unseen” label</th>
</tr>
</thead>
<tbody>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>mboxMessage</code> state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>
The following exception classes are defined in the `mailbox` module:

exception `mailbox.Error`
   The based class for all other module-specific exceptions.

exception `mailbox.NoSuchMailboxError`
   Raised when a mailbox is expected but is not found, such as when instantiating a `Mailbox` subclass with a path that does not exist (and with the `create` parameter set to `False`), or when opening a folder that does not exist.

exception `mailbox.NotEmptyError`
   Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception `mailbox.ExternalClashError`
   Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

exception `mailbox.FormatError`
   Raised when the data in a file cannot be parsed, such as when an `MH` instance attempts to read a corrupted `.mh_sequences` file.
Deprecated classes and methods

*Deprecated since version 2.6.*

Older versions of the `mailbox` module do not support modification of mailboxes, such as adding or removing message, and do not provide classes to represent format-specific message properties. For backward compatibility, the older mailbox classes are still available, but the newer classes should be used in preference to them. The old classes will be removed in Python 3.0.

Older mailbox objects support only iteration and provide a single public method:

```
oldmailbox.next()
```

Return the next message in the mailbox, created with the optional `factory` argument passed into the mailbox object's constructor. By default this is an `rfc822.Message` object (see the `rfc822` module). Depending on the mailbox implementation the `fp` attribute of this object may be a true file object or a class instance simulating a file object, taking care of things like message boundaries if multiple mail messages are contained in a single file, etc. If no more messages are available, this method returns `None`.

Most of the older mailbox classes have names that differ from the current mailbox class names, except for `Maildir`. For this reason, the new `Maildir` class defines a `next()` method and its constructor differs slightly from those of the other new mailbox classes.

The older mailbox classes whose names are not the same as their newer counterparts are as follows:

```
class mailbox.UnixMailbox(fp[, factory])
```
Access to a classic Unix-style mailbox, where all messages are contained in a single file and separated by \texttt{From} (a.k.a. \texttt{From_}) lines. The file object \texttt{fp} points to the mailbox file. The optional \texttt{factory} parameter is a callable that should create new message objects. \texttt{factory} is called with one argument, \texttt{fp} by the \texttt{next()} method of the mailbox object. The default is the \texttt{rfc822.Message} class (see the \texttt{rfc822} module – and the note below).

\textbf{Note:} For reasons of this module’s internal implementation, you will probably want to open the \texttt{fp} object in binary mode. This is especially important on Windows.

For maximum portability, messages in a Unix-style mailbox are separated by any line that begins exactly with the string \texttt{'From '} (note the trailing space) if preceded by exactly two newlines. Because of the wide-range of variations in practice, nothing else on the \texttt{From_} line should be considered. However, the current implementation doesn’t check for the leading two newlines. This is usually fine for most applications.

The \texttt{UnixMailbox} class implements a more strict version of \texttt{From_} line checking, using a regular expression that usually correctly matched \texttt{From_} delimiters. It considers delimiter line to be separated by \texttt{From name time} lines. For maximum portability, use the \texttt{PortableUnixMailbox} class instead. This class is identical to \texttt{UnixMailbox} except that individual messages are separated by only \texttt{From} lines.

\texttt{class mailbox. PortableUnixMailbox(fp[, factory])}

A less-strict version of \texttt{UnixMailbox}, which considers only the \texttt{From} at the beginning of the line separating messages. The “\texttt{name time}” portion of the From line is ignored, to protect against some variations that are observed in practice. This works since
lines in the message which begin with "From" are quoted by mail handling software at delivery-time.

class mailbox. **MmdfMailbox**(fp[, factory])

Access an MMDF-style mailbox, where all messages are contained in a single file and separated by lines consisting of 4 control-A characters. The file object fp points to the mailbox file. Optional factory is as with the UnixMailbox class.

class mailbox. **MHMailbox**(dirname[, factory])

Access an MH mailbox, a directory with each message in a separate file with a numeric name. The name of the mailbox directory is passed in dirname. factory is as with the UnixMailbox class.

class mailbox. **BabylMailbox**(fp[, factory])

Access a Babyl mailbox, which is similar to an MMDF mailbox. In Babyl format, each message has two sets of headers, the original headers and the visible headers. The original headers appear before a line containing only '*** E00H ***' (End-Of-Original-Headers) and the visible headers appear after the E00H line. Babyl-compliant mail readers will show you only the visible headers, and BabylMailbox objects will return messages containing only the visible headers. You'll have to do your own parsing of the mailbox file to get at the original headers. Mail messages start with the EOOH line and end with a line containing only '\037\014'. factory is as with the UnixMailbox class.

If you wish to use the older mailbox classes with the email module rather than the deprecated rfc822 module, you can do so as follows:

```python
import email
import email.Errors
import mailbox
```
def msgfactory(fp):
    try:
        return email.message_from_file(fp)
    except email.Errors.MessageParseError:
        # Don't return None since that will
        # stop the mailbox iterator
        return ''

mbox = mailbox.UnixMailbox(fp, msgfactory)

Alternatively, if you know your mailbox contains only well-formed MIME messages, you can simplify this to:

import email
import mailbox

mbox = mailbox.UnixMailbox(fp, email.message_from_file)
Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```python
import mailbox
for message in mailbox.mbox('~/mbox'):  
    subject = message['subject']          # Could possibly be None
    if subject and 'python' in subject.lower():
        print subject
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```python
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```python
import mailbox
import email.Errors
list_names = ('python-list', 'python-dev', 'python-bugs')
boxes = dict((name, mailbox.mbox('~/email/%s' % name)) for name in list_names)
inbox = mailbox.Maildir('~/Maildir', factory=None)
for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.Errors.MessageParseError:
continue  # The message is malformed. Just leave it.

for name in list_names:
    list_id = message['list-id']
    if list_id and name in list_id:
        # Get mailbox to use
        box = boxes[name]

        # Write copy to disk before removing original.
        # If there's a crash, you might duplicate a message
        # that's better than losing a message completely.
        box.lock()
        box.add(message)
        box.flush()
        box.unlock()

        # Remove original message
        inbox.lock()
        inboxdiscard(key)
        inbox.flush()
        inbox.unlock()
        break  # Found destination, so stop looking

for box in boxes.itervalues():
    box.close()
mhlib — Access to MH mailboxes

*Deprecated since version 2.6:* The `mhlib` module has been removed in Python 3.0. Use the `mailbox` instead.

The `mhlib` module provides a Python interface to MH folders and their contents.

The module contains three basic classes, `MH`, which represents a particular collection of folders, `Folder`, which represents a single folder, and `Message`, which represents a single message.

```python
class mhlib.MH([path[, profile]])
    MH represents a collection of MH folders.

class mhlib.Folder(mh, name)
    The Folder class represents a single folder and its messages.

class mhlib.Message(folder, number[, name])
    Message objects represent individual messages in a folder. The Message class is derived from `mimetypes.Message`.
```
MH Objects

MH instances have the following methods:

MH.error(format[, ...])
   Print an error message – can be overridden.

MH.getprofile(key)
   Return a profile entry (None if not set).

MH.getpath()
   Return the mailbox pathname.

MH.getcontext()
   Return the current folder name.

MH.setcontext(name)
   Set the current folder name.

MH.listfolders()
   Return a list of top-level folders.

MH.listallfolders()
   Return a list of all folders.

MH.listsubfolders(name)
   Return a list of direct subfolders of the given folder.

MH.listallsubfolders(name)
   Return a list of all subfolders of the given folder.

MH.makefolder(name)
   Create a new folder.
MH. `deletefolder(name)`
   Delete a folder – must have no subfolders.

MH. `openfolder(name)`
   Return a new open folder object.
Folder objects represent open folders and have the following methods:

- **Folder**. `error(format[, ...])`
  Print an error message – can be overridden.

- **Folder**. `fullname()`
  Return the folder's full pathname.

- **Folder**. `getsequencesfilename()`
  Return the full pathname of the folder’s sequences file.

- **Folder**. `getmessagefilename(n)`
  Return the full pathname of message `n` of the folder.

- **Folder**. `listmessages()`
  Return a list of messages in the folder (as numbers).

- **Folder**. `getcurrent()`
  Return the current message number.

- **Folder**. `setcurrent(n)`
  Set the current message number to `n`.

- **Folder**. `parsesequence(seq)`
  Parse msgs syntax into list of messages.

- **Folder**. `getlast()`
  Get last message, or 0 if no messages are in the folder.

- **Folder**. `setlast(n)`
Set last message (internal use only).

Folder. `getsequences()`
Return dictionary of sequences in folder. The sequence names are used as keys, and the values are the lists of message numbers in the sequences.

Folder. `putsequences(dict)`
Return dictionary of sequences in folder name: list.

Folder. `removemessages(list)`
Remove messages in list from folder.

Folder. `refilemessages(list, tofolder)`
Move messages in list to other folder.

Folder. `movemessage(n, tofolder, ton)`
Move one message to a given destination in another folder.

Folder. `copymessage(n, tofolder, ton)`
Copy one message to a given destination in another folder.
Message Objects

The `Message` class adds one method to those of `mimetypes.Message`:

`Message.openmessage(n)`

Return a new open message object (costs a file descriptor).
Deprecated since version 2.3: The email package should be used in preference to the mimetools module. This module is present only to maintain backward compatibility, and it has been removed in 3.x.

This module defines a subclass of the rfc822 module's Message class and a number of utility functions that are useful for the manipulation for MIME multipart or encoded message.

It defines the following items:

```python
class mimetools.Message(fp[, seekable])
```

Return a new instance of the Message class. This is a subclass of the rfc822.Message class, with some additional methods (see below). The seekable argument has the same meaning as for rfc822.Message.

```python
mimetools.choose_boundary()
```

Return a unique string that has a high likelihood of being usable as a part boundary. The string has the form 'hostipaddr.uid.pid.timestamp.random'.

```python
mimetools.decode(input, output, encoding)
```

Read data encoded using the allowed MIME encoding from open file object input and write the decoded data to open file object output. Valid values for encoding include 'base64', 'quoted-printable', 'uuencode', 'x-uuencode', 'uue', 'x-uue', '7bit', and '8bit'. Decoding messages encoded in '7bit' or '8bit' has no effect. The input is simply copied to the output.
mimetools. **encode**(input, output, encoding)

Read data from open file object `input` and write it encoded using the allowed MIME `encoding` to open file object `output`. Valid values for `encoding` are the same as for `decode()`.

mimetools. **copyliteral**(input, output)

Read lines from open file `input` until EOF and write them to open file `output`.

mimetools. **copybinary**(input, output)

Read blocks until EOF from open file `input` and write them to open file `output`. The block size is currently fixed at 8192.

**See also:**

**Module** email

Comprehensive email handling package; supersedes the `mimetypes` module.

**Module** rfc822

Provides the base class for `mimetypes.Message`.

**Module** multifile

Support for reading files which contain distinct parts, such as MIME data.

The MIME Frequently Asked Questions document. For an overview of MIME, see the answer to question 1.1 in Part 1 of this document.
Additional Methods of Message Objects

The Message class defines the following methods in addition to the rfc822.Message methods:

Message.getplist()
Return the parameter list of the Content-Type header. This is a list of strings. For parameters of the form key=value, key is converted to lower case but value is not. For example, if the message contains the header Content-type: text/html; spam=1; Spam=2; Spam then getplist() will return the Python list ['spam=1', 'spam=2', 'Spam'].

Message.getparam(name)
Return the value of the first parameter (as returned by getplist()) of the form name=value for the given name. If value is surrounded by quotes of the form '<...>' or '"..."', these are removed.

Message.getencoding()
Return the encoding specified in the Content-Transfer-Encoding message header. If no such header exists, return '7bit'. The encoding is converted to lower case.

Message.gettype()
Return the message type (of the form type/subtype) as specified in the Content-Type header. If no such header exists, return 'text/plain'. The type is converted to lower case.

Message.getmaintype()
Return the main type as specified in the Content-Type header. If no such header exists, return 'text'. The main type is converted
to lower case.

Message. **getsubtype()**

Return the subtype as specified in the *Content-Type* header. If no such header exists, return `'plain'`. The subtype is converted to lower case.
mimetypes — Map filenames to MIME types

The mimetypes module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call init() if they rely on the information init() sets up.

mimetypes.guess_type(filename[, strict])

Guess the type of a file based on its filename or URL, given by filename. The return value is a tuple (type, encoding) where type is None if the type can’t be guessed (missing or unknown suffix) or a string of the form ’type/subtype’, usable for a MIME content-type header.

encoding is None for no encoding or the name of the program used to encode (e.g. compress or gzip). The encoding is suitable for use as a Content-Encoding header, not as a Content-Transfer-Encoding header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

Optional strict is a flag specifying whether the list of known MIME
types is limited to only the official types registered with IANA are recognized. When strict is true (the default), only the IANA types are supported; when strict is false, some additional non-standard but commonly used MIME types are also recognized.

```python
mimetypes.guess_all_extensions(type, strict)
```

Guess the extensions for a file based on its MIME type, given by type. The return value is a list of strings giving all possible filename extensions, including the leading dot (\'.\'). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by guess_type().

Optional strict has the same meaning as with the guess_type() function.

```python
mimetypes.guess_extension(type, strict)
```

Guess the extension for a file based on its MIME type, given by type. The return value is a string giving a filename extension, including the leading dot (\'.\'). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by guess_type(). If no extension can be guessed for type, None is returned.

Optional strict has the same meaning as with the guess_type() function.

Some additional functions and data items are available for controlling the behavior of the module.

```python
mimetypes.init(files)
```

Initialize the internal data structures. If given, files must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from
knownfiles. Each file named in files or knownfiles takes precedence over those named before it. Calling init() repeatedly is allowed.

mimetypes.read_mime_types(filename)
Load the type map given in the file filename, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file filename does not exist or cannot be read, None is returned.

mimetypes.add_type(type, ext[, strict])
Add a mapping from the mimetype type to the extension ext. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When strict is True (the default), the mapping will added to the official MIME types, otherwise to the non-standard ones.

mimetypes.inited
Flag indicating whether or not the global data structures have been initialized. This is set to true by init().

mimetypes.knownfiles
List of type map file names commonly installed. These files are typically named mime.types and are installed in different locations by different packages.

mimetypes.suffix_map
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the .tgz extension is mapped to .tar.gz to allow the encoding and type to
be recognized separately.

**mimetypes.encodings_map**

Dictionary mapping filename extensions to encoding types.

**mimetypes.types_map**

Dictionary mapping filename extensions to MIME types.

**mimetypes.common_types**

Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

The **MimeTypes** class may be useful for applications which may want more than one MIME-type database:

```python
class mimetypes.MimeTypes([filenames])
```

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the `read()` or `readfp()` methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional `filenames` parameter can be used to cause additional files to be loaded “on top” of the default database.

*New in version 2.2.*

An example usage of the module:

```python
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
```
'gzip'

```python
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```
MimeTypes Objects

**MimeTypes** instances provide an interface which is very like that of the mimetypes module.

**MimeTypes.suffix_map**
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global `suffix_map` defined in the module.

**MimeTypes.encodings_map**
Dictionary mapping filename extensions to encoding types. This is initially a copy of the global `encodings_map` defined in the module.

**MimeTypes.types_map**
Dictionary mapping filename extensions to MIME types. This is initially a copy of the global `types_map` defined in the module.

**MimeTypes.common_types**
Dictionary mapping filename extensions to non-standard, but commonly found MIME types. This is initially a copy of the global `common_types` defined in the module.

**MimeTypes.guess_extension(type[, strict])**
Similar to the `guess_extension()` function, using the tables stored as part of the object.

**MimeTypes.guess_type(url[, strict])**
Similar to the `guess_type()` function, using the tables stored as
part of the object.

MimeTypes. **read**(path)

Load MIME information from a file named `path`. This uses `readfp()` to parse the file.

MimeTypes. **readfp**(file)

Load MIME type information from an open file. The file must have the format of the standard `mime.types` files.
**MimeWriter — Generic MIME file writer**

*Deprecated since version 2.3:* The `email` package should be used in preference to the `MimeWriter` module. This module is present only to maintain backward compatibility.

This module defines the class `MimeWriter`. The `MimeWriter` class implements a basic formatter for creating MIME multi-part files. It doesn’t seek around the output file nor does it use large amounts of buffer space. You must write the parts out in the order that they should occur in the final file. `MimeWriter` does buffer the headers you add, allowing you to rearrange their order.

class MimeWriter

Return a new instance of the `MimeWriter` class. The only argument passed, `fp`, is a file object to be used for writing. Note that a `StringIO` object could also be used.
**MimeWriter Objects**

*MimeWriter* instances have the following methods:

**MimeWriter.addheader**(key, value[, prefix])

Add a header line to the MIME message. The *key* is the name of the header, where the *value* obviously provides the value of the header. The optional argument *prefix* determines where the header is inserted; 0 means append at the end, 1 is insert at the start. The default is to append.

**MimeWriter.flushheaders()**

Causes all headers accumulated so far to be written out (and forgotten). This is useful if you don’t need a body part at all, e.g. for a subpart of type *message/rfc822* that’s (mis)used to store some header-like information.

**MimeWriter.startbody**(ctype[, plist[, prefix]])

Returns a file-like object which can be used to write to the body of the message. The content-type is set to the provided *ctype*, and the optional parameter *plist* provides additional parameters for the content-type declaration. *prefix* functions as in `addheader()` except that the default is to insert at the start.

**MimeWriter.startmultipartbody**(subtype[, boundary[, plist[, prefix]]])

Returns a file-like object which can be used to write to the body of the message. Additionally, this method initializes the multi-part code, where *subtype* provides the multipart subtype, *boundary* may provide a user-defined boundary specification, and *plist* provides optional parameters for the subtype. *prefix* functions as in `startbody()`. Subparts should be created using `nextpart()`.
MimeWriter. `nextpart()`

Returns a new instance of `MimeWriter` which represents an individual part in a multipart message. This may be used to write the part as well as used for creating recursively complex multipart messages. The message must first be initialized with `startmultipartbody()` before using `nextpart()`.

MimeWriter. `lastpart()`

This is used to designate the last part of a multipart message, and should *always* be used when writing multipart messages.
mimify — MIME processing of mail messages

Deprecated since version 2.3: The email package should be used in preference to the mimify module. This module is present only to maintain backward compatibility.

The mimify module defines two functions to convert mail messages to and from MIME format. The mail message can be either a simple message or a so-called multipart message. Each part is treated separately. Mimifying (a part of) a message entails encoding the message as quoted-printable if it contains any characters that cannot be represented using 7-bit ASCII. Unmimifying (a part of) a message entails undoing the quoted-printable encoding. Mimify and unmimify are especially useful when a message has to be edited before being sent. Typical use would be:

```
unmimify message
edit message
mimify message
send message
```

The modules defines the following user-callable functions and user-settable variables:

```
mimify(mimify(infile, outfile))
```

Copy the message in infile to outfile, converting parts to quoted-printable and adding MIME mail headers when necessary. infile and outfile can be file objects (actually, any object that has a readline() method (for infile) or a write() method (for outfile)) or strings naming the files. If infile and outfile are both strings, they may have the same value.
mimify.unmimify(infile, outfile[, decode_base64])

Copy the message in infile to outfile, decoding all quoted-printable parts. infile and outfile can be file objects (actually, any object that has a readline() method (for infile) or a write() method (for outfile)) or strings naming the files. If infile and outfile are both strings, they may have the same value. If the decode_base64 argument is provided and tests true, any parts that are coded in the base64 encoding are decoded as well.

mimify.mime_decode_header(line)

Return a decoded version of the encoded header line in line. This only supports the ISO 8859-1 charset (Latin-1).

mimify.mime_encode_header(line)

Return a MIME-encoded version of the header line in line.

mimify.MAXLEN

By default, a part will be encoded as quoted-printable when it contains any non-ASCII characters (characters with the 8th bit set), or if there are any lines longer than MAXLEN characters (default value 200).

mimify.CHARSET

When not specified in the mail headers, a character set must be filled in. The string used is stored in CHARSET, and the default value is ISO-8859-1 (also known as Latin1 (latin-one)).

This module can also be used from the command line. Usage is as follows:

```
mimify.py -e [-l length] [infile [outfile]]
mimify.py -d [-b] [infile [outfile]]
```

to encode (mimify) and decode (unmimify) respectively. infile defaults to standard input, outfile defaults to standard output. The
same file can be specified for input and output.

If the -I option is given when encoding, if there are any lines longer than the specified length, the containing part will be encoded.

If the -b option is given when decoding, any base64 parts will be decoded as well.

See also:

Module quopri

Encode and decode MIME quoted-printable files.
multifile — Support for files containing distinct parts

 Deprecated since version 2.5: The email package should be used in preference to the multifile module. This module is present only to maintain backward compatibility.

 The MultiFile object enables you to treat sections of a text file as file-like input objects, with '' being returned by readline() when a given delimiter pattern is encountered. The defaults of this class are designed to make it useful for parsing MIME multipart messages, but by subclassing it and overriding methods it can be easily adapted for more general use.

 class multifile.MultiFile(fp[, seekable])
     Create a multi-file. You must instantiate this class with an input object argument for the MultiFile instance to get lines from, such as a file object returned by open().

     MultiFile only ever looks at the input object’s readline(), seek() and tell() methods, and the latter two are only needed if you want random access to the individual MIME parts. To use MultiFile on a non-seekable stream object, set the optional seekable argument to false; this will prevent using the input object’s seek() and tell() methods.

 It will be useful to know that in MultiFile's view of the world, text is composed of three kinds of lines: data, section-dividers, and end-markers. MultiFile is designed to support parsing of messages that may have multiple nested message parts, each with its own pattern for section-divider and end-marker lines.
See also:

**Module email**

Comprehensive email handling package; supersedes the **multifile** module.
A `MultiFile` instance has the following methods:

**MultiFile.**`readline(str)`

Read a line. If the line is data (not a section-divider or end-marker or real EOF) return it. If the line matches the most-recently-stacked boundary, return `'` and set `self.last` to 1 or 0 according as the match is or is not an end-marker. If the line matches any other stacked boundary, raise an error. On encountering end-of-file on the underlying stream object, the method raises `Error` unless all boundaries have been popped.

**MultiFile.**`readlines(str)`

Return all lines remaining in this part as a list of strings.

**MultiFile.**`read()`

Read all lines, up to the next section. Return them as a single (multiline) string. Note that this doesn't take a size argument!

**MultiFile.**`seek(pos[, whence])`

Seek. Seek indices are relative to the start of the current section. The `pos` and `whence` arguments are interpreted as for a file seek.

**MultiFile.**`tell()`

Return the file position relative to the start of the current section.

**MultiFile.**`next()`

Skip lines to the next section (that is, read lines until a section-divider or end-marker has been consumed). Return true if there is such a section, false if an end-marker is seen. Re-enable the most-recently-pushed boundary.
MultiFile. **is_data**(str)
Return true if str is data and false if it might be a section boundary. As written, it tests for a prefix other than '---' at start of line (which all MIME boundaries have) but it is declared so it can be overridden in derived classes.

Note that this test is used intended as a fast guard for the real boundary tests; if it always returns false it will merely slow processing, not cause it to fail.

MultiFile. **push**(str)
Push a boundary string. When a decorated version of this boundary is found as an input line, it will be interpreted as a section-divider or end-marker (depending on the decoration, see RFC 2045). All subsequent reads will return the empty string to indicate end-of-file, until a call to pop() removes the boundary a or next() call reenables it.

It is possible to push more than one boundary. Encountering the most-recently-pushed boundary will return EOF; encountering any other boundary will raise an error.

MultiFile. **pop**()
Ppop a section boundary. This boundary will no longer be interpreted as EOF.

MultiFile. **section_divider**(str)
Turn a boundary into a section-divider line. By default, this method prepends '---' (which MIME section boundaries have) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

MultiFile. **end_marker**(str)
Turn a boundary string into an end-marker line. By default, this method prepends '---' and appends '---' (like a MIME-multipart end-of-message marker) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

Finally, **MultiFile** instances have two public instance variables:

**MultiFile.level**
- Nesting depth of the current part.

**MultiFile.last**
- True if the last end-of-file was for an end-of-message marker.
import mimetools
import multifile
import StringIO

def extract_mime_part_matching(stream, mimetype):
    """Return the first element in a multipart MIME message on stream
    matching mimetype."""

    msg = mimetools.Message(stream)
    msgtype = msg.gettype()
    params = msg.getplist()

    data = StringIO.StringIO()
    if msgtype[:10] == "multipart/"
        file = multifile.MultiFile(stream)
        file.push(msg.getparam("boundary"))
        while file.next():
            submsg = mimetools.Message(file)
            try:
                data = StringIO.StringIO()
                mimetools.decode(file, data, submsg.getencoding)
            except ValueError:
                continue
            if submsg.gettype() == mimetype:
                break
        file.pop()
    return data.getvalue()
Deprecated since version 2.3: The email package should be used in preference to the rfc822 module. This module is present only to maintain backward compatibility, and has been removed in 3.0.

This module defines a class, Message, which represents an “email message” as defined by the Internet standard RFC 2822. [1] Such messages consist of a collection of message headers, and a message body. This module also defines a helper class AddressList for parsing RFC 2822 addresses. Please refer to the RFC for information on the specific syntax of RFC 2822 messages.

The mailbox module provides classes to read mailboxes produced by various end-user mail programs.

class rfc822.Message(file[, seekable])

A Message instance is instantiated with an input object as parameter. Message relies only on the input object having a readline() method; in particular, ordinary file objects qualify. Instantiation reads headers from the input object up to a delimiter line (normally a blank line) and stores them in the instance. The message body, following the headers, is not consumed.

This class can work with any input object that supports a readline() method. If the input object has seek and tell capability, the rewindbody() method will work; also, illegal lines will be pushed back onto the input stream. If the input object lacks seek but has an unread() method that can push back a line of input, Message will use that to push back illegal lines. Thus this class can be used to parse messages coming from a buffered
stream.

The optional seekable argument is provided as a workaround for certain stdio libraries in which tell discards buffered data before discovering that the lseek system call doesn't work. For maximum portability, you should set the seekable argument to zero to prevent that initial tell() when passing in an unseekable object such as a file object created from a socket object.

Input lines as read from the file may either be terminated by CR-LF or by a single linefeed; a terminating CR-LF is replaced by a single linefeed before the line is stored.

All header matching is done independent of upper or lower case; e.g. m['From'], m['from'] and m['FROM'] all yield the same result.

class rfc822.AddressList(field)

You may instantiate the AddressList helper class using a single string parameter, a comma-separated list of RFC 2822 addresses to be parsed. (The parameter None yields an empty list.)

rfc822.quote(str)

Return a new string with backslashes in str replaced by two backslashes and double quotes replaced by backslash-double quote.

rfc822.unquote(str)

Return a new string which is an unquoted version of str. If str ends and begins with double quotes, they are stripped off. Likewise if str ends and begins with angle brackets, they are stripped off.

rfc822.parseaddr(address)

Parse address, which should be the value of some address-
containing field such as To or Cc, into its constituent “realname” and “email address” parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple (None, None) is returned.

**rfc822.dump_address_pair(pair)**

The inverse of parseaddr(), this takes a 2-tuple of the form (realname, email_address) and returns the string value suitable for a To or Cc header. If the first element of pair is false, then the second element is returned unmodified.

**rfc822.parsedate(date)**

Attempts to parse a date according to the rules in RFC 2822. however, some mailers don’t follow that format as specified, so parsedate() tries to guess correctly in such cases. date is a string containing an RFC 2822 date, such as 'Mon, 20 Nov 1995 19:12:08 -0500'. If it succeeds in parsing the date, parsedate() returns a 9-tuple that can be passed directly to time.mktime(); otherwise None will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**rfc822.parsedate_tz(date)**

Performs the same function as parsedate(), but returns either None or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to time.mktime(), and the tenth is the offset of the date’s timezone from UTC (which is the official term for Greenwich Mean Time). (Note that the sign of the timezone offset is the opposite of the sign of the time.timezone variable for the same timezone; the latter variable follows the POSIX standard while this module follows RFC 2822.) If the input string has no timezone, the last element of the tuple returned is None. Note that indexes 6, 7, and 8 of the result tuple are not usable.
rfc822.mktime_tz(tuple)

Turn a 10-tuple as returned by parsedate_tz() into a UTC timestamp. If the timezone item in the tuple is None, assume local time. Minor deficiency: this first interprets the first 8 elements as a local time and then compensates for the timezone difference; this may yield a slight error around daylight savings time switch dates. Not enough to worry about for common use.

Classes to read various mailbox formats produced by end-user mail programs.

Module mimetools
Subclass of rfc822.Message that handles MIME encoded messages.
Message Objects

A `Message` instance has the following methods:

**Message.** `rewindbody()`
Seek to the start of the message body. This only works if the file object is seekable.

**Message.** `isheader(line)`
Returns a line's canonicalized fieldname (the dictionary key that will be used to index it) if the line is a legal RFC 2822 header; otherwise returns `None` (implying that parsing should stop here and the line be pushed back on the input stream). It is sometimes useful to override this method in a subclass.

**Message.** `islast(line)`
Return `true` if the given line is a delimiter on which `Message` should stop. The delimiter line is consumed, and the file object's read location positioned immediately after it. By default this method just checks that the line is blank, but you can override it in a subclass.

**Message.** `iscomment(line)`
Return `True` if the given line should be ignored entirely, just skipped. By default this is a stub that always returns `False`, but you can override it in a subclass.

**Message.** `getallmatchingheaders(name)`
Return a list of lines consisting of all headers matching `name`, if any. Each physical line, whether it is a continuation line or not, is a separate list item. Return the empty list if no header matches `name`. 
Message. **getfirstmatchingheader**(name)
Return a list of lines comprising the first header matching name, and its continuation line(s), if any. Return None if there is no header matching name.

Message. **getrawheader**(name)
Return a single string consisting of the text after the colon in the first header matching name. This includes leading whitespace, the trailing linefeed, and internal linefeeds and whitespace if there any continuation line(s) were present. Return None if there is no header matching name.

Message. **getheader**(name[, default])
Return a single string consisting of the last header matching name, but strip leading and trailing whitespace. Internal whitespace is not stripped. The optional default argument can be used to specify a different default to be returned when there is no header matching name; it defaults to None. This is the preferred way to get parsed headers.

Message. **get**(name[, default])
An alias for getheader(), to make the interface more compatible with regular dictionaries.

Message. **getaddr**(name)
Return a pair (full name, email address) parsed from the string returned by getheader(name). If no header matching name exists, return (None, None); otherwise both the full name and the address are (possibly empty) strings.

Example: If m’s first From header contains the string 'jack@cwi.nl (Jack Jansen)', then m.getaddr('From') will yield the pair ('Jack Jansen', 'jack@cwi.nl'). If the header contained
'Jack Jansen <jack@cwi.nl>' instead, it would yield the exact same result.

Message **getaddrlist**(name)

This is similar to **getaddr** (list), but parses a header containing a list of email addresses (e.g. a To header) and returns a list of (full name, email address) pairs (even if there was only one address in the header). If there is no header matching name, return an empty list.

If multiple headers exist that match the named header (e.g. if there are several Cc headers), all are parsed for addresses. Any continuation lines the named headers contain are also parsed.

Message **getdate**(name)

Retrieve a header using **getheader** () and parse it into a 9-tuple compatible with **time.mktime** (); note that fields 6, 7, and 8 are not usable. If there is no header matching name, or it is unparsable, return None.

Date parsing appears to be a black art, and not all mailers adhere to the standard. While it has been tested and found correct on a large collection of email from many sources, it is still possible that this function may occasionally yield an incorrect result.

Message **getdate_tz**(name)

Retrieve a header using **getheader** () and parse it into a 10-tuple; the first 9 elements will make a tuple compatible with **time.mktime** (), and the 10th is a number giving the offset of the date’s timezone from UTC. Note that fields 6, 7, and 8 are not usable. Similarly to **getdate** (), if there is no header matching name, or it is unparsable, return None.

Message instances also support a limited mapping interface. In
particular: \texttt{m[name]} is like \texttt{m.getHeader(name)} but raises \texttt{KeyError} if there is no matching header; and \texttt{len(m)}, \texttt{m.getHeader(name[, default])}, \texttt{name in m}, \texttt{m.keys()}, \texttt{m.values()} \texttt{m.items()}, and \texttt{m.setdefault(name[, default])} act as expected, with the one difference that \texttt{setdefault()} uses an empty string as the default value. \texttt{Message} instances also support the mapping writable interface \texttt{m[name] = value} and \texttt{del m[name]}. \texttt{Message} objects do not support the \texttt{clear()}, \texttt{copy()}, \texttt{popitem()}, or \texttt{update()} methods of the mapping interface. (Support for \texttt{get()} and \texttt{setdefault()} was only added in Python 2.2.)

Finally, \texttt{Message} instances have some public instance variables:

\texttt{Message.headers}

A list containing the entire set of header lines, in the order in which they were read (except that setitem calls may disturb this order). Each line contains a trailing newline. The blank line terminating the headers is not contained in the list.

\texttt{Message.fp}

The file or file-like object passed at instantiation time. This can be used to read the message content.

\texttt{Message.unixfrom}

The Unix From line, if the message had one, or an empty string. This is needed to regenerate the message in some contexts, such as an \texttt{mbox}-style mailbox file.
AddressList Objects

An AddressList instance has the following methods:

AddressList.__len__()  
Return the number of addresses in the address list.

AddressList.__str__()  
Return a canonicalized string representation of the address list. Addresses are rendered in “name” <host@domain> form, comma-separated.

AddressList.__add__(alist)  
Return a new AddressList instance that contains all addresses in both AddressList operands, with duplicates removed (set union).

AddressList.__iadd__(alist)  
In-place version of __add__(); turns this AddressList instance into the union of itself and the right-hand instance, alist.

AddressList.__sub__(alist)  
Return a new AddressList instance that contains every address in the left-hand AddressList operand that is not present in the right-hand address operand (set difference).

AddressList.__isub__(alist)  
In-place version of __sub__(), removing addresses in this list which are also in alist.

Finally, AddressList instances have one public instance variable:

AddressList.addresslist  
A list of tuple string pairs, one per address. In each member, the
first is the canonicalized name part, the second is the actual route-address ('@'-separated username-host.domain pair).

**Footnotes**

This module originally conformed to [RFC 822](https://www.rfc-editor.org/rfc/rfc822), hence the name. Since then, [RFC 2822](https://www.rfc-editor.org/rfc/rfc2822) has been released as an update to RFC 822. This module should be considered [RFC 2822](https://www.rfc-editor.org/rfc/rfc2822)-conformant, especially in cases where the syntax or semantics have changed since [RFC 822](https://www.rfc-editor.org/rfc/rfc822).
This module provides data encoding and decoding as specified in RFC 3548. This standard defines the Base16, Base32, and Base64 algorithms for encoding and decoding arbitrary binary strings into text strings that can be safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the uuencode program.

There are two interfaces provided by this module. The modern interface supports encoding and decoding string objects using all three alphabets. The legacy interface provides for encoding and decoding to and from file-like objects as well as strings, but only using the Base64 standard alphabet.

The modern interface, which was introduced in Python 2.4, provides:

```python
base64.b64encode(s[, altchars])
Encode a string use Base64.

s is the string to encode. Optional altchars must be a string of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the + and / characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is None, for which the standard Base64 alphabet is used.

The encoded string is returned.
```

```python
base64.b64decode(s[, altchars])
Decode a Base64 encoded string.
```
s is the string to decode. Optional altchars must be a string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the `+` and `/` characters.

The decoded string is returned. A TypeError is raised if s were incorrectly padded or if there are non-alphabet characters present in the string.

base64. **standard_b64encode**(s)

   Encode string s using the standard Base64 alphabet.

base64. **standard_b64decode**(s)

   Decode string s using the standard Base64 alphabet.

base64. **urlsafe_b64encode**(s)

   Encode string s using a URL-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet.

base64. **urlsafe_b64decode**(s)

   Decode string s using a URL-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet.

base64. **b32encode**(s)

   Encode a string using Base32. s is the string to encode. The encoded string is returned.

base64. **b32decode**(s[, casefold[, map01]])

   Decode a Base32 encoded string.

   s is the string to decode. Optional casefold is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is False.

   **RFC 3548** allows for optional mapping of the digit 0 (zero) to the
letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument
map01 when not None, specifies which letter the digit 1 should be
mapped to (when map01 is not None, the digit 0 is always
mapped to the letter O). For security purposes the default is None,
so that 0 and 1 are not allowed in the input.

The decoded string is returned. A TypeError is raised if s were
incorrectly padded or if there are non-alphabet characters
present in the string.

```
base64.b16encode(s)
```
Encode a string using Base16.

s is the string to encode. The encoded string is returned.

```
base64.b16decode(s[casefold])
```
Decode a Base16 encoded string.

s is the string to decode. Optional casefold is a flag specifying
whether a lowercase alphabet is acceptable as input. For security
purposes, the default is False.

The decoded string is returned. A TypeError is raised if s were
incorrectly padded or if there are non-alphabet characters
present in the string.

The legacy interface:

```
base64.decode(input, output)
```
Decode the contents of the input file and write the resulting binary
data to the output file. input and output must either be file objects
or objects that mimic the file object interface. input will be read
until input.read() returns an empty string.
base64. **decodestring(s)**

Decode the string s, which must contain one or more lines of base64 encoded data, and return a string containing the resulting binary data.

base64. **encode(input, output)**

Encode the contents of the input file and write the resulting base64 encoded data to the output file. input and output must either be file objects or objects that mimic the file object interface. input will be read until input.read() returns an empty string. encode() returns the encoded data plus a trailing newline character ('\n').

base64. **encodestring(s)**

Encode the string s, which can contain arbitrary binary data, and return a string containing one or more lines of base64-encoded data. encodestring() returns a string containing one or more lines of base64-encoded data always including an extra trailing newline ('\n').

An example usage of the module:

```python
>>> import base64
>>> encoded = base64.b64encode('data to be encoded')
>>> encoded
'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
'data to be encoded'
```

**See also:**

**Module binascii**

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

**RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part**
One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies

Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.
This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. On the Macintosh, both forks of a file and the finder information are encoded (or decoded), on other platforms only the data fork is handled.

**Warning:** In 3.0, special Macintosh support is removed.

The `binhex` module defines the following functions:

```python
binhex.binhex(input, output)
```
Convert a binary file with filename `input` to binhex file `output`. The `output` parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

```python
binhex.hexbin(input[, output])
```
Decode a binhex file `input`. `input` may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named `output`, unless the argument is omitted in which case the output filename is read from the binhex file.

The following exception is also defined:

```python
exception binhex.Error
```
Exception raised when something can’t be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.

**See also:**
Module `binascii`

Support module containing ASCII-to-binary and binary-to-ASCII conversions.
Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).

As of this writing, `hexbin()` appears to not work in all cases.
The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu`, `base64`, or `binhex` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

The `binascii` module defines the following functions:

- **`binascii.a2b_uu(string)`**
  Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

- **`binascii.b2a_uu(data)`**
  Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of `data` should be at most 45.

- **`binascii.a2b_base64(string)`**
  Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

- **`binascii.b2a_base64(data)`**
  Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char. The length of `data` should be at most 57 to adhere to the base64 standard.

- **`binascii.a2b_qp(string[, header])`**
Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument header is present and true, underscores will be decoded as spaces.

```python
binascii.b2a_qp(data[, quotetabs, istext, header])
```

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument quotetabs is present and true, all tabs and spaces will be encoded. If the optional argument istext is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument header is present and true, spaces will be encoded as underscores per RFC1522. If the optional argument header is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

```python
binascii.a2b_hqx(string)
```

Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

```python
binascii.rledecode_hqx(data)
```

Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses `\x90` after a byte as a repeat indicator, followed by a count. A count of `0` specifies a byte value of `\x90`. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the Incomplete exception is raised.

```python
binascii.rlecode_hqx(data)
```

Perform binhex4 style RLE-compression on `data` and return the result.
**binascii.b2a_hqx(data)**

Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

**binascii.crc_hqx(data, crc)**

Compute the binhex4 crc value of data, starting with an initial crc and returning the result.

**binascii.crc32(data[, crc])**

Compute CRC-32, the 32-bit checksum of data, starting with an initial crc. This is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```python
print binascii.crc32("hello world")
# Or, in two pieces:
crc = binascii.crc32("hello")
crc = binascii.crc32(" world", crc)
print crc
```

**binascii.b2a_hex(data)**

**binascii.hexlify(data)**

Return the hexadecimal representation of the binary data. Every byte of data is converted into the corresponding 2-digit hex representation. The resulting string is therefore twice as long as the length of data.

**binascii.a2b_hex(hexstr)**

**binascii.unhexlify(hexstr)**

Return the binary data represented by the hexadecimal string hexstr. This function is the inverse of b2a_hex(). hexstr must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise a TypeError is raised.
exception `binascii.Error`
   Exception raised on errors. These are usually programming errors.

exception `binascii.Incomplete`
   Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

**Module base64**
   Support for base64 encoding used in MIME email messages.

**Module binhex**
   Support for the binhex format used on the Macintosh.

**Module uu**
   Support for UU encoding used on Unix.

**Module quopri**
   Support for quoted-printable encoding used in MIME email messages.
**quopri — Encode and decode MIME quoted-printable data**

This module performs quoted-printable transport encoding and decoding, as defined in RFC 1521: “MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies”. The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the base64 module is more compact if there are many such characters, as when sending a graphics file.

```python
quopri.decode(input, output[, header])
```

Decode the contents of the `input` file and write the resulting decoded binary data to the `output` file. `input` and `output` must either be file objects or objects that mimic the file object interface. `input` will be read until `input.readline()` returns an empty string. If the optional argument `header` is present and true, underscore will be decoded as space. This is used to decode “Q”-encoded headers as described in RFC 1522: “MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text”.

```python
quopri.encode(input, output, quotetabs)
```

Encode the contents of the `input` file and write the resulting quoted-printable data to the `output` file. `input` and `output` must either be file objects or objects that mimic the file object interface. `input` will be read until `input.readline()` returns an empty string. `quotetabs` is a flag which controls whether to encode embedded spaces and tabs; when true it encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always
encoded, as per RFC 1521.

```
quopri.decodestring(s[, header])
    Like decode(), except that it accepts a source string and returns
    the corresponding decoded string.
```

```
quopri.encodestring(s[, quotetabs])
    Like encode(), except that it accepts a source string and returns
    the corresponding encoded string. quotetabs is optional
    (defaulting to 0), and is passed straight through to encode().
```

  General utilities for processing of MIME messages.

- **Module base64**
  Encode and decode MIME base64 data
**uu — Encode and decode uuencode files**

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `-` is understood to mean the standard input or output. However, this interface is deprecated; it’s better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The **uu** module defines the following functions:

\[\texttt{uu.encode}(\texttt{in\_file, out\_file[, name[, mode]]})\]

Uuencode file \texttt{in\_file} into file \texttt{out\_file}. The uuencoded file will have the header specifying \texttt{name} and \texttt{mode} as the defaults for the results of decoding the file. The default defaults are taken from \texttt{in\_file}, or `-` and 0666 respectively.

\[\texttt{uu.decode}(\texttt{in\_file[, out\_file[, mode[, quiet]]}})\]

This call decodes uuencoded file \texttt{in\_file} placing the result on file \texttt{out\_file}. If \texttt{out\_file} is a pathname, \texttt{mode} is used to set the permission bits if the file must be created. Defaults for \texttt{out\_file} and \texttt{mode} are taken from the uuencode header. However, if the file specified in the header already exists, a uu.Error is raised.
decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting quiet to a true value silences this warning.

exception uu.Error

Subclass of Exception, this can be raised by uu.decode() under various situations, such as described above, but also including a badly formatted header, or truncated input file.

Module binascii

Support module containing ASCII-to-binary and binary-to-ASCII conversions.
Structured Markup Processing Tools

Python supports a variety of modules to work with various forms of structured data markup. This includes modules to work with the Standard Generalized Markup Language (SGML) and the Hypertext Markup Language (HTML), and several interfaces for working with the Extensible Markup Language (XML).

It is important to note that modules in the xml package require that there be at least one SAX-compliant XML parser available. Starting with Python 2.3, the Expat parser is included with Python, so the xml.parsers.expat module will always be available. You may still want to be aware of the PyXML add-on package; that package provides an extended set of XML libraries for Python.

The documentation for the xml.dom and xml.sax packages are the definition of the Python bindings for the DOM and SAX interfaces.

**HTMLParser — Simple HTML and XHTML parser**

**Note:** The `HTMLParser` module has been renamed to `html.parser` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

*New in version 2.2.*

This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML. Unlike the parser in `httplib`, this parser is not based on the SGML parser in `sgmllib`.

```python
class HTMLParser

The `HTMLParser` class is instantiated without arguments.

An `HTMLParser` instance is fed HTML data and calls handler functions when tags begin and end. The `HTMLParser` class is meant to be overridden by the user to provide a desired behavior.

Unlike the parser in `httplib`, this parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

An exception is defined as well:
```
``` exception HTMLParser. HTMLParseError

Exception raised by the `HTMLParser` class when it encounters an error while parsing. This exception provides three attributes: `msg` is a brief message explaining the error, `lineno` is the number of the line on which the broken construct was detected, and `offset`
is the number of characters into the line at which the construct starts.

**HTMLParser** instances have the following methods:

**HTMLParser.**reset()  
Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser.**feed(data)  
Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or close() is called.

**HTMLParser.**close()  
Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method close().

**HTMLParser.**getpos()  
Return current line number and offset.

**HTMLParser.**get_starttag_text()  
Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

**HTMLParser.**handle_starttag(tag, attrs)  
This method is called to handle the start of a tag. It is intended to be overridden by a derived class; the base class implementation
does nothing.

The tag argument is the name of the tag converted to lower case. The attrs argument is a list of \((name, value)\) pairs containing the attributes found inside the tag’s \(<>\) brackets. The name will be translated to lower case, and quotes in the value have been removed, and character and entity references have been replaced. For instance, for the tag \(<A HREF="http://www.cwi.nl/">\), this method would be called as `handle_starttag('a', [('href', 'http://www.cwi.nl/')])`.

**Changed in version 2.6:** All entity references from `htmlentitydefs` are now replaced in the attribute values.

**HTMLParser**. `handle_startendtag(tag, attrs)`

Similar to `handle_starttag()`, but called when the parser encounters an XHTML-style empty tag (`<a .../>`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simple calls `handle_starttag()` and `handle_endtag()`.

**HTMLParser**. `handle_endtag(tag)`

This method is called to handle the end tag of an element. It is intended to be overridden by a derived class; the base class implementation does nothing. The tag argument is the name of the tag converted to lower case.

**HTMLParser**. `handle_data(data)`

This method is called to process arbitrary data. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. `handle_charref(name)`

This method is called to process a character reference of the
form \&\#ref;. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. **handle_entityref**(name)

This method is called to process a general entity reference of the form \&name; where name is an general entity reference. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. **handle_comment**(data)

This method is called when a comment is encountered. The comment argument is a string containing the text between the -- and -- delimiters, but not the delimiters themselves. For example, the comment <!--text--> will cause this method to be called with the argument 'text'. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. **handle_decl**(decl)

Method called when an SGML declaration is read by the parser. The decl parameter will be the entire contents of the declaration inside the <!...> markup. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. **handle_pi**(data)

Method called when a processing instruction is encountered. The data parameter will contain the entire processing instruction. For example, for the processing instruction <?proc color='red'>, this method would be called as handle_pi("proc color='red'"). It is intended to be overridden by a derived class; the base class implementation does nothing.

**Note:** The **HTMLParser** class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using
the trailing '?' will cause the '?' to be included in data.
Example HTML Parser Application

As a basic example, below is a very basic HTML parser that uses the `HTMLParser` class to print out tags as they are encountered:

```python
from HTMLParser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print "Encountered the beginning of a %s tag" % tag

    def handle_endtag(self, tag):
        print "Encountered the end of a %s tag" % tag
```

sgmllib — Simple SGML parser

Deprecated since version 2.6: The sgmllib module has been removed in Python 3.0.

This module defines a class SGMLParser which serves as the basis for parsing text files formatted in SGML (Standard Generalized Mark-up Language). In fact, it does not provide a full SGML parser — it only parses SGML insofar as it is used by HTML, and the module only exists as a base for the htmllib module. Another HTML parser which supports XHTML and offers a somewhat different interface is available in the HTMLParser module.

class sgmllib.SGMLParser

The SGMLParser class is instantiated without arguments. The parser is hardcoded to recognize the following constructs:

- Opening and closing tags of the form `<tag attr="value" ...>` and `</tag>`, respectively.
- Numeric character references of the form `&#name;`.
- Entity references of the form `&name;`.
- SGML comments of the form `<!--text-->>`. Note that spaces, tabs, and newlines are allowed between the trailing `>` and the immediately preceding `-->`.

A single exception is defined as well:

exception sgmllib.SGMLParseError

Exception raised by the SGMLParser class when it encounters an error while parsing.

New in version 2.1.
SGMLParser instances have the following methods:

SGMLParser.reset()

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

SGMLParser.setnomoretags()

Stop processing tags. Treat all following input as literal input (CDATA). (This is only provided so the HTML tag `<PLAINTEXT>` can be implemented.)

SGMLParser.setliteral()

Enter literal mode (CDATA mode).

SGMLParser.feed(data)

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or close() is called.

SGMLParser.close()

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call close().

SGMLParser.get_starttag_text()

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

SGMLParser.handle_starttag(tag, method, attributes)

This method is called to handle start tags for which either a
start_tag() or do_tag() method has been defined. The tag argument is the name of the tag converted to lower case, and the method argument is the bound method which should be used to support semantic interpretation of the start tag. The attributes argument is a list of (name, value) pairs containing the attributes found inside the tag's <> brackets.

The name has been translated to lower case. Double quotes and backslashes in the value have been interpreted, as well as known character references and known entity references terminated by a semicolon (normally, entity references can be terminated by any non-alphanumerical character, but this would break the very common case of <A HREF="url?spam=1&eggs=2"> when eggs is a valid entity name).

For instance, for the tag <A HREF="http://www.cwi.nl/">, this method would be called as unknown_starttag('a', [('href', 'http://www.cwi.nl/')]). The base implementation simply calls method with attributes as the only argument.

New in version 2.5: Handling of entity and character references within attribute values.

SGMLParser.handle_endtag(tag, method)

This method is called to handle endtags for which an end_tag() method has been defined. The tag argument is the name of the tag converted to lower case, and the method argument is the bound method which should be used to support semantic interpretation of the end tag. If no end_tag() method is defined for the closing element, this handler is not called. The base implementation simply calls method.

SGMLParser.handle_data(data)

This method is called to process arbitrary data. It is intended to
be overridden by a derived class; the base class implementation does nothing.

SGMLParser.\texttt{handle\_charref}(\texttt{ref})
This method is called to process a character reference of the form \&\#\texttt{ref};. The base implementation uses \texttt{convert\_charref()} to convert the reference to a string. If that method returns a string, it is passed to \texttt{handle\_data()}, otherwise \texttt{unknown\_charref(ref)} is called to handle the error.

\textit{Changed in version 2.5}: Use \texttt{convert\_charref()} instead of hard-coding the conversion.

SGMLParser.\texttt{convert\_charref}(\texttt{ref})
Convert a character reference to a string, or \texttt{None}. \texttt{ref} is the reference passed in as a string. In the base implementation, \texttt{ref} must be a decimal number in the range 0-255. It converts the code point found using the \texttt{convert\_codepoint()} method. If \texttt{ref} is invalid or out of range, this method returns \texttt{None}. This method is called by the default \texttt{handle\_charref()} implementation and by the attribute value parser.

\textit{New in version 2.5}.

SGMLParser.\texttt{convert\_codepoint}(\texttt{codepoint})
Convert a codepoint to a \texttt{str} value. Encodings can be handled here if appropriate, though the rest of \texttt{sgmllib} is oblivious on this matter.

\textit{New in version 2.5}.

SGMLParser.\texttt{handle\_entityref}(\texttt{ref})
This method is called to process a general entity reference of the form \&\texttt{ref}; where \texttt{ref} is an general entity reference. It converts \texttt{ref}
by passing it to `convert_entityref()`. If a translation is returned, it calls the method `handle_data()` with the translation; otherwise, it calls the method `unknown_entityref(ref)`. The default `entitydefs` defines translations for `&`, `&apos`, `&gt`, `&lt`, and `&quot`.

*Changed in version 2.5:* Use `convert_entityref()` instead of hard-coding the conversion.

**SGMLParser.** `convert_entityref(ref)`

Convert a named entity reference to a `str` value, or `None`. The resulting value will not be parsed. `ref` will be only the name of the entity. The default implementation looks for `ref` in the instance (or class) variable `entitydefs` which should be a mapping from entity names to corresponding translations. If no translation is available for `ref`, this method returns `None`. This method is called by the default `handle_entityref()` implementation and by the attribute value parser.

*New in version 2.5.*

**SGMLParser.** `handle_comment(comment)`

This method is called when a comment is encountered. The `comment` argument is a string containing the text between the `<!--` and `-->` delimiters, but not the delimiters themselves. For example, the comment `<!--text-->` will cause this method to be called with the argument `text`. The default method does nothing.

**SGMLParser.** `handle_decl(data)`

Method called when an SGML declaration is read by the parser. In practice, the `DOCTYPE` declaration is the only thing observed in HTML, but the parser does not discriminate among different (or
broken) declarations. Internal subsets in a `doctype` declaration are not supported. The `data` parameter will be the entire contents of the declaration inside the `<!...>` markup. The default implementation does nothing.

SGMLParser. `report_unbalanced(tag)`
This method is called when an end tag is found which does not correspond to any open element.

SGMLParser. `unknown_starttag(tag, attributes)`
This method is called to process an unknown start tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

SGMLParser. `unknown_endtag(tag)`
This method is called to process an unknown end tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

SGMLParser. `unknown_charref(ref)`
This method is called to process unresolvable numeric character references. Refer to `handle_charref()` to determine what is handled by default. It is intended to be overridden by a derived class; the base class implementation does nothing.

SGMLParser. `unknown_entityref(ref)`
This method is called to process an unknown entity reference. It is intended to be overridden by a derived class; the base class implementation does nothing.

Apart from overriding or extending the methods listed above, derived classes may also define methods of the following form to define processing of specific tags. Tag names in the input stream are case independent; the `tag` occurring in method names must be in lower
case:

SGMLParser.\texttt{start\_tag}(\texttt{attributes})

This method is called to process an opening tag \textit{tag}. It has preference over \texttt{do\_tag()}. The \texttt{attributes} argument has the same meaning as described for \texttt{handle\_starttag()} above.

SGMLParser.\texttt{do\_tag}(\texttt{attributes})

This method is called to process an opening tag \textit{tag} for which no \texttt{start\_tag()} method is defined. The \texttt{attributes} argument has the same meaning as described for \texttt{handle\_starttag()} above.

SGMLParser.\texttt{end\_tag()}

This method is called to process a closing tag \textit{tag}.

Note that the parser maintains a stack of open elements for which no end tag has been found yet. Only tags processed by \texttt{start\_tag()} are pushed on this stack. Definition of an \texttt{end\_tag()} method is optional for these tags. For tags processed by \texttt{do\_tag()} or by \texttt{unknown\_tag()}, no \texttt{end\_tag()} method must be defined; if defined, it will not be used. If both \texttt{start\_tag()} and \texttt{do\_tag()} methods exist for a tag, the \texttt{start\_tag()} method takes precedence.
htmllib — A parser for HTML documents

Deprecated since version 2.6: The htmllib module has been removed in Python 3.0.

This module defines a class which can serve as a base for parsing text files formatted in the HyperText Mark-up Language (HTML). The class is not directly concerned with I/O — it must be provided with input in string form via a method, and makes calls to methods of a “formatter” object in order to produce output. The HTMLParser class is designed to be used as a base class for other classes in order to add functionality, and allows most of its methods to be extended or overridden. In turn, this class is derived from and extends the SGMLParser class defined in module sgmllib. The HTMLParser implementation supports the HTML 2.0 language as described in RFC 1866. Two implementations of formatter objects are provided in the formatter module; refer to the documentation for that module for information on the formatter interface.

The following is a summary of the interface defined by sgmllib.SGMLParser:

- The interface to feed data to an instance is through the feed() method, which takes a string argument. This can be called with as little or as much text at a time as desired; p.feed(a); p.feed(b) has the same effect as p.feed(a+b). When the data contains complete HTML markup constructs, these are processed immediately; incomplete constructs are saved in a buffer. To force processing of all unprocessed data, call the close() method.
For example, to parse the entire contents of a file, use:

```python
parser.feed(open('myfile.html').read())
parser.close()
```

- The interface to define semantics for HTML tags is very simple: derive a class and define methods called `start_tag()`, `end_tag()`, or `do_tag()`. The parser will call these at appropriate moments: `start_tag()` or `do_tag()` is called when an opening tag of the form `<tag ...>` is encountered; `end_tag()` is called when a closing tag of the form `<tag>` is encountered. If an opening tag requires a corresponding closing tag, like `<H1> ... </H1>`, the class should define the `start_tag()` method; if a tag requires no closing tag, like `<p>`, the class should define the `do_tag()` method.

The module defines a parser class and an exception:

```python
class htmllib.HTMLParser(formatter)

This is the basic HTML parser class. It supports all entity names required by the XHTML 1.0 Recommendation (http://www.w3.org/TR/xhtml1). It also defines handlers for all HTML 2.0 and many HTML 3.0 and 3.2 elements.
```

```python
exception htmllib.HTMLParseError

Exception raised by the HTMLParser class when it encounters an error while parsing.
```

`New in version 2.4.`

**See also:**

**Module `formatter`**

Interface definition for transforming an abstract flow of
formatting events into specific output events on writer objects.

**Module HTMLParser**
Alternate HTML parser that offers a slightly lower-level view of the input, but is designed to work with XHTML, and does not implement some of the SGML syntax not used in “HTML as deployed” and which isn't legal for XHTML.

**Module htmlentitydefs**
Definition of replacement text for XHTML 1.0 entities.

**Module sgmllib**
Base class for HTMLParser.
In addition to tag methods, the HTMLParser class provides some additional methods and instance variables for use within tag methods.

**HTMLParser.** formatter

This is the formatter instance associated with the parser.

**HTMLParser.** nofill

Boolean flag which should be true when whitespace should not be collapsed, or false when it should be. In general, this should only be true when character data is to be treated as “preformatted” text, as within a `<PRE>` element. The default value is false. This affects the operation of handle_data() and save_end().

**HTMLParser.** anchor_bgn(href, name, type)

This method is called at the start of an anchor region. The arguments correspond to the attributes of the `<A>` tag with the same names. The default implementation maintains a list of hyperlinks (defined by the HREF attribute for `<A>` tags) within the document. The list of hyperlinks is available as the data attribute anchorlist.

**HTMLParser.** anchor_end()

This method is called at the end of an anchor region. The default implementation adds a textual footnote marker using an index into the list of hyperlinks created by anchor_bgn().

**HTMLParser.** handle_image(source, alt[, ismap[, align[, width[, height]]]])
This method is called to handle images. The default implementation simply passes the alt value to the handle_data() method.

**HTMLParser.save_bgn()**

Begins saving character data in a buffer instead of sending it to the formatter object. Retrieve the stored data via save_end(). Use of the save_bgn() / save_end() pair may not be nested.

**HTMLParser.save_end()**

Ends buffering character data and returns all data saved since the preceding call to save_bgn(). If the nofill flag is false, whitespace is collapsed to single spaces. A call to this method without a preceding call to save_bgn() will raise a TypeError exception.
htmlentitydefs — Definitions of HTML general entities

**Note:** The `htmlentitydefs` module has been renamed to `html.entities` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines three dictionaries, `name2codepoint`, `codepoint2name`, and `entitydefs`. `entitydefs` is used by the `httplib` module to provide the `entitydefs` member of the `HTMLParser` class. The definition provided here contains all the entities defined by XHTML 1.0 that can be handled using simple textual substitution in the Latin-1 character set (ISO-8859-1).

**htmlentitydefs.entitydefs**

A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

**htmlentitydefs.name2codepoint**

A dictionary that maps HTML entity names to the Unicode codepoints.

*New in version 2.3.*

**htmlentitydefs.codepoint2name**

A dictionary that maps Unicode codepoints to HTML entity names.

*New in version 2.3.*
The `xml.parsers.expat` module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the `pyexpat` module to provide access to the Expat parser. Direct use of the `pyexpat` module is deprecated.

This module provides one exception and one type object:

- `exception xml.parsers.expat.ExpatError`
  - The exception raised when Expat reports an error. See section `ExpatError Exceptions` for more information on interpreting Expat errors.
- `exception xml.parsers.expat.error`
  - Alias for `ExpatError`.

`xml.parsers.expat.XMLParserType`
- The type of the return values from the `ParserCreate()` function.

The `xml.parsers.expat` module contains two functions:

- `xml.parsers.expat.ErrorString(errno)`
  - Returns an explanatory string for a given error number `errno`. 
xml.parsers.expat.ParserCreate([encoding[,namespace_separator]])

Creates and returns a new xmlparser object. encoding, if specified, must be a string naming the encoding used by the XML data. Expat doesn’t support as many encodings as Python does, and its repertoire of encodings can’t be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If encoding [1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for namespace_separator. The value must be a one-character string; a ValueError will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlersStartElementHandler and EndElementHandler will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (chr(0)) then the namespace URI and the local part will be concatenated without any separator.

For example, if namespace_separator is set to a space character (" ") and the following document is parsed:

```xml
<?xml version="1.0"?>
<root xmlns="http://default-namespace.org/
   xmlns:py = "http://www.python.org/ns/">
   <py:elem1 />
   <elem2 xmlns="" />
</root>
```
StartElementHandler will receive the following strings for each element:

http://default-namespace.org/ root
http://www.python.org/ns/ elem1
  elem2

See also:

The Expat XML Parser
  Home page of the Expat project.
XMLParser Objects

xmlparser objects have the following methods:

xmlparser.\texttt{Parse(data[, isfinal])}

Parses the contents of the string \texttt{data}, calling the appropriate handler functions to process the parsed data. \texttt{isfinal} must be true on the final call to this method. \texttt{data} can be the empty string at any time.

xmlparser.\texttt{ParseFile(file)}

Parse XML data reading from the object \texttt{file}. \texttt{file} only needs to provide the \texttt{read(nbytes)} method, returning the empty string when there’s no more data.

xmlparser.\texttt{SetBase(base)}

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the \texttt{base} argument to the \texttt{ExternalEntityRefHandler()}, \texttt{NotationDeclHandler()}, and \texttt{UnparsedEntityDeclHandler()} functions.

xmlparser.\texttt{GetBase()} 

Returns a string containing the base set by a previous call to \texttt{SetBase()}, or \texttt{None} if \texttt{SetBase()} hasn’t been called.

xmlparser.\texttt{GetInputContext()} 

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is \texttt{None}. 

New in version 2.1.

```python
xmlparser.ExternalEntityParserCreate(context [, encoding])
```

Create a “child” parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The `context` parameter should be the string passed to the `ExternalEntityRefHandler()` handler function, described below. The child parser is created with the `ordered_attributes`, `returns_unicode` and `specified_attributes` set to the values of this parser.

```python
xmlparser.UseForeignDTD([flag])
```

Calling this with a true value for `flag` (the default) will cause Expat to call the `ExternalEntityRefHandler` with `None` for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the `ExternalEntityRefHandler` will still be called, but the `StartDoctypeDeclHandler` and `EndDoctypeDeclHandler` will not be called.

Passing a false value for `flag` will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the `Parse()` or `ParseFile()` methods are called; calling it after either of those have been called causes `ExpatError` to be raised with the `code` attribute set to `errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING`.

New in version 2.3.

`xmlparser` objects have the following attributes:

```python
xmlparser.buffer_size
```
The size of the buffer used when `buffer_text` is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

*New in version 2.3.*

*Changed in version 2.6:* The buffer size can now be changed.

```python
xmlparser.buffer_text
```

Setting this to true causes the `xmlparser` object to buffer textual content returned by Expat to avoid multiple calls to the `CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

*New in version 2.3.*

```python
xmlparser.buffer_used
```

If `buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when `buffer_text` is false.

*New in version 2.3.*

```python
xmlparser.ordered_attributes
```

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false; it may be changed at any time.

*New in version 2.1.*
xmlparser.**returns_unicode**

If this attribute is set to a non-zero integer, the handler functions will be passed Unicode strings. If **returns_unicode** is **False**, 8-bit strings containing UTF-8 encoded data will be passed to the handlers. This is **True** by default when Python is built with Unicode support.

*Changed in version 1.6:* Can be changed at any time to affect the result type.

xmlparser.**specified_attributes**

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

*New in version 2.1.*

The following attributes contain values relating to the most recent error encountered by an xmlparser object, and will only have correct values once a call to Parse() or ParseFile() has raised a xml.parsers.expat.ExpatError exception.

xmlparser.**ErrorByteIndex**

Byte index at which an error occurred.

xmlparser.**ErrorCode**

Numeric code specifying the problem. This value can be passed to the ErrorString() function, or compared to one of the constants defined in the errors object.
The following attributes contain values relating to the current parse location in an `xmlparser` object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

*New in version 2.4.*

- `xmlparser.ErrorColumnNumber`
  - Column number at which an error occurred.

- `xmlparser.ErrorLineNumber`
  - Line number at which an error occurred.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object `o`, use `o.handlername = func`. `handlername` must be taken from the following list, and `func` must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

- `xmlparser.XmlDeclHandler(version, encoding, standalone)`
  - Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional “standalone” declaration. `version` and `encoding` will be strings of the type dictated by the `returns_unicode` attribute, and
standalone will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

New in version 2.1.

xmlparser.StartDoctypeDeclHandler(doctypeName, systemId, publicId, has_internal_subset)

Called when Expat begins parsing the document type declaration (<!DOCTYPE ...). The doctypeName is provided exactly as presented. The systemId and publicId parameters give the system and public identifiers if specified, or None if omitted. has_internal_subset will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

xmlparser.EndDoctypeDeclHandler()

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

xmlparser.ElementDeclHandler(name, model)

Called once for each element type declaration. name is the name of the element type, and model is a representation of the content model.

xmlparser.AttlistDeclHandler(elname, attname, type, default, required)

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. elname is the name of the element to which the declaration applies and attname is the name of the attribute declared. The attribute type is a string passed as type; the possible values are 'CDATA', 'ID', 'IDREF',
... default gives the default value for the attribute used when the attribute is not specified by the document instance, or None if there is no default value (#IMPLIED values). If the attribute is required to be given in the document instance, required will be true. This requires Expat version 1.95.0 or newer.

xmlparser.StartElementHandler(name, attributes)
Called for the start of every element. name is a string containing the element name, and attributes is a dictionary mapping attribute names to their values.

xmlparser.EndElementHandler(name)
Called for the end of every element.

xmlparser.ProcessingInstructionHandler(target, data)
Called for every processing instruction.

xmlparser.CharacterDataHandler(data)
Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the StartCdataSectionHandler, EndCdataSectionHandler, and ElementDeclHandler callbacks to collect the required information.

xmlparser.UnparsedEntityDeclHandler(entityName, base, systemId, publicId, notationName)
Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use EntityDeclHandler instead. (The underlying function in the Expat library has been declared obsolete.)

xmlparser.EntityDeclHandler(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)
Called for all entity declarations. For parameter and internal
entities, *value* will be a string giving the declared contents of the entity; this will be *None* for external entities. The *notationName* parameter will be *None* for parsed entities, and the name of the notation for unparsed entities. *is_parameter_entity* will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

*New in version 2.1.*

**xmlparser.** *NotationDeclHandler*(notationName, base, systemId, publicId)

Called for notation declarations. *notationName*, *base*, and *systemId*, and *publicId* are strings if given. If the public identifier is omitted, *publicId* will be *None*.

**xmlparser.** *StartNamespaceDeclHandler*(prefix, uri)

Called when an element contains a namespace declaration. Namespace declarations are processed before the *StartElementHandler* is called for the element on which declarations are placed.

**xmlparser.** *EndNamespaceDeclHandler*(prefix)

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the *StartNamespaceDeclHandler* was called to indicate the start of each namespace declaration’s scope. Calls to this handler are made after the corresponding *EndElementHandler* for the end of the element.

**xmlparser.** *CommentHandler*(data)

Called for comments. *data* is the text of the comment, excluding
the leading '<!- ->' and trailing ' -->'.

`xmlparser.StartCdataSectionHandler()`
Called at the start of a CDATA section. This and `EndCdataSectionHandler` are needed to be able to identify the syntactical start and end for CDATA sections.

`xmlparser.EndCdataSectionHandler()`
Called at the end of a CDATA section.

`xmlparser.DefaultHandler(data)`
Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

`xmlparser.DefaultHandlerExpand(data)`
This is the same as the `DefaultHandler()`, but doesn’t inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

`xmlparser.NotStandaloneHandler()`
Called if the XML document hasn’t been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns 0, then the parser will throw an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

`xmlparser.ExternalEntityRefHandler(context, base, systemId, publicId)`
Called for references to external entities. `base` is the current base, as set by a previous call to `SetBase()`. The public and
system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be *None*. The *context* value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using *ExternalEntityParserCreate(context)*, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will throw an *XML_ERROR_EXTERNAL_ENTITY_HANDLING* error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the *DefaultHandler* callback, if provided.
ExpatError Exceptions

**ExpatError** exceptions have a number of interesting attributes:

**ExpatError**.code

Expat’s internal error number for the specific error. This will match one of the constants defined in the `errors` object from this module.

*New in version 2.1.*

**ExpatError**.lineno

Line number on which the error was detected. The first line is numbered 1.

*New in version 2.1.*

**ExpatError**.offset

Character offset into the line where the error occurred. The first column is numbered 0.

*New in version 2.1.*
The following program defines three handlers that just print out their arguments.

```python
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()
p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?><parent id="top"><child1 name="paul">Text goes here</child1><child2 name="fred">More text</child2></parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '
'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '
'
End element: parent
```
Content Model Descriptions

Content modules are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content module descriptions.

The values of the first two fields are constants defined in the `model` object of the `xml.parsers.expat` module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

```python
xml.parsers.expat.XML_CTYPE_ANY
    The element named by the model name was declared to have a content model of ANY.
```

```python
xml.parsers.expat.XML_CTYPE_CHOICE
    The named element allows a choice from a number of options; this is used for content models such as (A | B | C).
```

```python
xml.parsers.expat.XML_CTYPE_EMPTY
    Elements which are declared to be EMPTY have this model type.
```

```python
xml.parsers.expat.XML_CTYPE_MIXED
```

```python
xml.parsers.expat.XML_CTYPE_NAME
```

```python
xml.parsers.expat.XML_CTYPE_SEQ
    Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as (A, B, C).
```

The constants in the quantifier group are:
xml.parsers.expat.XML_CQUANT_NONE
No modifier is given, so it can appear exactly once, as for A.

xml.parsers.expat.XML_CQUANT_OPT
The model is optional: it can appear once or not at all, as for A?.

xml.parsers.expat.XML_CQUANT_PLUS
The model must occur one or more times (like A+).

xml.parsers.expat.XML_CQUANT_REP
The model must occur zero or more times, as for A*.
### Expat error constants

The following constants are provided in the `errors` object of the `xml.parsers.expat` module. These constants are useful in interpreting some of the attributes of the `ExpatError` exception objects raised when an error has occurred.

The `errors` object has the following attributes:

- `xml.parsers.expat.XML_ERROR_ASYNC_ENTITY`
- `xml.parsers.expat.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`  
  An entity reference in an attribute value referred to an external entity instead of an internal entity.
- `xml.parsers.expat.XML_ERROR_BAD_CHAR_REF`  
  A character reference referred to a character which is illegal in XML (for example, character \0, or `&#0;`).
- `xml.parsers.expat.XML_ERROR_BINARY_ENTITY_REF`  
  An entity reference referred to an entity which was declared with a notation, so cannot be parsed.
- `xml.parsers.expat.XML_ERROR_DUPLICATE_ATTRIBUTE`  
  An attribute was used more than once in a start tag.
- `xml.parsers.expat.XML_ERROR_INCORRECT_ENCODING`
- `xml.parsers.expat.XML_ERROR_INVALID_TOKEN`  
  Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value \0) in a UTF-8 input stream.
- `xml.parsers.expat.XML_ERROR_JUNK_AFTER_DOC_ELEMENT`  
  Something other than whitespace occurred after the document
element.

xml.parsers.expat.XML_ERROR_MISPLACED_XML_PI
An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.XML_ERROR_NO_ELEMENTS
The document contains no elements (XML requires all documents to contain exactly one top-level element).

xml.parsers.expat.XML_ERROR_NO_MEMORY
Expat was not able to allocate memory internally.

xml.parsers.expat.XML_ERROR_PARAM_ENTITY_REF
A parameter entity reference was found where it was not allowed.

xml.parsers.expat.XML_ERROR_PARTIAL_CHAR
An incomplete character was found in the input.

xml.parsers.expat.XML_ERROR_RECURSIVE_ENTITY_REF
An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.XML_ERROR_SYNTAX
Some unspecified syntax error was encountered.

xml.parsers.expat.XML_ERROR_TAG_MISMATCH
An end tag did not match the innermost open start tag.

xml.parsers.expat.XML_ERROR_UNCLOSED_TOKEN
Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.XML_ERROR_UNDEFINED_ENTITY
A reference was made to a entity which was not defined.

xml.parsers.expat.XML_ERROR_UNKNOWN_ENCODING
The document encoding is not supported by Expat.
xml.parsers.expat.\texttt{XML\_ERROR\_UNCLOSED\_CDATA\_SECTION}
A CDATA marked section was not closed.

xml.parsers.expat.\texttt{XML\_ERROR\_EXTERNAL\_ENTITY\_HANDLING}

xml.parsers.expat.\texttt{XML\_ERROR\_NOT\_STANDALONE}
The parser determined that the document was not “standalone” though it declared itself to be in the XML declaration, and the NotStandaloneHandler was set and returned 0.

xml.parsers.expat.\texttt{XML\_ERROR\_UNEXPECTED\_STATE}

xml.parsers.expat.\texttt{XML\_ERROR\_ENTITY\_DECLARED\_IN\_PE}

xml.parsers.expat.\texttt{XML\_ERROR\_FEATURE\_REQUIRES\_XML\_DTD}
An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the xml.parsers.expat module.

xml.parsers.expat.\texttt{XML\_ERROR\_CANT\_CHANGE\_FEATURE\_ONCE\_PARSING}
A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by UseForeignDTD().

xml.parsers.expat.\texttt{XML\_ERROR\_UNBOUND\_PREFIX}
An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.\texttt{XML\_ERROR\_UNDECLARING\_PREFIX}
The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.\texttt{XML\_ERROR\_INCOMPLETE\_PE}
A parameter entity contained incomplete markup.

xml.parsers.expat.\texttt{XML\_ERROR\_XML\_DECL}
The document contained no document element at all.

```
xm.parsers.expat.XML_ERROR_TEXTDECL
  There was an error parsing a text declaration in an external entity.
```

```
xm.parsers.expat.XML_ERROR_PUBLICID
  Characters were found in the public id that are not allowed.
```

```
xm.parsers.expat.XML_ERROR_SUSPENDED
  The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.
```

```
xm.parsers.expat.XML_ERROR_NOT_SUSPENDED
  An attempt to resume the parser was made when the parser had not been suspended.
```

```
xm.parsers.expat.XML_ERROR_ABORTED
  This should not be reported to Python applications.
```

```
xm.parsers.expat.XML_ERROR_FINISHED
  The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.
```

```
xm.parsers.expat.XML_ERROR_SUSPEND_PE
```

**Footnotes**

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See [http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [http://www.iana.org/assignments/character-sets](http://www.iana.org/assignments/character-sets).
The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a
DOMImplementation object class which provides access to Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing Document object. In Python, each DOM implementation will provide a function getDOMImplementation(). DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

See also:

**Document Object Model (DOM) Level 2 Specification**

The W3C recommendation upon which the Python DOM API is based.

**Document Object Model (DOM) Level 1 Specification**

The W3C recommendation for the DOM supported by xml.dom.minidom.

**Python Language Mapping Specification**

This specifies the mapping from OMG IDL to Python.
The `xml.dom` contains the following functions:

```python
xml.dom.registerDOMImplementation(name, factory)
```
Register the `factory` function with the name `name`. The factory function should return an object which implements the `DOMImplementation` interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

```python
xml.dom.getDOMImplementation([name, features])
```
Return a suitable DOM implementation. The `name` is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a `DOMImplementation` object if the import succeeds. If no name is given, and if the environment variable `PYTHON_DOM` is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an `ImportError`. The features list must be a sequence of `(feature, version)` pairs which are passed to the `hasFeature()` method on available `DOMImplementation` objects.

Some convenience constants are also provided:

```python
xml.dom.EMTPY_NAMESPACE
```
The value used to indicate that no namespace is associated with a node in the DOM. This is typically found as the `namespaceURI` of a node, or used as the `namespaceURI` parameter to a
namespaces-specific method.

*New in version 2.2.*

**xml.dom.XML_NAMESPACE**

The namespace URI associated with the reserved prefix `xml`, as defined by *Namespaces in XML* (section 4).

*New in version 2.2.*

**xml.dom.XMLNS_NAMESPACE**

The namespace URI for namespace declarations, as defined by *Document Object Model (DOM) Level 2 Core Specification* (section 1.1.8).

*New in version 2.2.*

**xml.dom.XHTML_NAMESPACE**

The URI of the XHTML namespace as defined by *XHTML 1.0: The Extensible HyperText Markup Language* (section 3.1.1).

*New in version 2.2.*

In addition, `xml.dom` contains a base `Node` class and the DOM exception classes. The `Node` class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The `Node` class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete `Node` objects; they are located within the class rather than at the module level to conform with the DOM specifications.
Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

### DOMImplementation Objects

The DOMImplementation interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new Document and DocumentType objects using the DOMImplementation as well.

DOMImplementation. **hasFeature** *(feature, version)*

Return true if the feature identified by the pair of strings feature and version is implemented.

DOMImplementation. **createDocument** *(namespaceUri, qualifiedName, doctype)*

Return a new Document object (the root of the DOM), with a child Element object having the given namespaceUri and qualifiedName. The doctype must be a DocumentType object created by createDocumentType(), or None. In the Python DOM API, the first two arguments can also be None in order to indicate that no Element child is to be created.

DOMImplementation. **createDocumentType** *(qualifiedName, publicId, systemId)*

Return a new DocumentType object that encapsulates the given qualifiedName, publicId, and systemId strings, representing the
information contained in an XML document type declaration.

Node Objects

All of the components of an XML document are subclasses of Node.

Node. **nodeType**
An integer representing the node type. Symbolic constants for the types are on the Node object: **ELEMENT_NODE**, **ATTRIBUTE_NODE**, **TEXT_NODE**, **CDATA_SECTION_NODE**, **ENTITY_NODE**, **PROCESSING_INSTRUCTION_NODE**, **COMMENT_NODE**, **DOCUMENT_NODE**, **DOCUMENT_TYPE_NODE**, **NOTATION_NODE**. This is a read-only attribute.

Node. **parentNode**
The parent of the current node, or **None** for the document node. The value is always a Node object or **None**. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always **None**. This is a read-only attribute.

Node. **attributes**
A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide **None** for this attribute. This is a read-only attribute.

Node. **previousSibling**
The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the self element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be **None**. This is a read-only attribute.
Node. **nextSibling**
   The node that immediately follows this one with the same parent. See also **previousSibling**. If this is the last child of the parent, this attribute will be **None**. This is a read-only attribute.

Node. **childNodes**
   A list of nodes contained within this node. This is a read-only attribute.

Node. **firstChild**
   The first child of the node, if there are any, or **None**. This is a read-only attribute.

Node. **lastChild**
   The last child of the node, if there are any, or **None**. This is a read-only attribute.

Node. **localName**
   The part of the **tagName** following the colon if there is one, else the entire **tagName**. The value is a string.

Node. **prefix**
   The part of the **tagName** preceding the colon if there is one, else the empty string. The value is a string, or **None**.

Node. **namespaceURI**
   The namespace associated with the element name. This will be a string or **None**. This is a read-only attribute.

Node. **nodeName**
   This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the **tagName** property for elements or the **name** property for attributes. For all node types, the value of this attribute will be either a string or
None. This is a read-only attribute.

Node. **nodeValue**
This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with **nodeName**. The value is a string or None.

Node. **hasAttributes()**
Returns true if the node has any attributes.

Node. **hasChildNodes()**
Returns true if the node has any child nodes.

Node. **isSameNode(other)**
Returns true if other refers to the same node as this node. This is especially useful for DOM implementations which use any sort of proxy architecture (because more than one object can refer to the same node).

**Note:** This is based on a proposed DOM Level 3 API which is still in the “working draft” stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node. **appendChild(newChild)**
Add a new child node to this node at the end of the list of children, returning newChild. If the node was already in in the tree, it is removed first.

Node. **insertBefore(newChild, refChild)**
Insert a new child node before an existing child. It must be the case that refChild is a child of this node; if not, ValueError is raised. newChild is returned. If refChild is None, it inserts
newChild at the end of the children’s list.

Node. **removeChild**(oldChild)

Remove a child node. *oldChild* must be a child of this node; if not, *ValueError* is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its `unlink()` method should be called.

Node. **replaceChild**(newChild, oldChild)

Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, *ValueError* is raised.

Node. **normalize**()

Join adjacent text nodes so that all stretches of text are stored as single *Text* instances. This simplifies processing text from a DOM tree for many applications.

*New in version 2.1.*

Node. **cloneNode**(deep)

Clone this node. Setting *deep* means to clone all child nodes as well. This returns the clone.

**NodeList Objects**

A *NodeList* represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: the *Element* objects provides one as its list of child nodes, and the `getElementsByTagName()` and `getElementsByTagNameNS()` methods of *Node* return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

`NodeList.item(i)`
Return the $i$th item from the sequence, if there is one, or None. The index $i$ is not allowed to be less than zero or greater than or equal to the length of the sequence.

**NodeList. length**

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow **NodeList** objects to be used as Python sequences. All **NodeList** implementations must include support for __len__() and __getitem__(); this allows iteration over the **NodeList** in for statements and proper support for the len() built-in function.

If a DOM implementation supports modification of the document, the **NodeList** implementation must also support the __setitem__() and __delitem__() methods.

**DocumentType Objects**

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a **DocumentType** object. The **DocumentType** for a document is available from the **Document** object's doctype attribute; if there is no DOCTYPE declaration for the document, the document's doctype attribute will be set to None instead of an instance of this interface.

**DocumentType** is a specialization of **Node**, and adds the following attributes:

**DocumentType. publicId**

The public identifier for the external subset of the document type definition. This will be a string or None.
DocumentType. **systemId**

  The system identifier for the external subset of the document type definition. This will be a URI as a string, or **None**.

DocumentType. **internalSubset**

  A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be **None**.

DocumentType. **name**

  The name of the root element as given in the **DOCTYPE** declaration, if present.

DocumentType. **entities**

  This is a **NamedNodeMap** giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be **None** if the information is not provided by the parser, or if no entities are defined.

DocumentType. **notations**

  This is a **NamedNodeMap** giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be **None** if the information is not provided by the parser, or if no notations are defined.

### Document Objects

A **Document** represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from **Node**.

**Document**. **documentElement**

  The one and only root element of the document.
Document. `createElement(tagName)`

Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

Document. `createElementNS(namespaceURI, tagName)`

Create and return a new element with a namespace. The `tagName` may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

Document. `createTextNode(data)`

Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document. `createComment(data)`

Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document. `createProcessingInstruction(target, data)`

Create and return a processing instruction node containing the `target` and `data` passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

Document. `createAttribute(name)`

Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.
Document.\texttt{createAttributeNS}(namespaceURI, qualifiedName)
Create and return an attribute node with a namespace. The \texttt{tagName} may have a prefix. This method does not associate the attribute node with any particular element. You must use \texttt{setAttributeNode()} on the appropriate \texttt{Element} object to use the newly created attribute instance.

Document.\texttt{getElementsByTagName}(tagName)
Search for all descendants (direct children, children's children, etc.) with a particular element type name.

Document.\texttt{getElementsByTagNameNS}(namespaceURI, localName)
Search for all descendants (direct children, children's children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

\begin{description}[leftmargin=0pt]
\item[Element Objects]
\item[\texttt{Element}] is a subclass of \texttt{Node}, so inherits all the attributes of that class.

\item[\texttt{Element.tagName}]
The element type name. In a namespace-using document it may have colons in it. The value is a string.

\item[\texttt{Element.getElementsByTagName}(tagName)]
Same as equivalent method in the \texttt{Document} class.

\item[\texttt{Element.getElementsByTagNameNS}(namespaceURI, localName)]
Same as equivalent method in the \texttt{Document} class.

\item[\texttt{Element.hasAttribute}(name)]
Returns true if the element has an attribute named by \texttt{name}.
Element. **hasAttributeNS**(namespaceURI, localName)
   Returns true if the element has an attribute named by
   namespaceURI and localName.

Element. **getAttribute**(name)
   Return the value of the attribute named by name as a string. If no
   such attribute exists, an empty string is returned, as if the
   attribute had no value.

Element. **getAttributeNode**(attrname)
   Return the Attr node for the attribute named by attrname.

Element. **getAttributeNS**(namespaceURI, localName)
   Return the value of the attribute named by namespaceURI and
   localName as a string. If no such attribute exists, an empty string
   is returned, as if the attribute had no value.

Element. **getAttributeNodeNS**(namespaceURI, localName)
   Return an attribute value as a node, given a namespaceURI and
   localName.

Element. **removeAttribute**(name)
   Remove an attribute by name. If there is no matching attribute, a
   NotFoundErr is raised.

Element. **removeAttributeNode**(oldAttr)
   Remove and return oldAttr from the attribute list, if present. If
   oldAttr is not present, NotFoundErr is raised.

Element. **removeAttributeNS**(namespaceURI, localName)
   Remove an attribute by name. Note that it uses a localName, not
   a qname. No exception is raised if there is no matching attribute.

Element. **setAttribute**(name, value)
Set an attribute value from a string.

**Element**. **setAttributeNode**(newAttr)

Add a new attribute node to the element, replacing an existing attribute if necessary if the **name** attribute matches. If a replacement occurs, the old attribute node will be returned. If **newAttr** is already in use, **InuseAttributeErr** will be raised.

**Element**. **setAttributeNodeNS**(newAttr)

Add a new attribute node to the element, replacing an existing attribute if necessary if the **namespaceURI** and **localName** attributes match. If a replacement occurs, the old attribute node will be returned. If **newAttr** is already in use, **InuseAttributeErr** will be raised.

**Element**. **setAttributeNS**(namespaceURI, qname, value)

Set an attribute value from a string, given a **namespaceURI** and a **qname**. Note that a qname is the whole attribute name. This is different than above.

**Attr Objects**

**Attr** inherits from **Node**, so inherits all its attributes.

**Attr. name**

The attribute name. In a namespace-using document it may have colons in it.

**Attr. localName**

The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.

**Attr. prefix**

The part of the name preceding the colon if there is one, else the empty string.
NamedNodeMap Objects

**NamedNodeMap** does *not* inherit from **Node**.

**NamedNodeMap**. **length**

The length of the attribute list.

**NamedNodeMap**. **item**(index)

Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the **value** attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized **getAttribute**(index) family of methods on the **Element** objects.

Comment Objects

**Comment** represents a comment in the XML document. It is a subclass of **Node**, but cannot have child nodes.

**Comment**. **data**

The content of the comment as a string. The attribute contains all characters between the leading <!-- and trailing -->, but does not include them.

Text and CDATASection Objects

The **Text** interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in **CDATASection** objects. These two interfaces are identical, but provide
different values for the `nodeName` attribute.

These interfaces extend the `Node` interface. They cannot have child nodes.

**Text. `data`**
The content of the text node as a string.

**Note:** The use of a `CDATASection` node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent `CDATASection` nodes represent different CDATA marked sections.

**ProcessingInstruction Objects**

Represents a processing instruction in the XML document; this inherits from the `Node` interface and cannot have child nodes.

**ProcessingInstruction. `target`**
The content of the processing instruction up to the first whitespace character. This is a read-only attribute.

**ProcessingInstruction. `data`**
The content of the processing instruction following the first whitespace character.

**Exceptions**

*New in version 2.1.*

The DOM Level 2 recommendation defines a single exception, `DOMException`, and a number of constants that allow applications to
determine what sort of error occurred. **DOMException** instances carry a `code` attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the `code` attribute.

```python
exception xml.dom.DOMException
    Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception xml.dom.DomStringSizeErr
    Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception xml.dom.HierarchyRequestErr
    Raised when an attempt is made to insert a node where the node type is not allowed.

exception xml.dom.IndexSizeErr
    Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.InuseAttributeErr
    Raised when an attempt is made to insert an Attr node that is already present elsewhere in the document.

exception xml.dom.InvalidAccessErr
    Raised if a parameter or an operation is not supported on the underlying object.
exception xml.dom.**InvalidCharacterErr**
This exception is raised when a string parameter contains a character that is not permitted in the context it’s being used in by the XML 1.0 recommendation. For example, attempting to create an **Element** node with a space in the element type name will cause this error to be raised.

exception xml.dom.**InvalidModificationErr**
Raised when an attempt is made to modify the type of a node.

exception xml.dom.**InvalidStateErr**
Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.**NamespaceErr**
If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.**NotFoundErr**
Exception when a node does not exist in the referenced context. For example, **NamedNodeMap.removeNamedItem()** will raise this if the node passed in does not exist in the map.

exception xml.dom.**NotSupportedErr**
Raised when the implementation does not support the requested type of object or operation.

exception xml.dom.**NoDataAllowedErr**
This is raised if data is specified for a node which does not support data.

exception xml.dom.**NoModificationAllowedErr**
Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).
exception `xml.dom.SyntaxErr`  
Raised when an invalid or illegal string is specified.

exception `xml.dom.WrongDocumentErr`  
Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMSTRING_SIZE_ERR</td>
<td>DomStringSizeErr</td>
</tr>
<tr>
<td>HIERARCHY_REQUEST_ERR</td>
<td>HierarchyRequestErr</td>
</tr>
<tr>
<td>INDEX_SIZE_ERR</td>
<td>IndexSizeErr</td>
</tr>
<tr>
<td>INUSE_ATTRIBUTE_ERR</td>
<td>InuseAttributeErr</td>
</tr>
<tr>
<td>INVALID_ACCESS_ERR</td>
<td>InvalidAccessErr</td>
</tr>
<tr>
<td>INVALID_CHARACTER_ERR</td>
<td>InvalidCharacterErr</td>
</tr>
<tr>
<td>INVALID_MODIFICATION_ERR</td>
<td>InvalidModificationErr</td>
</tr>
<tr>
<td>INVALID_STATE_ERR</td>
<td>InvalidStateErr</td>
</tr>
<tr>

<td>WRONG_DOCUMENT_ERR</td>
<td>WrongDocumentErr</td>
</tr>
</tbody>
</table>
Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

Type Mapping

The primitive IDL types used in the DOM specification are mapped to Python types according to the following table.

<table>
<thead>
<tr>
<th>IDL Type</th>
<th>Python Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>IntegerType (with a value of 0 or 1)</td>
</tr>
<tr>
<td>int</td>
<td>IntegerType</td>
</tr>
<tr>
<td>long int</td>
<td>IntegerType</td>
</tr>
<tr>
<td>unsigned int</td>
<td>IntegerType</td>
</tr>
</tbody>
</table>

Additionally, the `DOMString` defined in the recommendation is mapped to a Python string or Unicode string. Applications should be able to handle Unicode whenever a string is returned from the DOM.

The IDL `null` value is mapped to `None`, which may be accepted or provided by the implementation whenever `null` is allowed by the API.

Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL `attribute` declarations in much the way the Java mapping does. Mapping the IDL declarations

```plaintext
readonly attribute string someValue;
attribute string anotherValue;
```
yields three accessor functions: a “get” method for `someValue` (_get_someValue()), and “get” and “set” methods for `anotherValue` (_get_anotherValue() and _set_anotherValue()). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: `object.someValue` is not required to work, and may raise an `AttributeError`.

The Python DOM API, however, does require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared `readonly` may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for `readonly` attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of `getElementsByTagName()`, being “live”. The Python DOM API does not require implementations to enforce such requirements.
xml.dom.minidom — Lightweight DOM implementation

New in version 2.0.

xml.dom.minidom is a light-weight implementation of the Document Object Model interface. It is intended to be simpler than the full DOM and also significantly smaller.

DOM applications typically start by parsing some XML into a DOM. With xml.dom.minidom, this is done through the parse functions:

```python
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\temp\mydata.xml')  # parse an XML file by name

datasource = open('c:\temp\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The `parse()` function can take either a filename or an open file object.

xml.dom.minidom. `parse(filename_or_file, parser)`

Return a `Document` from the given input. `filename_or_file` may be either a file name, or a file-like object. `parser`, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the `parseString()` function instead:
```python
from xml.dom.minidom import getDOMImplementation
impl = getDOMImplementation()
newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These
properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM, you should clean it up. This is necessary because some versions of Python do not support garbage collection of objects that refer to each other in a cycle. Until this restriction is removed from all versions of Python, it is safest to write your code as if cycles would not be cleaned up.

The way to clean up a DOM is to call its `unlink()` method:

```
dom1.unlink()
dom2.unlink()
dom3.unlink()
```

`unlink()` is a `xml.dom.minidom`-specific extension to the DOM API. After calling `unlink()` on a node, the node and its descendants are essentially useless.

See also:

**Document Object Model (DOM) Level 1 Specification**

The W3C recommendation for the DOM supported by `xml.dom.minidom`. 

DOM Objects

The definition of the DOM API for Python is given as part of the `xml.dom` module documentation. This section lists the differences between the API and `xml.dom.minidom`.

**Node. `unlink()`**

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the `Document` object, but may be called on child nodes to discard children of that node.

**Node. `writexml`**

Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The `indent` parameter is the indentation of the current node. The `addindent` parameter is the incremental indentation to use for subnodes of the current one. The `newl` parameter specifies the string to use to terminate newlines.

*Changed in version 2.1:* The optional keyword parameters `indent`, `addindent`, and `newl` were added to support pretty output.

*Changed in version 2.3:* For the `Document` node, an additional keyword argument `encoding` can be used to specify the encoding field of the XML header.

**Node. `toxml`**
Return the XML that the DOM represents as a string.

With no argument, the XML header does not specify an encoding, and the result is Unicode string if the default encoding cannot represent all characters in the document. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

With an explicit *encoding* [1] argument, the result is a byte string in the specified encoding. It is recommended that this argument is always specified. To avoid *UnicodeError* exceptions in case of unrepresentable text data, the encoding argument should be specified as “utf-8”.

*Changed in version 2.3:* the *encoding* argument was introduced; see *writexml()*.

Node.*toprettyxml*([*indent=*/"
*, *newl=*/"
*, *encoding=*/"
])

Return a pretty-printed version of the document. *indent* specifies the indentation string and defaults to a tabulator; *newl* specifies the string emitted at the end of each line and defaults to \n.

*New in version 2.1.*

*Changed in version 2.3:* the *encoding* argument was introduced; see *writexml()*.

The following standard DOM methods have special considerations with *xml.dom.minidom*:

Node.*cloneNode*(deep)

Although this method was present in the version of *xml.dom.minidom* packaged with Python 2.0, it was seriously broken. This has been corrected for subsequent releases.
This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```python
import xml.dom.minidom

document = """"
  <slideshow>
    <title>Demo slideshow</title>
    <slide>
      <title>Slide title</title>
      <point>This is a demo</point>
      <point>Of a program for processing slides</point>
    </slide>

    <slide>
      <title>Another demo slide</title>
      <point>It is important</point>
      <point>To have more than</point>
      <point>one slide</point>
    </slide>
  </slideshow>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = ""
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc = rc + node.data
    return rc

def handleSlideshow(slideshow):
    print "<html>"
    handleSlideshowTitle(slideshow.getElementsByTagName("title")
    slides = slideshow.getElementsByTagName("slide")
    handleToc(slides)
    handleSlides(slides)
    print "</html>"

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)
```
def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title")[0])
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print "<title>%s</title>" % getText(title.childNodes)

def handleSlideTitle(title):
    print "<h2>%s</h2>" % getText(title.childNodes)

def handlePoints(points):
    print "<ul>
        for point in points:
            handlePoint(point)
    print "</ul>"

def handlePoint(point):
    print "<li>%s</li>" % getText(point.childNodes)

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")[0]
        print "<p>%s</p>" % getText(title.childNodes)

handleSlideshow(dom)
The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the `Document` object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short`, `int`, `unsigned int`, `unsigned long`, `long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either byte or Unicode strings, but will normally produce Unicode strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- **DOMException** is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as `TypeError` and `AttributeError`.

- **NodeList** objects are implemented using Python’s built-in list type. Starting with Python 2.2, these objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more “Pythonic” than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom`:

- **DOMTimeStamp**
- **DocumentType** (added in Python 2.1)
- **DOMImplementation** (added in Python 2.1)
- **CharacterData**
- **CDATASection**
- **Notation**
- **Entity**
- **EntityReference**
- **DocumentFragment**

Most of these reflect information in the XML document that is not of general utility to most DOM users.

**Footnotes**

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and http://www.iana.org/assignments/character-sets.
New in version 2.0.

xml.dom.pulldom allows building only selected portions of a Document Object Model representation of a document from SAX events.

class xml.dom.pulldom.PullDOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

class xml.dom.pulldom.DOMEventStream(stream, parser, bufsize)
    ...

class xml.dom.pulldom.SAX2DOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

xml.dom.pulldom.parse(stream_or_string[, parser[, bufsize]])
    ...

xml.dom.pulldom.parseString(string[, parser])
    ...

xml.dom.pulldom.default_bufsize
    Default value for the bufsize parameter to parse().

    Changed in version 2.1: The value of this variable can be changed before calling parse() and the new value will take effect.
DOMEventStream Objects

```python
DOMEventStream.getEvent()
...
DOMEventStream.expandNode(node)
...
DOMEventStream.reset()
...
```
xml.sax — Support for SAX2 parsers

New in version 2.0.

The xml.sax package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

The convenience functions are:

xml.sax.make_parser([parser_list])
  Create and return a SAX XMLReader object. The first parser found will be used. If parser_list is provided, it must be a sequence of strings which name modules that have a function named create_parser(). Modules listed in parser_list will be used before modules in the default list of parsers.

xml.sax.parse(filename_or_stream, handler[, error_handler])
  Create a SAX parser and use it to parse a document. The document, passed in as filename_or_stream, can be a filename or a file object. The handler parameter needs to be a SAX ContentHandler instance. If error_handler is given, it must be a SAX ErrorHandler instance; if omitted, SAXParseException will be raised on all errors. There is no return value; all work must be done by the handler passed in.

xml.sax.parseString(string, handler[, error_handler])
  Similar to parse(), but parses from a buffer string received as a parameter.
A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The InputSource, Locator, Attributes, AttributesNS, and XMLReader interfaces are defined in the module xml.sax.xmlreader. The handler interfaces are defined in xml.sax.handler. For convenience, InputSource (which is often instantiated directly) and the handler classes are also available from xml.sax. These interfaces are described below.

In addition to these classes, xml.sax provides the following exception classes.

```
exception xml.sax.SAXException(msg[, exception])
Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the ErrorHandler interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.
```
When instantiated, \textit{msg} should be a human-readable description of the error. The optional \textit{exception} parameter, if given, should be \texttt{None} or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

\begin{verbatim}
exception xml.sax.SAXParseException(msg, exception, locator)
Subclass of \texttt{SAXException} raised on parse errors. Instances of this class are passed to the methods of the SAX \texttt{ErrorHandler} interface to provide information about the parse error. This class supports the SAX \texttt{Locator} interface as well as the \texttt{SAXException} interface.
\end{verbatim}

\begin{verbatim}
exception xml.sax.SAXNotRecognizedException(msg[, exception])
Subclass of \texttt{SAXException} raised when a SAX \texttt{XMLReader} is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.
\end{verbatim}

\begin{verbatim}
exception xml.sax.SAXNotSupportedException(msg[, exception])
Subclass of \texttt{SAXException} raised when a SAX \texttt{XMLReader} is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.
\end{verbatim}

\textbf{SAX: The Simple API for XML}
This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

\textbf{Module} \texttt{xml.sax.handler}
Definitions of the interfaces for application-provided objects.

**Module** `xml.sax.saxutils`
Convenience functions for use in SAX applications.

**Module** `xml.sax.xmlreader`
Definitions of the interfaces for parser-provided objects.
The `SAXException` exception class supports the following methods:

**SAXException. `getMessage()`**
Return a human-readable message describing the error condition.

**SAXException. `getException()`**
Return an encapsulated exception object, or `None`.
xml.sax.handler — Base classes for SAX handlers

New in version 2.0.

The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module xml.sax.handler, so that all methods get default implementations.

```python
class xml.sax.handler.ContentHandler
    This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

class xml.sax.handler.DTDHandler
    Handle DTD events.

    This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

class xml.sax.handler.EntityResolver
    Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

class xml.sax.handler.ErrorHandler
    Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are
handled in some other way.

In addition to these classes, `xml.sax.handler` provides symbolic constants for the feature and property names.

`xml.sax.handler.feature_namespaces`
Value: "http://xml.org/sax/features/namespaces" — true: Perform Namespace processing. — false: Optionally do not perform Namespace processing (implies namespace-prefixes; default). — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_namespace_prefixes`
Value: "http://xml.org/sax/features/namespace-prefixes" — true: Report the original prefixed names and attributes used for Namespace declarations. — false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default). — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_string_interning`
Value: "http://xml.org/sax/features/string-interning" — true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function. — false: Names are not necessarily interned, although they may be (default). — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_validation`
Value: "http://xml.org/sax/features/validation" — true: Report all validation errors (implies external-general-entities and external-parameter-entities). — false: Do not report validation errors. — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_external_ges`
Value: "http://xml.org/sax/features/external-general-entities" — true: Include all external general (text) entities. —
false: Do not include external general entities. — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_external_pes`
Value: "http://xml.org/sax/features/external-parameter-entities" — true: Include all external parameter entities, including the external DTD subset. — false: Do not include any external parameter entities, even the external DTD subset. — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.all_features`
List of all features.

`xml.sax.handler.property_lexical_handler`
Value: "http://xml.org/sax/properties/lexical-handler" — data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2) — description: An optional extension handler for lexical events like comments. — access: read/write

`xml.sax.handler.property_declaration_handler`
Value: "http://xml.org/sax/properties/declaration-handler" — data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2) — description: An optional extension handler for DTD-related events other than notations and unparsed entities. — access: read/write

`xml.sax.handler.property_dom_node`
Value: "http://xml.org/sax/properties/dom-node" — data type: org.w3c.dom.Node (not supported in Python 2) — description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration. — access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.property_xml_string`
Value: "http://xml.org/sax/properties/xml-string" — data
type: String — description: The literal string of characters that was the source for the current event. — access: read-only

xml.sax.handler.**all_properties**

List of all known property names.
Users are expected to subclass `ContentHandler` to support their application. The following methods are called by the parser on the appropriate events in the input document:

`ContentHandler.setDocumentLocator(locator)`

- Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

`ContentHandler.startDocument()`

- Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).
ContentHandler.\texttt{endDocument()}  
Receive notification of the end of a document.  

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler.\texttt{startPrefixMapping($\text{prefix}$, $\text{uri}$)}  
Begin the scope of a prefix-URI Namespace mapping.  

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the \texttt{feature\_namespaces} feature is enabled (the default).  

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the \texttt{startPrefixMapping()} and \texttt{endPrefixMapping()} events supply the information to the application to expand prefixes in those contexts itself, if necessary.  

Note that \texttt{startPrefixMapping()} and \texttt{endPrefixMapping()} events are not guaranteed to be properly nested relative to each-other: all \texttt{startPrefixMapping()} events will occur before the corresponding \texttt{startElement()} event, and all \texttt{endPrefixMapping()} events will occur after the corresponding \texttt{endElement()} event, but their order is not guaranteed.

ContentHandler.\texttt{endPrefixMapping($\text{prefix}$)}  
End the scope of a prefix-URI mapping.  

See \texttt{startPrefixMapping()} for details. This event will always
occur after the corresponding `endElement()` event, but the order of `endPrefixMapping()` events is not otherwise guaranteed.

**ContentHandler.** **startElement**(name, attrs)

Signals the start of an element in non-namespace mode.

The `name` parameter contains the raw XML 1.0 name of the element type as a string and the `attrs` parameter holds an object of the Attributes interface (see *The Attributes Interface*) containing the attributes of the element. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.

**ContentHandler.** **endElement**(name)

Signals the end of an element in non-namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElement()` event.

**ContentHandler.** **startElementNS**(name, qname, attrs)

Signals the start of an element in namespace mode.

The `name` parameter contains the name of the element type as a (uri, localname) tuple, the `qname` parameter contains the raw XML 1.0 name used in the source document, and the `attrs` parameter holds an instance of the AttributesNS interface (see *The AttributesNS Interface*) containing the attributes of the element. If no namespace is associated with the element, the `uri` component of `name` will be `None`. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.
Parsers may set the `qname` parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

```
ContentHandler.endElementNS(name, qname)
```
Signals the end of an element in namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElementNS()` method, likewise the `qname` parameter.

```
ContentHandler.characters(content)
```
Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

`content` may be a Unicode string or a byte string; the `expat` reader module produces always Unicode strings.

**Note:** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use `content` instead of slicing content with the old `offset` and `length` parameters.

```
ContentHandler.ignorableWhitespace(whitespace)
```
Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of
ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

**ContentHandler**. `processingInstruction(target, data)`

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

**ContentHandler**. `skippedEntity(name)`

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.
**DTDHandler Objects**

**DTDHandler** instances provide the following methods:

**`DTDHandler.notationDecl(name, publicId, systemId)`**
Handle a notation declaration event.

**`DTDHandler.unparsedEntityDecl(name, publicId, systemId, ndata)`**
Handle an unparsed entity declaration event.
EntityResolver Objects

EntityResolver. **resolveEntity**(publicId, systemId)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns systemId.
ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the `XMLReader`. If you create an object that implements this interface, then register the object with your `XMLReader`, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a `SAXParseException` as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

**ErrorHandler. `error(exception)`**

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

**ErrorHandler. `fatalError(exception)`**

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

**ErrorHandler. `warning(exception)`**

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.
xml.sax.saxutils — SAX Utilities

New in version 2.0.

The module xml.sax.saxutils contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

xml.sax.saxutils.escape(data[, entities])

Escape '&', '<', and '>' in a string of data.

You can escape other strings of data by passing a dictionary as the optional entities parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters '&', '<' and '>' are always escaped, even if entities is provided.

xml.sax.saxutils.unescape(data[, entities])

Unescape '&amp;', '&lt;', and '&gt;' in a string of data.

You can unescape other strings of data by passing a dictionary as the optional entities parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. '&amp;', '&lt;', and '&gt;' are always unescaped, even if entities is provided.

New in version 2.3.

xml.sax.saxutils.quoteattr(data[, entities])

Similar to escape(), but also prepares data to be used as an attribute value. The return value is a quoted version of data with any additional required replacements. quoteattr() will select a quote character based on the content of data, attempting to avoid
encoding any quote characters in the string. If both single- and double-quote characters are already in data, the double-quote characters will be encoded and data will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

```python
>>> print '<element attr=%s>' % quoteattr("ab cd \" ef")
<element attr="ab cd \" ef">
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

*New in version 2.2.*

```python
class xml.sax.saxutils.XMLGenerator([out[, encoding]])
```

This class implements the `ContentHandler` interface by writing SAX events back into an XML document. In other words, using an `XMLGenerator` as the content handler will reproduce the original document being parsed. `out` should be a file-like object which will default to `sys.stdout`. `encoding` is the encoding of the output stream which defaults to 'iso-8859-1'.

```python
class xml.sax.saxutils.XMLFilterBase(base)
```

This class is designed to sit between an `XMLReader` and the client application’s event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

```python
xml.sax.saxutils.prepare_input_source(source[, base])
```

This function takes an input source and an optional base URL and returns a fully resolved `InputSource` object ready for reading. The input source can be given as a string, a file-like object, or an
**InputSource** object; parsers will use this function to implement the polymorphic *source* argument to their *parse()* method.
xml.sax.xmlreader — Interface for XML parsers

New in version 2.0.

SAX parsers implement the XMLReader interface. They are implemented in a Python module, which must provide a function create_parser(). This function is invoked by xml.sax.make_parser() with no arguments to create a new parser object.

class xml.sax.xmlreader.XMLReader

    Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.IncrementalParser

    In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still parse() won’t return until the entire document is processed. So these interfaces should be used if the blocking behaviour of parse() is not desirable.

    When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

    Note that these methods must not be called during parsing, that is, after parse has been called and before it returns.

    By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0
driver writers.

class xml.sax.xmlreader.Locator

   Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return None.

class xml.sax.xmlreader.InputSource([systemId])

   Encapsulation of the information needed by the XMLReader to read entities.

   This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

   Applications will create objects of this class for use in the XMLReader.parse() method and for returning from EntityResolver.resolveEntity.

   An InputSource belongs to the application, the XMLReader is not allowed to modify InputSource objects passed to it from the application, although it may make copies and modify those.

class xml.sax.xmlreader.AttributesImpl(attrs)

   This is an implementation of the Attributes interface (see section The Attributes Interface). This is a dictionary-like object which represents the element attributes in a startElement() call.

   In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; attrs must be a dictionary-like object containing a mapping from attribute names to attribute values.
class xml.sax.xmlreader.AttributesNSImpl(attrs, qnames)

Namespace-aware variant of AttributesImpl, which will be passed to startElementNS(). It is derived from AttributesImpl, but understands attribute names as two-tuples of namespaceURI and localname. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the AttributesNS interface (see section The AttributesNS Interface).
XMLReader Objects

The `XMLReader` interface supports the following methods:

**`XMLReader.parse(source)`**
Process an input source, producing SAX events. The `source` object can be a system identifier (a string identifying the input source – typically a file name or an URL), a file-like object, or an `InputSource` object. When `parse()` returns, the input is completely processed, and the parser object can be discarded or reset. As a limitation, the current implementation only accepts byte streams; processing of character streams is for further study.

**`XMLReader.getContentHandler()`**
Return the current `ContentHandler`.

**`XMLReader.setContentHandler(handler)`**
Set the current `ContentHandler`. If no `ContentHandler` is set, content events will be discarded.

**`XMLReader.getDTDHandler()`**
Return the current `DTDHandler`.

**`XMLReader.setDTDHandler(handler)`**
Set the current `DTDHandler`. If no `DTDHandler` is set, DTD events will be discarded.

**`XMLReader.getEntityResolver()`**
Return the current `EntityResolver`.

**`XMLReader.setEntityResolver(handler)`**
Set the current `EntityResolver`. If no `EntityResolver` is set,
attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

`XMLReader.getErrorHandler()`
Return the current `ErrorHandler`.

`XMLReader setErrorHandler(handler)`
Set the current error handler. If no `ErrorHandler` is set, errors will be raised as exceptions, and warnings will be printed.

`XMLReader.setLocale(locale)`
Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must throw a SAX exception. Applications may request a locale change in the middle of a parse.

`XMLReader.getFeature(featurename)`
Return the current setting for feature `featurename`. If the feature is not recognized, `SAXNotRecognizedException` is raised. The well-known featurenames are listed in the module `xml.sax.handler`.

`XMLReader.setFeature(featurename, value)`
Set the `featurename` to `value`. If the feature is not recognized, `SAXNotRecognizedException` is raised. If the feature or its setting is not supported by the parser, `SAXNotSupportedException` is raised.

`XMLReader.getProperty(propertyname)`
Return the current setting for property `propertyname`. If the property is not recognized, a `SAXNotRecognizedException` is raised. The well-known propertynames are listed in the module `xml.sax.handler`. 
XMLReader. **setProperty**(propertyname, value)

Set the *propertyname* to *value*. If the property is not recognized, *SAXNotRecognizedException* is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.
IncrementalParser Objects

Instances of IncrementalParser offer the following additional methods:

IncrementalParser. **feed**(data)

Process a chunk of data.

IncrementalParser. **close**()

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser. **reset**()

This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.
Instances of `Locator` provide these methods:

`Locator.getColumnNumber()`  
Return the column number where the current event ends.

`Locator.getLineNumber()`  
Return the line number where the current event ends.

`Locator.getPublicId()`  
Return the public identifier for the current event.

`Locator.getSystemId()`  
Return the system identifier for the current event.
InputSource Objects

**InputSource.**`setPublicId(id)`
Sets the public identifier of this `InputSource`.

**InputSource.**`getPublicId()`
Returns the public identifier of this `InputSource`.

**InputSource.**`setSystemId(id)`
Sets the system identifier of this `InputSource`.

**InputSource.**`getSystemId()`
Returns the system identifier of this `InputSource`.

**InputSource.**`setEncoding(encoding)`
Sets the character encoding of this `InputSource`.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the `InputSource` is ignored if the `InputSource` also contains a character stream.

**InputSource.**`getEncoding()`
Get the character encoding of this InputSource.

**InputSource.**`setByteStream(bytefile)`
Set the byte stream (a Python file-like object which does not perform byte-to-character conversion) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.
If the application knows the character encoding of the byte stream, it should set it with the setEncoding method.

**InputSource**. `getBytesStream()`  
Get the byte stream for this input source.

The getEncoding method will return the character encoding for this byte stream, or None if unknown.

**InputSource**. `setCharacterStream`(*charfile*)  
Set the character stream for this input source. (The stream must be a Python 1.6 Unicode-wrapped file-like that performs conversion to Unicode strings.)

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

**InputSource**. `getCharacterStream()`  
Get the character stream for this input source.
The Attributes Interface

Attributes objects implement a portion of the mapping protocol, including the methods copy(), get(), has_key(), items(), keys(), and values(). The following methods are also provided:

Attributes. **getLength()**
- Return the number of attributes.

Attributes. **getNames()**
- Return the names of the attributes.

Attributes. **getType(name)**
- Returns the type of the attribute name, which is normally 'CDATA'.

Attributes. **getValue(name)**
- Return the value of attribute name.
The **AttributesNS Interface**

This interface is a subtype of the **Attributes interface** (see section *The Attributes Interface*). All methods supported by that interface are also available on **AttributesNS** objects.

The following methods are also available:

- **AttributesNS.** `getValueByQName(name)`
  Return the value for a qualified name.

- **AttributesNS.** `getNameByQName(name)`
  Return the (namespace, localname) pair for a qualified name.

- **AttributesNS.** `getQNameByName(name)`
  Return the qualified name for a (namespace, localname) pair.

- **AttributesNS.** `getQNames()`
  Return the qualified names of all attributes.
xml.etree.ElementTree — The ElementTree XML API

New in version 2.5.

The Element type is a flexible container object, designed to store hierarchical data structures in memory. The type can be described as a cross between a list and a dictionary.

Each element has a number of properties associated with it:

- a tag which is a string identifying what kind of data this element represents (the element type, in other words).
- a number of attributes, stored in a Python dictionary.
- a text string.
- an optional tail string.
- a number of child elements, stored in a Python sequence.

To create an element instance, use the Element or SubElement factory functions.

The ElementTree class can be used to wrap an element structure, and convert it from and to XML.

A C implementation of this API is available as xml.etree.cElementTree.

See http://effbot.org/zone/element-index.htm for tutorials and links to other docs. Fredrik Lundh's page is also the location of the development version of the xml.etree.ElementTree.
Functions

xml.etree.ElementTree.Comment([text])
Comment element factory. This factory function creates a special element that will be serialized as an XML comment. The comment string can be either an 8-bit ASCII string or a Unicode string. text is a string containing the comment string. Returns an element instance representing a comment.

xml.etree.ElementTree.dump(elem)
Writes an element tree or element structure to sys.stdout. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

elem is an element tree or an individual element.

xml.etree.ElementTree.Element(tag[, attrib][, **extra])
Element factory. This function returns an object implementing the standard Element interface. The exact class or type of that object is implementation dependent, but it will always be compatible with the _ElementInterface class in this module.

The element name, attribute names, and attribute values can be either 8-bit ASCII strings or Unicode strings. tag is the element name. attrib is an optional dictionary, containing element attributes. extra contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.fromstring(text)
 Parses an XML section from a string constant. Same as XML. text is a string containing XML data. Returns an Element
instance.

xmlelement(element)

Checks if an object appears to be a valid element object. element is an element instance. Returns a true value if this is an element object.

xml.etree.ElementTree.iterparse(source[, events])

Parses an XML section into an element tree incrementally, and reports what's going on to the user. source is a filename or file object containing XML data. events is a list of events to report back. If omitted, only “end” events are reported. Returns an iterator providing (event, elem) pairs.

xml.etree.ElementTree.parse(source[, parser])

Parses an XML section into an element tree. source is a filename or file object containing XML data. parser is an optional parser instance. If not given, the standard XMLTreeBuilder parser is used. Returns an ElementTree instance.

xml.etree.ElementTree.ProcessingInstruction(target[, text])

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. target is a string containing the PI target. text is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

xml.etree.ElementTree.SubElement(parent, tag[, attrib[, **extra]])

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either 8-bit ASCII strings or Unicode strings. parent is the parent element. tag is the subelement name. attrib is an optional
dictionary, containing element attributes. extra contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.\texttt{tostring(element[, encoding])}

Generates a string representation of an XML element, including all subelements. element is an Element instance. encoding is the output encoding (default is US-ASCII). Returns an encoded string containing the XML data.

xml.etree.ElementTree.\texttt{XML(text)}

Parses an XML section from a string constant. This function can be used to embed “XML literals” in Python code. text is a string containing XML data. Returns an Element instance.

xml.etree.ElementTree.\texttt{XMLID(text)}

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. text is a string containing XML data. Returns a tuple containing an Element instance and a dictionary.
The Element Interface

Element objects returned by Element or SubElement have the following methods and attributes.

**Element.tag**
A string identifying what kind of data this element represents (the element type, in other words).

**Element.text**
The *text* attribute can be used to hold additional data associated with the element. As the name implies this attribute is usually a string but may be any application-specific object. If the element is created from an XML file the attribute will contain any text found between the element tags.

**Element.tail**
The *tail* attribute can be used to hold additional data associated with the element. This attribute is usually a string but may be any application-specific object. If the element is created from an XML file the attribute will contain any text found after the element’s end tag and before the next tag.

**Element.attrib**
A dictionary containing the element’s attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

**Element.clear()**
Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to None.

```python
Element.get(key[, default=None])
```

Gets the element attribute named `key`.

Returns the attribute value, or `default` if the attribute was not found.

```python
Element.items()
```

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

```python
Element.keys()
```

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

```python
Element.set(key, value)
```

Set the attribute `key` on the element to `value`.

The following methods work on the element’s children (subelements).

```python
Element.append(subelement)
```

Adds the element `subelement` to the end of this elements internal list of subelements.

```python
Element.find(match)
```

Finds the first subelement matching `match`. `match` may be a tag name or path. Returns an element instance or `None`.

```python
Element.findall(match)
```

Finds all subelements matching `match`. `match` may be a tag name or path. Returns an iterable yielding all matching elements in document order.
Element. **findtext**(*condition*, *default=None*)

Finds text for the first subelement matching *condition*. *condition* may be a tag name or path. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned.

Element. **getchildren**()

Returns all subelements. The elements are returned in document order.

Element. **getiterator**(*tag=None*)

Creates a tree iterator with the current element as the root. The iterator iterates over this element and all elements below it that match the given tag. If tag is *None* or '*' then all elements are iterated over. Returns an iterable that provides element objects in document (depth first) order.

Element. **insert**(*index, element*)

Inserts a subelement at the given position in this element.

Element. **makeelement**(*tag, attrib*)

Creates a new element object of the same type as this element. Do not call this method, use the SubElement factory function instead.

Element. **remove**(*subelement*)

Removes *subelement* from the element. Unlike the findXYZ methods this method compares elements based on the instance identity, not on tag value or contents.

Element objects also support the following sequence type methods for working with subelements: **__delitem__()**, **__getitem__()**, **__setitem__()**, **__len__()**.
Caution: Because Element objects do not define a \_\_nonzero\_\_() method, elements with no subelements will test as \texttt{False}.

```python
element = root.find('foo')

if not element:  # careful!
    print "element not found, or element has no subelements"

if element is None:
    print "element not found"
```
ElementTree Objects

class xml.etree.ElementTree.ElementTree([element], file)
    ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

    element is the root element. The tree is initialized with the contents of the XML file if given.

    _setroot(element)
    Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. element is an element instance.

    find(path)
    Finds the first toplevel element with given tag. Same as getroot().find(path). path is the element to look for. Returns the first matching element, or None if no element was found.

   .findall(path)
    Finds all toplevel elements with the given tag. Same as getroot().findall(path). path is the element to look for. Returns a list or iterator containing all matching elements, in document order.

    findtext(path[, default])
    Finds the element text for the first toplevel element with given tag. Same as getroot().findtext(path). path is the toplevel element to look for. default is the value to return if the element was not found. Returns the text content of the first matching element, or the default value no element was found. Note that if the element has is found, but has no text content, this
method returns an empty string.

getiterator([tag])
Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. tag is the tag to look for (default is to return all elements)

getroot()
Returns the root element for this tree.

parse(source[, parser])
Loads an external XML section into this element tree. source is a file name or file object. parser is an optional parser instance. If not given, the standard XMLTreeBuilder parser is used. Returns the section root element.

write(file[, encoding])
Writes the element tree to a file, as XML. file is a file name, or a file object opened for writing. encoding [1] is the output encoding (default is US-ASCII).

This is the XML file that is going to be manipulated:

```xml
<html>
<head>
  <title>Example page</title>
</head>
<body>
  <p>Moved to <a href="http://example.org/">example.org</a> or <a href="http://example.com/">example.com</a>.</p>
</body>
</html>
```

Example of changing the attribute “target” of every link in first paragraph:

```python
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
```
```python
>>> tree.parse("index.xhtml")
<Element html at b7d3f1ec>
>>> p = tree.find("body/p")  # Finds first occurrence of tag
>>> p
<Element p at 8416e0c>
>>> links = p.getiterator("a")  # Returns list of all links
>>> links
[<Element a at b7d4f9ec>, <Element a at b7d4fb0c>]
>>> for i in links:
...    i.attrib["target"] = "blank"
>>> tree.write("output.xhtml")
```
QName Objects

class xml.etree.ElementTree.QName(text_or_uri[, tag])

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. *text_or_uri* is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If *tag* is given, the first argument is interpreted as an URI, and this argument is interpreted as a local name. QName instances are opaque.
TreeBuilder Objects

class xml.etree.ElementTree.TreeBuilder([element_factory])

Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format. The element_factory is called to create new Element instances when given.

close()

Flushes the parser buffers, and returns the toplevel document element. Returns an Element instance.

data(data)

Adds text to the current element. data is a string. This should be either an 8-bit string containing ASCII text, or a Unicode string.

data(tag)

Closes the current element. tag is the element name. Returns the closed element.

start(tag, attrs)

Opens a new element. tag is the element name. attrs is a dictionary containing element attributes. Returns the opened element.
XMLTreeBuilder Objects

class xml.etree.ElementTree.XMLTreeBuilder([html][, target])

Element structure builder for XML source data, based on the expat parser. html are predefined HTML entities. This flag is not supported by the current implementation. target is the target object. If omitted, the builder uses an instance of the standard TreeBuilder class.

close()

Finishes feeding data to the parser. Returns an element structure.

doctype(name, pubid, system)

Handles a doctype declaration. name is the doctype name. pubid is the public identifier. system is the system identifier.

feed(data)

Feeds data to the parser. data is encoded data.

XMLTreeBuilder.feed() calls target's start() method for each opening tag, its end() method for each closing tag, and data is processed by method data(). XMLTreeBuilder.close() calls target's method close(). XMLTreeBuilder can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```python
>>> from xml.etree.ElementTree import XMLTreeBuilder
>>> class MaxDepth:
...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib):
...         self.depth += 1
...         if self.depth > self.maxDepth:
...             self.maxDepth = self.depth
...     def end(self, tag):
```
... def data(self, data):
    pass  # We do not need to do anything with data.
... def close(self):  # Called when all data has been parsed.
    return self.maxDepth

>>> target = MaxDepth()
>>> parser = XMLTreeBuilder(target=target)
>>> exampleXml = ""
... <a>
...   <b>
...     <c>
...       <d>
...     </d>
...   </c>
... </b>
... </a>"

>>> parser.feed(exampleXml)
>>> parser.close()
4

Footnotes

Internet Protocols and Support

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module `socket`, which is currently supported on most popular platforms. Here is an overview:

- **webbrowser** — Convenient Web-browser controller
  - Browser Controller Objects

- **cgi** — Common Gateway Interface support.
  - Introduction
  - Using the cgi module
  - Higher Level Interface
  - Old classes
  - Functions
  - Caring about security
  - Installing your CGI script on a Unix system
  - Testing your CGI script
  - Debugging CGI scripts
  - Common problems and solutions

- **cgitb** — Traceback manager for CGI scripts

- **wsgiref** — WSGI Utilities and Reference Implementation
  - `wsgiref.util` — WSGI environment utilities
  - `wsgiref.headers` — WSGI response header tools
  - `wsgiref.simple_server` — a simple WSGI HTTP server
  - `wsgiref.validate` — WSGI conformance checker
  - `wsgiref.handlers` — server/gateway base classes
  - Examples
• **urllib** — Open arbitrary resources by URL
  - High-level interface
  - Utility functions
  - URL Opener objects
  - **urllib** Restrictions
  - Examples

• **urllib2** — extensible library for opening URLs
  - Request Objects
  - OpenerDirector Objects
  - BaseHandler Objects
  - HTTPRedirectHandler Objects
  - HTTPCookieProcessor Objects
  - ProxyHandler Objects
  - HTTPPasswordMgr Objects
  - AbstractBasicAuthHandler Objects
  - HTTPBasicAuthHandler Objects
  - ProxyBasicAuthHandler Objects
  - AbstractDigestAuthHandler Objects
  - HTTPDigestAuthHandler Objects
  - ProxyDigestAuthHandler Objects
  - HTTPHandler Objects
  - HTTPSHandler Objects
  - FileHandler Objects
  - FTPHandler Objects
  - CacheFTPHandler Objects
  - UnknownHandler Objects
  - HTTPErrorProcessor Objects
  - Examples

• **httpplib** — HTTP protocol client
  - HTTPConnection Objects
  - HTTPResponse Objects
  - Examples
- **ftplib** — FTP protocol client
  - FTP Objects
- **poplib** — POP3 protocol client
  - POP3 Objects
  - POP3 Example
- **imaplib** — IMAP4 protocol client
  - IMAP4 Objects
  - IMAP4 Example
- **nntplib** — NNTP protocol client
  - NNTP Objects
- **smtplib** — SMTP protocol client
  - SMTP Objects
  - SMTP Example
- **smtpd** — SMTP Server
  - SMTPServer Objects
  - DebuggingServer Objects
  - PureProxy Objects
  - MailmanProxy Objects
- **telnetlib** — Telnet client
  - Telnet Objects
  - Telnet Example
- **uuid** — UUID objects according to RFC 4122
  - Example
- **urlparse** — Parse URLs into components
  - Results of **urlparse** and **urlsplit**
- **SocketServer** — A framework for network servers
○ Server Creation Notes
○ Server Objects
○ RequestHandler Objects
○ Examples
  ■ `SocketServer.TCPServer` Example
  ■ `SocketServer.UDPServer` Example
  ■ Asynchronous Mixins

○ `BaseHTTPServer` — Basic HTTP server

○ `SimpleHTTPServer` — Simple HTTP request handler

○ `CGIHTTPS Infer` — CGI-capable HTTP request handler

○ `cookielib` — Cookie handling for HTTP clients
  ○ CookieJar and FileCookieJar Objects
  ○ FileCookieJar subclasses and co-operation with web browsers
  ○ CookiePolicy Objects
  ○ DefaultCookiePolicy Objects
  ○ Cookie Objects
  ○ Examples

○ `Cookie` — HTTP state management
  ○ Cookie Objects
  ○ Morsel Objects
  ○ Example

○ `xmlrpclib` — XML-RPC client access
  ○ ServerProxy Objects
  ○ Boolean Objects
  ○ DateTime Objects
  ○ Binary Objects
  ○ Fault Objects
  ○ ProtocolError Objects
- MultiCall Objects
- Convenience Functions
- Example of Client Usage
- Example of Client and Server Usage

- **SimpleXMLRPCServer** — Basic XML-RPC server
  - SimpleXMLRPCServer Objects
    - SimpleXMLRPCServer Example
  - CGIXMLRPCRequestHandler

- **DocXMLRPCServer** — Self-documenting XML-RPC server
  - DocXMLRPCServer Objects
  - DocCGIXMLRPCRequestHandler
The `webbrowser` module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the `open()` function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn't available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable `BROWSER` exists, it is interpreted to override the platform default list of browsers, as a `os.pathsep`-separated list of browsers to try in order. When the value of a list part contains the string `%s`, then it is interpreted as a literal browser command line to be used with the argument URL substituted for `%s`; if the part does not contain `%s`, it is simply interpreted as the name of the browser to launch.

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script `webbrowser` can be used as a command-line interface for the module. It accepts an URL as the argument. It accepts the following optional parameters: `-n` opens the URL in a new browser window, if possible; `-t` opens the URL in a new browser page (“tab”). The options are, naturally, mutually exclusive.
The following exception is defined:

```python
exception webbrowser.Error
    Exception raised when a browser control error occurs.
```

The following functions are defined:

```python
webbrowser.open(url[, new=0[, autoraise=1]])
    Display url using the default browser. If new is 0, the url is opened in the same browser window if possible. If new is 1, a new browser window is opened if possible. If new is 2, a new browser page ("tab") is opened if possible. If autoraise is true, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

    Changed in version 2.5: new can now be 2.
```

```python
webbrowser.open_new(url)
    Open url in a new window of the default browser, if possible, otherwise, open url in the only browser window.
```

```python
webbrowser.open_new_tab(url)
    Open url in a new page ("tab") of the default browser, if possible, otherwise equivalent to open_new().

    New in version 2.5.
```

```python
webbrowser.get([name])
    Return a controller object for the browser type name. If name is empty, return a controller for a default browser appropriate to the caller’s environment.
```

```python
webbrowser.register(name, constructor[, instance])
    Register the browser type name. Once a browser type is
registered, the `get()` function can return a controller for that browser type. If `instance` is not provided, or is `None`, `constructor` will be called without parameters to create an instance when needed. If `instance` is provided, `constructor` will never be called, and may be `None`.

This entry point is only useful if you plan to either set the `BROWSER` variable or call `get()` with a nonempty argument matching the name of a handler you declare.

A number of browser types are predefined. This table gives the type names that may be passed to the `get()` function and the corresponding instantiations for the controller classes, all defined in this module.

<td>(2)</td>
</tr>
</tbody>
</table>
Notes:

1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the `KDEDIR` variable is not sufficient. Note also that the name “kfm” is used even when using the `konqueror` command with KDE 2 — the implementation selects the best strategy for running Konqueror.

2. Only on Windows platforms.

3. Only on Mac OS platforms; requires the standard MacPython `ic` module.

4. Only on Mac OS X platform.

Here are some simple examples:

```python
url = 'http://www.python.org'

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url + '/doc')

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```
Browser Controller Objects

Browser controllers provide two methods which parallel two of the module-level convenience functions:

```python
ccontroller.open(url[, new[, autoraise=1]]))
```

Display `url` using the browser handled by this controller. If `new` is 1, a new browser window is opened if possible. If `new` is 2, a new browser page ("tab") is opened if possible.

```python
ccontroller.open_new(url)
```

Open `url` in a new window of the browser handled by this controller, if possible, otherwise, open `url` in the only browser window. Alias `open_new()`.

```python
ccontroller.open_new_tab(url)
```

Open `url` in a new page ("tab") of the browser handled by this controller, if possible, otherwise equivalent to `open_new()`.

*New in version 2.5.*
Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.
Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the “query string” part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```python
print "Content-Type: text/html" # HTML is following
print # blank line, end of header
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML:

```python
print "<TITLE>CGI script output</TITLE>"
print "<H1>This is my first CGI script</H1>"
print "Hello, world!"
```
Using the cgi module

Begin by writing `import cgi`. Do not use `from cgi import *` — the module defines all sorts of names for its own use or for backward compatibility that you don’t want in your namespace.

When you write a new script, consider adding the line:

```python
import cgitb; cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you'd rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with a line like this:

```python
import cgitb; cgitb.enable(display=0, logdir="/tmp")
```

It's very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, it's best to use the `FieldStorage` class. The other classes defined in this module are provided mostly for backward compatibility. Instantiate it exactly once, without arguments. This reads the form contents from standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The `FieldStorage` instance can be indexed like a Python dictionary, and also supports the standard dictionary methods `has_key()` and
The built-in `len()` is also supported. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the `FieldStorage` instance.

For instance, the following code (which assumes that the `Content-Type` header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```python
form = cgi.FieldStorage()
if not (form.has_key("name") and form.has_key("addr")):
    print "<H1>Error</H1>"
    print "Please fill in the name and addr fields."
    return
print "<p>name:", form["name"].value
print "<p>addr:", form["addr"].value
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of `FieldStorage` (or `MiniFieldStorage`, depending on the form encoding). The `value` attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a `FieldStorage` or `MiniFieldStorage` instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` function, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:
value = form.getlist("username")
usernames = ",".join(value)

If a field represents an uploaded file, accessing the value via the `value` attribute or the `getvalue()` method reads the entire file in memory as a string. This may not be what you want. You can test for an uploaded file by testing either the `filename` attribute or the `file` attribute. You can then read the data at leisure from the `file` attribute:

```python
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while 1:
        line = fileitem.file.readline()
        if not line: break
        linecount = linecount + 1
```

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive `multipart/*` encoding). When this occurs, the item will be a dictionary-like `FieldStorage` item. This can be determined by testing its `type` attribute, which should be `multipart/form-data` (or perhaps another MIME type matching `multipart/*`). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type `application/x-www-form-urlencoded`), the items will actually be instances of the class `MiniFieldStorage`. In this case, the `list`, `file`, and `filename` attributes are always `None`. 
A form submitted via POST that also has a query string will contain both `FieldStorage` and `MiniFieldStorage` items.
Higher Level Interface

New in version 2.2.

The previous section explains how to read CGI form data using the FieldStorage class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```python
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```html
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:
The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `form.getvalue("user")` method call returns a list instead of a string. Calling the `toupper()` method on a list is not valid (since lists do not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

**FieldStorage.getfirst(name[, default])**

This method always returns only one value associated with form field `name`. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. [1] If no such form field or value exists then the method returns the value specified by the optional parameter `default`. This parameter defaults to `None` if not specified.

**FieldStorage.getlist(name)**

This method always returns a list of values associated with form field `name`. The method returns an empty list if no such form field or value exists for `name`. It returns a list consisting of one item if only one such value exists.
Using these methods you can write nice compact code:

```python
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", ").upper()  # This way it's safe
for item in form.getlist("item"):
    do_something(item)
```
**Old classes**

*Deprecated since version 2.6.*

**SvFormContentDict** stores single value form content as dictionary; it assumes each field name occurs in the form only once.

**FormContentDict** stores multiple value form content as a dictionary (the form items are lists of values). Useful if your form contains multiple fields with the same name.

Other classes (**FormContent**, **InterpFormContentDict**) are present for backwards compatibility with really old applications only.
Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

```python
cgi.parse(fp[, keep_blank_values[, strict_parsing]])
```
Parse a query in the environment or from a file (the file defaults to `sys.stdin`). The `keep_blank_values` and `strict_parsing` parameters are passed to `urlparse.parse_qs()` unchanged.

```python
cgi.parse_qs(qs[, keep_blank_values[, strict_parsing]])
```
This function is deprecated in this module. Use `urlparse.parse_qs()` instead. It is maintained here only for backward compatibility.

```python
cgi.parse_qsl(qs[, keep_blank_values[, strict_parsing]])
```
This function is deprecated in this module. Use `urlparse.parse_qsl()` instead. It is maintained here only for backward compatibility.

```python
cgi.parse_multipart(fp, pdict)
```
Parse input of type `multipart/form-data` (for file uploads). Arguments are `fp` for the input file and `pdict` for a dictionary containing other parameters in the `Content-Type` header.

Returns a dictionary just like `urlparse.parse_qs()` keys are the field names, each value is a list of values for that field. This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the `FieldStorage` class instead which is much more flexible.
Note that this does not parse nested multipart parts — use FieldStorage for that.

cgi.\texttt{parse\_header}(\textit{string})
Parse a MIME header (such as Content-Type) into a main value and a dictionary of parameters.

cgi.\texttt{test}()
Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.\texttt{print\_enviro}n()
Format the shell environment in HTML.

cgi.\texttt{print\_form}(\textit{form})
Format a form in HTML.

cgi.\texttt{print\_directory}()
Format the current directory in HTML.

cgi.\texttt{print\_enviro\_usage}()
Print a list of useful (used by CGI) environment variables in HTML.

cgi.\texttt{escape}(\textit{s}, \textit{quote})
Convert the characters '&', '<' and '>' in string \textit{s} to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag \textit{quote} is true, the quotation mark character (""') is also translated; this helps for inclusion in an HTML attribute value, as in \texttt{<A HREF="...">}. If the value to be quoted might include single- or double-quote characters, or both, consider using the \texttt{quoteattr()} function in the \texttt{xml.sax.saxutils} module instead.
Caring about security

There's one important rule: if you invoke an external program (via the `os.system()` or `os.popen()` functions. or others with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.
Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be 0755 octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!/` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be 0644 for readable and 0666 for writable. This is because, for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s `cgi-bin` directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (`PATH`) or the Python module search path (`PYTHONPATH`) to be set to anything interesting.

If you need to load modules from a directory which is not on Python’s default module search path, you can change the path in your script,
before importing other modules. For example:

```python
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).
Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.
Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (cgi.py) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it's installed in the standard cgi-bin directory, it should be possible to send it a request by entering a URL into your browser of the form:

http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home

If this gives an error of type 404, the server cannot find the script — perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the cgi.py script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the cgi module's test() function from your script: replace its main code with the single statement

cgi.test()

This should produce the same results as those gotten from installing the cgi.py file itself.

When an ordinary Python script raises an unhandled exception (for
whatever reason: of a typo in a module name, a file that can’t be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server’s log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute some code, you can easily send tracebacks to the Web browser using the cgitb module. If you haven’t done so already, just add the line:

```python
import cgitb; cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the cgitb module, you can use an even more robust approach (which only uses built-in modules):

```python
import sys
sys.stderr = sys.stdout
print "Content-Type: text/plain"
print ...

...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.
Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. *(tail -f logfile in a separate window may be useful!)*
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — `PATH` is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server's `suEXEC` feature.
- Don't try to give a CGI script a set-uid mode. This doesn't work on most systems, and is a security liability as well.

Footnotes

Note that some recent versions of the HTML specification do not state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.
The **cgitb** module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add one line to the top of your CGI script:

```python
import cgitb; cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```python
cgitb.enable([display[, logdir[, context[, format]]]])
```

This function causes the **cgitb** module to take over the interpreter’s default handling for exceptions by setting the value of `sys.excepthook`.

The optional argument `display` defaults to 1 and can be set to 0 to suppress sending the traceback to the browser. If the
argument `logdir` is present, the traceback reports are written to files. The value of `logdir` should be a directory where these files will be placed. The optional argument `context` is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument `format` is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

cgitb.handler([info])

This function handles an exception using the default settings (that is, show a report in the browser, but don't log to a file). This can be used when you've caught an exception and want to report it using `cgitb`. The optional `info` argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the `info` argument is not supplied, the current exception is obtained from `sys.exc_info()`.
wsgiref — WSGI Utilities and Reference Implementation

New in version 2.5.

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don’t need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

wsgiref is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (PEP 333).

See http://www.wsgi.org for more information about WSGI, and links to tutorials and other resources.
wsgiref.util – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in PEP 333. All of the functions taking an `environ` parameter expect a WSGI-compliant dictionary to be supplied; please see PEP 333 for a detailed specification.

**wsgiref.util.guess_scheme(environ)**

Return a guess for whether `wsgi.url_scheme` should be “http” or “https”, by checking for a `HTTPS` environment variable in the `environ` dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a `HTTPS` variable with a value of “1” “yes”, or “on” when a request is received via SSL. So, this function returns “https” if such a value is found, and “http” otherwise.

**wsgiref.util.request_uri(environ[, include_query=1])**

Return the full request URI, optionally including the query string, using the algorithm found in the “URL Reconstruction” section of PEP 333. If `include_query` is false, the query string is not included in the resulting URI.

**wsgiref.util.application_uri(environ)**

Similar to `request_uri()`, except that the `PATH_INFO` and `QUERY_STRING` variables are ignored. The result is the base URI of the application object addressed by the request.

**wsgiref.util.shift_path_info(environ)**
Shift a single name from `PATH_INFO` to `SCRIPT_NAME` and return the name. The `environ` dictionary is modified in-place; use a copy if you need to keep the original `PATH_INFO` or `SCRIPT_NAME` intact.

If there are no remaining path segments in `PATH_INFO`, `None` is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at `/foo`, and the request URI path is `/foo/bar/baz`, and the WSGI application at `/foo` calls `shift_path_info()`, it will receive the string “bar”, and the environment will be updated to be suitable for passing to a WSGI application at `/foo/bar`. That is, `SCRIPT_NAME` will change from `/foo` to `/foo/bar`, and `PATH_INFO` will change from `/bar/baz` to `/baz`.

When `PATH_INFO` is just a “/”, this routine returns an empty string and appends a trailing slash to `SCRIPT_NAME`, even though empty path segments are normally ignored, and `SCRIPT_NAME` doesn’t normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in `/x` from ones ending in `/x/` when using this routine to do object traversal.

`wsgiref.util.setup_testing_defaults(environ)`

Update `environ` with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including `HTTP_HOST`, `SERVER_NAME`, `SERVER_PORT`, `REQUEST_METHOD`, `SCRIPT_NAME`, `PATH_INFO`, and all of the PEP 333-defined `wsgi.*` variables. It only supplies default values, and does not replace
any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```python
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print
# environment dictionary after being updated by setup_testing_defaults

def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain')]

    start_response(status, headers)

    ret = ['%s: %s
    for key, value in environ.iteritems()]
    return ret

httpd = make_server('', 8000, simple_app)
print "Serving on port 8000..."
hpddp.serve_forever()
```

In addition to the environment functions above, the `wsgiref.util` module also provides these miscellaneous utilities:

`wsgiref.util.is_hop_by_hop(header_name)`
Return true if ‘header_name’ is an HTTP/1.1 “Hop-by-Hop” header, as defined by RFC 2616.

class wsgiref.util.FileWrapper(filelike[, blksize=8192])
A wrapper to convert a file-like object to an iterator. The resulting objects support both __getitem__() and __iter__() iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional blksize parameter will be repeatedly passed to the filelike object’s read() method to obtain strings to yield. When read() returns an empty string, iteration is ended and is not resumable.

If filelike has a close() method, the returned object will also have a close() method, and it will invoke the filelike object’s close() method when called.

Example usage:

```python
from StringIO import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object"*10)
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print chunk
```
This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

```python
class wsgiref.headers.Headers(headers)
    Create a mapping-like object wrapping `headers`, which must be a list of header name/value tuples as described in PEP 333. Any changes made to the new `Headers` object will directly update the `headers` list it was created with.

    `Headers` objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()`, `__contains__()` and `has_key()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers’ existing order is generally maintained, with new headers added to the end of the wrapped list.

    Unlike a dictionary, `Headers` objects do not raise an error when you try to get or delete a key that isn’t in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

    `Headers` objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a `Headers` object is the same as the length of its
items(), which is the same as the length of the wrapped header list. In fact, the items() method just returns a copy of the wrapped header list.

Calling str() on a Headers object returns a formatted string suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the string is terminated with a blank line.

In addition to their mapping interface and formatting features, Headers objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

get_all(name)

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

add_header(name, value, **_params)

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or None. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include dashes. If the parameter value is a string, it is added to the header value parameters in the form name="value". If it
is None, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```python
h.add_header('content-disposition', 'attachment', filename=None)
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.gif"
```
wsgiref.simple_server — a simple WSGI HTTP server

This module implements a simple HTTP server (based on BaseHTTPServer) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses PATH_INFO to select which application to invoke for each request. (E.g., using the shift_path_info() function from wsgiref.util.)

wsgiref.simple_server.make_server(host, port, app[, server_class=WSGIServer[, handler_class=WSGIRequestHandler]])

Create a new WSGI server listening on host and port, accepting connections for app. The return value is an instance of the supplied server_class, and will process requests using the specified handler_class. app must be a WSGI application object, as defined by PEP 333.

Example usage:

```python
from wsgiref.simple_server import make_server, demo_app

httpd = make_server('', 8000, demo_app)
print "Serving HTTP on port 8000..."

# Respond to requests until process is killed
httpd.serve_forever()

# Alternative: serve one request, then exit
httpd.handle_request()
```
wsgiref.simple_server.demo_app(environ, start_response)

This function is a small but complete WSGI application that returns a text page containing the message “Hello world!” and a list of the key/value pairs provided in the environ parameter. It's useful for verifying that a WSGI server (such as wsgiref.simple_server) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)

Create a WSGIServer instance. server_address should be a (host,port) tuple, and RequestHandlerClass should be the subclass of BaseHTTPServer.BaseHTTPRequestHandler that will be used to process requests.

You do not normally need to call this constructor, as the make_server() function can handle all the details for you.

WSGIServer is a subclass of BaseHTTPServer.HTTPServer, so all of its methods (such as serve_forever() and handle_request()) are available. WSGIServer also provides these WSGI-specific methods:

set_app(application)

Sets the callable application as the WSGI application that will receive requests.

get_app()

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as set_app() is normally called by make_server(), and the get_app() exists mainly for the benefit of request handler
class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)
    Create an HTTP handler for the given request (i.e. a socket), client_address (a (host, port) tuple), and server (WSGIServer instance).

You do not need to create instances of this class directly; they are automatically created as needed by WSGIServer objects. You can, however, subclass this class and supply it as a handler_class to the make_server() function. Some possibly relevant methods for overriding in subclasses:

get_environ()
    Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the WSGIServer object’s base_environ dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in PEP 333.

get_stderr()
    Return the object that should be used as the wsgi.errors stream. The default implementation just returns sys.stderr.

handle()
    Process the HTTP request. The default implementation creates a handler instance using a wsgiref.handlers class to implement the actual WSGI application interface.
When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using `wsgiref.validate`. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete PEP 333 compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking’s “Python Paste” library.

```
 wsgiref.validate.validator(application)
```

Wrap `application` and return a new WSGI application object. The returned application will forward all requests to the original `application`, and will check that both the `application` and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an `AssertionError` being raised; note, however, that how these errors are handled is server-dependent. For example, `wsgiref.simple_server` and other servers based on `wsgiref.handlers` (that don’t override the error handling methods to do something else) will simply output a message that an error has occurred, and dump the traceback to
sys.stderr or some other error stream.

This wrapper may also generate output using the warnings module to indicate behaviors that are questionable but which may not actually be prohibited by PEP 333. Unless they are suppressed using Python command-line options or the warnings API, any such warnings will be written to sys.stderr (not wsgi.errors, unless they happen to be the same object).

Example usage:

```python
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not compliant to the standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and the validator is going to inform us
    return "Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

httpd = make_server('', 8000, validator_app)
print "Listening on port 8000...."
httpd.serve_forever()
```
This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

class wsgiref.handlers.CGIHandler

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

This class is a subclass of `BaseCGIHandler` that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses `sys` and `os` to obtain the necessary CGI streams and environment.

class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ[, multithread=True[, multiprocess=False]])

Similar to `CGIHandler`, but instead of using the `sys` and `os` modules, the CGI environment and I/O streams are specified explicitly. The `multithread` and `multiprocess` values are used to set the `wsgi.multithread` and `wsgi.multiprocess` flags for any applications run by the handler instance.

This class is a subclass of `SimpleHandler` intended for use with software other than HTTP “origin servers”. If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a `status:` header to send an HTTP status, you
probably want to subclass this instead of SimpleHandler.

class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ[, multithread=True[, multiprocess=False]])

Similar to BaseCGIHandler, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of BaseCGIHandler

This class is a subclass of BaseHandler. It overrides the __init__(), get_stdin(), get_stderr(), add_cgi_vars(), _write(), and _flush() methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the stdin, stdout, stderr, and environ attributes.

class wsgiref.handlers.BaseHandler

This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

BaseHandler instances have only one method intended for external use:

run(app)

Run the specified WSGI application, app.

All of the other BaseHandler methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:

_write(data)
Buffer the string `data` for transmission to the client. It's okay if this method actually transmits the data; `BaseHandler` just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

`_flush()`
Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if `_write()` actually sends the data).

`get_stdin()`
Return an input stream object suitable for use as the `wsgi.input` of the request currently being processed.

`get_stderr()`
Return an output stream object suitable for use as the `wsgi.errors` of the request currently being processed.

`add_cgi_vars()`
Insert CGI variables for the current request into the `environ` attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized `BaseHandler` subclass.

Attributes and methods for customizing the WSGI environment:

`wsgi_multithread`
The value to be used for the `wsgi.multithread` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.
**wsgi_multiprocess**

The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_run_once**

The value to be used for the `wsgi.run_once` environment variable. It defaults to false in `BaseHandler`, but `CGIHandler` sets it to true by default.

**os_environ**

The default environment variables to be included in every request’s WSGI environment. By default, this is a copy of `os.environ` at the time that `wsgiref.handlers` was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

**server_software**

If the `origin_server` attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as `BaseCGIHandler` and `CGIHandler`) that are not HTTP origin servers.

**get_scheme()**

Return the URL scheme being used for the current request. The default implementation uses the `guess_scheme()` function from `wsgiref.util` to guess whether the scheme should be “http” or “https”, based on the current request’s `environ` variables.

**setup_environ()**
Set the `environ` attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the `get_stdin()`, `get_stderr()`, and `add_cgi_vars()` methods and the `wsgi_file_wrapper` attribute. It also inserts a `SERVER_SOFTWARE` key if not present, as long as the `origin_server` attribute is a true value and the `server_software` attribute is set.

Methods and attributes for customizing exception handling:

**`log_exception(exc_info)`**

Log the `exc_info` tuple in the server log. `exc_info` is a `(type, value, traceback)` tuple. The default implementation simply writes the traceback to the request's `wsgi.errors` stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

**`traceback_limit`**

The maximum number of frames to include in tracebacks output by the default `log_exception()` method. If `None`, all frames are included.

**`error_output(environ, start_response)`**

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to `start_response` when calling it (as described in the “Error Handling” section of PEP 333).
The default implementation just uses the error_status, error_headers, and error_body attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it’s not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn’t include any.

**error_status**
The HTTP status used for error responses. This should be a status string as defined in PEP 333; it defaults to a 500 code and message.

**error_headers**
The HTTP headers used for error responses. This should be a list of WSGI response headers (name, value) tuples, as described in PEP 333. The default list just sets the content type to text/plain.

**error_body**
The error response body. This should be an HTTP response body string. It defaults to the plain text, “A server error occurred. Please contact the administrator.”

Methods and attributes for PEP 333’s “Optional Platform-Specific File Handling” feature:

**wsgi_file_wrapper**
A wsgi.file_wrapper factory, or None. The default value of this attribute is the FileWrapper class from wsgiref.util.

**sendfile()**
Override to implement platform-specific file transmission. This
method is called only if the application's return value is an instance of the class specified by the `wsgi_file_wrapper` attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

**origin_server**
This attribute should be set to a true value if the handler's `_write()` and `_flush()` are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute's default value is true in `BaseHandler`, but false in `BaseCGIHandler` and `CGIHandler`.

**http_version**
If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".
Examples

This is a working “Hello World” WSGI application:

```python
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object - a call object that accepts two arguments. For that purpose, we're going to use a function (note that you're not limited to a function, you can use a class for example). The first argument passed to the function is a dictionary containing CGI-style environment variables and the second variable is the callable object (see PEP333)
def hello_world_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # The returned object is going to be printed
    return ['Hello World']

httpd = make_server('', 8000, hello_world_app)
print "Serving on port 8000..."

# Serve until process is killed
httpd.serve_forever()
```
**urllib — Open arbitrary resources by URL**

**Note:** The `urllib` module has been split into parts and renamed in Python 3.0 to `urllib.request`, `urllib.parse`, and `urllib.error`. The `2to3` tool will automatically adapt imports when converting your sources to 3.0. Also note that the `urllib.urlopen()` function has been removed in Python 3.0 in favor of `urllib2.urlopen()`.

This module provides a high-level interface for fetching data across the World Wide Web. In particular, the `urlopen()` function is similar to the built-in function `open()`, but accepts Universal Resource Locators (URLs) instead of filenames. Some restrictions apply — it can only open URLs for reading, and no seek operations are available.
**High-level interface**

`urllib.urlopen(url[, data[, proxies]])`

Open a network object denoted by a URL for reading. If the URL does not have a scheme identifier, or if it has `file:` as its scheme identifier, this opens a local file (without universal newlines); otherwise it opens a socket to a server somewhere on the network. If the connection cannot be made the `IOError` exception is raised. If all went well, a file-like object is returned. This supports the following methods: `read()`, `readline()`, `readlines()`, `fileno()`, `close()`, `info()`, `getcode()` and `geturl()`. It also has proper support for the `iterator` protocol. One caveat: the `read()` method, if the size argument is omitted or negative, may not read until the end of the data stream; there is no good way to determine that the entire stream from a socket has been read in the general case.

Except for the `info()`, `getcode()` and `geturl()` methods, these methods have the same interface as for file objects — see section *File Objects* in this manual. (It is not a built-in file object, however, so it can’t be used at those few places where a true built-in file object is required.)

The `info()` method returns an instance of the class `mimetools.Message` containing meta-information associated with the URL. When the method is HTTP, these headers are those returned by the server at the head of the retrieved HTML page (including Content-Length and Content-Type). When the method is FTP, a Content-Length header will be present if (as is now usual) the server passed back a file length in response to the FTP retrieval request. A Content-Type header will be present if the MIME type can be guessed. When the method is local-file,
returned headers will include a Date representing the file’s last-modified time, a Content-Length giving file size, and a Content-Type containing a guess at the file’s type. See also the description of the `mimetypes` module.

The `geturl()` method returns the real URL of the page. In some cases, the HTTP server redirects a client to another URL. The `urlopen()` function handles this transparently, but in some cases the caller needs to know which URL the client was redirected to. The `geturl()` method can be used to get at this redirected URL.

The `getcode()` method returns the HTTP status code that was sent with the response, or `None` if the URL is no HTTP URL.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a `POST` request (normally the request type is `GET`). The `data` argument must be in standard `application/x-www-form-urlencoded` format; see the `urlencode()` function below.

The `urlopen()` function works transparently with proxies which do not require authentication. In a Unix or Windows environment, set the `http_proxy`, or `ftp_proxy` environment variables to a URL that identifies the proxy server before starting the Python interpreter. For example (the '%' is the command prompt):

```
% http_proxy="http://www.someproxy.com:3128"
% export http_proxy
% python
...
```

The `no_proxy` environment variable can be used to specify hosts which shouldn’t be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port`
appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

In a Windows environment, if no proxy environment variables are set, proxy settings are obtained from the registry’s Internet Settings section.

In a Macintosh environment, `urlopen()` will retrieve proxy information from Internet Config.

Alternatively, the optional `proxies` argument may be used to explicitly specify proxies. It must be a dictionary mapping scheme names to proxy URLs, where an empty dictionary causes no proxies to be used, and `None` (the default value) causes environmental proxy settings to be used as discussed above. For example:

```python
# Use http://www.someproxy.com:3128 for http proxying
proxies = {'http': 'http://www.someproxy.com:3128'}
filehandle = urllib.urlopen(some_url, proxies=proxies)

# Don't use any proxies
filehandle = urllib.urlopen(some_url, proxies={})

# Use proxies from environment - both versions are equivalent
filehandle = urllib.urlopen(some_url, proxies=None)
filehandle = urllib.urlopen(some_url)
```

Proxies which require authentication for use are not currently supported; this is considered an implementation limitation.

*Changed in version 2.3:* Added the `proxies` support.

*Changed in version 2.6:* Added `getcode()` to returned object and support for the `no_proxy` environment variable.

*Deprecated since version 2.6:* The `urlopen()` function has been
removed in Python 3.0 in favor of `urllib2.urlopen()`.

```python
urllib.urlopen(url[, filename[, reporthook[, data]]])
```

Copy a network object denoted by a URL to a local file, if necessary. If the URL points to a local file, or a valid cached copy of the object exists, the object is not copied. Return a tuple `(filename, headers)` where `filename` is the local file name under which the object can be found, and `headers` is whatever the `info()` method of the object returned by `urlopen()` returned (for a remote object, possibly cached). Exceptions are the same as for `urlopen()`.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a `POST` request (normally the request type is `GET`). The `data` argument must in standard `application/x-www-form-urlencoded` format; see the `urlencode()` function below.

*Changed in version 2.5:* `urllib2.urlopen()` will raise `ContentTooShortError` when it detects that the amount of data available was less than the expected amount (which is the size reported by a `Content-Length` header). This can occur, for example, when the download is interrupted.
The *Content-Length* is treated as a lower bound: if there’s more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no *Content-Length* header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

**urllib._urloper**

The public functions `urlopen()` and `urlretrieve()` create an instance of the `FancyURLopener` class and use it to perform their requested actions. To override this functionality, programmers can create a subclass of `URLopener` or `FancyURLopener`, then assign an instance of that class to the `urllib._urloper` variable before calling the desired function. For example, applications may want to specify a different *User-Agent* header than `URLopener` defines. This can be accomplished with the following code:

```python
import urllib

class AppURLopener(urllib.FancyURLopener):
    version = "App/1.7"

urllib._urloper = AppURLopener()

urllib.urlcleanup()
```

Clear the cache that may have been built up by previous calls to `urlretrieve()`.
Utility functions

**urllib.quote** *(string[, safe])*

Replace special characters in `string` using the `%xx` escape. Letters, digits, and the characters `_.-` are never quoted. The optional `safe` parameter specifies additional characters that should not be quoted — its default value is `'/`.

Example: `quote('~/connolly/')` yields `'/%7Econnolly/'`.

**urllib.quote_plus** *(string[, safe])*

Like `quote()`, but also replaces spaces by plus signs, as required for quoting HTML form values. Plus signs in the original string are escaped unless they are included in `safe`. It also does not have `safe` default to `'/'`.

**urllib.unquote** *(string)*

Replace `%xx` escapes by their single-character equivalent.

Example: `unquote('/%7Econnolly/')` yields `'~/connolly/'`.

**urllib.unquote_plus** *(string)*

Like `unquote()`, but also replaces plus signs by spaces, as required for unquoting HTML form values.

**urllib.urlencode** *(query[, doseq])*

Convert a mapping object or a sequence of two-element tuples to a “url-encoded” string, suitable to pass to `urlopen()` above as the optional `data` argument. This is useful to pass a dictionary of form fields to a `POST` request. The resulting string is a series of `key=value` pairs separated by `&` characters, where both `key` and
value are quoted using quote_plus() above. If the optional parameter doseq is present and evaluates to true, individual key=value pairs are generated for each element of the sequence. When a sequence of two-element tuples is used as the query argument, the first element of each tuple is a key and the second is a value. The order of parameters in the encoded string will match the order of parameter tuples in the sequence. The urlparse module provides the functions parse_qs() and parse_qsl() which are used to parse query strings into Python data structures.

urllib.pathname2url(path)
Convert the pathname path from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the quote() function.

urllib.url2pathname(path)
Convert the path component path from an encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses unquote() to decode path.
URL Opener objects

class `urllib.URLopener([proxies, **x509])`

Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than `http:`, `ftp:`, or `file:`, you probably want to use `FancyURLopener`.

By default, the `URLopener` class sends a `User-Agent` header of `urllib/VVV`, where `VVV` is the `urllib` version number. Applications can define their own `User-Agent` header by subclassing `URLopener` or `FancyURLopener` and setting the class attribute `version` to an appropriate string value in the subclass definition.

The optional `proxies` parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is `None`, in which case environmental proxy settings will be used if present, as discussed in the definition of `urlopen()`, above.

Additional keyword parameters, collected in `x509`, may be used for authentication of the client when using the `https:` scheme. The keywords `key_file` and `cert_file` are supported to provide an SSL key and certificate; both are needed to support client authentication.

`URLopener` objects will raise an `IOError` exception if the server returns an error code.

```python
open(fullurl[, data])
```

Open `fullurl` using the appropriate protocol. This method sets up cache and proxy information, then calls the
appropriate open method with its input arguments. If the scheme is not recognized, `open_unknown()` is called. The `data` argument has the same meaning as the `data` argument of `urlopen()`.

```python
open_unknown(fullurl[, data])
```

Overridable interface to open unknown URL types.

```python
retrieve(url[, filename[, reporthook[, data]]]])
```

Retrieves the contents of `url` and places it in `filename`. The return value is a tuple consisting of a local filename and either a `mimetypes.Message` object containing the response headers (for remote URLs) or `None` (for local URLs). The caller must then open and read the contents of `filename`. If `filename` is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and `filename` is not given, the filename is the output of `tempfile.mktemp()` with a suffix that matches the suffix of the last path component of the input URL. If `reporthook` is given, it must be a function accepting three numeric parameters. It will be called after each chunk of data is read from the network. `reporthook` is ignored for local URLs.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a POST request (normally the request type is GET). The `data` argument must in standard `application/x-www-form-urlencoded` format; see the `urlencode()` function below.

```python
version
```

Variable that specifies the user agent of the opener object. To get `urllib` to tell servers that it is a particular user agent, set this in a subclass as a class variable or in
the constructor before calling the base constructor.

```python
class urllib.FancyURLopener(...)

FancyURLopener subclasses URLopener providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the Location header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the maxtries attribute, which defaults to 10.

For all other response codes, the method http_error_default() is called which you can override in subclasses to handle the error appropriately.
```

**Note:** According to the letter of RFC 2616, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and urllib reproduces this behaviour.

The parameters to the constructor are the same as those for URLopener.

**Note:**

When performing basic authentication, a FancyURLopener instance calls its prompt_user_passwd() method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The FancyURLopener class offers one additional method that
should be overloaded to provide the appropriate behavior:

### `prompt_user_passwd(host, realm)`

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, `(user, password)`, which can be used for basic authentication. The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.

### Exception: `urlib.ContentTooShortError(msg[, content])`

This exception is raised when the `urlretrieve()` function detects that the amount of the downloaded data is less than the expected amount (given by the `Content-Length` header). The `content` attribute stores the downloaded (and supposedly truncated) data.

*New in version 2.5.*
Current only the following protocols are supported: HTTP, (versions 0.9 and 1.0), FTP, and local files.

The caching feature of `urlretrieve()` has been disabled until I find the time to hack proper processing of Expiration time headers.

There should be a function to query whether a particular URL is in the cache.

For backward compatibility, if a URL appears to point to a local file but the file can’t be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

The `urlopen()` and `urlretrieve()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

The data returned by `urlopen()` or `urlretrieve()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `httplib` to parse it.

The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to
read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the ftplib module, subclassing FancyURLopener, or changing _urloperner to meet your needs.

- This module does not support the use of proxies which require authentication. This may be implemented in the future.

- Although the urllib module contains (undocumented) routines to parse and unparse URL strings, the recommended interface for URL manipulation is in module urlparse.
Examples

Here is an example session that uses the `GET` method to retrieve a URL containing parameters:

```python
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> f = urllib.urlopen('http://www.musical.com/cgi-bin/query?' + params)
>>> print f.read()
```

The following example uses the `POST` method instead:

```python
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> f = urllib.urlopen('http://www.musical.com/cgi-bin/query', params)
>>> print f.read()
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.FancyURLopener(proxies)
>>> f = opener.open('http://www.python.org')
>>> f.read()
```

The following example uses no proxies at all, overriding environment settings:

```python
>>> import urllib
>>> opener = urllib.FancyURLopener({})
>>> f = opener.open('http://www.python.org')
>>> f.read()
```
**urllib2 — extensible library for opening URLs**

**Note:** The `urllib2` module has been split across several modules in Python 3.0 named `urllib.request` and `urllib.error`. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The `urllib2` module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

The `urllib2` module defines the following functions:

```python
urllib2.urlopen(url[, data][, timeout])
```

Open the URL `url`, which can be either a string or a `Request` object.

`data` may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use `data`; the HTTP request will be a POST instead of a GET when the `data` parameter is provided. `data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format.

The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS, FTP and FTPS connections.
This function returns a file-like object with two additional methods:

- **geturl()** — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- **info()** — return the meta-information of the page, such as headers, in the form of an `httplib.HTTPMessage` instance (see Quick Reference to HTTP Headers)

Raises `URLError` on errors.

Note that `None` may be returned if no handler handles the request (though the default installed global `OpenerDirector` uses `UnknownHandler` to ensure this never happens).

*Changed in version 2.6: timeout was added.*

**urllib2.install_opener(opener)**

Install an `OpenerDirector` instance as the default global opener. Installing an opener is only necessary if you want `urlopen` to use that opener; otherwise, simply call `OpenerDirector.open()` instead of `urlopen()`. The code does not check for a real `OpenerDirector`, and any class with the appropriate interface will work.

**urllib2.build_opener([handler, ...])**

Return an `OpenerDirector` instance, which chains the handlers in the order given. `handlers` can be either instances of `BaseHandler`, or subclasses of `BaseHandler` (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the `handlers`, unless the `handlers` contain them, instances of them or subclasses of them: `ProxyHandler`, `UnknownHandler`, `HTTPHandler`, `HTTPDefaultErrorHandler`, `HTTPRedirectHandler`, `FTPHandler`, `FileHandler`, `HTTPErrorProcessor`. 
If the Python installation has SSL support (i.e., if thesslmodule can be imported), HTTPSHandler will also be added.

Beginning in Python 2.3, a BaseHandler subclass may also change its handler_order member variable to modify its position in the handlers list.

The following exceptions are raised as appropriate:

exceptionurllib2.URLError

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of IOError.

reason

The reason for this error. It can be a message string or another exception instance (socket.error for remote URLs, OSError for local URLs).

exceptionurllib2.HTTPError

Though being an exception (a subclass of URLError), an HTTPError can also function as a non-exceptional file-like return value (the same thing thaturlopen()returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

code

An HTTP status code as defined in RFC 2616. This numeric value corresponds to a value found in the dictionary of codes as found inBaseHTTPServer.BaseHTTPRequestHandler.responses.

The following classes are provided:

classurllib2.Request(url[, data][, headers][, origin_req_host][, ...)]
This class is an abstraction of a URL request.

`url` should be a string containing a valid URL.

`data` may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use `data`; the HTTP request will be a POST instead of a GET when the `data` parameter is provided. `data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format.

`headers` should be a dictionary, and will be treated as if `add_header()` was called with each key and value as arguments. This is often used to “spoof” the `User-Agent` header, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11", while `urllib2`’s default user agent string is "Python-urllib/2.6" (on Python 2.6).

The final two arguments are only of interest for correct handling of third-party HTTP cookies:

`origin_req_host` should be the request-host of the origin transaction, as defined by RFC 2965. It defaults to `cookielib.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.
unverifiable should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to False. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

class urllib2.OpenerDirector
    The OpenerDirector class opens URLs via BaseHandler s chained together. It manages the chaining of handlers, and recovery from errors.

class urllib2.BaseHandler
    This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib2.HTTPDefaultErrorHandler
    A class which defines a default handler for HTTP error responses; all responses are turned into HTTPError exceptions.

class urllib2.HTTPRedirectHandler
    A class to handle redirections.

class urllib2.HTTPCookieProcessor([cookiejar])
    A class to handle HTTP Cookies.

class urllib2.ProxyHandler([proxies])
    Cause requests to go through a proxy. If proxies is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables . To disable autodetected proxy pass an empty dictionary.

class urllib2.HTTPPasswordMgr
Keep a database of \((\text{realm}, \text{uri}) \rightarrow (\text{user}, \text{password})\) mappings.

class \texttt{urllib2.\ HTTPPasswordMgrWithDefaultRealm}

Keep a database of \((\text{realm}, \text{uri}) \rightarrow (\text{user}, \text{password})\) mappings. A realm of \texttt{None} is considered a catch-all realm, which is searched if no other realm fits.

class \texttt{urllib2.\ AbstractBasicAuthHandler([\texttt{password\_mgr}])}

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. \texttt{password\_mgr}, if given, should be something that is compatible with \texttt{HTTPPasswordMgr}; refer to section \textit{HTTPPasswordMgr Objects} for information on the interface that must be supported.

class \texttt{urllib2.\ HTTPBasicAuthHandler([\texttt{password\_mgr}])}

Handle authentication with the remote host. \texttt{password\_mgr}, if given, should be something that is compatible with \texttt{HTTPPasswordMgr}; refer to section \textit{HTTPPasswordMgr Objects} for information on the interface that must be supported.

class \texttt{urllib2.\ ProxyBasicAuthHandler([\texttt{password\_mgr}])}

Handle authentication with the proxy. \texttt{password\_mgr}, if given, should be something that is compatible with \texttt{HTTPPasswordMgr}; refer to section \textit{HTTPPasswordMgr Objects} for information on the interface that must be supported.

class \texttt{urllib2.\ AbstractDigestAuthHandler([\texttt{password\_mgr}])}

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. \texttt{password\_mgr}, if given, should be something that is compatible with \texttt{HTTPPasswordMgr}; refer to section \textit{HTTPPasswordMgr Objects} for information on the interface that must be supported.
class urllib2.HTTPDigestAuthHandler([password_mgr])
Handle authentication with the remote host. password_mgr, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib2.ProxyDigestAuthHandler([password_mgr])
Handle authentication with the proxy. password_mgr, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib2.HTTPHandler
A class to handle opening of HTTP URLs.

class urllib2.HTTPSHandler
A class to handle opening of HTTPS URLs.

class urllib2.FileHandler
Open local files.

class urllib2.FTPHandler
Open FTP URLs.

class urllib2.CacheFTPHandler
Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib2.UnknownHandler
A catch-all class to handle unknown URLs.
Request Objects

The following methods describe all of Request's public interface, and so all must be overridden in subclasses.

Request. `add_data(data)`
Set the Request data to `data`. This is ignored by all handlers except HTTP handlers — and there it should be a byte string, and will change the request to be POST rather than GET.

Request. `get_method()`
Return a string indicating the HTTP request method. This is only meaningful for HTTP requests, and currently always returns 'GET' or 'POST'.

Request. `has_data()`
Return whether the instance has a non-None data.

Request. `get_data()`
Return the instance’s data.

Request. `add_header(key, val)`
Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the key collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request. `add_unredirected_header(key, header)`
Add a header that will not be added to a redirected request.
New in version 2.4.

Request. **has_header**(*header*)

Return whether the instance has the named header (checks both regular and unredirected).

New in version 2.4.

Request. **get_full_url**()

Return the URL given in the constructor.

Request. **get_type**()

Return the type of the URL — also known as the scheme.

Request. **get_host**()

Return the host to which a connection will be made.

Request. **get_selector**()

Return the selector — the part of the URL that is sent to the server.

Request. **set_proxy**(*host*, *type*)

Prepare the request by connecting to a proxy server. The *host* and *type* will replace those of the instance, and the instance’s selector will be the original URL given in the constructor.

Request. **get_origin_req_host**()

Return the request-host of the origin transaction, as defined by [RFC 2965](https://tools.ietf.org/html/rfc2965). See the documentation for the Request constructor.

Request. **is_unverifiable**()

Return whether the request is unverifiable, as defined by RFC 2965. See the documentation for the Request constructor.
OpenerDirector Objects

OpenerDirector instances have the following methods:

OpenerDirector. **add_handler**(handler)

*handler* should be an instance of BaseHandler. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- **protocol_open()** — signal that the handler knows how to open protocol URLs.
- **http_error_type()** — signal that the handler knows how to handle HTTP errors with HTTP error code *type*.
- **protocol_error()** — signal that the handler knows how to handle errors from (non-http) *protocol*.
- **protocol_request()** — signal that the handler knows how to pre-process *protocol* requests.
- **protocol_response()** — signal that the handler knows how to post-process *protocol* responses.

OpenerDirector. **open**(url[, data][, timeout])

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of *urlopen()* (which simply calls the open() method on the currently installed global OpenerDirector). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS, FTP and FTPS connections.

*Changed in version 2.6: timeout was added.*
OpenerDirector.error(proto[, arg[, ...]])

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the http_error_*() methods of the handler classes.

Return values and exceptions raised are the same as those of urlopen().

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like protocol_request() has that method called to pre-process the request.

2. Handlers with a method named like protocol_open() are called to handle the request. This stage ends when a handler either returns a non-None value (ie. a response), or raises an exception (usually URLError). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named default_open(). If all such methods return None, the algorithm is repeated for methods named like protocol_open(). If all such methods return None, the algorithm is repeated for methods named unknown_open().

Note that the implementation of these methods may involve calls of the parent OpenerDirector instance's open() and error() methods.
3. Every handler with a method named like `protocol_response()` has that method called to post-process the response.
BaseHandler Objects

**BaseHandler** objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

**BaseHandler.add_parent**(director)

Add a director as parent.

**BaseHandler.close**()

Remove any parents.

The following members and methods should only be used by classes derived from **BaseHandler**.

**Note:** The convention has been adopted that subclasses defining `protocol_request()` or `protocol_response()` methods are named *Processor*; all others are named *Handler*.

**BaseHandler.parent**

A valid **OpenerDirector**, which can be used to open using a different protocol, or handle errors.

**BaseHandler.default_open**(req)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent **OpenerDirector**. It should return a file-like object as described in the return value of the `open()` of **OpenerDirector**, or **None**. It should raise `URLError`, unless a truly exceptional thing happens (for example, **MemoryError** should not be mapped to `URLError`).
This method will be called before any protocol-specific open method.

**BaseHandler.**\texttt{protocol\_open}(\texttt{req})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent \texttt{OpenerDirector}. Return values should be the same as for \texttt{default\_open}.

**BaseHandler.**\texttt{unknown\_open}(\texttt{req})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent \texttt{OpenerDirector}. Return values should be the same as for \texttt{default\_open}.

**BaseHandler.**\texttt{http\_error\_default}(\texttt{req}, \texttt{fp}, \texttt{code}, \texttt{msg}, \texttt{hdrs})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the \texttt{OpenerDirector} getting the error, and should not normally be called in other circumstances.

\texttt{req} will be a \texttt{Request} object, \texttt{fp} will be a file-like object with the HTTP error body, \texttt{code} will be the three-digit code of the error, \texttt{msg} will be the user-visible explanation of the code and \texttt{hdrs} will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of \texttt{urlopen}.
BaseHandler.\texttt{http\_error\_nnn}(\textit{req}, \textit{fp}, \textit{code}, \textit{msg}, \textit{hdrs})

\textit{nnn} should be a three-digit HTTP error code. This method is also not defined in \texttt{BaseHandler}, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code \textit{nnn} occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for \texttt{http\_error\_default()}. 

BaseHandler.\texttt{protocol\_request}(\textit{req})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent \texttt{OpenerDirector}. \textit{req} will be a \texttt{Request} object. The return value should be a \texttt{Request} object.

BaseHandler.\texttt{protocol\_response}(\textit{req}, \textit{response})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent \texttt{OpenerDirector}. \textit{req} will be a \texttt{Request} object. \textit{response} will be an object implementing the same interface as the return value of \texttt{urlopen()}. The return value should implement the same interface as the return value of \texttt{urlopen()}. 

HTTPRedirectHandler Objects

**Note:** Some HTTP redirections require action from this module's client code. If this is the case, HTTPError is raised. See RFC 2616 for details of the precise meanings of the various redirection codes.

HTTPRedirectHandler. **redirect_request**(req, fp, code, msg, hdrs)

Return a Request or None in response to a redirect. This is called by the default implementations of the http_error_30*() methods when a redirection is received from the server. If a redirection should take place, return a new Request to allow http_error_30*() to perform the redirect. Otherwise, raise HTTPError if no other handler should try to handle this URL, or return None if you can’t but another handler might.

**Note:** The default implementation of this method does not strictly follow RFC 2616, which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

HTTPRedirectHandler. **http_error_301**(req, fp, code, msg, hdrs)

Redirect to the Location: URL. This method is called by the parent OpenerDirector when getting an HTTP ‘moved permanently’ response.

HTTPRedirectHandler. **http_error_302**(req, fp, code, msg, hdrs)

The same as http_error_301(), but called for the ‘found’ response.
HTTPRedirectHandler. **http_error_303**(*req, fp, code, msg, hdrs*)  
The same as **http_error_301()**, but called for the ‘see other’ response.

HTTPRedirectHandler. **http_error_307**(*req, fp, code, msg, hdrs*)  
The same as **http_error_301()**, but called for the ‘temporary redirect’ response.
HTTPCookieProcessor Objects

New in version 2.4.

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor. **cookiejar**

The `cookielib.CookieJar` in which cookies are stored.
ProxyHandler Objects

ProxyHandler. **protocol_open**(request)

The **ProxyHandler** will have a method **protocol_open()** for every protocol which has a proxy in the **proxies** dictionary given in the constructor. The method will modify requests to go through the proxy, by calling **request.set_proxy()**, and call the next handler in the chain to actually execute the protocol.
HTTPPasswordMgr Objects

These methods are available on HTTPPasswordMgr and HTTPPasswordMgrWithDefaultRealm objects.

HTTPPasswordMgr. **add_password**(realm, uri, user, passwd)

*uri* can be either a single URI, or a sequence of URIs. *realm*, *user* and *passwd* must be strings. This causes *(user, passwd)* to be used as authentication tokens when authentication for *realm* and a super-URI of any of the given URIs is given.

HTTPPasswordMgr. **find_user_password**(realm, authuri)

Get user/password for given realm and URI, if any. This method will return *(None, None)* if there is no matching user/password.

For HTTPPasswordMgrWithDefaultRealm objects, the realm *None* will be searched if the given *realm* has no matching user/password.
AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler. **http_error_auth_reqed**(authreq, host, req, headers)

Handle an authentication request by getting a user/password pair, and re-trying the request. authreq should be the name of the header where the information about the realm is included in the request, host specifies the URL and path to authenticate for, req should be the (failed) Request object, and headers should be the error headers.

host is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
HTTPBasicAuthHandler

HTTPBasicAuthHandler. **http_error_401**(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.\texttt{http\_error\_407}(\textit{req, fp, code, msg, hdrs})

Retry the request with authentication information, if available.
AbstractDigestAuthHandler Objects

AbstractDigestAuthHandler. **http_error_auth_reqed(authreq, host, req, headers)**

*authreq* should be the name of the header where the information about the realm is included in the request, *host* should be the host to authenticate to, *req* should be the (failed) *Request* object, and *headers* should be the error headers.
HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.http_error_401(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
ProxyDigestAuthHandler Objects

ProxyDigestAuthHandler.\texttt{http\_error\_407}(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
HTTPHandler Objects

HTTPHandler. **http_open**(req)
   Send an HTTP request, which can be either GET or POST, depending on req.has_data().
HTTPSHandler. `https_open(req)`

Send an HTTPS request, which can be either GET or POST, depending on `req.has_data()`.
FileHandler Objects

FileHandler. **file_open**(req)

Open the file locally, if there is no host name, or the host name is 'localhost'. Change the protocol to ftp otherwise, and retry opening it using parent.
FTPHandler objects

FTPHandler. **ftp_open**(req)

Open the FTP file indicated by *req*. The login is always done with empty username and password.
CacheFTPHandler Objects

CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler. **setTimeout**(\(t\))

Set timeout of connections to \(t\) seconds.

CacheFTPHandler. **setMaxConns**(\(m\))

Set maximum number of cached connections to \(m\).
UnknownHandler Objects

UnknownHandler. unknown_open()

Raise a URLError exception.
HTTPErrorProcessor Objects

New in version 2.4.

HTTPErrorProcessor. `unknown_open()`  
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the `protocol_error_code()` handler methods, via `OpenerDirector.error()`. Eventually, `urllib2.HTTPDefaultErrorHandler` will raise an `HTTPError` if no other handler handles the error.
Examples

This example gets the python.org main page and displays the first 100 bytes of it:

```python
>>> import urllib2
>>> f = urllib2.urlopen('http://www.python.org/')
>>> print f.read(100)
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN">
<?xml-stylesheet href="./css/ht2html

Here we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```python
>>> import urllib2
>>> req = urllib2.Request(url='https://localhost/cgi-bin-test.cgi
... data='This data is passed to stdin of the CGI'
>>> f = urllib2.urlopen(req)
>>> print f.read()
Got Data: "This data is passed to stdin of the CGI"

The code for the sample CGI used in the above example is:

```
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print 'Content-type: text-plain

Got Data: "%s"' % data
```

Use of Basic HTTP Authentication:

```python
import urllib2
# Create an OpenerDirector with support for Basic HTTP Authenti
auth_handler = urllib2.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
    uri='https://mahler:8092/site-updates.py',
    user='klem',
    passwd='kadidd!ehopper')

opener = urllib2.build_opener(auth_handler)
```
# ...and install it globally so it can be used with urlopen.
urllib2.install_opener(opener)
urllib2.urlopen('http://www.example.com/login.html')

**build_opener()** provides many handlers by default, including a **ProxyHandler**. By default, **ProxyHandler** uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the **http_proxy** environment variable is read to obtain the HTTP proxy’s URL.

This example replaces the default **ProxyHandler** with one that uses programatically-supplied proxy URLs, and adds proxy authorization support with **ProxyBasicAuthHandler**.

```python
proxy_handler = urllib2.ProxyHandler({'http': 'http://www.example.com:3128/'}
proxy_auth_handler = urllib2.HTTPBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password'
opener = build_opener(proxy_handler, proxy_auth_handler)
# This time, rather than install the OpenerDirector, we use it
opener.open('http://www.example.com/login.html')
```

Adding HTTP headers:

Use the **headers** argument to the **Request** constructor, or:

```python
import urllib2
req = urllib2.Request('http://www.example.com/)
req.add_header('Referer', 'http://www.python.org/)
r = urllib2.urlopen(req)
```

**OpenerDirector** automatically adds a **User-Agent** header to every **Request**. To change this:

```python
import urllib2
opener = urllib2.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/)
```
Also, remember that a few standard headers (*Content-Length*, *Content-Type* and *Host*) are added when the `Request` is passed to `urlopen()` (or `OpenerDirector.open()`).
This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib` uses it to handle URLs that use HTTP and HTTPS.

**Note:** HTTPS support is only available if the `socket` module was compiled with SSL support.

**Note:** The public interface for this module changed substantially in Python 2.0. The `HTTP` class is retained only for backward compatibility with 1.5.2. It should not be used in new code. Refer to the online docstrings for usage.

The module provides the following classes:

```python
class http.client.HTTPConnection(host[, port[, strict[, timeout]]])
```

An `HTTPConnection` instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. When True, the optional parameter `strict` causes `BadStatusLine` to be raised if the status line can’t be parsed as a valid HTTP/1.0 or 1.1 status line. If the optional `timeout` parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used).
For example, the following calls all create instances that connect to the server at the same host and port:

```python
>>> h1 = httplib.HTTPConnection('www.cwi.nl')
>>> h2 = httplib.HTTPConnection('www.cwi.nl:80')
>>> h3 = httplib.HTTPConnection('www.cwi.nl', 80)
>>> h3 = httplib.HTTPConnection('www.cwi.nl', 80, timeout=10)
```

*New in version 2.0.*

*Changed in version 2.6: timeout was added.*

class `httplib.HTTPSConnection(host[, port[, key_file[, cert_file[, strict[, timeout]]]]]])`

A subclass of `HTTPConnection` that uses SSL for communication with secure servers. Default port is 443. `key_file` is the name of a PEM formatted file that contains your private key. `cert_file` is a PEM formatted certificate chain file.

**Warning:** This does not do any certificate verification!

*New in version 2.0.*

*Changed in version 2.6: timeout was added.*

class `httplib.HTTPResponse(sock[, debuglevel=0][, strict=0])`

Class whose instances are returned upon successful connection. Not instantiated directly by user.

*New in version 2.0.*

The following exceptions are raised as appropriate:

element `httplib.HTTPException`
The base class of the other exceptions in this module. It is a subclass of `Exception`.

*New in version 2.0.*

exception `httplib.NotConnected`
A subclass of `HTTPException`.

*New in version 2.0.*

exception `httplib.InvalidURL`
A subclass of `HTTPException`, raised if a port is given and is either non-numeric or empty.

*New in version 2.3.*

exception `httplib.UnknownProtocol`
A subclass of `HTTPException`.

*New in version 2.0.*

exception `httplib.UnknownTransferEncoding`
A subclass of `HTTPException`.

*New in version 2.0.*

exception `httplib.Unimplemented FileMode`
A subclass of `HTTPException`.

*New in version 2.0.*

exception `httplib.IncompleteRead`
A subclass of `HTTPException`.

*New in version 2.0.*
exception `httpclient.ImproperConnectionState`

A subclass of `HTTPException`.

New in version 2.0.

exception `httpclient.CannotSendRequest`

A subclass of `ImproperConnectionState`.

New in version 2.0.

exception `httpclient.CannotSendHeader`

A subclass of `ImproperConnectionState`.

New in version 2.0.

exception `httpclient.ResponseNotReady`

A subclass of `ImproperConnectionState`.

New in version 2.0.

exception `httpclient.BadStatusLine`

A subclass of `HTTPException`. Raised if a server responds with a HTTP status code that we don’t understand.

New in version 2.0.

The constants defined in this module are:

`httplib.HTTP_PORT`

The default port for the HTTP protocol (always 80).

`httplib.HTTPS_PORT`

The default port for the HTTPS protocol (always 443).

and also the following constants for integer status codes:

**httplib.responses**

This dictionary maps the HTTP 1.1 status codes to the W3C names.
Example: `httplib.responses[httpbin.NOT_FOUND]` is 'Not Found'.

*New in version 2.5.*
HTTPConnection Objects

HTTPConnection instances have the following methods:

HTTPConnection. `request(method, url[, body[, headers]])`
This will send a request to the server using the HTTP request method `method` and the selector `url`. If the `body` argument is present, it should be a string of data to send after the headers are finished. Alternatively, it may be an open file object, in which case the contents of the file is sent; this file object should support `fileno()` and `read()` methods. The header Content-Length is automatically set to the correct value. The `headers` argument should be a mapping of extra HTTP headers to send with the request.

*Changed in version 2.6:* `body` can be a file object.

HTTPConnection. `getresponse()`
Should be called after a request is sent to get the response from the server. Returns an HTTPResponse instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

HTTPConnection. `set_debuglevel(level)`
Set the debugging level (the amount of debugging output printed). The default debug level is 0, meaning no debugging output is printed.

HTTPConnection. `connect()`
Connect to the server specified when the object was created.
HTTPConnection.close()
    Close the connection to the server.

As an alternative to using the request() method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.putrequest(request, selector[, skip_host[, skip_accept_encoding]])
    This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the request string, the selector string, and the HTTP version (HTTP/1.1). To disable automatic sending of Host: or Accept-Encoding: headers (for example to accept additional content encodings), specify skip_host or skip_accept_encoding with non-False values.

    Changed in version 2.4: skip_accept_encoding argument added.

HTTPConnection.putheader(header, argument[, ...])
    Send an RFC 822-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders()
    Send a blank line to the server, signalling the end of the headers.

HTTPConnection.send(data)
    Send data to the server. This should be used directly only after the endheaders() method has been called and before getresponse() is called.
HTTPResponse Objects

HTTPResponse instances have the following methods and attributes:

HTTPResponse. **read**(amt)

Reads and returns the response body, or up to the next *amt* bytes.

HTTPResponse. **getheader**(name[, default])

Get the contents of the header *name*, or *default* if there is no matching header.

HTTPResponse. **getheaders**()

Return a list of (header, value) tuples.

*New in version 2.4.*

HTTPResponse. **msg**

A `mimetypes.Message` instance containing the response headers.

HTTPResponse. **version**

HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse. **status**

Status code returned by server.

HTTPResponse. **reason**

Reason phrase returned by server.
Examples

Here is an example session that uses the **GET** method:

```python
>>> import httpplib
>>> conn = httpplib.HTTPConnection("www.python.org")
>>> conn.request("GET", "/index.html")
>>> r1 = conn.getresponse()
>>> print r1.status, r1.reason
200 OK
>>> data1 = r1.read()
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print r2.status, r2.reason
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that shows how to **POST** requests:

```python
>>> import httpplib, urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> headers = {'Content-type': 'application/x-www-form-urlencoded',
...            'Accept': 'text/plain'}
>>> conn = httpplib.HTTPConnection("musi-cal.mojam.com:80")
>>> conn.request("POST", "/cgi-bin/query", params, headers)
>>> response = conn.getresponse()
>>> print response.status, response.reason
200 OK
>>> data = response.read()
>>> conn.close()
```
This module defines the class `FTP` and a few related items. The `FTP` class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other ftp servers. It is also used by the module `urllib` to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here's a sample session using the `ftplib` module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.cwi.nl') # connect to host, default port
>>> ftp.login() # user anonymous, passwd anonymous
>>> ftp.retrlines('LIST') # list directory contents
total 24418
drwxrwsr-x 5 ftp-usr pdmaint 1536 Mar 20 09:48 .
dr-xr-srwt 105 ftp-usr pdmaint 1536 Mar 21 14:32 ..
-rw-r--r-- 1 ftp-usr pdmaint 5305 Mar 20 09:48 INDEX
.
.
>>> ftp.retrbinary('RETR README', open('README', 'wb').write) # '226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:

```python
class ftplib.FTP([host[, user[, passwd[, acct[, timeout]]]]])
```

Return a new instance of the `FTP` class. When `host` is given, the method call `connect(host)` is made. When `user` is given, additionally the method call `login(user, passwd, acct)` is made (where `passwd` and `acct` default to the empty string when not given). The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used).
Changed in version 2.6: timeout was added.

**all_errors**

The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed below as well as `socket.error` and `IOError`.

exception **error_reply**
Exception raised when an unexpected reply is received from the server.

exception **ftplib.error_temp**
Exception raised when an error code in the range 400–499 is received.

exception **ftplib.error_perm**
Exception raised when an error code in the range 500–599 is received.

exception **ftplib.error_proto**
Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

**See also:**

**Module netrc**
Parser for the `.netrc` file format. The file `.netrc` is typically used by FTP clients to load user authentication information before prompting the user.

The file `Tools/scripts/ftpmirror.py` in the Python source distribution is a script that can mirror FTP sites, or portions thereof, using the `ftplib` module. It can be used as an extended example that applies this module.
FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by `lines` for the text version or `binary` for the binary version.

FTP instances have the following methods:

**FTP.set_debuglevel(level)**

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**FTP.connect(host[, port[, timeout]])**

Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made.

The optional `timeout` parameter specifies a timeout in seconds for the connection attempt. If no `timeout` is passed, the global default timeout setting will be used.

*Changed in version 2.6: timeout was added.*

**FTP.getwelcome()**

Return the welcome message sent by the server in reply to the
initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**FTP. `login([user[, passwd[, acct]]])`**

Log in as the given `user`. The `passwd` and `acct` parameters are optional and default to the empty string. If no `user` is specified, it defaults to `anonymous`. If `user` is `anonymous`, the default `passwd` is `anonymous@`. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in.

**FTP. `abort()`**

Abort a file transfer that is in progress. Using this does not always work, but it’s worth a try.

**FTP. `sendcmd(command)`**

Send a simple command string to the server and return the response string.

**FTP. `voidcmd(command)`**

Send a simple command string to the server and handle the response. Return nothing if a response code in the range 200–299 is received. Raise an exception otherwise.

**FTP. `retrbinary(command, callback[, maxblocksize[, rest]])`**

Retrieve a file in binary transfer mode. `command` should be an appropriate `RETR` command: `RETR filename`. The `callback` function is called for each block of data received, with a single string argument giving the data block. The optional `maxblocksize` argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to `callback`). A
reasonable default is chosen. *rest* means the same thing as in the `transfercmd()` method.

**FTP. `retrlines(command[, callback])`**
Retrieve a file or directory listing in ASCII transfer mode. *command* should be an appropriate RETR command (see `retrbinary()`), or a command such as *LIST*, *NLST* or *MLSD* (usually just the string 'LIST'). The *callback* function is called for each line, with the trailing CRLF stripped. The default *callback* prints the line to `sys.stdout`.

**FTP. `set_pasv(boolean)`**
Enable “passive” mode if *boolean* is true, otherwise disable passive mode. (In Python 2.0 and before, passive mode was off by default; in Python 2.1 and later, it is on by default.)

**FTP. `storbinary(command, file[, blocksize, callback])`**
Store a file in binary transfer mode. *command* should be an appropriate STOR command: "STOR filename". *file* is an open file object which is read until EOF using its `read()` method in blocks of size *blocksize* to provide the data to be stored. The *blocksize* argument defaults to 8192. *callback* is an optional single parameter callable that is called on each block of data after it is sent.

*Changed in version 2.1:* default for *blocksize* added.

*Changed in version 2.6:* *callback* parameter added.

**FTP. `storlines(command, file[, callback])`**
Store a file in ASCII transfer mode. *command* should be an appropriate STOR command (see `storbinary()`). Lines are read until EOF from the open file object *file* using its `readline()`
method to provide the data to be stored. *callback* is an optional single parameter callable that is called on each line after it is sent.

*Changed in version 2.6: callback parameter added.*

**FTP.transfercmd(cmd[, rest])**

Initiate a transfer over the data connection. If the transfer is active, send a `EPRT` or `PORT` command and the transfer command specified by `cmd`, and accept the connection. If the server is passive, send a `EPSV` or `PASV` command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional `rest` is given, a `REST` command is sent to the server, passing `rest` as an argument. `rest` is usually a byte offset into the requested file, telling the server to restart sending the file's bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that `rest` be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The `transfercmd()` method, therefore, converts `rest` to a string, but no check is performed on the string's contents. If the server does not recognize the `REST` command, an `error_reply` exception will be raised. If this happens, simply call `transfercmd()` without a `rest` argument.

**FTP.ntransfercmd(cmd[, rest])**

Like `transfercmd()`, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, `None` will be returned as the expected size. `cmd` and `rest` means the same thing as in `transfercmd()`.

**FTP.nlst(argument[, ...])**
Return a list of files as returned by the `NLST` command. The optional *argument* is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the `NLST` command.

**FTP.** `dir(argument[, ...])`

Produce a directory listing as returned by the `LIST` command, printing it to standard output. The optional *argument* is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the `LIST` command. If the last argument is a function, it is used as a *callback* function as for `retrlines()`; the default prints to `sys.stdout`. This method returns `None`.

**FTP.** `rename(fromname, toname)`

Rename file *fromname* on the server to *toname*.

**FTP.** `delete(filename)`

Remove the file named *filename* from the server. If successful, returns the text of the response, otherwise raises `error_perm` on permission errors or `error_reply` on other errors.

**FTP.** `cwd(pathname)`

Set the current directory on the server.

**FTP.** `mkd(pathname)`

Create a new directory on the server.

**FTP.** `pwd()`

Return the pathname of the current directory on the server.

**FTP.** `rmd(dirname)`

Remove the directory named *dirname* on the server.
FTP. `size(filename)`
Request the size of the file named `filename` on the server. On success, the size of the file is returned as an integer, otherwise `None` is returned. Note that the `SIZE` command is not standardized, but is supported by many common server implementations.

FTP. `quit()`
Send a `QUIT` command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception of the server responds with an error to the `QUIT` command. This implies a call to the `close()` method which renders the FTP instance useless for subsequent calls (see below).

FTP. `close()`
Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to `quit()`. After this call the FTP instance should not be used any more (after a call to `close()` or `quit()` you cannot reopen the connection by issuing another `login()` method).
This module defines a class, `POP3`, which encapsulates a connection to a POP3 server and implements the protocol as defined in RFC 1725. The `POP3` class supports both the minimal and optional command sets. Additionally, this module provides a class `POP3_SSL`, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

A single class is provided by the `poplib` module:

```python
class poplib.POP3(host[, port[, timeout]])

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

Changed in version 2.6: `timeout` was added.
```

```python
class poplib.POP3_SSL(host[, port[, keyfile[, certfile]]])

This is a subclass of `POP3` that connects to the server over an SSL encrypted socket. If `port` is not specified, 995, the standard POP3-over-SSL port is used. `keyfile` and `certfile` are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.
```
New in version 2.4.

One exception is defined as an attribute of the `poplib` module:

```python
exception poplib.error_proto
```

Exception raised on any errors from this module (errors from `socket` module are not caught). The reason for the exception is passed to the constructor as a string.

See also:

**Module imaplib**

The standard Python IMAP module.

**Frequently Asked Questions About Fetchmail**

The FAQ for the `fetchmail` POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.
POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An **POP3** instance has the following methods:

**POP3.set_debuglevel**(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**POP3.getwelcome()**
Returns the greeting string sent by the POP3 server.

**POP3.user**(username)
Send user command, response should indicate that a password is required.

**POP3.pass**(password)
Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until **quit()** is called.

**POP3.apop**(user, secret)
Use the more secure APOP authentication to log into the POP3 server.

**POP3.rpop**(user)
Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

**POP3.** `stat()`  
Get mailbox status. The result is a tuple of 2 integers: `(message count, mailbox size)`.

**POP3.** `list([which])`  
Request message list, result is in the form `(response, ['mesg_num octets', ...], octets)`. If `which` is set, it is the message to list.

**POP3.** `retr(which)`  
Retrieve whole message number `which`, and set its seen flag. Result is in form `(response, ['line', ...], octets)`.

**POP3.** `dele(which)`  
Flag message number `which` for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

**POP3.** `rset()`  
Remove any deletion marks for the mailbox.

**POP3.** `noop()`  
Do nothing. Might be used as a keep-alive.

**POP3.** `quit()`  
Signoff: commit changes, unlock mailbox, drop connection.

**POP3.** `top(which, howmuch)`  
Retrieves the message header plus `howmuch` lines of the message after the header of message number `which`. Result is in form `(response, ['line', ...], octets)`. 
The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

**POP3.uid1([which])**

Return message digest (unique id) list. If which is specified, result contains the unique id for that message in the form `response mesgnum uid`, otherwise result is list `(response, ['mesgnum uid', ..., octets]).`

Instances of **POP3_SSL** have no additional methods. The interface of this subclass is identical to its parent.
Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib
M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print j
```

At the end of the module, there is a test section that contains a more extensive example of usage.
This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in RFC 2060. It is backward compatible with IMAP4 (RFC 1730) servers, but note that the `STATUS` command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class:

```python
class imaplib.IMAP4([host[, port]])
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If `host` is not specified, `'.'` (the local host) is used. If `port` is omitted, the standard IMAP4 port (143) is used.

Three exceptions are defined as attributes of the `IMAP4` class:

```python
exception IMAP4.error
```

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

```python
exception IMAP4.abort
```

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

```python
exception IMAP4.readonly
```

This exception is raised when a writable mailbox has its status
changed by the server. This is a sub-class of `IMAP4.error`. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There's also a subclass for secure connections:

```python
class imaplib.IMAP4_SSL([host[, port[, keyfile[, certfile]]]])
```

This is a subclass derived from `IMAP4` that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If `host` is not specified, '' (the local host) is used. If `port` is omitted, the standard IMAP4-over-SSL port (993) is used. `keyfile` and `certfile` are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.

The second subclass allows for connections created by a child process:

```python
class imaplib.IMAP4_stream(command)
```

This is a subclass derived from `IMAP4` that connects to the stdin/stdout file descriptors created by passing `command` to `os.popen2()`.

*New in version 2.3.*

The following utility functions are defined:

```python
imaplib.Internaldate2tuple(datestr)
```

Converts an IMAP4 INTERNALDATE string to Coordinated Universal Time. Returns a `time` module tuple.

```python
imaplib.Int2AP(num)
```

Converts an integer into a string representation using characters from the set `[A .. P]`. 
imaplib.**ParseFlags**(flagstr)

Converts an IMAP4 **FLAGS** response to a tuple of individual flags.

imaplib.**Time2Internaldate**(date_time)

Converts a time module tuple to an IMAP4 **INTERNALDATE** representation. Returns a string in the form: 

"DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes).

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an **EXPUNGE** command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

**See also:** Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the University of Washington’s IMAP Information Center (http://www.washington.edu/imap/).
All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn't enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'("Deleted")').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: 'literal' value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3,6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:*').

An IMAP4 instance has the following methods:

```python
IMAP4.append(mailbox, flags, date_time, message)
```

Append message to named mailbox.
authenticate\textit{(mechanism, authobject)}

Authenticate command — requires response processing.

\textit{mechanism} specifies which authentication mechanism is to be used - it should appear in the instance variable \texttt{capabilities} in the form \texttt{AUTH=mechanism}.

\textit{authobject} must be a callable object:

```
data = authobject(response)
```

It will be called to process server continuation responses. It should return \texttt{data} that will be encoded and sent to server. It should return \texttt{None} if the client abort response * should be sent instead.

\textbf{check()} 

Checkpoint mailbox on server.

\textbf{close()} 

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before \texttt{LOGOUT}.

\textbf{copy(message\_set, new\_mailbox)}

Copy \texttt{message\_set} messages onto end of \texttt{new\_mailbox}.

\textbf{create(mailbox)}

Create new mailbox named \texttt{mailbox}.

\textbf{delete(mailbox)}

Delete old mailbox named \texttt{mailbox}.

\textbf{deleteacl(mailbox, who)}
Delete the ACLs (remove any rights) set for who on mailbox.

*New in version 2.4.*

**IMAP4. `expunge()`**

Permanently remove deleted items from selected mailbox. Generates an EXPUNGE response for each deleted message. Returned data contains a list of EXPUNGE message numbers in order received.

**IMAP4. `fetch(message_set, message_parts)`**

Fetch (parts of) messages. `message_parts` should be a string of message part names enclosed within parentheses, eg: "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

**IMAP4. `getacl(mailbox)`**

Get the ACLs for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. `getannotation(mailbox, entry, attribute)`**

Retrieve the specified ANNOTATIONS for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

*New in version 2.5.*

**IMAP4. `getquota(root)`**

Get the quota `root`'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

*New in version 2.3.*

**IMAP4. `getquotaroot(mailbox)`**

Get the list of quota `roots` for the named `mailbox`. This method is
part of the IMAP4 QUOTA extension defined in rfc2087.

New in version 2.3.

**IMAP4. list([directory[, pattern]])**

List mailbox names in directory matching pattern. directory defaults to the top-level mail folder, and pattern defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4. login(user, password)**

Identify the client using a plaintext password. The password will be quoted.

**IMAP4. login_cram_md5(user, password)**

Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server CAPABILITY response includes the phrase AUTH=CRAM-MD5.

New in version 2.3.

**IMAP4. logout()**

Shutdown connection to server. Returns server BYE response.

**IMAP4. lsub([directory[, pattern]])**

List subscribed mailbox names in directory matching pattern. directory defaults to the top level directory and pattern defaults to match any mailbox. Returned data are tuples of message part envelope and data.

**IMAP4. myrights(mailbox)**

Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

New in version 2.4.
**IMAP4. namespace()**

Returns IMAP namespaces as defined in RFC2342.

*New in version 2.3.*

**IMAP4. noop()**

Send **NOOP** to server.

**IMAP4. open(host, port)**

Opens socket to *port* at *host*. The connection objects established by this method will be used in the read, readline, send, and shutdown methods. You may override this method.

**IMAP4. partial(message_num, message_part, start, length)**

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4. proxyauth(user)**

Assume authentication as *user*. Allows an authorised administrator to proxy into any user’s mailbox.

*New in version 2.3.*

**IMAP4. read(size)**

Reads *size* bytes from the remote server. You may override this method.

**IMAP4. readline()**

Reads one line from the remote server. You may override this method.

**IMAP4. recent()**

Prompt server for an update. Returned data is **None** if no new messages, else value of **RECENT** response.
**IMAP4. rename(oldmailbox, newmailbox)**

Rename mailbox named *oldmailbox* to *newmailbox*.

**IMAP4. response(code)**

Return data for response *code* if received, or *None*. Returns the given code, instead of the usual type.

**IMAP4. search(charset, criterion[, ...])**

Search mailbox for matching messages. *charset* may be *None*, in which case no CHARSET will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error.

Example:

```python
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '\"LDJ\"')

# or:
typ, msgnums = M.search(None, '(FROM \"LDJ\")')
```

**IMAP4. select([mailbox[, readonly]])**

Select a mailbox. Returned data is the count of messages in *mailbox* (EXISTS response). The default *mailbox* is '\INBOX\'. If the *readonly* flag is set, modifications to the mailbox are not allowed.

**IMAP4. send(data)**

Sends *data* to the remote server. You may override this method.

**IMAP4. setacl(mailbox, who, what)**

Set an ACL for *mailbox*. The method is non-standard, but is supported by the Cyrus server.
**IMAP4. `setannotation(mailbox, entry, attribute[, ...])`**

Set **Annotations** for `mailbox`. The method is non-standard, but is supported by the **cyrus** server.

*New in version 2.5.*

**IMAP4. `setquota(root, limits)`**

Set the **quota** `root`'s resource **limits**. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

*New in version 2.3.*

**IMAP4. `shutdown()`**

Close connection established in `open`. You may override this method.

**IMAP4. `socket()`**

Returns socket instance used to connect to server.

**IMAP4. `sort(sort_criteria, charset, search_criterion[, ...])`**

The **sort** command is a variant of **search** with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the `search_criterion` argument(s); a parenthesized list of `sort_criteria`, and the searching `charset`. Note that unlike **search**, the searching `charset` argument is mandatory. There is also a **uid sort** command which corresponds to **sort** the way that **uid search** corresponds to **search**. The **sort** command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.
This is an **IMAP4rev1** extension command.

**IMAP4. status(mailbox, names)**
Request named status conditions for `mailbox`.

**IMAP4. store(message_set, command, flag_list)**
Alters flag dispositions for messages in `mailbox`. `command` is specified by section 6.4.6 of **RFC 2060** as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of “.SILENT”.

For example, to set the delete flag on all messages:

```
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\\Deleted')
M.expunge()
```

**IMAP4. subscribe(mailbox)**
Subscribe to new `mailbox`.

**IMAP4. thread(threading_algorithm, charset, search_criterion[, ...])**
The `thread` command is a variant of `search` with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the `search_criterion` argument(s); a `threading_algorithm`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid thread` command which corresponds to `thread` the way that `uid search` corresponds to `search`. The `thread` command first searches the mailbox for
messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an `IMAP4rev1` extension command.

*New in version 2.4.*

**IMAP4. `uid(command, arg[, ...])`**

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

**IMAP4. `unsubscribe(mailbox)`**

Unsubscribe from old mailbox.

**IMAP4. `xatom(name[, arg[, ...]])`**

Allow simple extension commands notified by server in `CAPABILITY` response.

Instances of `IMAP4_SSL` have just one additional method:

**IMAP4_SSL. `ssl()`**

Returns SSLObject instance used for the secure connection with the server.

The following attributes are defined on instances of `IMAP4`:

**IMAP4. `PROTOCOL_VERSION`**

The most recent supported protocol in the `CAPABILITY` response from the server.
IMAP4. **debug**

Integer value to control debugging output. The initialize value is taken from the module variable `Debug`. Values greater than three trace each command.
Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print 'Message %s
%s
' % (num, data[0][1])
M.close()
M.logout()
```
This module defines the class `NNTP` which implements the client side of the NNTP protocol. It can be used to implement a news reader or poster, or automated news processors. For more information on NNTP (Network News Transfer Protocol), see Internet RFC 977.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = NNTP('news.cwi.nl')
>>> resp, count, first, last, name = s.group('comp.lang.python')
>>> print ('Group', name, 'has', count, 'articles, range', first, '+', last)
Group comp.lang.python has 59 articles, range 3742 to 3803

>>> resp, subs = s.xhdr('subject', first + '-' + last)
>>> for id, sub in subs[-10:]:
...    print id, sub
...
3792 Re: Removing elements from a list while iterating...
3793 Re: Who likes Info files?
3794 Emacs and doc strings
3795 a few questions about the Mac implementation
3796 Re: executable python scripts
3797 Re: executable python scripts
3798 Re: a few questions about the Mac implementation
3799 Re: PROPOSAL: A Generic Python Object Interface for Python
3802 Re: executable python scripts
3803 Re: \POSIX{} wait and SIGCHLD

>>> s.quit()
'205 news.cwi.nl closing connection. Goodbye.'
```

To post an article from a file (this assumes that the article has valid headers):

```python
>>> s = NNTP('news.cwi.nl')
>>> f = open('/tmp/article')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 news.cwi.nl closing connection. Goodbye.'
```
The module itself defines the following items:

class nntplib.NNTP(host[, port[, user[, password[, readermode]][, usenetrc]]]])

Return a new instance of the NNTP class, representing a connection to the NNTP server running on host host, listening at port port. The default port is 119. If the optional user and password are provided, or if suitable credentials are present in ~/.netrc and the optional flag usenetrc is true (the default), the AUTHINFO USER and AUTHINFO PASS commands are used to identify and authenticate the user to the server. If the optional flag readermode is true, then a mode reader command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as group. If you get unexpected NNTPPermanentErrors, you might need to set readermode. readermode defaults to None. usenetrc defaults to True.

*Changed in version 2.4:* usenetrc argument added.

exception nntplib.NNTPError

Derived from the standard exception Exception, this is the base class for all exceptions raised by the nntplib module.

exception nntplib.NNTPReplyError

Exception raised when an unexpected reply is received from the server. For backwards compatibility, the exception error_reply is equivalent to this class.

exception nntplib.NNPTemporaryError

Exception raised when an error code in the range 400–499 is received. For backwards compatibility, the exception error_temp
is equivalent to this class.

exception nntplib.NNTPPermanentError
   Exception raised when an error code in the range 500–599 is received. For backwards compatibility, the exception error_perm is equivalent to this class.

exception nntplib.NNTPProtocolError
   Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5. For backwards compatibility, the exception error_proto is equivalent to this class.

exception nntplib.NNTPDataError
   Exception raised when there is some error in the response data. For backwards compatibility, the exception error_data is equivalent to this class.
NNTP Objects

NNTP instances have the following methods. The `response` that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

NNTP.getwelcome()

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

NNTP.set_debuglevel(level)

Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

NNTP.newgroups(date, time[, file])

Send a `NEWGROUPS` command. The `date` argument should be a string of the form ‘yymmd’ indicating the date, and `time` should be a string of the form ‘hhmmss’ indicating the time. Return a pair (response, groups) where `groups` is a list of group names that are new since the given date and time. If the `file` parameter is supplied, then the output of the `NEWGROUPS` command is stored in a file. If `file` is a string, then the method will open a file object with that name, write to it then close it. If `file` is a file object, then it will start calling `write()` on it to store the lines of the command
output. If file is supplied, then the returned list is an empty list.

NNTP. newnews\(\text{\texttt{\textbf{(}group, date, time[, file]\text{\texttt{)}}}}\)
Send a \texttt{NEWNEWS} command. Here, \textit{group} is a group name or \texttt{\texttt{\texttt{*}}}*, and \textit{date} and \textit{time} have the same meaning as for \texttt{newgroups()}. Return a pair \texttt{(response, articles)} where \texttt{articles} is a list of message ids. If the \textit{file} parameter is supplied, then the output of the \texttt{NEWNEWS} command is stored in a file. If \textit{file} is a string, then the method will open a file object with that name, write to it then close it. If \textit{file} is a file object, then it will start calling \texttt{write()} on it to store the lines of the command output. If \textit{file} is supplied, then the returned list is an empty list.

NNTP. list\(\text{\texttt{\textbf{[}file\text{\texttt{)}}}}\)
Send a \texttt{LIST} command. Return a pair \texttt{(response, list)} where \textit{list} is a list of tuples. Each tuple has the form \texttt{(group, last, first, flag)}, where \textit{group} is a group name, \textit{last} and \textit{first} are the last and first article numbers (as strings), and \textit{flag} is \texttt{'y'} if posting is allowed, \texttt{'n'} if not, and \texttt{'m'} if the newsgroup is moderated. (Note the ordering: \textit{last}, \textit{first}.) If the \textit{file} parameter is supplied, then the output of the \texttt{LIST} command is stored in a file. If \textit{file} is a string, then the method will open a file object with that name, write to it then close it. If \textit{file} is a file object, then it will start calling \texttt{write()} on it to store the lines of the command output. If \textit{file} is supplied, then the returned \textit{list} is an empty list.

NNTP. descriptions\(\text{\texttt{\textbf{(}grouppattern\text{\texttt{)}}}}\)
Send a \texttt{LIST NEWSGROUPS} command, where \textit{grouppattern} is a wildmat string as specified in RFC2980 (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair \texttt{(response, list)}, where \textit{list} is a list of tuples containing \texttt{(name, title)}. 
New in version 2.4.

NNTP. **description**(group)
Get a description for a single group group. If more than one
group matches (if ‘group’ is a real wildmat string), return the first
match. If no group matches, return an empty string.

This elides the response code from the server. If the response
code is needed, use descriptions().

New in version 2.4.

NNTP. **group**(name)
Send a **GROUP** command, where name is the group name. Return
a tuple (response, count, first, last, name) where count is
the (estimated) number of articles in the group, first is the first
article number in the group, last is the last article number in the
group, and name is the group name. The numbers are returned
as strings.

NNTP. **help**([file])
Send a **HELP** command. Return a pair (response, list) where
list is a list of help strings. If the file parameter is supplied, then
the output of the **HELP** command is stored in a file. If file is a
string, then the method will open a file object with that name,
write to it then close it. If file is a file object, then it will start calling
write() on it to store the lines of the command output. If file is
supplied, then the returned list is an empty list.

NNTP. **stat**(id)
Send a **STAT** command, where id is the message id (enclosed in
'<' and '>') or an article number (as a string). Return a triple
(response, number, id) where number is the article number (as
a string) and id is the message id (enclosed in '<' and '>').
NNTP. **next()**
Send a `NEXT` command. Return as for `stat()`.

NNTP. **last()**
Send a `LAST` command. Return as for `stat()`.

NNTP. **head(id)**
Send a `HEAD` command, where `id` has the same meaning as for `stat()`. Return a tuple `(response, number, id, list)` where the first three are the same as for `stat()`, and `list` is a list of the article's headers (an uninterpreted list of lines, without trailing newlines).

NNTP. **body(id[, file])**
Send a `BODY` command, where `id` has the same meaning as for `stat()`. If the `file` parameter is supplied, then the body is stored in a file. If `file` is a string, then the method will open a file object with that name, write to it then close it. If `file` is a file object, then it will start calling `write()` on it to store the lines of the body. Return as for `head()`. If `file` is supplied, then the returned `list` is an empty list.

NNTP. **article(id)**
Send an `ARTICLE` command, where `id` has the same meaning as for `stat()`. Return as for `head()`.

NNTP. **slave()**
Send a `SLAVE` command. Return the server's `response`.

NNTP. **xhdr(header, string[, file])**
Send an `XHDR` command. This command is not defined in the RFC but is a common extension. The `header` argument is a header keyword, e.g. `'subject'`. The `string` argument should
have the form 'first-last' where first and last are the first and last article numbers to search. Return a pair (response, list), where list is a list of pairs (id, text), where id is an article number (as a string) and text is the text of the requested header for that article. If the file parameter is supplied, then the output of the XHDR command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

**NNTP.post(file)**

Post an article using the POST command. The file argument is an open file object which is read until EOF using its readline() method. It should be a well-formed news article, including the required headers. The post() method automatically escapes lines beginning with ..

**NNTP.ihave(id, file)**

Send an IHAVE command. id is a message id (enclosed in '<' and '>'). If the response is not an error, treat file exactly as for the post() method.

**NNTP.date()**

Return a triple (response, date, time), containing the current date and time in a form suitable for the newnews() and newgroups() methods. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP.xgtitle(name[, file])**

Process an XGTITLE command, returning a pair (response, list), where list is a list of tuples containing (name, title). If the
file parameter is supplied, then the output of the XGTITLE command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

RFC2980 says “It is suggested that this extension be deprecated”. Use descriptions() or description() instead.

**NNTP. xover(start, end[, file])**

Return a pair (resp, list). list is a list of tuples, one for each article in the range delimited by the start and end article numbers. Each tuple is of the form (article number, subject, poster, date, id, references, size, lines). If the file parameter is supplied, then the output of the XOVER command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP. xpath(id)**

Return a pair (resp, path), where path is the directory path to the article with message ID id. This is an optional NNTP extension, and may not be supported by all servers.

**NNTP. quit()**

Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.
The `smtplib` module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult RFC 821 (Simple Mail Transfer Protocol) and RFC 1869 (SMTP Service Extensions).

```python
class smtplib.SMTP([host[, port[, local_hostname[, timeout]]]])
```

A `SMTP` instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the SMTP `connect()` method is called with those parameters during initialization. An `SMTPConnectError` is raised if the specified host doesn't respond correctly. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

For normal use, you should only require the initialization/connect, `sendmail()`, and `quit()` methods. An example is included below.

*Changed in version 2.6*: `timeout` was added.

```python
class smtplib.SMTP_SSL([host[, port[, local_hostname[, keyfile[, certfile[, timeout]]]]]])
```

A `SMTP_SSL` instance behaves exactly the same as instances of `SMTP`. `SMTP_SSL` should be used for situations where SSL is required from the beginning of the connection and using `starttls()` is not appropriate. If `host` is not specified, the local host is used. If `port` is omitted, the standard SMTP-over-SSL port (465) is used. `keyfile` and `certfile` are also optional, and can
contain a PEM formatted private key and certificate chain file for the SSL connection. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

*Changed in version 2.6: timeout was added.*

```python
class smtplib.LMTP([host[, port[, local_hostname]]])
```

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It’s common to use Unix sockets for LMTP, so our `connect()` method must support that as well as a regular host:port server. To specify a Unix socket, you must use an absolute path for `host`, starting with a ‘/’.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don’t support or require any authentication, but your mileage might vary.

*New in version 2.6.*

A nice selection of exceptions is defined as well:

```python
exception smtplib.SMTPException
    Base exception class for all exceptions raised by this module.

exception smtplib.SMTPServerDisconnected
    This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the SMTP instance before connecting it to a server.

exception smtplib.SMTPResponseException
    Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in
the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

```
exception smtplib.SMTPSenderRefused
    Sender address refused. In addition to the attributes set by on all
    SMTPResponseException exceptions, this sets ‘sender’ to the string
    that the SMTP server refused.
```

```
exception smtplib.SMTPRecipientsRefused
    All recipient addresses refused. The errors for each recipient are
    accessible through the attribute `recipients`, which is a dictionary
    of exactly the same sort as `SMTP.sendmail()` returns.
```

```
exception smtplib.SMTPDataError
    The SMTP server refused to accept the message data.
```

```
exception smtplib.SMTPConnectError
    Error occurred during establishment of a connection with the
    server.
```

```
exception smtplib.SMTPHeloError
    The server refused our `HELO` message.
```

```
exception smtplib.SMTPAuthenticationError
    SMTP authentication went wrong. Most probably the server didn’t
    accept the username/password combination provided.
```

See also:

**RFC 821 - Simple Mail Transfer Protocol**

Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869 - SMTP Service Extensions**

Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands,
supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
SMTP Objects

An SMTP instance has the following methods:

**SMTP. set_debuglevel(level)**

Set the debug output level. A true value for level results in debug messages for connection and for all messages sent to and received from the server.

**SMTP. connect([host[, port]])**

Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (‘:’) followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation.

**SMTP. docmd(cmd[, argstring])**

Send a command cmd to the server. The optional argument argstring is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, `SMTPServerDisconnected` will be raised.
SMTP. **helo**([`hostname`])**
Identify yourself to the SMTP server using `HELO`. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the `helo_resp` attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

SMTP. **ehlo**([`hostname`])**
Identify yourself to an ESMTP server using `EHLO`. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by `has_extn()`. Also sets several informational attributes: the message returned by the server is stored as the `ehlo_resp` attribute, `does_esmtp` is set to true or false depending on whether the server supports ESMTP, and `esmtp_features` will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

SMTP. **ehlo_or_helo_if_needed()**
This method call `ehlo()` and or `helo()` if there has been no previous `EHLO` or `HELO` command this session. It tries ESMTP `EHLO` first.

:exc:SMTPHeloError
The server didn’t reply properly to the `HELO` greeting.
New in version 2.6.

**SMTP. has_extn(name)**
Return True if name is in the set of SMTP service extensions returned by the server, False otherwise. Case is ignored.

**SMTP. verify(address)**
Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

**Note:** Many sites disable SMTP VRFY in order to foil spammers.

**SMTP. login(user, password)**
Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

**SMTPHeloError**
The server didn’t reply properly to the HELO greeting.

**SMTPAuthenticationError**
The server didn’t accept the username/password combination.

**SMTPException**
No suitable authentication method was found.
**SMTP.starttls([keyfile, certfile])**

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call `ehlo()` again.

If `keyfile` and `certfile` are provided, these are passed to the `socket` module's `ssl()` function.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

*Changed in version 2.6.*

**SMTPHeloError**

The server didn't reply properly to the `HELO` greeting.

**SMTPException**

The server does not support the STARTTLS extension.

*Changed in version 2.6.*

**RuntimeError**

SSL/TLS support is not available to your python interpreter.

**SMTP.sendmail(from_addr, to_addrs, msg[, mail_options, rcpt_options])**

Send mail. The required arguments are an RFC 822 from-address string, a list of RFC 822 to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used in `MAIL FROM` commands as `mail_options`. ESMTP options (such as `DSN` commands) that should be used with all `RCPT` commands can be passed as `rcpt_options`. (If you need to use different ESMTP options to different recipients you have to
use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message.)

**Note:** The `from_addr` and `to_addrs` parameters are used to construct the message envelope used by the transport agents. The SMTP does not modify the message headers in any way.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will throw an exception. That is, if this method does not throw an exception, then someone should get your mail. If this method does not throw an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

This method may raise the following exceptions:

```python
SMTPRecipientsRefused
All recipients were refused. Nobody got the mail. The recipients attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

SMTPHe1oError
The server didn’t reply properly to the HELO greeting.

SMTPSenderRefused
The server didn’t accept the from_addr.
```
**SMTPDataError**

The server replied with an unexpected error code (other than a refusal of a recipient).

Unless otherwise noted, the connection will be open even after an exception is raised.

**SMTP.quit()**

Terminate the SMTP session and close the connection. Return the result of the SMTP **QUIT** command.

*Changed in version 2.6:* Return a value.

Low-level methods corresponding to the standard SMTP/ESMTP commands **HELP**, **RSET**, **NOOP**, **MAIL**, **RCPT**, and **DATA** are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
This example prompts the user for addresses needed in the message envelope ('To' and 'From' addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn’t do any processing of the `RFC 822` headers. In particular, the ‘To’ and ‘From’ addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return raw_input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print "Enter message, end with ^D (Unix) or ^Z (Windows):

# Add the From: and To: headers at the start!
msg = ("From: %s\nTo: %s\n\n" % (fromaddr, ", ".join(toaddrs)))
while 1:
    try:
        line = raw_input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print "Message length is " + repr(len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
server.quit()
```
using Sphinx 0.5.
This module offers several classes to implement SMTP servers. One is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.
SMTPServer Objects

class smtpd.SMTPServer(localaddr, remoteaddr)

Create a new SMTPServer object, which binds to local address localaddr. It will treat remoteaddr as an upstream SMTP relayer. It inherits from asyncore.dispatcher, and so will insert itself into asyncore's event loop on instantiation.

process_message(peer, mailfrom, rcpttos, data)

Raise NotImplemented exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as remoteaddr will be available as the _remoteaddr attribute. peer is the remote host's address, mailfrom is the envelope originator, rcpttos are the envelope recipients and data is a string containing the contents of the e-mail (which should be in RFC 2822 format).
class smtpd. **DebuggingServer** *(localaddr, remoteaddr)*

Create a new debugging server. Arguments are as per **SMTPServer**. Messages will be discarded, and printed on stdout.
class smtpd.PureProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr. Note that running this has a good chance to make you into an open relay, so please be careful.

PureProxy Objects
class smtpd.MailmanProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.
The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

class telnetlib.Telnet([host[, port[, timeout]]])

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port and timeout can be passed to the constructor, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

A number can be passed to the constructor, to, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, or passed as None, the global default timeout setting will be used).
Do not reopen an already connected instance.

This class has many `read_*()` methods. Note that some of them raise `EOFError` when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

*Changed in version 2.6: timeout was added.*

**See also:**

**RFC 854 - Telnet Protocol Specification**

Definition of the Telnet protocol.
Telnet Objects

Telnet instances have the following methods:

Telnet.\texttt{read\_until}(\texttt{expected}[\texttt{timeout}])

Read until a given string, \texttt{expected}, is encountered or until \texttt{timeout} seconds have passed.

When no match is found, return whatever is available instead, possibly the empty string. Raise \texttt{EOFError} if the connection is closed and no cooked data is available.

Telnet.\texttt{read\_all}()

Read all data until EOF; block until connection closed.

Telnet.\texttt{read\_some}()

Read at least one byte of cooked data unless EOF is hit. Return '' if EOF is hit. Block if no data is immediately available.

Telnet.\texttt{read\_very\_eager}()

Read everything that can be without blocking in I/O (eager).

Raise \texttt{EOFError} if connection closed and no cooked data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.\texttt{read\_eager}()

Read readily available data.

Raise \texttt{EOFError} if connection closed and no cooked data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
**Telnet.** `read_lazy()`  
Process and return data already in the queues (lazy).

Raise `EOFError` if connection closed and no data available. Return `' '` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

**Telnet.** `read_very_lazy()`  
Return any data available in the cooked queue (very lazy).

Raise `EOFError` if connection closed and no data available. Return `' '` if no cooked data available otherwise. This method never blocks.

**Telnet.** `read_sb_data()`  
Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a `SE` command. This method never blocks.

*New in version 2.3.*

**Telnet.** `open(host[, port[, timeout]])`  
Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

*Changed in version 2.6:* `timeout` was added.

**Telnet.** `msg(msg[, *args])`  
Print a debug message when the debug level is > 0. If extra
arguments are present, they are substituted in the message using the standard string formatting operator.

Telnet. **set_debuglevel**(*debuglevel*)
Set the debug level. The higher the value of *debuglevel*, the more debug output you get (on `sys.stdout`).

Telnet. **close**()
Close the connection.

Telnet. **get_socket**()
Return the socket object used internally.

Telnet. **fileno**()
Return the file descriptor of the socket object used internally.

Telnet. **write**(*buffer*)
Write a string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise `socket.error` if the connection is closed.

Telnet. **interact**()
Interaction function, emulates a very dumb Telnet client.

Telnet. **mt_interact**()
Multithreaded version of `interact()`.

Telnet. **expect**(*list[, timeout]*)
Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (`re.RegexObject` instances) or uncompiled (strings). The optional second argument is a timeout, in seconds; the default is to block indefinitely.
Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the text read up till and including the match.

If end of file is found and no text was read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, text)` where `text` is the text received so far (may be the empty string if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are indeterministic, and may depend on the I/O timing.

**Telnet.** `set_option_negotiation_callback(callback)`

Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.
Telnet Example

A simple example illustrating typical use:

```python
import getpass
import sys
import telnetlib

HOST = "localhost"
user = raw_input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)

tn.read_until("login: ")
if password:
    tn.read_until("Password: ")
    tn.write(password + "\n")

tn.write("ls\n")

print tn.read_all()
```
New in version 2.5.

This module provides immutable UUID objects (the UUID class) and the functions uuid1(), uuid3(), uuid4(), uuid5() for generating version 1, 3, 4, and 5 UUIDs as specified in RFC 4122.

If all you want is a unique ID, you should probably call uuid1() or uuid4(). Note that uuid1() may compromise privacy since it creates a UUID containing the computer's network address. uuid4() creates a random UUID.

class uuid.UUID([hex[, bytes[, bytes_le[, fields[, int[, version]]]]]]))

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the bytes argument, a string of 16 bytes in little-endian order as the bytes_le argument, a tuple of six integers (32-bit time_low, 16-bit time_mid, 16-bit time_hi_version, 8-bit clock_seq_hi_variant, 8-bit clock_seq_low, 48-bit node) as the fields argument, or a single 128-bit integer as the int argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes='\x12\x34\x56\x78'*4)
UUID(bytes_le='\x78\x56\x34\x12\x34\x12\x78\x56' +
    '\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x34, 0x56781
Exactly one of *hex*, *bytes*, *bytes_le*, *fields*, or *int* must be given. The version argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given *hex*, *bytes*, *bytes_le*, *fields*, or *int*.

**UUID** instances have these read-only attributes:

**UUID.** *bytes*

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.** *bytes_le*

The UUID as a 16-byte string (with *time_low*, *time_mid*, and *time_hi_version* in little-endian byte order).

**UUID.** *fields*

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>time_low</em></td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td><em>time_mid</em></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><em>time_hi_version</em></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><em>clock_seq_hi_variant</em></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><em>clock_seq_low</em></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><em>node</em></td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td><em>time</em></td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td><em>clock_seq</em></td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>

**UUID.** *hex*

The UUID as a 32-character hexadecimal string.
UUID. int
The UUID as a 128-bit integer.

UUID. urn
The UUID as aURN as specified in RFC 4122.

UUID. variant
The UUID variant, which determines the internal layout of the UUID. This will be one of the integer constants RESERVED_NCS, RFC_4122, RESERVED_MICROSOFT, or RESERVED_FUTURE.

UUID. version
The UUID version number (1 through 5, meaningful only when the variant is RFC_4122).

The uuid module defines the following functions:

uuid. getnode()
Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

uuid. uuid1([node[, clock_seq]])
Generate a UUID from a host ID, sequence number, and the current time. If node is not given, getnode() is used to obtain the hardware address. If clock_seq is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

uuid. uuid3(namespace, name)
Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

**uuid**. `uuid4()`  
Generate a random UUID.

**uuid**. `uuid5(namespace, name)`  
Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The `uuid` module defines the following namespace identifiers for use with `uuid3()` or `uuid5()`.

**uuid**. `NAMESPACE_DNS`  
When this namespace is specified, the `name` string is a fully-qualified domain name.

**uuid**. `NAMESPACE_URL`  
When this namespace is specified, the `name` string is a URL.

**uuid**. `NAMESPACE_OID`  
When this namespace is specified, the `name` string is an ISO OID.

**uuid**. `NAMESPACE_X500`  
When this namespace is specified, the `name` string is an X.500 DN in DER or a text output format.

The `uuid` module defines the following constants for the possible values of the `variant` attribute:

**uuid**. `RESERVED_NCS`  
Reserved for NCS compatibility.

**uuid**. `RFC_4122`  
Specifies the UUID layout given in RFC 4122.
uuid. **RESERVED MICROSOFT**

Reserved for Microsoft compatibility.

uuid. **RESERVED FUTURE**

Reserved for future definition.

**See also:**

**RFC 4122 - A Universally Unique IDentifier (UUID) URN Namespace**

This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
Here are some examples of typical usage of the `uuid` module:

```python
>>> import uuid
# make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

# make a UUID using an MD5 hash of a namespace UUID and a name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

# make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

# make a UUID using a SHA-1 hash of a namespace UUID and a name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9ae199e5d')

# make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

# convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

# get the raw 16 bytes of the UUID
>>> x.bytes
'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r\x0e\x0f'

# make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
UUID('00010203-0405-0607-0809-0a0b0c0d0e0f')
```
urlparse — Parse URLs into components

**Note:** The `urlparse` module is renamed to `urllib.parse` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators (and discovered a bug in an earlier draft!). It supports the following URL schemes: file, ftp, gopher, hdl, http, https, imap, mailto, mms, news, nntp, prospero, rsync, rtsp, rtspu, sftp, shttp, sip, sips, snews, svn, svn+ssh, telnet, wais.

*New in version 2.5:* Support for the sftp and sips schemes.

The `urlparse` module defines the following functions:

```python
urlparse(urlstring[, default_scheme[, allowfragments]])
```

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash.
in the *path* component, which is retained if present. For example:

```python
>>> from urlparse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o  # doctest: +NORMALIZE_WHITESPACE
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

If the *default_scheme* argument is specified, it gives the default addressing scheme, to be used only if the URL does not specify one. The default value for this argument is the empty string.

If the *allow_fragments* argument is false, fragment identifiers are not allowed, even if the URL's addressing scheme normally does support them. The default value for this argument is `True`.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>params</td>
<td>3</td>
<td>Parameters for last path element</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>4</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>5</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>----------</td>
<td>---</td>
<td>---------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>username</td>
<td>User name</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>password</td>
<td>Password</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>hostname</td>
<td>Host name (lower case)</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>port</td>
<td>Port number as integer, if present</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

See section *Results of urlparse() and urlsplit()* for more information on the result object.

*Changed in version 2.5:* Added attributes to return value.

`urlparse.parse_qs(qs[, keep_blank_values[, strict_parsing]])`

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument `keep_blank_values` is a flag indicating whether blank values in URL encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

Use the `urllib.urlencode()` function to convert such dictionaries into query strings.

`urlparse.parse_qsl(qs[, keep_blank_values[, strict_parsing]])`

Parse a query string given as a string argument (data of type

```python
urlparse.parse_qs(qs[, keep_blank_values[, strict_parsing]])
```
application/x-www-form-urlencoded). Data are returned as a list of name, value pairs.

The optional argument `keep_blank_values` is a flag indicating whether blank values in URL encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

Use the `urllib.urlencode()` function to convert such lists of pairs into query strings.

```
urlparse.urlunparse(parts)
```

Construct a URL from a tuple as returned by `urlparse()`. The `parts` argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

```
urlparse.urlsplit(urlstring[, default_scheme[, allow_fragments]])
```

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the path portion of the URL (see RFC 2396) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).
The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>3</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>4</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td>None</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td>None</td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

See section *Results of urlparse() and urlsplit()* for more information on the result object.

*New in version 2.2.*

*Changed in version 2.5:* Added attributes to return value.

`urlparse.urlunsplit(parts)`

Combine the elements of a tuple as returned by `urlsplit()` into a complete URL as a string. The `parts` argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a `?` with an empty query; the RFC states that these are equivalent).

*New in version 2.2.*
urlparse.**urljoin**(base, url[, allowfragments])

Construct a full (“absolute”) URL by combining a “base URL” (base) with another URL (url). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```python
>>> from urlparse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The **allowfragments** argument has the same meaning and default as for urlparse().

**Note:** If url is an absolute URL (that is, starting with // or scheme://), the url’s host name and/or scheme will be present in the result. For example:

```python
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html',
               ...     '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the url with urlsplit() and urlunsplit(), removing possible scheme and netloc parts.

urlparse.**urldefrag**(url)

If url contains a fragment identifier, returns a modified version of url with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in url, returns url unmodified and an empty string.

**See also:**
**RFC 1738 - Uniform Resource Locators (URL)**

   This specifies the formal syntax and semantics of absolute URLs.

**RFC 1808 - Relative Uniform Resource Locators**

   This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 2396 - Uniform Resource Identifiers (URI): Generic Syntax**

   Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).
Results of `urlparse()` and `urlsplit()`

The result objects from the `urlparse()` and `urlsplit()` functions are subclasses of the `tuple` type. These subclasses add the attributes described in those functions, as well as provide an additional method:

```python
>>> import urlparse
>>> url = 'HTTP://www.Python.org/doc/#'
```

```python
>>> r1 = urlparse.urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
```

```python
>>> r2 = urlparse.urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

*New in version 2.5.*

The following classes provide the implementations of the parse results:
Base class for the concrete result classes. This provides most of the attribute definitions. It does not provide a `geturl()` method. It is derived from `tuple`, but does not override the `__init__()` or `__new__()` methods.

```python
class urlparse.ParseResult(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results. The `__new__()` method is overridden to support checking that the right number of arguments are passed.

```python
class urlparse.SplitResult(scheme, netloc, path, query, fragment)
```
Concrete class for `urlsplit()` results. The `__new__()` method is overridden to support checking that the right number of arguments are passed.
SocketServer — A framework for network servers

Note: The `socketServer` module has been renamed to `socketserver` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The `SocketServer` module simplifies the task of writing network servers.

There are four basic server classes: `TCPserver` uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. `UDPServer` uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The more infrequently used `UnixStreamServer` and `UnixDatagramServer` classes are similar, but use Unix domain sockets; they're not available on non-Unix platforms. For more details on network programming, consult a book such as W. Richard Steven's UNIX Network Programming or Ralph Davis's Win32 Network Programming.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the `ForkingMixIn` and `ThreadingMixIn` mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the `BaseRequestHandler` class,
and overriding its `handle()` method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server’s address and the request handler class. Finally, call the `handle_request()` or `serve_forever()` method of the server object to process one or many requests.

When inheriting from `ThreadingMixIn` for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The `ThreadingMixIn` class defines an attribute `daemon_threads`, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is `False`, meaning that Python will not exit until all threads created by `ThreadingMixIn` have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.
Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+
| BaseServer |
+------------+
    v
+------------+   +------------------+
| TCPServer |------>|
+-----------+   +------------------+
    v
+-----------+   +--------------------+
| UDPServer |------>|
+-----------+   +--------------------+
```

Note that `UnixDatagramServer` derives from `UDPServer`, not from `UnixStreamServer` — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

Forking and threading versions of each type of server can be created using the `ForkingMixIn` and `ThreadingMixIn` mix-in classes. For instance, a threading UDP server class is created as follows:

```
class ThreadingUDPServer(ForkingMixIn, UDPServer): pass
```

The mix-in class must come first, since it overrides a method defined in `UDPServer`. Setting the various member variables also changes the behavior of the underlying server mechanism.

To implement a service, you must derive a class from `BaseRequestHandler` and redefine its `handle()` method. You can then run various versions of the service by combining one of the server
classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses StreamRequestHandler or DatagramRequestHandler.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class `handle()` method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor `fork()` (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use `select()` to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See asyncore
for another way to manage this.
Server Objects

SocketServer. **fileno()**

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to `select.select()`, to allow monitoring multiple servers in the same process.

SocketServer. **handle_request()**

Process a single request. This function calls the following methods in order: `get_request()`, `verify_request()`, and `process_request()`. If the user-provided `handle()` method of the handler class raises an exception, the server’s `handle_error()` method will be called. If no request is received within `self.timeout` seconds, `handle_timeout()` will be called and `handle_request()` will return.

SocketServer. **serve_forever**( **poll_interval=0.5**)

Handle requests until an explicit `shutdown()` request. Polls for shutdown every `poll_interval` seconds.

SocketServer. **shutdown()**

Tells the `serve_forever()` loop to stop and waits until it does.

*New in version 2.6.*

SocketServer. **address_family**

The family of protocols to which the server’s socket belongs. Common examples are `socket.AF_INET` and `socket.AF_UNIX`.

SocketServer. **RequestHandlerClass**

The user-provided request handler class; an instance of this class is created for each request.
SocketServer. `server_address`
The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the socket module for details. For Internet protocols, this is a tuple containing a string giving the address, and an integer port number: `('127.0.0.1', 80)`, for example.

SocketServer. `socket`
The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

SocketServer. `allow_reuse_address`
Whether the server will allow the reuse of an address. This defaults to `False`, and can be set in subclasses to change the policy.

SocketServer. `request_queue_size`
The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to `request_queue_size` requests. Once the queue is full, further requests from clients will get a “Connection denied” error. The default value is usually 5, but this can be overridden by subclasses.

SocketServer. `socket_type`
The type of socket used by the server; `socket.SOCK_STREAM` and `socket.SOCK_DGRAM` are two common values.

SocketServer. `timeout`
Timeout duration, measured in seconds, or `None` if no timeout is desired. If `handle_request()` receives no incoming requests within the timeout period, the `handle_timeout()` method is called.
There are various server methods that can be overridden by subclasses of base server classes like `TCPServer`; these methods aren’t useful to external users of the server object.

**SocketServer.** \texttt{finish\_request()}

Actually processes the request by instantiating \texttt{RequestHandlerClass} and calling its \texttt{handle()} method.

**SocketServer.** \texttt{get\_request()}

Must accept a request from the socket, and return a 2-tuple containing the new socket object to be used to communicate with the client, and the client’s address.

**SocketServer.** \texttt{handle\_error(request, client\_address)}

This function is called if the \texttt{RequestHandlerClass}'s \texttt{handle()} method raises an exception. The default action is to print the traceback to standard output and continue handling further requests.

**SocketServer.** \texttt{handle\_timeout()}

This function is called when the \texttt{timeout} attribute has been set to a value other than \texttt{None} and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**SocketServer.** \texttt{process\_request(request, client\_address)}

Calls \texttt{finish\_request()} to create an instance of the \texttt{RequestHandlerClass}. If desired, this function can create a new process or thread to handle the request; the \texttt{ForkingMixIn} and \texttt{ThreadingMixIn} classes do this.

**SocketServer.** \texttt{server\_activate()}

Called by the server’s constructor to activate the server. The
default behavior just `listen()`s to the server’s socket. May be overridden.

**SocketServer. server_bind()**
Called by the server’s constructor to bind the socket to the desired address. May be overridden.

**SocketServer. verify_request(request, client_address)**
Must return a Boolean value; if the value is `True`, the request will be processed, and if it’s `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`. 
RequestHandler Objects

The request handler class must define a new handle() method, and can override any of the following methods. A new instance is created for each request.

SocketServer.finish()

Called after the handle() method to perform any clean-up actions required. The default implementation does nothing. If setup() or handle() raise an exception, this function will not be called.

SocketServer.handle()

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as self.request; the client address as self.client_address; and the server instance as self.server, in case it needs access to per-server information.

The type of self.request is different for datagram or stream services. For stream services, self.request is a socket object; for datagram services, self.request is a pair of string and socket. However, this can be hidden by using the request handler subclasses StreamRequestHandler or DatagramRequestHandler, which override the setup() and finish() methods, and provide self.rfile and self.wfile attributes. self.rfile and self.wfile can be read or written, respectively, to get the request data or return data to the client.

SocketServer.setup()

Called before the handle() method to perform any initialization actions required. The default implementation does nothing.
Examples

**SocketServer.TCPServer Example**

This is the server side:

```python
import SocketServer
class MyTCPHandler(SocketServer.BaseRequestHandler):
    """
    The RequestHandler class for our server.

    It is instantiated once per connection to the server, and m
    override the handle() method to implement communication to
    client.
    """
    def handle(self):
        # self.request is the TCP socket connected to the clien
        self.data = self.request.recv(1024).strip()
        print "%s wrote: " % self.client_address[0]
        print self.data
        # just send back the same data, but upper-cased
        self.request.send(self.data.upper())

if __name__ == '__main__':
    HOST, PORT = "localhost", 9999
    # Create the server, binding to localhost on port 9999
    server = SocketServer.TCPServer((HOST, PORT), MyTCPHandler)
    # Activate the server; this will keep running until you
    # interrupt the program with Ctrl-C
    server.serve_forever()
```

An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```python
class MyTCPHandler(SocketServer.StreamRequestHandler):
```
The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `send()` call.

This is the client side:

```python
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

# Connect to server and send data
sock.connect((HOST, PORT))
sock.send(data + "\n")

# Receive data from the server and shut down
received = sock.recv(1024)
sock.close()

print "Sent:   %s" % data
print "Received: %s" % received
```

The output of the example should look something like this:

Server:

```
$ python TCPServer.py
127.0.0.1 wrote:
```
hello world with TCP
127.0.0.1 wrote:
python is nice

Client:

$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE

**SocketServer.UDPServer Example**

This is the server side:

```python
import SocketServer

class MyUDPHandler(SocketServer.BaseRequestHandler):
    ""
    This class works similar to the TCP handler class, except that self.request consists of a pair of data and client socket, and since there is no connection the client address must be given explicitly when sending data back via sendto().
    ""

    def handle(self):
        data = self.request[0].strip()
        socket = self.request[1]
        print "%s wrote:" % self.client_address[0]
        print data
        socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    server = SocketServer.UDPServer((HOST, PORT), BaseUDPRequestHandler)
    server.serve_forever()
```

This is the client side:

```python
import socket
import sys
```
HOST, PORT = "localhost"
data = " ".join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has no connection.
# Instead, data is directly sent to the recipient via sendto().
sock.sendto(data + "\n", (HOST, PORT))
received = sock.recv(1024)

print "Sent: %s" % data
print "Received: %s" % received

The output of the example should look exactly like for the TCP server example.

**Asynchronous Mixins**

To build asynchronous handlers, use the **ThreadingMixIn** and **ForkingMixIn** classes.

An example for the **ThreadingMixIn** class:

```python
import socket
import threading
import SocketServer

class ThreadedTCPRequestHandler(SocketServer.BaseRequestHandler):
    def handle(self):
        data = self.request.recv(1024)
        cur_thread = threading.currentThread()
        response = "%s: %s" % (cur_thread.getName(), data)
        self.request.send(response)

class ThreadedTCPServer(SocketServer.ThreadingMixIn, SocketServer)
pass

def client(ip, port, message):  
    sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)  
    sock.connect((ip, port))
```
sock.send(message)
response = sock.recv(1024)
print "Received: %s" % response
sock.close()

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    ip, port = server.server_address

    # Start a thread with the server -- that thread will then start one
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)
    # Exit the server thread when the main thread terminates
    server_thread.setDaemon(True)
    server_thread.start()
    print "Server loop running in thread: ", t.getName()

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()

The output of the example should look something like this:

$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3

The ForkingMixIn class is used in the same way, except that the server will spawn a new process for each request.
BaseHTTPServer — Basic HTTP server

**Note:** The `BaseHTTPServer` module has been merged into `http.server` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines two classes for implementing HTTP servers (Web servers). Usually, this module isn’t used directly, but is used as a basis for building functioning Web servers. See the `SimpleHTTPServer` and `CGIHTTPServer` modules.

The first class, `HTTPServer`, is a `SocketServer.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=BaseHTTPServer.HTTPServer,
        handler_class=BaseHTTPServer.BaseHTTPRequestHandler):
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

class `BaseHTTPServer.HTTPServer`(`server_address`, `RequestHandlerClass`)  
This class builds on the `TCPServer` class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler’s `server` instance variable.

class `BaseHTTPServer.BaseHTTPRequestHandler`(`request`, `client_address`, `server`)  
This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it
must be subclassed to handle each request method (e.g. GET or POST). BaseHTTPRequestHandler provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method **SPAM**, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

BaseHTTPRequestHandler has the following instance variables:

**client_address**
Contains a tuple of the form `(host, port)` referring to the client's address.

**server**
Contains the server instance.

**command**
Contains the command (request type). For example, `'GET'`.

**path**
Contains the request path.

**request_version**
Contains the version string from the request. For example, `'HTTP/1.0'`.

**headers**
Holds an instance of the class specified by the `MessageClass` class variable. This instance parses and manages the headers in the HTTP request.

**rfile**
Contains an input stream, positioned at the start of the optional input data.

wfile
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream.

BaseHTTPRequestHandler has the following class variables:

server_version
 Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.

sys_version
Contains the Python system version, in a form usable by the version_string method and the server_version class variable. For example, 'Python/1.4'.

error_message_format
 Specifies a format string for building an error response to the client. It uses parenthesized, keyed format specifiers, so the format operand must be a dictionary. The code key should be an integer, specifying the numeric HTTP error code value. message should be a string containing a (detailed) error message of what occurred, and explain should be an explanation of the error code number. Default message and explain values can found in the responses class variable.

error_content_type
Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

New in version 2.6: Previously, the content type was always
protocol_version

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server must then include an accurate Content-Length header (using send_header()) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

MessageClass

Specifies a rfc822.Message-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to mimetools.Message.

responses

This variable contains a mapping of error code integers to two-element tuples containing a short and long message. For example, {code: (shortmessage, longmessage)}. The shortmessage is usually used as the message key in an error response, and longmessage as the explain key (see the error_message_format class variable).

A BaseHTTPRequestHandler instance has the following methods:

handle()

Calls handle_one_request() once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate do_*() methods.

handle_one_request()

This method will parse and dispatch the request to the appropriate do_*() method. You should never need to override it.
send_error\((code[, message])\)
Sends and logs a complete error reply to the client. The numeric \(code\) specifies the HTTP error code, with \(message\) as optional, more specific text. A complete set of headers is sent, followed by text composed using the \error_message_format\ class variable.

send_response\((code[, message])\)
Sends a response header and logs the accepted request. The HTTP response line is sent, followed by \Server\ and \Date\ headers. The values for these two headers are picked up from the \version_string()\ and \date_time_string()\ methods, respectively.

send_header\((keyword, value)\)
Writes a specific HTTP header to the output stream. \(keyword\) should specify the header keyword, with \(value\) specifying its value.

end_headers()
Sends a blank line, indicating the end of the HTTP headers in the response.

log_request\([code[, size]]\)
Logs an accepted (successful) request. \(code\) should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the \(size\) parameter.

log_error(...)
Logs an error when a request cannot be fulfilled. By default, it passes the message to \log_message()\, so it takes the same arguments (\format\ and additional values).

log_message\(format, \ldots\)
Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The _format_ argument is a standard printf-style format string, where the additional arguments to `log_message()` are applied as inputs to the formatting. The client address and current date and time are prefixed to every message logged.

**version_string()**

Returns the server software’s version string. This is a combination of the `server_version` and `sys_version` class variables.

**date_time_string([timestamp])**

Returns the date and time given by `timestamp` (which must be in the format returned by `time.time()`), formatted for a message header. If `timestamp` is omitted, it uses the current date and time.

The result looks like ‘Sun, 06 Nov 1994 08:49:37 GMT’.

*New in version 2.5:* The `timestamp` parameter.

**log_date_time_string()**

Returns the current date and time, formatted for logging.

**address_string()**

Returns the client address, formatted for logging. A name lookup is performed on the client’s IP address.

**See also:**

- **Module CGIHTTPServer**
  
  Extended request handler that supports CGI scripts.

- **Module SimpleHTTPServer**
  
  Basic request handler that limits response to files actually
under the document root.
The `SimpleHTTPServer` module defines a single class, `SimpleHTTPRequestHandler`, which is interface-compatible with `BaseHTTPServer.BaseHTTPRequestHandler`.

The `SimpleHTTPServer` module defines the following class:

```python
class SimpleHTTPServer.SimpleHTTPRequestHandler(request, client_address, server)
```

This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class `BaseHTTPServer.BaseHTTPRequestHandler`. This class implements the `do_GET()` and `do_HEAD()` functions.

The following are defined as class-level attributes of `SimpleHTTPRequestHandler`:

- `server_version`
  
  This will be "SimpleHTTP/" + `__version__`, where `__version__` is defined at the module level.

- `extensions_map`
  
  A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be
application/octet-stream. The mapping is used case-insensitively, and so should contain only lower-cased keys.

The **SimpleHTTPRequestHandler** class defines the following methods:

**do_HEAD()**
This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the **do_GET()** method for a more complete explanation of the possible headers.

**do_GET()**
The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named **index.html** or **index.htm** (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the **list_directory()** method. This method uses **os.listdir()** to scan the directory, and returns a 404 error response if the **listdir()** fails.

If the request was mapped to a file, it is opened and the contents are returned. Any IOError exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the **guess_type()** method, which in turn uses the **extensions_map** variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.
Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file’s MIME type starts with `text/` the file is opened in text mode; otherwise binary mode is used.

For example usage, see the implementation of the `test()` function.

*New in version 2.5:* The `'Last-Modified'` header.

**See also:**

**Module** `BaseHTTPServer`

Base class implementation for Web server and request handler.
The CGIHTTPServer module defines a request-handler class, interface compatible with BaseHTTPServer.BaseHTTPRequestHandler and inherits behavior from SimpleHTTPServer.SimpleHTTPRequestHandler but can also run CGI scripts.

Note: This module can run CGI scripts on Unix and Windows systems.

Note: CGI scripts run by the CGIHTTPRequestHandler class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The CGIHTTPServer module defines the following class:

```
class CGIHTTPServer.CGIHTTPRequestHandler(request, client_address, server)
```

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in SimpleHTTPServer.SimpleHTTPRequestHandler.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat...
special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The `CGIHTTPRequestHandler` defines the following data member:

`cgi_directories`

This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

The `CGIHTTPRequestHandler` defines the following methods:

`do_POST()`

This method serves the `'POST'` request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

For example usage, see the implementation of the `test()` function.

See also:

**Module** BaseHTTPServer

Base class implementation for Web server and request handler.
**cookielib — Cookie handling for HTTP clients**

**Note:** The *cookielib* module has been renamed to *http.cookiejar* in Python 3.0. The *2to3* tool will automatically adapt imports when converting your sources to 3.0.

*New in version 2.4.*

The *cookielib* module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by *RFC 2965* are handled. RFC 2965 handling is switched off by default. *RFC 2109* cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the ‘policy’ in effect. Note that the great majority of cookies on the Internet are Netscape cookies. *cookielib* attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the *max-age* and *port* cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in *Set-Cookie* and *Set-Cookie2* headers (eg. *domain* and *expires*) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.
The module defines the following exception:

exception `cookielib.LoadError`

Instances of `FileCookieJar` raise this exception on failure to load cookies from a file.

**Note:** For backwards-compatibility with Python 2.4 (which raised an `IOError`), `LoadError` is a subclass of `IOError`.

The following classes are provided:

**class** `cookielib.CookieJar(policy=None)`

*`policy`* is an object implementing the `CookiePolicy` interface.

The `CookieJar` class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. `CookieJar` instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

**class** `cookielib.FileCookieJar(filename, delayload=None, policy=None)`

*`policy`* is an object implementing the `CookiePolicy` interface. For the other arguments, see the documentation for the corresponding attributes.

A `CookieJar` which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are **NOT** loaded from the named file until either the `load()` or `revert()` method is called. Subclasses of this class are documented in section `FileCookieJar subclasses and co-operation with web browsers`.

**class** `cookielib.CookiePolicy`

This class is responsible for deciding whether each cookie should
be accepted from / returned to the server.

class cookielib.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)

Constructor arguments should be passed as keyword arguments only. blocked_domains is a sequence of domain names that we never accept cookies from, nor return cookies to. allowed_domains if not None, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for CookiePolicy and DefaultCookiePolicy objects.

DefaultCookiePolicy implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or rfc2109_as_netscape is True, RFC 2109 cookies are ‘downgraded’ by the CookieJar instance to Netscape cookies, by setting the version attribute of the Cookie instance to 0. DefaultCookiePolicy also provides some parameters to allow some fine-tuning of policy.

class cookielib.Cookie

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of cookielib construct their own Cookie instances. Instead, if necessary, call make_cookies() on a CookieJar instance.
See also:

**Module urllib2**

URL opening with automatic cookie handling.

**Module Cookie**

HTTP cookie classes, principally useful for server-side code. The `cookielib` and `Cookie` modules do not depend on each other.

[http://wwwsearch.sf.net/ClientCookie/](http://wwwsearch.sf.net/ClientCookie/)

Extensions to this module, including a class for reading Microsoft Internet Explorer cookies on Windows.

The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and `cookielib`) only bears a passing resemblance to the one sketched out in `cookie_spec.html`.

**RFC 2109 - HTTP State Management Mechanism**

Obsoleted by RFC 2965. Uses `Set-Cookie` with version=1.

**RFC 2965 - HTTP State Management Mechanism**

The Netscape protocol with the bugs fixed. Uses `Set-Cookie2` in place of `Set-Cookie`. Not widely used.

[http://kristol.org/cookie/errata.html](http://kristol.org/cookie/errata.html)

Unfinished errata to RFC 2965.

**RFC 2964 - Use of HTTP State Management**
CookieJar and FileCookieJar Objects

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.add_cookie_header(request)
Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar's CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The request object (usually a urllib2.Request instance) must support the methods get_full_url(), get_host(), get_type(), unverifiable(), get_origin_req_host(), has_header(), get_header(), header_items(), and add_unredirected_header(), as documented by urllib2.

CookieJar.extract_cookies(response, request)
Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-Cookie2 headers in the response argument, and store cookies as appropriate (subject to the CookiePolicy.set_ok() method's approval).

The response object (usually the result of a call to urllib2.urlopen(), or similar) should support an info() method,
which returns an object with a `getallmatchingheaders()` method (usually a `mimetypes.Message` instance).

The `request` object (usually a `urllib2.Request` instance) must support the methods `get_full_url()`, `get_host()`, `unverifiable()`, and `get_origin_req_host()`, as documented by `urllib2`. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

```python
CookieJar.set_policy(policy)
```

Set the `CookiePolicy` instance to be used.

```python
CookieJar.make_cookies(response, request)
```

Return sequence of `Cookie` objects extracted from `response` object.

See the documentation for `extract_cookies()` for the interfaces required of the `response` and `request` arguments.

```python
CookieJar.set_cookie_if_ok(cookie, request)
```

Set a `Cookie` if policy says it's OK to do so.

```python
CookieJar.set_cookie(cookie)
```

Set a `Cookie`, without checking with policy to see whether or not it should be set.

```python
CookieJar.clear([domain[, path[, name]]])
```

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that `domain` will be removed. If given two arguments, cookies belonging to the specified `domain` and URL `path` are removed. If given three arguments,
then the cookie with the specified domain, path and name is removed.

Raises KeyError if no matching cookie exists.

CookieJar.clear_session_cookies()
Discard all session cookies.

Discards all contained cookies that have a true discard attribute (usually because they had either no max-age or expires cookie-attribute, or an explicit discard cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the save() method won’t save session cookies anyway, unless you ask otherwise by passing a true ignore_discard argument.

FileCookieJar implements the following additional methods:

FileCookieJar.save(filename=None, ignore_discard=False, ignore_expires=False)
Save cookies to a file.

This base class raises NotImplementedError. Subclasses may leave this method unimplemented.

filename is the name of file in which to save cookies. If filename is not specified, self.filename is used (whose default is the value passed to the constructor, if any); if self.filename is None, ValueError is raised.

ignore_discard: save even cookies set to be discarded.
ignore_expires: save even cookies that have expired
The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the `load()` or `revert()` methods.

FileCookieJar.load(filename=None, ignore_discard=False, ignore_expires=False)

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for `save()`.

The named file must be in the format understood by the class, or `LoadError` will be raised. Also, `IOError` may be raised, for example if the file does not exist.

**Note:** For backwards-compatibility with Python 2.4 (which raised an `IOError`), `LoadError` is a subclass of `IOError`.

FileCookieJar.revert(filename=None, ignore_discard=False, ignore_expires=False)

Clear all cookies and reload cookies from a saved file.

`revert()` can raise the same exceptions as `load()`. If there is a failure, the object's state will not be altered.

**FileCookieJar** instances have the following public attributes:

FileCookieJar.filename

Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayLoad

If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects
performance, not behaviour (unless the cookies on disk are changing). A `CookieJar` object may ignore it. None of the `FileCookieJar` classes included in the standard library lazily loads cookies.
FileCookieJar subclasses and co-operation with web browsers

The following CookieJar subclasses are provided for reading and writing. Further CookieJar subclasses, including one that reads Microsoft Internet Explorer cookies, are available at http://wwwsearch.sf.net/ClientCookie/.

class cookielib.MozillaCookieJar(filename, delayload=None, policy=None)

A FileCookieJar that can load from and save cookies to disk in the Mozilla cookies.txt file format (which is also used by the Lynx and Netscape browsers).

Note: This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as port.

Warning: Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

class cookielib.LWPCookieJar(filename, delayload=None, policy=None)

A FileCookieJar that can load from and save cookies to disk in format compatible with the libwww-perl library’s Set-Cookie3 file format. This is convenient if you want to store cookies in a human-readable file.
CookiePolicy Objects

Objects implementing the CookiePolicy interface have the following methods:

CookiePolicy.set_ok(cookie, request)
   Return boolean value indicating whether cookie should be accepted from server.

   cookie is a cookielib.Cookie instance. request is an object implementing the interface defined by the documentation for CookieJar.extract_cookies().

CookiePolicy.return_ok(cookie, request)
   Return boolean value indicating whether cookie should be returned to server.

   cookie is a cookielib.Cookie instance. request is an object implementing the interface defined by the documentation for CookieJar.add_cookie_header().

CookiePolicy.domain_return_ok(domain, request)
   Return false if cookies should not be returned, given cookie domain.

   This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from domain_return_ok() and path_return_ok() leaves all the work to return_ok().

   If domain_return_ok() returns true for the cookie domain, path_return_ok() is called for the cookie path. Otherwise, path_return_ok() and return_ok() are never called for that
cookie domain. If `path_return_ok()` returns true, `return_ok()` is called with the `Cookie` object itself for a full check. Otherwise, `return_ok()` is never called for that cookie path.

Note that `domain_return_ok()` is called for every `cookie` domain, not just for the `request` domain. For example, the function might be called with both "example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for `path_return_ok()`.

The `request` argument is as documented for `return_ok()`.

`CookiePolicy.path_return_ok(path, request)`

Return false if cookies should not be returned, given cookie path.

See the documentation for `domain_return_ok()`.

In addition to implementing the methods above, implementations of the `CookiePolicy` interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

`CookiePolicy.netscape`

Implement Netscape protocol.

`CookiePolicy.rfc2965`

Implement RFC 2965 protocol.

`CookiePolicy.hide_cookie2`

Don’t add `Cookie2` header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).

The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of
the methods above. CookiePolicy itself may be used as a ‘null policy’ to allow setting and receiving any and all cookies (this is unlikely to be useful).
DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import cookielib

class MyCookiePolicy(cookielib.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not cookielib.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the CookiePolicy interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the blocked_domains constructor argument, and blocked_domains() and set_blocked_domains() methods (and the corresponding argument and methods for allowed_domains). If you set a whitelist, you can turn it off again by setting it to None.
Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.blocked_domains()
    Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.set_blocked_domains(blocked_domains)
    Set the sequence of blocked domains.

DefaultCookiePolicy.is_blocked(domain)
    Return whether domain is on the blacklist for setting or receiving cookies.

DefaultCookiePolicy.allowed_domains()
    Return None, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.set_allowed_domains(allowed_domains)
    Set the sequence of allowed domains, or None.

DefaultCookiePolicy.is_not_allowed(domain)
    Return whether domain is not on the whitelist for setting or receiving cookies.

DefaultCookiePolicy instances have the following attributes, which are all initialised from the constructor arguments of the same name,
and which may all be assigned to.

DefaultCookiePolicy. **rfc2109_as_netscape**

If true, request that the CookieJar instance downgrade RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the Cookie instance to 0. The default value is **None**, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

*New in version 2.5.*

General strictness switches:

DefaultCookiePolicy. **strict_domain**

Don't allow sites to set two-component domains with country-code top-level domains like .co.uk, .gov.uk, .co.nz etc. This is far from perfect and isn't guaranteed to work!

RFC 2965 protocol strictness switches:

DefaultCookiePolicy. **strict_rfc2965_unverifiable**

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are never blocked on the basis of verifiability

Netscape protocol strictness switches:

DefaultCookiePolicy. **strict_ns_unverifiable**

apply RFC 2965 rules on unverifiable transactions even to Netscape cookies

DefaultCookiePolicy. **strict_ns_domain**

Flags indicating how strict to be with domain-matching rules for
Netscape cookies. See below for acceptable values.

DefaultCookiePolicy. **strict_ns_set_initial_dollar**

Ignore cookies in Set-Cookie: headers that have names starting with `$`.

DefaultCookiePolicy. **strict_ns_set_path**

Don’t allow setting cookies whose path doesn’t path-match request URI.

**strict_ns_domain** is a collection of flags. Its value is constructed by or-ing together (for example, `DomainStrictNoDots|DomainStrictNonDomain` means both flags are set).

DefaultCookiePolicy. **DomainStrictNoDots**

When setting cookies, the ‘host prefix’ must not contain a dot (eg. www.foo.bar.com can’t set a cookie for .bar.com, because www.foo contains a dot).

DefaultCookiePolicy. **DomainStrictNonDomain**

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. spam.example.com won’t be returned cookies from example.com that had no domain cookie-attribute).

DefaultCookiePolicy. **DomainRFC2965Match**

When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy. **DomainLiberal**

Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).
DefaultCookiePolicy. **DomainStrict**

Equivalent to `DomainStrictNoDots|DomainStrictNonDomain`. 
Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by cookielib from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie. version
   Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that cookielib may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie. name
   Cookie name (a string).

Cookie. value
   Cookie value (a string), or None.

Cookie. port
   String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie. path
   Cookie path (a string, eg. '/acme/rocket_launchers').
Cookie. **secure**
  True if cookie should only be returned over a secure connection.

Cookie. **expires**
  Integer expiry date in seconds since epoch, or None. See also the `is_expired()` method.

Cookie. **discard**
  True if this is a session cookie.

Cookie. **comment**
  String comment from the server explaining the function of this cookie, or None.

Cookie. **comment_url**
  URL linking to a comment from the server explaining the function of this cookie, or None.

Cookie. **rfc2109**
  True if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a `Set-Cookie` header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because cookielib may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

    *New in version 2.5.*

Cookie. **port_specified**
  True if a port or set of ports was explicitly specified by the server (in the `Set-Cookie / Set-Cookie2` header).

Cookie. **domain_specified**
  True if a domain was explicitly specified by the server.

Cookie. **domain_initial_dot**
  True if the domain explicitly specified by the server began with a
Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

**Cookie.** `has_nonstandard_attr(name)`
- Return true if cookie has the named cookie-attribute.

**Cookie.** `get_nonstandard_attr(name, default=None)`
- If cookie has the named cookie-attribute, return its value. Otherwise, return `default`.

**Cookie.** `set_nonstandard_attr(name, value)`
- Set the value of the named cookie-attribute.

The **Cookie** class also defines the following method:

**Cookie.** `is_expired([now=const:`None`])`
- True if cookie has passed the time at which the server requested it should expire. If `now` is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
Examples

The first example shows the most common usage of `cookiejar`

```python
import cookielib, urllib2
cj = cookielib.CookieJar()
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, cookielib, urllib2
cj = cookielib.MozillaCookieJar()
cj.load(os.path.join(os.environ["HOME"], ".netscape/cookies.txt")
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```python
import urllib2
from cookielib import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStrict,
    blocked_domains=["ads.net", ".ads.net"])
cj = CookieJar(policy)
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```
Note: The Cookie module has been renamed to http.cookies in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

The Cookie module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the RFC 2109 and RFC 2068 specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs. As a result, the parsing rules used are a bit less strict.

Note: On encountering an invalid cookie, CookieError is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch CookieError on parsing.

exception Cookie.CookieError
    Exception failing because of RFC 2109 invalidity: incorrect attributes, incorrect Set-Cookie header, etc.

class Cookie.BaseCookie([input])
    This class is a dictionary-like object whose keys are strings and whose values are Morsel instances. Note that upon setting a key to a value, the value is first converted to a Morsel containing the key and the value.

    If input is given, it is passed to the load() method.
class Cookie. SimpleCookie([input])

This class derives from BaseCookie and overrides value_decode() and value_encode() to be the identity and str() respectively.

class Cookie. SerialCookie([input])

This class derives from BaseCookie and overrides value_decode() and value_encode() to be the pickle.loads() and pickle.dumps().

Deprecation warning: Since version 2.3: Reading pickled values from untrusted cookie data is a huge security hole, as pickle strings can be crafted to cause arbitrary code to execute on your server. It is supported for backwards compatibility only, and may eventually go away.

class Cookie. SmartCookie([input])

This class derives from BaseCookie. It overrides value_decode() to be pickle.loads() if it is a valid pickle, and otherwise the value itself. It overrides value_encode() to be pickle.dumps() unless it is a string, in which case it returns the value itself.

Deprecation warning: Since version 2.3: The same security warning from SerialCookie applies here.

A further security note is warranted. For backwards compatibility, the Cookie module exports a class named cookie which is just an alias for SmartCookie. This is probably a mistake and will likely be removed in a future version. You should not use the Cookie class in your applications, for the same reason why you should not use the SerialCookie class.

See also:
Module **cookielib**

HTTP cookie handling for web clients. The **cookielib** and **Cookie** modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**

This is the state management specification implemented by this module.
**Cookie Objects**

`BaseCookie.value_decode(val)`

Return a decoded value from a string representation. Return value can be any type. This method does nothing in `BaseCookie` — it exists so it can be overridden.

`BaseCookie.value_encode(val)`

Return an encoded value. `val` can be any type, but return value must be a string. This method does nothing in `BaseCookie` — it exists so it can be overridden.

In general, it should be the case that `value_encode()` and `value_decode()` are inverses on the range of `value_decode`.

`BaseCookie.output([attrs[, header[, sep]]])`  

Return a string representation suitable to be sent as HTTP headers. `attrs` and `header` are sent to each `Morsel's output()` method. `sep` is used to join the headers together, and is by default the combination `'
'` (CRLF).

*Changed in version 2.5:* The default separator has been changed from `'
'` to match the cookie specification.

`BaseCookie.js_output([attrs])`

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for `attrs` is the same as in `output()`.

`BaseCookie.load(rawdata)`
If `rawdata` is a string, parse it as an `HTTP_COOKIE` and add the values found there as `Morsels`. If it is a dictionary, it is equivalent to:

```python
for k, v in rawdata.items():
    cookie[k] = v
```
class Cookie.Morsel

Abstract a key/value pair, which has some RFC 2109 attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

- `expires`
- `path`
- `comment`
- `domain`
- `max-age`
- `secure`
- `version`
- `httponly`

The attribute `httponly` specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive.

*New in version 2.6:* The `httponly` attribute was added.

Morsel.value

The value of the cookie.

Morsel.coded_value

The encoded value of the cookie — this is what should be sent.

Morsel.key

The name of the cookie.
Morsel.set(key, value, coded_value)
Set the key, value and coded_value members.

Morsel.isReservedKey(K)
Whether K is a member of the set of keys of a Morsel.

Morsel.output([attrs[, header]])
Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless attrs is given, in which case it should be a list of attributes to use. header is by default "Set-Cookie:"

Morsel.js_output([attrs])
Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for attrs is the same as in output().

Morsel.OutputString([attrs])
Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for attrs is the same as in output().
The following example demonstrates how to use the `Cookie` module.

```python
>>> import Cookie
>>> C = Cookie.SimpleCookie()
>>> C = Cookie.SerialCookie()
>>> C = Cookie.SmartCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print C  # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer

>>> print C.output()  # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer

>>> C = Cookie.SmartCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]['path'] = "/cookie"
>>> print C.output(header="Cookie:")
Cookie: rocky=road; Path=/cookie

>>> C = Cookie.SmartCookie()
>>> C.load("chips=ahoy; vienna=finger")  # load from a string (HTTP header)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger

>>> C = Cookie.SmartCookie()
>>> C.load('keebler="E=everybody; L="Loves"; fudge=\012;"')
Set-Cookie: keebler=E=everybody; L=\"Loves\"; fudge=\012;

>>> C = Cookie.SmartCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]['path'] = "/"
>>> print C
Set-Cookie: oreo=doublestuff; Path=/

>>> C = Cookie.SmartCookie()
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'

>>> C = Cookie.SimpleCookie()
>>> C["number"] = 7  # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
```
>>> C["string"]).value
'seven'
>>> print C
Set-Cookie: number=7
Set-Cookie: string=seven
>>> C = Cookie.SerialCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number"]).value
7
>>> C["string"]).value
'seven'
>>> print C
Set-Cookie: number="I7\012.
Set-Cookie: string="S\'seven\'\012p1\012."
>>> C = Cookie.SmartCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number"]).value
7
>>> C["string"]).value
'seven'
>>> print C
Set-Cookie: number=I7\012.
Set-Cookie: string=seven
Set-Cookie: string=seven
Set-Cookie: string=seven
Set-Cookie: string=seven
xmlrpclib — XML-RPC client access

Note: The xmlrpclib module has been renamed to xmlrpc.client in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

New in version 2.2.

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

class xmlrpclib.ServerProxy(uri[, transport[, encoding[, verbose[, allow_none[, use_datetime]]]]])

A ServerProxy instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal SafeTransport instance for https: URLs and an internal HTTP Transport instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag. If allow_none is true, the Python constant None will be translated into XML; the default behaviour is for None to raise a TypeError. This is a commonly-used extension to the XML-RPC specification, but isn’t supported by all clients and servers; see http://ontosys.com/xml-rpc/extensions.php for a description. The use_datetime flag can be used to cause date/time values to be presented as
**datetime.datetime** objects; this is false by default. **datetime.datetime** objects may be passed to calls.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: `http://user:pass@host:port/path`. The `user:pass` portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

**ServerProxy** instance methods take Python basic types and objects as arguments and return Python basic types and classes. Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>boolean</code></td>
<td>The <code>True</code> and <code>False</code> constants</td>
</tr>
<tr>
<td><code>integers</code></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><code>floating-point numbers</code></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><code>strings</code></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><code>arrays</code></td>
<td>Any Python sequence type containing conformable elements. Arrays are returned as lists</td>
</tr>
<tr>
<td></td>
<td>A Python dictionary. Keys must be</td>
</tr>
<tr>
<td>structures</td>
<td>strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <strong>dict</strong> attribute is transmitted.</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>dates</td>
<td>in seconds since the epoch (pass in an instance of the DateTime class) or a <code>datetime.datetime</code> instance.</td>
</tr>
<tr>
<td>binary data</td>
<td>pass in an instance of the Binary wrapper class</td>
</tr>
</tbody>
</table>

This is the full set of data types supported by XML-RPC. Method calls may also raise a special Fault instance, used to signal XML-RPC server errors, or ProtocolError used to signal an error in the HTTP/HTTPS transport layer. Both Fault and ProtocolError derive from a base class called Error. Note that even though starting with Python 2.2 you can subclass builtin types, the xmlrpclib module currently does not marshal instances of such subclasses.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it’s the caller’s responsibility to ensure that the string is free of characters that aren’t allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn’t well-formed XML. If you have to pass arbitrary strings via XML-RPC, use the Binary wrapper class described below.

Server is retained as an alias for ServerProxy for backwards compatibility. New code should use ServerProxy.

Changed in version 2.5: The use_datetime flag was added.
Changed in version 2.6: Instances of new-style classes can be passed in if they have an \_\_dict\_ attribute and don’t have a base class that is marshalled in a special way.

**XML-RPC HOWTO**
A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

**XML-RPC Introspection**
Describes the XML-RPC protocol extension for introspection.

**XML-RPC Specification**
The official specification.

**Unofficial XML-RPC Errata**
Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best practices’ to use when designing your own XML-RPC implementations.”
**ServerProxy Objects**

A **ServerProxy** instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a **Fault** or **ProtocolError** object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved `system` member:

**ServerProxy.system.listMethods()**

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

**ServerProxy.system.methodSignature(name)**

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”. 
If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than a list.

ServerProxy.system.<code>methodHelp(name)</code>

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.
**Boolean Objects**

This class may be initialized from any Python value; the instance returned depends only on its truth value. It supports various Python operators through `__cmp__()`, `__repr__()`, `__int__()`, and `__nonzero__()` methods, all implemented in the obvious ways.

It also has the following method, supported mainly for internal use by the unmarshalling code:

```
Boolean.encode(out)
```

Write the XML-RPC encoding of this Boolean item to the output stream object.

A working example follows. The server code:

```python
import xmlrpclib
from SimpleXMLRPCServer import SimpleXMLRPCServer

def is_even(n):
    return n%2 == 0

server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/"
print "3 is even: %s" % str(proxy.is_even(3))
print "100 is even: %s" % str(proxy.is_even(100))
```
DateTime Objects

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8001 time/date string, or a `datetime.datetime` instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

- `DateTime.decode(string)`
  Accept a string as the instance’s new time value.

- `DateTime.encode(out)`
  Write the XML-RPC encoding of this `DateTime` item to the `out` stream object.

It also supports certain of Python’s built-in operators through `__cmp__()` and `__repr__()` methods.

A working example follows. The server code:

```python
import datetime
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib

def today():
    today = datetime.datetime.today()
    return xmlrpclib.DateTime(today)

server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib
import datetime

proxy = xmlrpclib.ServerProxy("http://localhost:8000/"")
```
today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, "%Y%m%dT%H:")
print "Today: %s" % converted.strftime("%d.%m.%Y, %H:%M")
Binary Objects

This class may be initialized from string data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

Binary.data

The binary data encapsulated by the Binary instance. The data is provided as an 8-bit string.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

Binary.decode(string)

Accept a base64 string and decode it as the instance’s new data.

Binary.encode(out)

Write the XML-RPC base 64 encoding of this binary item to the out stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python’s built-in operators through a __cmp__() method.

Example usage of the binary objects. We’re going to transfer an image over XMLRPC:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib

def python_logo():
    handle = open("python_logo.jpg")
    return xmlrpclib.Binary(handle.read())
```
handle.close()

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(python_logo, 'python_logo')
server.serve_forever()

The client gets the image and saves it to a file:

```python
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
handle = open("fetched_python_logo.jpg", "w")
handle.write(proxy.python_logo().data)
handle.close()
```
Fault Objects

A Fault object encapsulates the content of an XML-RPC fault tag. Fault objects have the following members:

**Fault. faultCode**
A string indicating the fault type.

**Fault. faultString**
A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a Fault by returning a complex type object. The server code:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning
# complex number
def add(x, y):
    return x + y + 0j

server = SimpleXMLRPCServer(('localhost', 8000))
print 'Listening on port 8000...' 
server.register_function(add, 'add')
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
try:
    proxy.add(2, 5)
except xmlrpclib.Fault, err:
    print "A fault occurred"
    print "Fault code: %d" % err.faultCode
    print "Fault string: %s" % err.faultString
```
A `ProtocolError` object describes a protocol error in the underlying transport layer (such as a 404 ‘not found’ error if the server named by the URI does not exist). It has the following members:

`ProtocolError.url`  
The URI or URL that triggered the error.

`ProtocolError.errcode`  
The error code.

`ProtocolError.errmsg`  
The error message or diagnostic string.

`ProtocolError.headers`  
A string containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we're going to intentionally cause a `ProtocolError` by providing an invalid URI:

```python
import xmlrpclib

# create a ServerProxy with an invalid URI
proxy = xmlrpclib.ServerProxy("http://invalidaddress/")

try:
    proxy.some_method()
except xmlrpclib.ProtocolError, err:
    print "A protocol error occurred"
    print "URL: %s" % err.url
    print "HTTP/HTTPS headers: %s" % err.headers
    print "Error code: %d" % err.errcode
    print "Error message: %s" % err.errmsg
```
MultiCall Objects

New in version 2.4.

In http://www.xmlrpc.com/discuss/msgReader%241208, an approach is presented to encapsulate multiple calls to a remote server into a single request.

class xmlrpclib.MultiCall(server)

Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.

A usage example of this class follows. The server code

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer

def add(x,y):
    return x+y

def subtract(x, y):
    return x-y

def multiply(x, y):
    return x*y

def divide(x, y):
    return x/y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_multicall_functions()
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
```
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()

The client code for the preceding server:

```python
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
multicall = xmlrpclib.MultiCall(proxy)
multicall.add(7,3)
multicall.subtract(7,3)
multicall.multiply(7,3)
multicall.divide(7,3)
result = multicall()

print "7+3=%d, 7-3=%d, 7*3=%d, 7/3=%d" % tuple(result)
```
**Convenience Functions**

```python
def boolean(value):
    # Convert any Python value to one of the XML-RPC Boolean constants, True or False.
```

```python
def dumps(params, methodname=None, methodresponse=None, encoding=None, allow_none=None):
    # Convert params into an XML-RPC request. or into a response if methodresponse is true. params can be either a tuple of arguments or an instance of the Fault exception class. If methodresponse is true, only a single value can be returned, meaning that params must be of length 1. encoding, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python's None value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for allow_none.
```

```python
def loads(data, use_datetime=None):
    # Convert an XML-RPC request or response into Python objects, a (params, methodname). params is a tuple of argument; methodname is a string, or None if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a Fault exception. The use_datetime flag can be used to cause date/time values to be presented as datetime.datetime objects; this is false by default.
```

*Changed in version 2.5:* The use_datetime flag was added.
Example of Client Usage

```
# simple test program (from the XML-RPC specification)
from xmlrpclib import ServerProxy, Error

# server = ServerProxy("http://localhost:8000")  # local server
server = ServerProxy("http://betty.userland.com")

print server

try:
    print server.examples.getStateName(41)
except Error, v:
    print "ERROR", v
```

To access an XML-RPC server through a proxy, you need to define a custom transport. The following example shows how:

```
import xmlrpclib, httplib

class ProxiedTransport(xmlrpclib.Transport):
    def set_proxy(self, proxy):
        self.proxy = proxy
    def make_connection(self, host):
        self.realhost = host
        h = httplib.HTTP(self.proxy)
        return h
    def send_request(self, connection, handler, request_body):
        connection.putrequest("POST", 'http://%s%s' % (self.realhost, handler))
        connection.putheader('Host', self.realhost)
        p = ProxiedTransport()
    p.set_proxy('proxy-server:8080')
    print server.currentTime.getCurrentTime()
```
Example of Client and Server Usage

See *SimpleXMLRPCServer Example*. 
SimpleXMLRPCServer — Basic XML-RPC server

Note: The SimpleXMLRPCServer module has been merged into xmlrpc.server in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

New in version 2.2.

The SimpleXMLRPCServer module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using SimpleXMLRPCServer, or embedded in a CGI environment, using CGIXMLRPCRequestHandler.

class SimpleXMLRPCServer.

SimpleXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding]]]])

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The requestHandler parameter should be a factory for request handler instances; it defaults to SimpleXMLRPCRequestHandler. The addr and requestHandler parameters are passed to the SocketServer.TCPServer constructor. If logRequests is true (the default), requests will be logged; setting this parameter to false will turn off logging. The allow_none and encoding parameters are passed on to xmlrpclib and control the XML-RPC responses that will be returned from the server. The bind_and_activate parameter controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound.
Changed in version 2.5: The allow_none and encoding parameters were added.

Changed in version 2.6: The bind_and_activate parameter was added.

class SimpleXMLRPCServer.CGIXMLRPCRequestHandler([allow_none[,
encoding]])

Create a new instance to handle XML-RPC requests in a CGI environment. The allow_none and encoding parameters are passed on to xmlrpclib and control the XML-RPC responses that will be returned from the server.

New in version 2.3.

Changed in version 2.5: The allow_none and encoding parameters were added.

class SimpleXMLRPCServer.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the logRequests parameter to the SimpleXMLRPCServer constructor parameter is honored.
SimpleXMLRPCServer Objects

The SimpleXMLRPCServer class is based on SocketServer.TCPServer and provides a means of creating simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.register_function(function[, name])
Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

SimpleXMLRPCServer.register_instance(instance[, allow_dotted_names])
Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request. Its API is def _dispatch(self, method, params) (note that params does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as func(*params), expanding the parameter list. The return value from _dispatch() is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method.

If the optional allow_dotted_names argument is true and the instance does not have a _dispatch() method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that
a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the `allow_dotted_names` option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

*Changed in version 2.3.5,: 2.4.1* `allow_dotted_names` was added to plug a security hole; prior versions are insecure.

**SimpleXMLRPCServer.** `register_introspection_functions()`  
Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.  
*New in version 2.3.*

**SimpleXMLRPCServer.** `register_multicall_functions()`  
Registers the XML-RPC multicall function `system.multicall`.

**SimpleXMLRPCRequestHandler.** `rpc_paths`  
An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 "no such page" HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.  
*New in version 2.5.*

**SimpleXMLRPCServer Example**

Server code:
from SimpleXMLRPCServer import SimpleXMLRPCServer
from SimpleXMLRPCServer import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
server = SimpleXMLRPCServer(('localhost', 8000),
                             requestHandler=RequestHandler)
server.register_introspection_functions()

# Register pow() function; this will use the value of
# pow.__name__ as the name, which is just 'pow'.
server.register_function(pow)

# Register a function under a different name
def adder_function(x, y):
    return x + y
server.register_function(adder_function, 'add')

# Register an instance; all the methods of the instance are
# published as XML-RPC methods (in this case, just 'div').
class MyFuncs:
    def div(self, x, y):
        return x // y
server.register_instance(MyFuncs())

# Run the server's main loop
server.serve_forever()

The following client code will call the methods made available by the preceding server:

import xmlrpclib
s = xmlrpclib.ServerProxy('http://localhost:8000')
print s.pow(2, 3)  # Returns 2**3 = 8
print s.add(2, 3)  # Returns 5
print s.div(5, 2)  # Returns 5//2 = 2

# Print list of available methods
print s.system.listMethods()
The `CGIXMLRPCRequestHandler` class can be used to handle XML-RPC requests sent to Python CGI scripts.

`CGIXMLRPCRequestHandler.register_function(function[, name])`

Register a function that can respond to XML-RPC requests. If `name` is given, it will be the method name associated with function, otherwise `function.__name__` will be used. `name` can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

`CGIXMLRPCRequestHandler.register_instance(instance)`

Register an object which is used to expose method names which have not been registered using `register_function()`. If instance contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

`CGIXMLRPCRequestHandler.register_introspection_functions()`

Register the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

`CGIXMLRPCRequestHandler.register_multicall_functions()`
Register the XML-RPC multicall function `system.multicall`.

CGIXMLRPCRequestHandler.**handle_request**([`request_text = None`])

Handle a XML-RPC request. If `request_text` is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

```python
class MyFuncs:
    def div(self, x, y) : return x // y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```
DocXMLRPCServer — Self-documenting XML-RPC server

Note: The DocXMLRPCServer module has been merged into xmlrpc.server in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

New in version 2.3.

The DocXMLRPCServer module extends the classes found in SimpleXMLRPCServer to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using DocXMLRPCServer, or embedded in a CGI environment, using DocCGIXMLRPCRequestHandler.

class DocXMLRPCServer. DocXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding[, bind_and_activate]]]]]])

Create a new server instance. All parameters have the same meaning as for SimpleXMLRPCServer.SimpleXMLRPCServer; requestHandler defaults to DocXMLRPCRequestHandler.

class DocXMLRPCServer. DocCGIXMLRPCRequestHandler

Create a new instance to handle XML-RPC requests in a CGI environment.

class DocXMLRPCServer. DocXMLRPCRequestHandler

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the logRequests parameter to the DocXMLRPCServer constructor parameter is honored.
DocXMLRPCServer Objects

The `DocXMLRPCServer` class is derived from `SimpleXMLRPCServer.SimpleXMLRPCServer` and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

`DocXMLRPCServer.set_server_title(server_title)`

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

`DocXMLRPCServer.set_server_name(server_name)`

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

`DocXMLRPCServer.set_server_documentation(server_documentation)`

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
The `DocCGIXMLRPCRequestHandler` class is derived from `SimpleXMLRPCServer.CGIXMLRPCRequestHandler` and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

`DocCGIXMLRPCRequestHandler.set_server_title(server_title)`
Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

`DocCGIXMLRPCRequestHandler.set_server_name(server_name)`
Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

`DocCGIXMLRPCRequestHandler.set_server_documentation(server_doc)`
Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **audioop** — Manipulate raw audio data
- **imageop** — Manipulate raw image data
- **aifc** — Read and write AIFF and AIFC files
- **sunau** — Read and write Sun AU files
  - AU_read Objects
  - AU_write Objects
- **wave** — Read and write WAV files
  - Wave_read Objects
  - Wave_write Objects
- **chunk** — Read IFF chunked data
- **colorsys** — Conversions between color systems
- **imghdr** — Determine the type of an image
- **sndhdr** — Determine type of sound file
- **ossaudiodev** — Access to OSS-compatible audio devices
  - Audio Device Objects
  - Mixer Device Objects
The `audioop` module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16 or 32 bits wide, stored in Python strings. This is the same format as used by the `al` and `sunaudiodev` modules. All scalar items are integers, unless specified otherwise.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

- **exception audioop.error**
  
  This exception is raised on all errors, such as unknown number of bytes per sample, etc.

- **audioop.add(fragment1, fragment2, width)**
  
  Return a fragment which is the addition of the two samples passed as parameters. `width` is the sample width in bytes, either 1, 2 or 4. Both fragments should have the same length.

- **audioop.adpcm2lin(adpcmfragment, width, state)**
  
  Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of `lin2adpcm()` for details on ADPCM coding. Return a tuple `(sample, newstate)` where the sample has the width specified in `width`. 
audioop. `alaw2lin(fragment, width)`

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so `width` refers only to the sample width of the output fragment here.

*New in version 2.5.*

audioop. `avg(fragment, width)`

Return the average over all samples in the fragment.

audioop. `avgpp(fragment, width)`

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop. `bias(fragment, width, bias)`

Return a fragment that is the original fragment with a bias added to each sample.

audioop. `cross(fragment, width)`

Return the number of zero crossings in the fragment passed as an argument.

audioop. `findfactor(fragment, reference)`

Return a factor $F$ such that $\text{rms}(\text{add(fragment, mul(reference, -F))})$ is minimal, i.e., return the factor with which you should multiply `reference` to make it match as well as possible to `fragment`. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to `len(fragment)`.

audioop. `findfit(fragment, reference)`

Try to match `reference` as well as possible to a portion of `fragment` (which should be the longer fragment). This is
(conceptually) done by taking slices out of `fragment`, using `findfactor()` to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple `(offset, factor)` where `offset` is the (integer) offset into `fragment` where the optimal match started and `factor` is the (floating-point) factor as per `findfactor()`.

`audioop.findmax(fragment, length)`

Search `fragment` for a slice of length `length` samples (not bytes!) with maximum energy, i.e., return `i` for which `rms(fragment[i*2: (i+length)*2])` is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to `len(fragment)`.

`audioop.getsample(fragment, width, index)`

Return the value of sample `index` from the fragment.

`audioop.lin2adpcm(fragment, width, state)`

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

`state` is a tuple containing the state of the coder. The coder returns a tuple `(adpcmfrag, newstate)`, and the `newstate` should be passed to the next call of `lin2adpcm()`. In the initial call, `None` can be passed as the state. `adpcmfrag` is the ADPCM coded fragment packed 2 4-bit values per byte.

`audioop.lin2alaw(fragment, width)`

Convert samples in the audio fragment to a-LAW encoding and return this as a Python string. a-LAW is an audio encoding format
whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

New in version 2.5.

audioop. **lin2lin**(fragment, width, newwidth)

Convert samples between 1-, 2- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```python
new_frames = audioop.lin2lin(frames, old_width, 1)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16 or 32 bit width samples.

audioop. **lin2ulaw**(fragment, width)

Convert samples in the audio fragment to u-LAW encoding and return this as a Python string. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop. **minmax**(fragment, width)

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop. **max**(fragment, width)

Return the maximum of the absolute value of all samples in a fragment.

audioop. **maxpp**(fragment, width)

Return the maximum peak-peak value in the sound fragment.
audioop.mul(fragment, width, factor)

Return a fragment that has all samples in the original fragment multiplied by the floating-point value factor. Overflow is silently ignored.

audioop.ratecv(fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]])

Convert the frame rate of the input fragment.

state is a tuple containing the state of the converter. The converter returns a tuple (newfragment, newstate), and newstate should be passed to the next call of ratecv(). The initial call should pass None as the state.

The weightA and weightB arguments are parameters for a simple digital filter and default to 1 and 0 respectively.

audioop.reverse(fragment, width)

Reverse the samples in a fragment and returns the modified fragment.

audioop.rms(fragment, width)

Return the root-mean-square of the fragment, i.e. \( \sqrt{\frac{\text{sum}(S_i^2)}{n}} \).

This is a measure of the power in an audio signal.

audioop.tomono(fragment, width, Ifactor, Rfactor)

Convert a stereo fragment to a mono fragment. The left channel is multiplied by Ifactor and the right channel by Rfactor before adding the two channels to give a mono signal.

audioop.tostereo(fragment, width, Ifactor, Rfactor)

Generate a stereo fragment from a mono fragment. Each pair of
samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by \textit{lfactor} and right channel samples by \textit{rfactor}.

\texttt{audioop.ulaw2lin(fragment, width)}

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so \textit{width} refers only to the sample width of the output fragment here.

Note that operations such as \texttt{mul()} or \texttt{max()} make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:

```python
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(sample, width, lfactor)
    rsample = audioop.mul(sample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    \textbf{return} audioop.add(lsample, rsample, width)
```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the initial state (the one you passed to \texttt{lin2adpcm()}) along to the decoder, not the final state (as returned by the coder). If you want to use \texttt{struct.struct()} to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the
respective standards.

The `find*()` routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

```python
def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one tenth second
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test)
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)],
    #                           out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(inputdata)-len(prefill)-len(outputdata)
    outputdata = prefill + audioop.mul(outputdata, 2, -factor) +
    return audioop.add(inputdata, outputdata, 2)
```
imageop — Manipulate raw image data

Deprecated since version 2.6: The imageop module has been removed in Python 3.0.

The imageop module contains some useful operations on images. It operates on images consisting of 8 or 32 bit pixels stored in Python strings. This is the same format as used by gl.lrectwrite() and the imgfile module.

The module defines the following variables and functions:

exception imageop.error

This exception is raised on all errors, such as unknown number of bits per pixel, etc.

imageop.crop(image, psize, width, height, x0, y0, x1, y1)

Return the selected part of image, which should be width by height in size and consist of pixels of psize bytes. x0, y0, x1 and y1 are like the gl.lrectread() parameters, i.e. the boundary is included in the new image. The new boundaries need not be inside the picture. Pixels that fall outside the old image will have their value set to zero. If x0 is bigger than x1 the new image is mirrored. The same holds for the y coordinates.

imageop.scale(image, psize, width, height, newwidth, newheight)

Return image scaled to size newwidth by newheight. No interpolation is done, scaling is done by simple-minded pixel duplication or removal. Therefore, computer-generated images or dithered images will not look nice after scaling.

imageop.tovideo(image, psize, width, height)
Run a vertical low-pass filter over an image. It does so by computing each destination pixel as the average of two vertically-aligned source pixels. The main use of this routine is to forestall excessive flicker if the image is displayed on a video device that uses interlacing, hence the name.

imageop. **grey2mono**(*image*, *width*, *height*, *threshold*)
Convert a 8-bit deep greyscale image to a 1-bit deep image by thresholding all the pixels. The resulting image is tightly packed and is probably only useful as an argument to **mono2grey**().

imageop. **dither2mono**(*image*, *width*, *height*)
Convert an 8-bit greyscale image to a 1-bit monochrome image using a (simple-minded) dithering algorithm.

imageop. **mono2grey**(*image*, *width*, *height*, *p0*, *p1*)
Convert a 1-bit monochrome image to an 8 bit greyscale or color image. All pixels that are zero-valued on input get value \(p0\) on output and all one-value input pixels get value \(p1\) on output. To convert a monochrome black-and-white image to greyscale pass the values 0 and 255 respectively.

imageop. **grey2grey4**(*image*, *width*, *height*)
Convert an 8-bit greyscale image to a 4-bit greyscale image without dithering.

imageop. **grey2grey2**(*image*, *width*, *height*)
Convert an 8-bit greyscale image to a 2-bit greyscale image without dithering.

imageop. **dither2grey2**(*image*, *width*, *height*)
Convert an 8-bit greyscale image to a 2-bit greyscale image with dithering. As for **dither2mono()**, the dithering algorithm is currently very simple.
imageop. **grey42grey**(*image*, *width*, *height*)
   Convert a 4-bit greyscale image to an 8-bit greyscale image.

imageop. **grey22grey**(*image*, *width*, *height*)
   Convert a 2-bit greyscale image to an 8-bit greyscale image.

imageop. **backward_compatible**
   If set to 0, the functions in this module use a non-backward compatible way of representing multi-byte pixels on little-endian systems. The SGI for which this module was originally written is a big-endian system, so setting this variable will have no effect. However, the code wasn’t originally intended to run on anything else, so it made assumptions about byte order which are not universal. Setting this variable to 0 will cause the byte order to be reversed on little-endian systems, so that it then is the same as on big-endian systems.
**aifc — Read and write AIFF and AIFC files**

This module provides support for reading and writing AIFF and AIFC files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

**Warning:** Some operations may only work under IRIX; these will raise `ImportError` when attempting to import the `cl` module, which is only available on IRIX.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of `nchannels**samplesize*` bytes, and a second's worth of audio consists of `nchannels**samplesize***framerate*` bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second's worth occupies 2*2*44100 bytes (176,400 bytes).

Module `aifc` defines the following function:

```python
aifc.open([file[, mode]])
```

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument `file` is either a string naming a file or a file object. `mode` must be `'r'` or `'rb'`
when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, `file.mode` is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use `writeframesraw()` and `setnframes()`.

Objects returned by `open()` when a file is opened for reading have the following methods:

```python
aifc.getnchannels()
```
Return the number of audio channels (1 for mono, 2 for stereo).

```python
aifc.getsampwidth()
```
Return the size in bytes of individual samples.

```python
aifc.getframerate()
```
Return the sampling rate (number of audio frames per second).

```python
aifc.getnframes()
```
Return the number of audio frames in the file.

```python
aifc.getcomptype()
```
Return a four-character string describing the type of compression used in the audio file. For AIFF files, the returned value is 'NONE'.

```python
aifc.getcompname()
```
Return a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is 'not compressed'.

```python
aifc.getparams()
```
Return a tuple consisting of all of the above values in the above order.
aifc.getmarkers()
Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

aifc.getmark(id)
Return the tuple as described in getmarkers() for the mark with the given id.

aifc.readframes(nframes)
Read and return the next nframes frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

aifc.rewind()
Rewind the read pointer. The next readframes() will start from the beginning.

aifc.setpos(pos)
Seek to the specified frame number.

aifc.tell()
Return the current frame number.

aifc.close()
Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by open() when a file is opened for writing have all the above methods, except for readframes() and setpos(). In addition the following methods exist. The get*() methods can only be called after the corresponding set*() methods have been called. Before the first writeframes() or writeframesraw(), all parameters
except for the number of frames must be filled in.

\texttt{aifc.aiff()}

Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in '.aiff' in which case the default is an AIFF file.

\texttt{aifc.aifc()}

Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in '.aiff' in which case the default is an AIFF file.

\texttt{aifc.setnchannels(nchannels)}

Specify the number of channels in the audio file.

\texttt{aifc.setsampwidth(width)}

Specify the size in bytes of audio samples.

\texttt{aifc.setframerate(rate)}

Specify the sampling frequency in frames per second.

\texttt{aifc.setnframes(nframes)}

Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

\texttt{aifc.setcomptype(type, name)}

Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type, the type parameter should be a four-character string. Currently the following compression types are supported: NONE, ULAW, ALAW, G722.

\texttt{aifc.setparams(nchannels, sampwidth, framerate, comptype,}
Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a `getparams()` call as argument to `setparams()`.

```python
aifc.setmark(id, pos, name)
```
Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before `close()`.

```python
aifc.tell()
```
Return the current write position in the output file. Useful in combination with `setmark()`.

```python
aifc.writeframes(data)
```
Write data to the output file. This method can only be called after the audio file parameters have been set.

```python
aifc.writeframesraw(data)
```
Like `writeframes()`, except that the header of the audio file is not updated.

```python
aifc.close()
```
Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.
sunau — Read and write Sun AU files

The sunau module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules aifc and wave.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes .snd.</td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes).</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The sunau module defines the following functions:

sunau.open(file, mode)

If file is a string, open the file by that name, otherwise treat it as a seekable file-like object. mode can be any of

' r'
  Read only mode.

' w'
  Write mode.
Write only mode.

Note that it does not allow read/write files.

A mode of 'r' returns a AU_read object, while a mode of 'w' or 'wb' returns a AU_write object.

sunau.openfp(file, mode)
A synonym for open(), maintained for backwards compatibility.

The sunau module defines the following exception:

exception sunau.Error
An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The sunau module defines the following data items:

sunau.AUDIO_FILE_MAGIC
An integer every valid Sun AU file begins with, stored in big-endian form. This is the string .snd interpreted as an integer.

sunau.AUDIO_FILE_ENCODING_MULAW_8
sunau.AUDIO_FILE_ENCODING_LINEAR_8
sunau.AUDIO_FILE_ENCODING_LINEAR_16
sunau.AUDIO_FILE_ENCODING_LINEAR_24
sunau.AUDIO_FILE_ENCODING_LINEAR_32
sunau.AUDIO_FILE_ENCODING_ALAW_8

Values of the encoding field from the AU header which are supported by this module.

sunau.AUDIO_FILE_ENCODING_FLOAT
sunau.AUDIO_FILE_ENCODING_DOUBLE
sunau.AUDIO_FILE_ENCODING_ADPCM_G721
sunau.AUDIO_FILE_ENCODING_ADPCM_G722
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_3
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_5

Additional known values of the encoding field from the AU
header, but which are not supported by this module.
**AU_read Objects**

AU_read objects, as returned by `open()` above, have the following methods:

**AU_read.close()**

Close the stream, and make the instance unusable. (This is called automatically on deletion.)

**AU_read.getnchannels()**

Returns number of audio channels (1 for mono, 2 for stereo).

**AU_read.getsampwidth()**

Returns sample width in bytes.

**AU_read.getframerate()**

Returns sampling frequency.

**AU_read.getnframes()**

Returns number of audio frames.

**AU_read.getcomptype()**

Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

**AU_read.getcompname()**

Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

**AU_read.getparams()**

Returns a tuple `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the `get*()` methods.
\texttt{AU\_read. readframes(n)}
\begin{itemize}
\item Reads and returns at most $n$ frames of audio, as a string of bytes.
\item The data will be returned in linear format. If the original data is in
\texttt{u-LAW} format, it will be converted.
\end{itemize}

\texttt{AU\_read. rewind()}
\begin{itemize}
\item Rewind the file pointer to the beginning of the audio stream.
\end{itemize}

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

\texttt{AU\_read. setpos(pos)}
\begin{itemize}
\item Set the file pointer to the specified position. Only values returned
\item from \texttt{tell()} should be used for \texttt{pos}.
\end{itemize}

\texttt{AU\_read. tell()}
\begin{itemize}
\item Return current file pointer position. Note that the returned value
\item has nothing to do with the actual position in the file.
\end{itemize}

The following two functions are defined for compatibility with the \texttt{aifc}, and don’t do anything interesting.

\texttt{AU\_read. getmarkers()}
\begin{itemize}
\item Returns \texttt{None}.
\end{itemize}

\texttt{AU\_read. getmark(id)}
\begin{itemize}
\item Raise an error.
\end{itemize}
AU_write Objects

AU_write objects, as returned by open() above, have the following methods:

AU_write.setnchannels\( (n) \)
Set the number of channels.

AU_write.setsampwidth\( (n) \)
Set the sample width (in bytes.)

AU_write.setframerate\( (n) \)
Set the frame rate.

AU_write.setnframes\( (n) \)
Set the number of frames. This can be later changed, when and if more frames are written.

AU_write.setcomptype\( (type, name) \)
Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

AU_write.setparams\( (tuple) \)
The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

AU_write.tell\( () \)
Return current position in the file, with the same disclaimer for the AU_read.tell() and AU_read.setpos() methods.

AU_write.writeframesraw\( (data) \)
Write audio frames, without correcting nframes.
AU_write.writeframes(data)

Write audio frames and make sure nframes is correct.

AU_write.close()

Make sure nframes is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw().
The `wave` module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The `wave` module defines the following function and exception:

```python
wave.open(file[, mode])
```

If `file` is a string, open the file by that name, otherwise treat it as a seekable file-like object. `mode` can be any of

`'r', 'rb'`

Read only mode.

`'w', 'wb'`

Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'r'` or `'rb'` returns a `Wave_read` object, while a `mode` of `'w'` or `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode` (the `'b'` flag is still added if necessary).

```python
wave.openfp(file, mode)
```

A synonym for `open()`, maintained for backwards compatibility.

**exception** `wave.Error`

An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.
Wave_read Objects

Wave_read objects, as returned by \texttt{open()}, have the following methods:

\texttt{Wave_read.close()}

Close the stream, and make the instance unusable. This is called automatically on object collection.

\texttt{Wave_read.getnchannels()}

Returns number of audio channels (1 for mono, 2 for stereo).

\texttt{Wave_read.getsampwidth()}

Returns sample width in bytes.

\texttt{Wave_read.getframerate()}

Returns sampling frequency.

\texttt{Wave_read.getnframes()}

Returns number of audio frames.

\texttt{Wave_read.getcomptype()}

Returns compression type ('NONE' is the only supported type).

\texttt{Wave_read.getcompname()}

Human-readable version of \texttt{getcomptype()}. Usually 'not compressed' parallels 'NONE'.

\texttt{Wave_read.getparams()}

Returns a tuple \texttt{(nchannels, sampwidth, framerate, nframes, comptype, compname)}, equivalent to output of the \texttt{get*()} methods.

\texttt{Wave_read.readframes(n)}
Reads and returns at most $n$ frames of audio, as a string of bytes.

`Wave_read.rewind()`
Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the `aifc` module, and don’t do anything interesting.

`Wave_read.getmarkers()`
Returns `None`.

`Wave_read.getmark(id)`
Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

`Wave_read.setpos(pos)`
Set the file pointer to the specified position.

`Wave_read.tell()`
Return current file pointer position.
Wave_write Objects

Wave_write objects, as returned by open(), have the following methods:

Wave_write.close()
  Make sure nframes is correct, and close the file. This method is called upon deletion.

Wave_write.setnchannels(n)
  Set the number of channels.

Wave_write.setsampwidth(n)
  Set the sample width to n bytes.

Wave_write.setframerate(n)
  Set the frame rate to n.

Wave_write.setnframes(n)
  Set the number of frames to n. This will be changed later if more frames are written.

Wave_write.setcomptype(type, name)
  Set the compression type and description. At the moment, only compression type NONE is supported, meaning no compression.

Wave_write.setparams(tuple)
  The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Sets all parameters.

Wave_write.tell()
  Return current position in the file, with the same disclaimer for the
Wave_read.tell() and Wave_read.setpos() methods.

Wave_write.writeframesraw(data)
Write audio frames, without correcting nframes.

Wave_write.writeframes(data)
Write audio frames and make sure nframes is correct.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw(), and any attempt to do so will raise wave.Error.
This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>n</td>
<td>Data bytes, where n is the size given in the preceding field</td>
</tr>
<tr>
<td>8 + n</td>
<td>0 or 1</td>
<td>Pad byte needed if n is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the `Chunk` class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with a `EOFError` exception.

```python
class chunk.Chunk(file[, align, bigendian, inclheader])
```

Class which represents a chunk. The `file` argument is expected to be a file-like object. An instance of this class is specifically
allowed. The only method that is needed is \texttt{read()}. If the methods \texttt{seek()} and \texttt{tell()} are present and don't raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument \texttt{align} is true, chunks are assumed to be aligned on 2-byte boundaries. If \texttt{align} is false, no alignment is assumed. The default value is true. If the optional argument \texttt{bigendian} is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument \texttt{inclheader} is true, the size given in the chunk header includes the size of the header. The default value is false.

A \texttt{Chunk} object supports the following methods:

\texttt{getname()}

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

\texttt{getsize()}

Returns the size of the chunk.

\texttt{close()}

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise \texttt{IOError} if called after the \texttt{close()} method has been called.

\texttt{isatty()}

Returns \texttt{False}.

\texttt{seek(pos[, whence])}

Set the chunk's current position. The \texttt{whence} argument is optional and defaults to 0 (absolute file positioning); other
values are \(1\) (seek relative to the current position) and \(2\) (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

**tell()**

Return the current position into the chunk.

**read([size])**

Read at most \(size\) bytes from the chunk (less if the read hits the end of the chunk before obtaining \(size\) bytes). If the \(size\) argument is negative or omitted, read all data until the end of the chunk. The bytes are returned as a string object. An empty string is returned when the end of the chunk is encountered immediately.

**skip()**

Skip to the end of the chunk. All further calls to **read()** for the chunk will return `'`. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

**Footnotes**

The `colorsys` module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

The `colorsys` module defines the following functions:

- **`rgb_to_yiq(r, g, b)`**
  Convert the color from RGB coordinates to YIQ coordinates.

- **`yiq_to_rgb(y, i, q)`**
  Convert the color from YIQ coordinates to RGB coordinates.

- **`rgb_to_hls(r, g, b)`**
  Convert the color from RGB coordinates to HLS coordinates.

- **`hls_to_rgb(h, l, s)`**
  Convert the color from HLS coordinates to RGB coordinates.

- **`rgb_to_hsv(r, g, b)`**
  Convert the color from RGB coordinates to HSV coordinates.
colorsyst** hsv_to_rgb**(*h, s, v*)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```python
>>> import colorsys
>>> colorsys.rgb_to_hsv(.3, .4, .2)
(0.25, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.25, 0.5, 0.4)
(0.3, 0.4, 0.2)
```
**imghdr — Determine the type of an image**

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

```python
imghdr.what(filename[, h])
```

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pbm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>'rast'</td>
<td>Sun Raster Files</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
</tbody>
</table>

*New in version 2.5:* Exif detection.
You can extend the list of file types `imghdr` can recognize by appending to this variable:

```
imghdr.tests
```

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```python
>>> import imghdr
>>> imghdr.what('/tmp/bass.gif')
'gif'
```
The `sndhdr` provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a tuple `(type, sampling_rate, channels, frames, bits_per_sample)`. The value for `type` indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The `sampling_rate` will be either the actual value or 0 if unknown or difficult to decode. Similarly, `channels` will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for `frames` will be either the number of frames or -1. The last item in the tuple, `bits_per_sample`, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

`sndhdr.what(filename)`

Determine the type of sound data stored in the file `filename` using `whathdr()`. If it succeeds, returns a tuple as described above, otherwise `None` is returned.

`sndhdr.whathdr(filename)`

Determines the type of sound data stored in a file based on the file header. The name of the file is given by `filename`. This function returns a tuple as described above on success, or `None`.
ossaudiodev — Access to OSS-compatible audio devices

Platforms: Linux, FreeBSD

New in version 2.3.

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

See also:

Open Sound System Programmer’s Guide
    the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see <sys/soundcard.h> on either Linux or FreeBSD for a listing.

ossaudiodev defines the following variables and functions:

exception ossaudiodev.OSSAudioError
    This exception is raised on certain errors. The argument is a string describing what went wrong.

    (If ossaudiodev receives an error from a system call such as open, write, or ioctl, it raises IOError. Errors detected directly by ossaudiodev result in OSSAudioError.)

    (For backwards compatibility, the exception class is also available as ossaudiodev.error.)
ossaudiodev.\texttt{open}([\textit{device}], \textit{mode})

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as \texttt{read()}, \texttt{write()}, and \texttt{fileno()} (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

\textit{device} is the audio device filename to use. If it is not specified, this module first looks in the environment variable \texttt{AUDIODEV} for a device to use. If not found, it falls back to \texttt{/dev/dsp}.

\textit{mode} is one of \texttt{'r'} for read-only (record) access, \texttt{'w'} for write-only (playback) access and \texttt{'rw'} for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the \textit{first} argument is optional, and the second is required. This is a historical artifact for compatibility with the older \texttt{linuxaudiodev} module which \texttt{ossaudiodev} supersedes.

ossaudiodev.\texttt{openmixer}([\textit{device}])

Open a mixer device and return an OSS mixer device object. \textit{device} is the mixer device filename to use. If it is not specified, this module first looks in the environment variable \texttt{MIXERDEV} for a device to use. If not found, it falls back to \texttt{/dev/mixer}.
Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

- `oss_audio_device.close()`
  Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

- `oss_audio_device.fileno()`
  Return the file descriptor associated with the device.

- `oss_audio_device.read(size)`
  Read `size` bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

- `oss_audio_device.write(data)`
  Write the Python string `data` to the audio device and return the number of bytes written. If the audio device is in blocking mode
(the default), the entire string is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written — see `writeall()`.

```python
oss_audio_device.writeall(data)
```

Write the entire Python string `data` to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until `data` has been completely written. If the device is in blocking mode (the default), this has the same effect as `write()`: `writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` ioctl, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise `IOError`.

```python
oss_audio_device.nonblock()
```

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

```python
oss_audio_device.getfmts()
```

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMT_IMA_ADPCM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
</tbody>
</table>
AFMT_U8       Unsigned, 8-bit audio
AFMT_S16_LE   Signed, 16-bit audio, little-endian byte order (as used by Intel processors)
AFMT_S16_BE   Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)
AFMT_S8       Signed, 8 bit audio
AFMT_U16_LE   Unsigned, 16-bit little-endian audio
AFMT_U16_BE   Unsigned, 16-bit big-endian audio

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support AFMT_U8; the most common format used today is AFMT_S16_LE.

oss_audio_device.setfmt(format)
Try to set the current audio format to format—see getfmts() for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of AFMT_QUERY.

oss_audio_device.channels(nchannels)
Set the number of output channels to nchannels. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

oss_audio_device.speed(samplerate)
Try to set the audio sampling rate to samplerate samples per second. Returns the rate actually set. Most sound devices don't support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
8000  default rate for `/dev/audio`
11025  speech recording
22050
44100  CD quality audio (at 16 bits/sample and 2 channels)
96000  DVD quality audio (at 24 bits/sample)

\begin{verbatim}
oss_audio_device.sync()
\end{verbatim}
Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using `sync()`.

\begin{verbatim}
oss_audio_device.reset()
\end{verbatim}
Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling `reset()`.

\begin{verbatim}
oss_audio_device.post()
\end{verbatim}
Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctls, or one ioctl and some simple calculations.

\begin{verbatim}
oss_audio_device.setparameters(\texttt{format}, \texttt{nchannels}, \texttt{samplerate}[], \texttt{strict=False})
\end{verbatim}
Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. `format`, `nchannels`, and `samplerate` should be as specified in the `setfmt()`, `channels()`, and `speed()` methods. If `strict` is true,
setparameters() checks to see if each parameter was actually set to the requested value, and raises OSSAudioError if not. Returns a tuple (format, nchannels, samplerate) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of setfmt(), channels(), and speed()).

For example,

\[
(fmt, channels, rate) = \text{dsp.setparameters(fmt, channels, rate)}
\]

is equivalent to

\[
\text{fmt} = \text{dsp.setfmt(fmt)} \\
\text{channels} = \text{dsp.channels(channels)} \\
\text{rate} = \text{dsp.rate(channels)}
\]

oss_audio_device.bufsize()

Returns the size of the hardware buffer, in samples.

oss_audio_device.obufcount()

Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.obuffree()

Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.closed

Boolean indicating whether the device has been closed.

oss_audio_device.name
String containing the name of the device file.

oss_audio_device.mode

The I/O mode for the file, either "r", "rw", or "w".
Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an IOError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_* constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, SOUND_MIXER_VOLUME does not exist.
oss.mixer_device.stereocontrols()
Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with controls() to determine which).

See the code example for the controls() function for an example of getting data from a bitmask.

oss.mixer_device.reccontrols()
Returns a bitmask specifying the mixer controls that may be used to record. See the code example for controls() for an example of reading from a bitmask.

oss.mixer_device.get(control)
Returns the volume of a given mixer control. The returned volume is a 2-tuple \((\text{left}_\text{volume}, \text{right}_\text{volume})\). Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises OSSAudioError if an invalid control was specified, or IOError if an unsupported control is specified.

oss.mixer_device.set(control, (left, right))
Sets the volume for a given mixer control to \((\text{left}, \text{right})\). left and right must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple. Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard’s mixers.

Raises OSSAudioError if an invalid mixer control was specified, or if the specified volumes were out-of-range.
This method returns a bitmask indicating which control(s) are currently being used as a recording source.

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises IOError if an invalid source was specified. To set the current recording source to the microphone input:

```python
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```
The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **gettext** — Multilingual internationalization services
  - GNU gettext API
  - Class-based API
    - The NullTranslations class
    - The GNUTranslations class
    - Solaris message catalog support
    - The Catalog constructor
  - Internationalizing your programs and modules
    - Localizing your module
    - Localizing your application
    - Changing languages on the fly
    - Deferred translations
    - gettext vs. lgettext
  - Acknowledgements

- **locale** — Internationalization services
  - Background, details, hints, tips and caveats
  - For extension writers and programs that embed Python
  - Access to message catalogs
The `gettext` module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU `gettext` message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
The gettext module defines the following API, which is very similar to the GNU gettext API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

```
gettext.bindtextdomain(domain[, localedir])
```

Bind the `domain` to the locale directory `localedir`. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix): `localedir/language/LC_MESSAGES/domain.mo`, where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or `None`, then the current binding for `domain` is returned. [1]

```
gettext.bind_textdomain_codeset(domain[, codeset])
```

Bind the `domain` to `codeset`, changing the encoding of strings returned by the `gettext()` family of functions. If `codeset` is omitted, then the current binding is returned.

*New in version 2.4.*

```
gettext.textdomain([domain])
```

Change or query the current global domain. If `domain` is `None`, then the current global domain is returned, otherwise the global domain is set to `domain`, which is returned.
gettext. **gettext**(message)

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as `_()` in the local namespace (see examples below).

gettext. **lgettext**(message)

Equivalent to gettext(), but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

*New in version 2.4.*

gettext. **dgettext**(domain, message)

Like gettext(), but look the message up in the specified *domain*.

gettext. **ldgettext**(domain, message)

Equivalent to dgettext(), but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

*New in version 2.4.*

gettext. **ngettext**(singular, plural, n)

Like gettext(), but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in **.po** files.
files and the formulas for a variety of languages.

*New in version 2.3.*

`gettext.\texttt{lngettext}(\textit{singular, plural, n})`

Equivalent to `\texttt{ngettext()}`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `\texttt{bind_textdomain_codeset()}`.

*New in version 2.4.*

`gettext.\texttt{dngettext}(\textit{domain, singular, plural, n})`

Like `\texttt{ngettext()}`, but look the message up in the specified `domain`.

*New in version 2.3.*

`gettext.\texttt{ldngettext}(\textit{domain, singular, plural, n})`

Equivalent to `\texttt{dngettext()}`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `\texttt{bind_textdomain_codeset()}`.

*New in version 2.4.*

Note that GNU `gettext` also defines a `\texttt{dcgettext()}` method, but this was deemed not useful and so it is currently unimplemented.

Here’s an example of typical usage for this API:

```python
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my/language/d')
ggettext.textdomain('myapplication')
_
# ...
print _('This is a translatable string.')
```
Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning either standard 8-bit strings or Unicode strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function `_()`.

```python
gettext.find(domain[, localedir[, languages[, all]]]])
```

This function implements the standard .mo file search algorithm. It takes a `domain`, identical to what `textdomain()` takes. Optional `localedir` is as in `bindtextdomain()`. Optional `languages` is a list of strings, where each string is a language code.

If `localedir` is not given, then the default system locale directory is used. [2] If `languages` is not given, then the following environment variables are searched: `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG`. The first one returning a non-empty value is used for the `languages` variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

`find()` then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

```python
localedir/language/LC_MESSAGES/domain.mo
```

The first such file name that exists is returned by `find()`. If no
such file is found, then None is returned. If all is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

gettext.translation(domain[, localedir[, languages[, class_[, fallback[, codeset]]]]])

Return a Translations instance based on the domain, localedir, and languages, which are first passed to find() to get a list of the associated .mo file paths. Instances with identical .mo file names are cached. The actual class instantiated is either class_ if provided, otherwise GNUTranslations. The class's constructor must take a single file object argument. If provided, codeset will change the charset used to encode translated strings.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, copy.copy() is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no .mo file is found, this function raises IOError if fallback is false (which is the default), and returns a NullTranslations instance if fallback is true.

Changed in version 2.4: Added the codeset parameter.

gettext.install(domain[, localedir[, unicode[, codeset[, names]]]]))

This installs the function _() in Python's builtin namespace, based on domain, localedir, and codeset which are passed to the function translation(). The unicode flag is passed to the resulting translation object's install() method.

For the names parameter, please see the description of the
translation object’s `install()` method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the `()` function, like this:

```python
print _('This string will be translated.')
```

For convenience, you want the `()` function to be installed in Python’s builtin namespace, so it is easily accessible in all modules of your application.

*Changed in version 2.4:* Added the `codeset` parameter.

*Changed in version 2.5:* Added the `names` parameter.

---

**The `NullTranslations` class**

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is `NullTranslations`; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of `NullTranslations`:

```python
class gettext.NullTranslations([fp])
    Takes an optional file object `fp`, which is ignored by the base class. Initializes “protected” instance variables `_info` and `_charset` which are set by derived classes, as well as `_fallback`, which is set through `add_fallback()`. It then calls `self._parse(fp)` if `fp` is not `None`.

    `_parse(fp)`
    No-op’d in the base class, this method takes file object `fp`, and
reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add_fallback(fallback)**
Add *fallback* as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext(message)**
If a fallback has been set, forward **gettext()** to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lgettext(message)**
If a fallback has been set, forward **lgettext()** to the fallback. Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.4.*

**ugettext(message)**
If a fallback has been set, forward **ugettext()** to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

**ngettext(singular, plural, n)**
If a fallback has been set, forward **ngettext()** to the fallback. Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.3.*

**lngettext(singular, plural, n)**
If a fallback has been set, forward **ngettext()** to the fallback.
Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.4.*

**ungettext**(singular, plural, n)

If a fallback has been set, forward `ungettext()` to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

*New in version 2.3.*

**info()**

Return the “protected” `_info` variable.

**charset()**

Return the “protected” `_charset` variable.

**output_charset()**

Return the “protected” `_output_charset` variable, which defines the encoding used to return translated messages.

*New in version 2.4.*

**set_output_charset**(charset)

Change the “protected” `_output_charset` variable, which defines the encoding used to return translated messages.

*New in version 2.4.*

**install**(unicode[, names])

If the `unicode` flag is false, this method installs `self.gettext()` into the built-in namespace, binding it to `_`. If `unicode` is true, it binds `self.ugettext()` instead. By default, `unicode` is false.
If the names parameter is given, it must be a sequence containing the names of functions you want to install in the builtin namespace in addition to _(). Supported names are 'gettext' (bound to self.gettext() or self.ugettext() according to the unicode flag), 'ngettext' (bound to self.ngettext() or self.ungettext() according to the unicode flag), 'lgettext' and 'lngettext'.

Note that this is only one way, albeit the most convenient way, to make the _() function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install _(). Instead, they should use this code to make _() available to their module:

```python
import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
```

This puts _() only in the module's global namespace and so only affects calls within this module.

*Changed in version 2.5:* Added the names parameter.

**The GNUTranslations class**

The gettext module provides one additional class derived from NullTranslations: **GNUTranslations**. This class overrides _parse() to enable reading GNU gettext format .mo files in both big-endian and little-endian format. It also coerces both message ids and message strings to Unicode.

**GNUTranslations** parses optional meta-data out of the translation
catalog. It is convention with GNU gettext to include meta-data as the translation for the empty string. This meta-data is in RFC 822-style key: value pairs, and should contain the Project-Id-Version key. If the key Content-Type is found, then the charset property is used to initialize the “protected” _charset instance variable, defaulting to None if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding. The ugettext() method always returns a Unicode, while the gettext() returns an encoded 8-bit string. For the message id arguments of both methods, either Unicode strings or 8-bit strings containing only US-ASCII characters are acceptable. Note that the Unicode version of the methods (i.e. ugettext() and ungettext()) are the recommended interface to use for internationalized Python programs.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” _info instance variable.

If the .mo file’s magic number is invalid, or if other problems occur while reading the file, instantiating a GNUTranslations class can raise IOError.

The following methods are overridden from the base class implementation:

GNUTranslations.gettext(message)
Look up the message id in the catalog and return the corresponding message string, as an 8-bit string encoded with the catalog’s charset encoding, if known. If there is no entry in the catalog for the message id, and a fallback has been set, the look up is forwarded to the fallback’s gettext() method. Otherwise, the message id is returned.

GNUTranslations.lgettext(message)
Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `set_output_charset()`.

*New in version 2.4.*

**GNUTranslations. `uggettext`**

Look up the `message` id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the `message` id, and a fallback has been set, the lookup is forwarded to the fallback's `uggettext()` method. Otherwise, the `message` id is returned.

**GNUTranslations. `ngettext`**

Do a plural-forms lookup of a message id. `singular` is used as the message id for purposes of lookup in the catalog, while `n` is used to determine which plural form to use. The returned message string is an 8-bit string encoded with the catalog’s charset encoding, if known.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback’s `ngettext()` method. Otherwise, when `n` is 1 `singular` is returned, and `plural` is returned in all other cases.

*New in version 2.3.*

**GNUTranslations. `lngettext`**

Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `set_output_charset()`.

*New in version 2.4.*

**GNUTranslations. `ungettext`**
Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback’s `ungettext()` method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations('somefile')
message = cat.ungettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

*New in version 2.3.*

### Solaris message catalog support

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

### The Catalog constructor

 GNOME uses a version of the `gettext` module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```python
import gettext
cat = gettext.Catalog(domain, localedir)
```
_ = catgettext
print _('hello world')

For compatibility with this older module, the function `Catalog()` is an alias for the `translation()` function described above.

One difference between this module and Henstridge's: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.
Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the gettext module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in \_\_(\ldots\) — that is, a call to the function \_\_. For example:

```python
filename = 'mylog.txt'
message = \_(\'writing a log message\')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

In this example, the string ')writing a log message' is marked as a candidate for translation, while the strings 'mylog.txt' and 'w' are not.

The Python distribution comes with two tools which help you
generate the message catalogs once you’ve prepared your source code. These may or may not be available from a binary distribution, but they can be found in a source distribution, in the `Tools/i18n` directory.

The `pygettext` program scans all your Python source code looking for the strings you previously marked as translatable. It is similar to the GNU `gettext` program except that it understands all the intricacies of Python source code, but knows nothing about C or C++ source code. You don’t need GNU `gettext` unless you’re also going to be translating C code (such as C extension modules).

`pygettext` generates textual Uniforum-style human readable message catalog `.pot` files, essentially structured human readable files which contain every marked string in the source code, along with a placeholder for the translation strings. `pygettext` is a command line script that supports a similar command line interface as `xgettext`; for details on its use, run:

```
pygettext.py --help
```

Copies of these `.pot` files are then handed over to the individual human translators who write language-specific versions for every supported natural language. They send you back the filled in language-specific versions as a `.po` file. Using the `msgfmt.py` program (in the `Tools/i18n` directory), you take the `.po` files from your translators and generate the machine-readable `.mo` binary catalog files. The `.mo` files are what the `gettext` module uses for the actual translation processing during run-time.

How you use the `gettext` module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.
Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU gettext API but instead the class-based API.

Let’s say your module is called “spam” and the module’s various natural language translation .mo files reside in /usr/share/locale in GNU gettext format. Here’s what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.lgettext
```

If your translators were providing you with Unicode strings in their .po files, you’d instead do:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.ugettext
```

Localizing your application

If you are localizing your application, you can install the _() function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use _('...') without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
ggettext.install('myapplication')
```

If you need to set the locale directory or the unicode flag, you can
pass these into the `install()` function:

```python
import gettext
gettext.install('myapplication', '/usr/share/locale', unicode=1)
```

## Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', languages=['en'])
lang2 = gettext.translation('myapplication', languages=['fr'])
lang3 = gettext.translation('myapplication', languages=['de'])

# start by using language 1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

## Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:

```python
animals = ['mollusk',
          'albatross',
          'rat',
          'penguin',
          'python',
          ]

# ...
```
Here, you want to mark the strings in the animals list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

```python
for a in animals:
    print a
```

This works because the dummy definition of `()` simply returns the string unchanged. And this dummy definition will temporarily override any definition of `()` in the built-in namespace (until the `del` command). Take care, though if you have a previous definition of `()` in the local namespace.

Note that the second use of `()` will not identify “a” as being translatable to the `pygettext` program, since it is not a string.

Another way to handle this is with the following example:

```python
def N_(message): return message
animals = [N_('mollusk'),
    N_('albatross'),
    N_('rat'),
    N_('penguin'),
    N_('python'),
]`
N_('python'),
]

# ...
for a in animals:
    print _(a)

In this case, you are marking translatable strings with the function N_(), [5] which won't conflict with any definition of _(). However, you will need to teach your message extraction program to look for translatable strings marked with N_. **pygettext** and **xpot** both support this through the use of command line switches.

### gettext() VS. lgettext()

In Python 2.4 the **lgettext()** family of functions were introduced. The intention of these functions is to provide an alternative which is more compliant with the current implementation of GNU gettext. Unlike **gettext()**, which returns strings encoded with the same codeset used in the translation file, **lgettext()** will return strings encoded with the preferred system encoding, as returned by **locale.getpreferredencoding()**. Also notice that Python 2.4 introduces new functions to explicitly choose the codeset used in translated strings. If a codeset is explicitly set, even **lgettext()** will return translated strings in the requested codeset, as would be expected in the GNU gettext implementation.

Footnotes

The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call `bindtextdomain()` with an explicit absolute path at the start of your application.

[1] See the footnote for `bindtextdomain()` above.

François Pinard has written a program called `xpot` which does a similar job. It is available as part of his `po-utils` package at http://po-utils.progiciels-bpi.ca/.

`msgfmt.py` is binary compatible with GNU `msgfmt` except that it provides a simpler, all-Python implementation. With this and `pygettext.py`, you generally won't need to install the GNU `gettext` package to internationalize your Python applications.

[2] The choice of `N_()` here is totally arbitrary; it could have just as easily been `MarkThisStringForTranslation()`.

[3] `msgfmt.py` is binary compatible with GNU `msgfmt` except that it provides a simpler, all-Python implementation. With this and `pygettext.py`, you generally won't need to install the GNU `gettext` package to internationalize your Python applications.

[4] The choice of `N_()` here is totally arbitrary; it could have just as easily been `MarkThisStringForTranslation()`.

[5] The choice of `N_()` here is totally arbitrary; it could have just as easily been `MarkThisStringForTranslation()`.
locale — Internationalization services

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

**exception locale.Error**
Exception raised when `setlocale()` fails.

**locale.setlocale(category[, locale])**
If `locale` is specified, it may be a string, a tuple of the form `(language code, encoding)`, or `None`. If it is a tuple, it is converted to a string using the locale aliasing engine. If `locale` is given and not `None`, `setlocale()` modifies the locale setting for the `category`. The available categories are listed in the data description below. The value is the name of a locale. An empty string specifies the user’s default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If `locale` is omitted or `None`, the current setting for `category` is returned.

`setlocale()` is not thread safe on most systems. Applications
typically start with a call of

```python
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

*Changed in version 2.0:* Added support for tuple values of the `locale` parameter.

```python
locale.localeconv()
```

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>'decimal_point'</td>
<td>Decimal point character.</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td>Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. If the sequence is terminated with CHAR_MAX, no further grouping is performed. If the sequence terminates with a 0, the last group size is repeatedly</td>
</tr>
<tr>
<td>Environment</td>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>'thousands_sep'</td>
<td>Character used between groups.</td>
</tr>
<tr>
<td>LC_MONETARY</td>
<td>'int_curr_symbol'</td>
<td>International currency symbol.</td>
</tr>
<tr>
<td></td>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
</tr>
<tr>
<td></td>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether the currency symbol precedes the value (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether the currency symbol is separated from the value by a space (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
</tr>
<tr>
<td></td>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
</tr>
<tr>
<td></td>

<td>The position of the sign (for positive resp. negative values), see below.</td>
<td></td>
</tr>
</tbody>
</table>

All numeric values can be set to **CHAR_MAX** to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
</tbody>
</table>
The sign should precede the value and currency symbol.

The sign should follow the value and currency symbol.

The sign should immediately precede the value.

The sign should immediately follow the value.

Nothing is specified in this locale.

**locale.** `nl_langinfo(option)`

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

**locale.** `getdefaultlocale([envvars])`

Tries to determine the default locale settings and returns them as a tuple of the form (language code, encoding).

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'C' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the `LANG` variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the `LANG` variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. `envvars` defaults to the search path used in GNU gettext; it must always contain the variable name `LANG`. The GNU gettext search path contains `LANGUAGE`, `LC_ALL`, `LC_CTYPE`, and `LANG`, in that order.
Except for the code 'c', the language code corresponds to RFC 1766. language code and encoding may be None if their values cannot be determined.

New in version 2.0.

```
locale.getlocale([category])
```

Returns the current setting for the given locale category as sequence containing language code, encoding. category may be one of the LC_* values except LC_ALL. It defaults to LC_CTYPE.

Except for the code 'c', the language code corresponds to RFC 1766. language code and encoding may be None if their values cannot be determined.

New in version 2.0.

```
locale.getpreferredencoding([do_setlocale])
```

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke setlocale() to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, do_setlocale should be set to False.

New in version 2.3.

```
locale.normalize(localename)
```

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with setlocale(). If normalization fails, the original name is returned unchanged.
If the given encoding is not known, the function defaults to the default encoding for the locale code just like `setlocale()`.

New in version 2.0.

```python
locale.resetlocale([category])
```
Sets the locale for `category` to the default setting.

The default setting is determined by calling `getdefaultlocale(). category` defaults to `LC_ALL`.

New in version 2.0.

```python
locale.strcoll(string1, string2)
```
Compares two strings according to the current `LC_COLLATE` setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether `string1` collates before or after `string2` or is equal to it.

```python
locale.strxfrm(string)
```
Transforms a string to one that can be used for the built-in function `cmp()`, and still returns locale-aware results. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

```python
locale.format(format, val[, grouping[, monetary]])
```
Formats a number `val` according to the current `LC_NUMERIC` setting. The format follows the conventions of the `%` operator. For floating point values, the decimal point is modified if appropriate. If `grouping` is true, also takes the grouping into account.

If `monetary` is true, the conversion uses monetary thousands separator and grouping strings.
Please note that this function will only work for exactly one %char specifier. For whole format strings, use `format_string()`.

*Changed in version 2.5:* Added the `monetary` parameter.

```python
locale.format_string(format, val[, grouping])
```
Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

*New in version 2.5.*

```python
locale.currency(val[, symbol[, grouping[, international]]]])
```
Formats a number `val` according to the current `LC_MONETARY` settings.

The returned string includes the currency symbol if `symbol` is true, which is the default. If `grouping` is true (which is not the default), grouping is done with the value. If `international` is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have to set a locale via `setlocale()` first.

*New in version 2.5.*

```python
locale.str(float)
```
Formats a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

```python
locale.atof(string)
```
Converts a string to a floating point number, following the `LC_NUMERIC` settings.
locale.**atoi**(string)
Converts a string to an integer, following the **LC_NUMERIC** conventions.

locale.**LC_CTYPE**
Locale category for the character type functions. Depending on the settings of this category, the functions of module *string* dealing with case change their behaviour.

locale.**LC_COLLATE**
Locale category for sorting strings. The functions *strcoll()* and *strxfrm()* of the *locale* module are affected.

locale.**LC_TIME**
Locale category for the formatting of time. The function *time.strftime()* follows these conventions.

locale.**LC_MONETARY**
Locale category for formatting of monetary values. The available options are available from the *localeconv()* function.

locale.**LC_MESSAGES**
Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by *os.strerror()* might be affected by this category.

locale.**LC_NUMERIC**
Locale category for formatting numbers. The functions *format()*,* atoi()*, *atof()* and *str()* of the *locale* module are affected by that category. All other numeric formatting operations are not affected.

locale.**LC_ALL**
Combination of all locale settings. If this flag is used when the
locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale. **CHAR_MAX**

This is a symbolic constant used for different values returned by `localeconv()`.

The `nl_langinfo()` function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

locale. **CODESET**

Return a string with the name of the character encoding used in the selected locale.

locale. **D_T_FMT**

Return a string that can be used as a format string for `strftime(3)` to represent time and date in a locale-specific way.

locale. **D_FMT**

Return a string that can be used as a format string for `strftime(3)` to represent a date in a locale-specific way.

locale. **T_FMT**

Return a string that can be used as a format string for `strftime(3)` to represent a time in a locale-specific way.

locale. **T_FMT_AMPM**

The return value can be used as a format string for ‘strftime’ to represent time in the am/pm format.

**DAY_1** . . . **DAY_7**

Return name of the n-th day of the week.
**Warning:** This follows the US convention of **DAY_1** being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

**ABDAY_1** . . . **ABDAY_7**

Return abbreviated name of the n-th day of the week.

**MON_1** . . . **MON_12**

Return name of the n-th month.

**ABMON_1** . . . **ABMON_12**

Return abbreviated name of the n-th month.

locale. **RADIXCHAR**

Return radix character (decimal dot, decimal comma, etc.)

locale. **THOUSEP**

Return separator character for thousands (groups of three digits).

locale. **YESEXPR**

Return a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

**Warning:** The expression is in the syntax suitable for the **regex** function from the C library, which might differ from the syntax used in **re**.

locale. **NOEXPR**

Return a regular expression that can be used with the regex(3) function to recognize a negative response to a yes/no question.

locale. **CRNCYSTR**

Return the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.
locale. **ERA**

The return value represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the `E` modifier in their format strings causes the `strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

locale. **ERA_YEAR**

The return value gives the year in the relevant era of the locale.

locale. **ERA_D_T_FMT**

This return value can be used as a format string for `strftime()` to represent dates and times in a locale-specific era-based way.

locale. **ERA_D_FMT**

This return value can be used as a format string for `strftime()` to represent time in a locale-specific era-based way.

locale. **ALT_DIGITS**

The return value is a representation of up to 100 values used to represent the values 0 to 99.

Example:

```python
>>> import locale
>>> loc = locale.getlocale(locale.LC_ALL) # get current locale
>>> locale.setlocale(locale.LC_ALL, 'de_DE') # use German locale
>>> locale.strftime('f\xe4n', 'foo') # compare a string containing a non-ASCII character
>>> locale.setlocale(locale.LC_ALL, '') # use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, 'C') # use default (C) locale
>>> locale.setlocale(locale.LC_ALL, loc) # restore saved locale
```
The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. The program must explicitly say that it wants the user’s preferred locale settings by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call `setlocale()` in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as `string.lower()`, or certain formats used with `time.strftime()`), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The case conversion functions in the `string` module are affected by the locale settings. When a call to the `setlocale()` function changes the `LC_CTYPE` settings, the variables `string.lowercase`, `string.uppercase` and `string.letters` are recalculated. Note that code that uses these variable through `from ... import ...`, e.g. `from ... import ...`}
string import letters, is not affected by subsequent setlocale() calls.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: atof(), atoi(), format(), str().
For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
Access to message catalogs

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions gettext(), dgettext(), dcgettext(), textdomain(), bindtextdomain(), and bind_textdomain_codeset(). These are similar to the same functions in the gettext module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use gettext instead. A known exception to this rule are applications that link use additional C libraries which internally invoke gettext or dcgettext(). For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

- **cmd** — Support for line-oriented command interpreters
  - Cmd Objects

- **shlex** — Simple lexical analysis
  - shlex Objects
  - Parsing Rules
The `Cmd` class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

```python
class cmd.Cmd([completekey[, stdin[, stdout]]])
```

A `Cmd` instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate `Cmd` itself; rather, it’s useful as a superclass of an interpreter class you define yourself in order to inherit `Cmd`’s methods and encapsulate action methods.

The optional argument `completekey` is the `readline` name of a completion key; it defaults to `Tab`. If `completekey` is not `None` and `readline` is available, command completion is done automatically.

The optional arguments `stdin` and `stdout` specify the input and output file objects that the `Cmd` instance or subclass instance will use for input and output. If not specified, they will default to `sys.stdin` and `sys.stdout`.

If you want a given `stdin` to be used, make sure to set the instance’s `use_rawinput` attribute to `False`, otherwise `stdin` will be ignored.

*Changed in version 2.3:* The `stdin` and `stdout` parameters were added.
A `Cmd` instance has the following methods:

```python
Cmd.cmdloop(["intro"])  # Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.
```

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the `intro` class member).

If the `readline` module is loaded, input will automatically inherit `bash`-like history-list editing (e.g. `Control-P` scrolls back to the last command, `Control-N` forward to the next one, `Control-F` moves the cursor to the right non-destructively, `Control-B` moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string `EOF`.

An interpreter instance will recognize a command name `foo` if and only if it has a method `do_foo()`. As a special case, a line beginning with the character `?` is dispatched to the method `do_help()`. As another special case, a line beginning with the character `!` is dispatched to the method `do_shell()` (if such a method is defined).

This method will return when the `postcmd()` method returns a true value. The `stop` argument to `postcmd()` is the return value from the command’s corresponding `do_*()` method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling `complete_foo()` with arguments `text`, `line`, `begidx`, and `endidx`. `text` is the string prefix we are attempting to match: all returned matches must begin with it. `line` is the current input line with leading whitespace removed, `begidx` and `endidx` are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of `Cmd` inherit a predefined `do_help()`. This method, called with an argument `'bar'`, invokes the corresponding method `help_bar()`. With no argument, `do_help()` lists all available help topics (that is, all commands with corresponding `help_*()` methods), and also lists any undocumented commands.

**Cmd. onecmd(str)**

Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the `precmd()` and `postcmd()` methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a `do_*()` method for the command `str`, the return value of that method is returned, otherwise the return value from the `default()` method is returned.

**Cmd. emptyline()**

Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.

**Cmd. default(line)**

Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error
message and returns.

**Cmd. `completedefault(text, line, begidx, endidx)`**
Method called to complete an input line when no command-specific `complete_*()` method is available. By default, it returns an empty list.

**Cmd. `precmd(line)`**
Hook method executed just before the command line `line` is interpreted, but after the input prompt is generated and issued. This method is a stub in `Cmd`; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the `onecmd()` method; the `precmd()` implementation may re-write the command or simply return `line` unchanged.

**Cmd. `postcmd(stop, line)`**
Hook method executed just after a command dispatch is finished. This method is a stub in `Cmd`; it exists to be overridden by subclasses. `line` is the command line which was executed, and `stop` is a flag which indicates whether execution will be terminated after the call to `postcmd()`; this will be the return value of the `onecmd()` method. The return value of this method will be used as the new value for the internal flag which corresponds to `stop`; returning false will cause interpretation to continue.

**Cmd. `preloop()`**
Hook method executed once when `cmdloop()` is called. This method is a stub in `Cmd`; it exists to be overridden by subclasses.

**Cmd. `postloop()`**
Hook method executed once when `cmdloop()` is about to return. This method is a stub in `Cmd`; it exists to be overridden by
Instances of \texttt{Cmd} subclasses have some public instance variables:

\texttt{Cmd} . \texttt{prompt} \\
The prompt issued to solicit input.

\texttt{Cmd} . \texttt{identchars} \\
The string of characters accepted for the command prefix.

\texttt{Cmd} . \texttt{lastcmd} \\
The last nonempty command prefix seen.

\texttt{Cmd} . \texttt{intro} \\
A string to issue as an intro or banner. May be overridden by giving the \texttt{cmdloop()} method an argument.

\texttt{Cmd} . \texttt{doc\_header} \\
The header to issue if the help output has a section for documented commands.

\texttt{Cmd} . \texttt{misc\_header} \\
The header to issue if the help output has a section for miscellaneous help topics (that is, there are \texttt{help\_*()} methods without corresponding \texttt{do\_*()} methods).

\texttt{Cmd} . \texttt{undoc\_header} \\
The header to issue if the help output has a section for undocumented commands (that is, there are \texttt{do\_*()} methods without corresponding \texttt{help\_*()} methods).

\texttt{Cmd} . \texttt{ruler} \\
The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to '='.
Cmd. **use_rawinput**

A flag, defaulting to true. If true, `cmdloop()` uses `raw_input()` to display a prompt and read the next command; if false, `sys.stdout.write()` and `sys.stdin.readline()` are used. (This means that by importing `readline`, on systems that support it, the interpreter will automatically support **Emacs**-like line editing and command-history keystrokes.)
New in version 1.5.2.

The shlex class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

Note: The shlex module currently does not support Unicode input.

The shlex module defines the following functions:

```python
shlex.split(s[, comments[, posix]]])
```

Split the string s using shell-like syntax. If comments is False (the default), the parsing of comments in the given string will be disabled (setting the commenters member of the shlex instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the posix argument is false.

New in version 2.3.

Changed in version 2.6: Added the posix parameter.

Note: Since the split() function instantiates a shlex instance, passing None for s will read the string to split from standard input.

The shlex module defines the following class:

```python
class shlex(shlex([in_stream[, in_file[, posix]])])
```
A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string (strings are accepted since Python 2.3). If no argument is given, input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the `infile` member. If the `instream` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument was introduced in Python 2.3, and defines the operational mode. When `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules.

See also:

**Module ConfigParser**

Parser for configuration files similar to the Windows `.ini` files.
A `shlex` instance has the following methods:

**shlex.get_token()**
Return a token. If tokens have been stacked using `push_token()`, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, `self.eof` is returned (the empty string (`''`) in non-POSIX mode, and `None` in POSIX mode).

**shlex.push_token(str)**
Push the argument onto the token stack.

**shlex.read_token()**
Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

**shlex.sourcehook(filename)**
When `shlex` detects a source request (see `source` below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as `sys.stdin`), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor
handles `#include "file.h"`).

The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding ‘close’ hook, but a `shlex` instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

```
shlex.push_source(stream[, filename])
```

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

*New in version 2.1.*

```
shlex.pop_source()
```

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

*New in version 2.1.*

```
shlex.error_leader([file[, line]])
```

This method generates an error message leader in the format of a Unix C compiler error label; the format is `'"%s", line %d: '`,
where the %s is replaced with the name of the current source file and the %d with the current input line number (the optional arguments can be used to override these).

This convenience is provided to encourage shlex users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of shlex subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

shlex.commenters

The string of characters that are recognized as comment beginners. All characters from the comment begin to end of line are ignored. Includes just '#' by default.

shlex.wordchars

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore.

shlex.whitespace

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

shlex.escape

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.

*New in version 2.3.*

shlex.quotes

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.)
default, includes ASCII single and double quotes.

**shlexescapedquotes**

Characters in quotes that will interpret escape characters defined in escape. This is only used in POSIX mode, and includes just \" by default.

*New in version 2.3.*

**shlexwhitespace_split**

If True, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with shlex, getting tokens in a similar way to shell arguments.

*New in version 2.3.*

**shlexinfile**

The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

**shlexinstream**

The input stream from which this shlex instance is reading characters.

**shlexsource**

This member is None by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion request similar to the source keyword in various shells. That is, the immediately following token will opened as a filename and input taken from that stream until EOF, at which point the close() method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

**shlexdebug**
If this member is numeric and 1 or more, a `shlex` instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

`shlex.linenon`

Source line number (count of newlines seen so far plus one).

`shlex.token`

The token buffer. It may be useful to examine this when catching exceptions.

`shlex.eof`

Token used to determine end of file. This will be set to the empty string (``), in non-POSIX mode, and to `None` in POSIX mode.

*New in version 2.3.*
When operating in non-POSIX mode, `shlex` will try to obey to the following rules.

- Quote characters are not recognized within words (Do"Not"Separate is parsed as the single word Do"Not"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do"Separate is parsed as Do and Separate);
- If `whitespace_split` is `False`, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is `True`, `shlex` will only split words in whitespaces;
- EOF is signaled with an empty string ('');
- It’s not possible to parse empty strings, even if quoted.

When operating in POSIX mode, `shlex` will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do"Not"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of escapedquotes (e.g. "'") preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of escapedquotes (e.g. "'") preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in
escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a `None` value;
- Quoted empty strings ("") are allowed;
Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the Tkinter module, and its extension, the Tix module.

The Tkinter module is a thin object-oriented layer on top of Tcl/Tk. To use Tkinter, you don’t need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. Tkinter is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module _tkinter provides a threadsafe mechanism which allows Python and Tcl to interact.

Tkinter’s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. Tkinter is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the Other Graphical User Interface Packages section.

Tkinter — Python interface to Tcl/Tk

The **Tkinter** module (“Tk interface”) is the standard Python interface to the Tk GUI toolkit. Both Tk and **Tkinter** are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.)

**Note:** **Tkinter** has been renamed to **tkinter** in Python 3.0. The **2to3** tool will automatically adapt imports when converting your sources to 3.0.

**See also:**

**Python and Tkinter Programming**
Tkinter Modules

Most of the time, the **Tkinter** module is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, **Tkinter** includes a number of Python modules. The two most important modules are the **Tkinter** module itself, and a module called **Tkconstants**. The former automatically imports the latter, so to use Tkinter, all you need to do is to import one module:

```
import Tkinter
```

Or, more often:

```
from Tkinter import *
```

class **Tkinter.Tk**(screenName=None, baseName=None, className='Tk', useTk=1)

The **Tk** class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

*Changed in version 2.4*: The `useTk` parameter was added.

class **Tkinter.Tcl**(screenName=None, baseName=None, className='Tk', useTk=0)

The **Tcl()** function is a factory function which creates an object much like that created by the **Tk** class, except that it does not
initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn’t want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the `Tcl()` object can have a Toplevel window created (and the Tk subsystem initialized) by calling its `loadtk()` method.

*New in version 2.4.*

Other modules that provide Tk support include:

**ScrolledText**
- Text widget with a vertical scroll bar built in.

**tkColorChooser**
- Dialog to let the user choose a color.

**tkCommonDialog**
- Base class for the dialogs defined in the other modules listed here.

**tkFileDialog**
- Common dialogs to allow the user to specify a file to open or save.

**tkFont**
- Utilities to help work with fonts.

**tkMessageBox**
- Access to standard Tk dialog boxes.

**tkSimpleDialog**
- Basic dialogs and convenience functions.

**TkDnd**
- Drag-and-drop support for Tkinter. This is experimental and should become deprecated when it is replaced with the Tk DND.

**turtle**
- Turtle graphics in a Tk window.
These have been renamed as well in Python 3.0; they were all made submodules of the new tkinter package.
Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tkinter was written by Steen Lumholt and Guido van Rossum.
- Tk was written by John Ousterhout while at Berkeley.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The html rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do“blah” in straight Tk, and then convert this back into the corresponding Tkinter call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists. Here are some hints:
• The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the `man` directory are most useful. The `man3` man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
• Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
• Tkinter.py is a last resort for most, but can be a good place to go when nothing else makes sense.

### A Simple Hello World Program

```python
from Tkinter import *

class Application(Frame):
    def say_hi(self):
        print "hi there, everyone!"

    def createWidgets(self):
        self.QUIT = Button(self)
        self.QUIT["text"] = "QUIT"
        self.QUIT["fg"] = "red"
        self.QUIT["command"] = self.quit

        self.QUIT.pack({"side": "left"})
```
self.hi_there = Button(self)
self.hi_there["text"] = "Hello",
self.hi_there["command"] = self.say_hi

self.hi_there.pack({"side": "left"})

def __init__(self, master=None):
    Frame.__init__(self, master)
    self.pack()
    self.createWidgets()

root = Tk()
app = Application(master=root)
app.mainloop()
root.destroy()
A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren’t meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the Tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

```tcl
classCommand newPathname options
```

`classCommand`
denotes which kind of widget to make (a button, a label, a menu...)

newPathname

is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with pathnames, just like files in a file system. The top level widget, the root, is called . (period) and children are delimited by more periods. For example, .myApp.controlPanel.okButton might be the name of a widget.

options

configure the widget's appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

<table>
<thead>
<tr>
<th>button</th>
<th>.fred</th>
<th>-fg red -text &quot;hi there&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>new</td>
<td>options</td>
</tr>
<tr>
<td>command</td>
<td>widget</td>
<td>(-opt val -opt val ...)</td>
</tr>
</tbody>
</table>

Once created, the pathname to the widget becomes a new command. This new widget command is the programmer's handle for getting the new widget to perform some action. In C, you'd express this as someAction(fred, someOptions), in C++, you would express this as fred.someAction(someOptions), and in Tk, you say:

.fred someAction someOptions

Note that the object name, .fred, starts with a dot.

As you'd expect, the legal values for someAction will depend on the
widget's class: .fred disable works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of someOptions is action dependent. Some actions, like disable, require no arguments, others, like a text-entry box's delete command, would need arguments to specify what range of text to delete.
Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```
button .fred           ===>  fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```
button .panel.fred    ===>  fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

```
button .fred -fg red  ===>  fred = Button(panel, fg = "red"
.fred configure -fg red ===>  fred["fg"] = red
OR ==>  fred.config(fg = "red")
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in the Tkinter.py module.

```
.fred invoke       ===>  fred.invoke()
```

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this functionality, and the various forms of the pack command are implemented as methods. All widgets in Tkinter are subclassed
from the Packer, and so inherit all the packing methods. See the `Tix` module documentation for additional information on the Form geometry manager.

```
pack .fred -side left       ===> fred.pack(side = "left")
```
How Tk and Tkinter are Related

From the top down:

Your App Here (Python)
A Python application makes a Tkinter call.

Tkinter (Python Module)
This call (say, for example, creating a button widget), is implemented in the Tkinter module, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

tkinter (C)
These commands and their arguments will be passed to a C function in the tkinter - note the lowercase - extension module.

Tk Widgets (C and Tcl)
This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python Tkinter module is imported. (The user never sees this stage).

Tk (C)
The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)
the Xlib library to draw graphics on the screen.
Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg = "red", bg = "blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the `config()` method to update multiple attrs subsequent to object creation

```python
fred.config(fg = "red", bg = "blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the `options(3)` man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a command option,
The options supported by a given widget are listed in that widget’s man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `'relief'`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (`bg` is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as `('bg', 'background')`).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print fred.config()
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

**The Packer**

The packer is one of Tk’s geometry-management mechanisms. Geometry managers are used to specify the relative positioning of
the positioning of widgets within their container - their mutual *master*. In contrast to the more cumbersome *placer* (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - *above*, *to the left of*, *filling*, etc - and works everything out to determine the exact placement coordinates for you.

The size of any *master* widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It’s a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s *pack()* method applied to it.

The pack()* method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
fred.pack() # defaults to side = "top"
fred.pack(side = "left")
fred.pack(expand = 1)
```

**Packer Options**

For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout’s book.

anchor
Anchor type. Denotes where the packer is to place each slave in its parcel.

expand
- Boolean, 0 or 1.

fill
- Legal values: 'x', 'y', 'both', 'none'.

ipadx and ipady
- A distance - designating internal padding on each side of the slave widget.

pady and pady
- A distance - designating external padding on each side of the slave widget.

side
- Legal values are: 'left', 'right', 'top', 'bottom'.

**Coupling Widget Variables**

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are `variable`, `textvariable`, `onvalue`, `offvalue`, and `value`. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of **Tkinter** it is not possible to hand over an arbitrary Python variable to a widget through a `variable` or `textvariable` option. The only kinds of variables for which this works are variables that are subclassed from a class called `Variable`, defined in the **Tkinter** module.

There are many useful subclasses of `Variable` already defined: `StringVar`, `IntVar`, `DoubleVar`, and `BooleanVar`. To read the current
value of such a variable, call the `get()` method on it, and to change its value you call the `set()` method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

```python
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return.
        # we will have the program print out the value of the
        # application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
            self.print_contents)

def print_contents(self, event):
    print "hi. contents of entry is now ----->", \
        self.contents.get()
```

**The Window Manager**

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In Tkinter, these commands have been implemented as methods on the `Wm` class. Toplevel widgets are subclassed from the `Wm` class, and so can call the `wm` methods directly.
To get at the toplevel window that contains a given widget, you can often just refer to the widget’s master. Of course if the widget has been packed inside of a frame, the master won’t represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the \_\texttt{root()} method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
from Tkinter import *
class App(Frame):
    def \_\texttt{init\_}(self, master=None):
        Frame.\_\texttt{init\_}(self, master)
        self.pack()

    # create the application
    myapp = App()

    # here are method calls to the window manager class
    #
    myapp.master.title("My Do-Nothing Application")
    myapp.master.maxsize(1000, 400)

    # start the program
    myapp.mainloop()
```

## Tk Option Data Types

### anchor

Legal values are points of the compass: \texttt{"n"}, \texttt{"ne"}, \texttt{"e"}, \texttt{"se"}, \texttt{"s"}, \texttt{"sw"}, \texttt{"w"}, \texttt{"nw"}, and also \texttt{"center"}.

### bitmap

There are eight built-in, named bitmaps: \texttt{\textquote{error}}, \texttt{\textquote{gray25}}, \texttt{\textquote{gray50}}, \texttt{\textquote{hourglass}}, \texttt{\textquote{info}}, \texttt{\textquote{questhead}}, \texttt{\textquote{question}}, \texttt{\textquote{warning}}. To specify an X bitmap filename, give the full path to
the file, preceded with an @, as in "@/usr/contrib(bitmap/gumby.bit)."

boolean
You can pass integers 0 or 1 or the strings "yes" or "no".

callback
This is any Python function that takes no arguments. For example:

```python
def print_it():
    print "hi there"
fred["command"] = print_it
```

color
Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: "#RGB", 8 bit: "#RRGGBB", 12 bit: "#RRRGGGBBB", or 16 bit: "#RRRRGGGGBBBB" ranges, where R,G,B here represent any legal hex digit. See page 160 of Ousterhout's book for details.

cursor
The standard X cursor names from cursorfont.h can be used, without the xc prefix. For example to get a hand cursor (xc_hand2), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

font
Tk uses a list font name format, such as {courier 10 bold}. Font
sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry
This is a string of the form widthxheight, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: `fred["geometry"] = "200x100"`.

justify
Legal values are the strings: "left", "center", "right", and "fill".

region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.

relief
Determines what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

scrollcommand
This is almost always the set() method of some scrollbar widget, but can be any widget method that takes a single argument. Refer to the file Demo/tkinter/matt/canvas-with-scrollbars.py in the Python source distribution for an example.

wrap:
Must be one of: "none", "char", or "word".

Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:
def bind(self, sequence, func, add=''):  

where:

sequence

is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout's book for details).

func

is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as callbacks.)

add

is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.

For example:

def turnRed(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turnRed)

Notice how the widget field of the event is being accessed in the turnRed() callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
</tr>
<tr>
<td>%h</td>
<td>height</td>
</tr>
<tr>
<td>%k</td>
<td>keycode</td>
</tr>
<tr>
<td>%s</td>
<td>state</td>
</tr>
<tr>
<td>%A</td>
<td>char</td>
</tr>
<tr>
<td>%E</td>
<td>send_event</td>
</tr>
<tr>
<td>%K</td>
<td>keysym</td>
</tr>
<tr>
<td>%N</td>
<td>keysym_num</td>
</tr>
</tbody>
</table>
The index Parameter

A number of widgets require "index" parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)

Entry widgets have options that refer to character positions in the text being displayed. You can use these Tkinter functions to access these special points in text widgets:

- `AtEnd()`
  refers to the last position in the text

- `AtInsert()`
  refers to the point where the text cursor is

- `AtSelFirst()`
  indicates the beginning point of the selected text

- `AtSelLast()`
  denotes the last point of the selected text and finally

- `At(x[, y])`
  refers to the character at pixel location x, y (with y not used in the case of a text entry widget, which contains a single line of text).

Text widget indexes

The index notation for Text widgets is very rich and is best described in the Tk man pages.
Menu indexes (menu.invoke(), menu.entryconfig(), etc.)

Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string 'active', which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

Images

Bitmap/Pixelmap images can be created through the subclasses of Tkinter.Image:

- **BitmapImage** can be used for X11 bitmap data.
- **PhotoImage** can be used for GIF and PPM/PGM color bitmaps.

Either type of image is created through either the `file` or the `data` option (other options are available as well).
The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
The Tix (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The Tix library provides most of the commonly needed widgets that are missing from standard Tk: HList, ComboBox, Control (a.k.a. SpinBox) and an assortment of scrollable widgets. Tix also includes many more widgets that are generally useful in a wide range of applications: NoteBook, FileEntry, PanedWindow, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

**Note:** Tix has been renamed to tkinter.tix in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

The home page for Tix. This includes links to additional documentation and downloads.

**Tix Man Pages**
On-line version of the man pages and reference material.

**Tix Programming Guide**
On-line version of the programmer’s reference material.

**Tix Development Applications**
Tix applications for development of Tix and Tkinter programs.
Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
Using Tix

class Tix.Tix(screenName[, baseName[, className]])

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the Tix module subclasses the classes in the Tkinter module. The former imports the latter, so to use Tix with Tkinter, all you need to do is to import one module. In general, you can just import Tix, and replace the toplevel call to Tkinter.Tk with Tix.Tk:

```python
import Tix
from Tkconstants import *
root = Tix.Tk()
```

To use Tix, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```python
import Tix
root = Tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (tix8183.dll or libtix8183.so) in the same directory that contains your Tk dynamic object library (tk8183.dll or libtk8183.so). The directory with the dynamic object library should also have a file called pkgIndex.tcl (case sensitive), which contains the line:
package ifneeded Tix 8.1 [list load "$dir tix8183.dll"]
Tix Widgets

Tix introduces over 40 widget classes to the Tkinter repertoire. There is a demo of all the tix widgets in the demo/tix directory of the standard distribution.

Basic Widgets

class Tix. Balloon
A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

class Tix. ButtonBox
The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

class Tix. ComboBox
The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

class Tix. Control
The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

class Tix. LabelEntry
The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.
class Tix.LabelFrame

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

class Tix.Meter

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

class Tix.OptionMenu

The OptionMenu creates a menu button of options.

class Tix.PopupMenu

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

class Tix.Select

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class Tix.StdButtonBox

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

File Selectors

class Tix.DirList

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

class Tix.DirTree
The **DirTree** widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class Tix.DirSelectDialog**

The **DirSelectDialog** widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

**class Tix.DirSelectBox**

The **DirSelectBox** is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class Tix.ExFileSelectBox**

The **ExFileSelectBox** widget is usually embedded in a tixExFileSelectDialog widget. It provides an convenient method for the user to select files. The style of the **ExFileSelectBox** widget is very similar to the standard file dialog on MS Windows 3.1.

**class Tix.FileSelectBox**

The **FileSelectBox** is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a **ComboBox** widget so that they can be quickly selected again.

**class Tix.FileEntry**

The **FileEntry** widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the button widget that sits next to the entry, which will bring up a file selection dialog.
Hierarchical ListBox

class Tix.HList

The HList widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

class Tix.CheckList

The CheckList widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

class Tix.Tree

The Tree widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

Tabular ListBox

class Tix.TList

The TList widget can be used to display data in a tabular format. The list entries of a TList widget are similar to the entries in the Tk listbox widget. The main differences are (1) the TList widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.

Manager Widgets

class Tix.PanedWindow

The PanedWindow widget allows the user to interactively manipulate the sizes of several panes. The panes can be
arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

class Tix.ListNoteBook
The ListNoteBook widget is very similar to the TixNoteBook widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the hlist subwidget.

class Tix.NoteBook
The NoteBook widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

Image Types

The tix module adds:

- **pixmap** capabilities to all Tix and Tkinter widgets to create color images from XPM files.
- **Compound** image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

Miscellaneous Widgets
class Tix. **InputOnly**

The **InputOnly** widgets are to accept inputs from the user, which can be done with the `bind` command (Unix only).

---

**Form Geometry Manager**

In addition, **Tix** augments **Tkinter** by providing:

class Tix. **Form**

The **Form** geometry manager based on attachment rules for all Tk widgets.
class Tix.tixCommand

The tix commands provide access to miscellaneous elements of Tix’s internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```python
import Tix
root = Tix.Tk()
print root.tix_configure()
```

tixCommand.tix_configure([cnf], **kw)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(option)

Returns the current value of the configuration option given by option. Option may be any of the configuration options.

tixCommand.tix_getbitmap(name)

Locates a bitmap file of the name name.xpm or name in one of the
bitmap directories (see the \texttt{tix_addbitmapdir()} method). By using \texttt{tix_getbitmap()}, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character @. The returned value can be used to configure the \texttt{bitmap} option of the Tk and Tix widgets.

\texttt{tixCommand}.

\texttt{tix_addbitmapdir(directory)}

Tix maintains a list of directories under which the \texttt{tix_getimage()} and \texttt{tix_getbitmap()} methods will search for image files. The standard bitmap directory is \texttt{$TIX_LIBRARY/bitmaps}. The \texttt{tix_addbitmapdir()} method adds \texttt{directory} into this list. By using this method, the image files of an applications can also be located using the \texttt{tix_getimage()} or \texttt{tix_getbitmap()} method.

\texttt{tixCommand}.

\texttt{tix_filedialog([dlgclass])}

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to \texttt{tix_filedialog()}. An optional \texttt{dlgclass} parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are \texttt{tix}, \texttt{FileSelectDialog} or \texttt{tixExFileSelectDialog}.

\texttt{tixCommand}.

\texttt{tix_getimage(self, name)}

Locates an image file of the name \texttt{name.xpm}, \texttt{name.xbm} or \texttt{name.ppm} in one of the bitmap directories (see the \texttt{tix_addbitmapdir()} method above). If more than one file with the same name (but different extensions) exist, then the image type is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are
chosen on color displays. By using `tix_getimage()`, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the `image` option of the Tk and Tix widgets.

```python
tixCommand.tix_option_get(name)
```

Gets the options maintained by the Tix scheme mechanism.

```python
tixCommand.tix_resetoptions(newScheme, newFontSet[, newScmPrio])
```

Resets the scheme and fontset of the Tix application to `newScheme` and `newFontSet`, respectively. This affects only those widgets created after this call. Therefore, it is best to call the resetoptions method before the creation of any widgets in a Tix application.

The optional parameter `newScmPrio` can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and initied, it is not possible to reset the color schemes and font sets using the `tix_config()` method. Instead, the `tix_resetoptions()` method must be used.
**ScrolledText — Scrolled Text Widget**

*Platforms:* Tk

The `ScrolledText` module provides a class of the same name which implements a basic text widget which has a vertical scroll bar configured to do the “right thing.” Using the `ScrolledText` class is a lot easier than setting up a text widget and scroll bar directly. The constructor is the same as that of the `Tkinter.Text` class.

**Note:** `ScrolledText` has been renamed to `tkinter.scrolledtext` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

`ScrolledText.frame`

The frame which surrounds the text and scroll bar widgets.

`ScrolledText.vbar`

The scroll bar widget.
turtle — Turtle graphics for Tk
Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. Give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.left(25)`, and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The `turtle` module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the `-n` switch.

The turtle module provides turtle graphics primitives, in both object-oriented and procedure-oriented ways. Because it uses `Tkinter` for the underlying graphics, it needs a version of python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The `TurtleScreen` class defines graphics windows as a playground for the drawing turtles. Its constructor needs a
Tkinter.Canvas or a ScrolledCanvas as argument. It should be used when turtle is used as part of some application.

The function Screen() returns a singleton object of a TurtleScreen subclass. This function should be used when turtle is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. RawTurtle (alias: RawPen) defines Turtle objects which draw on a TurtleScreen. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

Derived from RawTurtle is the subclass Turtle (alias: Pen), which draws on “the” Screen - instance which is automatically created, if not already present.

All methods of RawTurtle/Turtle also exist as functions, i.e. part of the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes Screen and Turtle. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles an a screen one has to use the object-oriented interface.

Note: In the following documentation the argument list for
functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
Overview over available Turtle and Screen methods

Turtle methods

Turtle motion
Move and draw

- forward() | fd()
- backward() | bk() | back()
- right() | rt()
- left() | lt()
- goto() | setpos() | setposition()
- setx()
- sety()
- setheading() | seth()
- home()
- circle()
- dot()
- stamp()
- clearstamp()
- clearstamps()
- undo()
- speed()

Tell Turtle's state

- position() | pos()
- towards()
- xcor()
- ycor()
- heading()
- distance()
Setting and measurement
   degrees()
   radians()

Pen control
   Drawing state
   pendown() | pd() | down()
   penup() | pu() | up()
   pensize() | width()
   pen()
   isdown()

Color control
   color()
   pencolor()
   fillcolor()

Filling
   fill()
   begin_fill()
   end_fill()

More drawing control
   reset()
   clear()
   write()

Turtle state
   Visibility
   showturtle() | st()
   hideturtle() | ht()
   isvisible()

   Appearance
   shape()
   resizemode()
shapesize() | turtlesize()
settiltangle()
tiltangle()
tilt()

Using events
onclick()
onrelease()
ondrag()

Special Turtle methods
begin_poly()
end_poly()
get_poly()
clone()
getturtle() | getpen()
getscreen()
setundobuffer()
undobufferentries()
tracer()
window_width()
window_height()

Methods of TurtleScreen/Screen

Window control
bgcolor()
bgpic()
clear() | clearrayscreen()
reset() | resetscreen()
screensize()
setworldcoordinates()

Animation control
delay()
tracer()
update()

Using screen events
listen()
onkey()
onclick() | on screenclick()
ontimer()

Settings and special methods
mode()
colormode()
getcanvas()
getshapes()
register_shape() | addshape()
turtles()
window_height()
window_width()

Methods specific to Screen
bye()
exitonclick()
setup()
title()
Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

Turtle motion

turtle.**forward**(distance)
turtle.**fd**(distance)

**Parameters:** • distancea number (integer or float)

Move the turtle forward by the specified distance, in the direction the turtle is headed.

```python
>>> turtle.position()
(0.00, 0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00, 0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00, 0.00)
```

turtle.**back**(distance)
turtle.**bk**(distance)
turtle.**backward**(distance)

**Parameters:** • distancea number

Move the turtle backward by distance, opposite to the direction the turtle is headed. Do not change the turtle's heading.
turtle.position()
(0.00, 0.00)
turtle.backward(30)
turtle.position()
(-30.00, 0.00)

turtle.right(angle)
turtle.rt(angle)
  Parameters: • angle a number (integer or float)
  Turn turtle right by angle units. (Units are by default degrees, but can be set via the degrees() and radians() functions.) Angle orientation depends on the turtle mode, see mode().

turtle.heading()
22.0
turtle.right(45)
turtle.heading()
337.0

turtle.left(angle)
turtle.lt(angle)
  Parameters: • angle a number (integer or float)
  Turn turtle left by angle units. (Units are by default degrees, but can be set via the degrees() and radians() functions.) Angle orientation depends on the turtle mode, see mode().

turtle.heading()
22.0
turtle.left(45)
turtle.heading()
67.0
turtle.**goto**(*x*, *y=None*)
turtle.**setpos**(*x*, *y=None*)
turtle.**setposition**(*x*, *y=None*)

**Parameters:**
- *x* a number or a pair/vector of numbers
- *y* a number or None

If *y* is None, *x* must be a pair of coordinates or a **Vec2D** (e.g. as returned by pos()).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle’s orientation.

```python
>>> tp = turtle.pos()
>>> tp
(0.00, 0.00)
>>> turtle.setpos(60,30)
>>> turtle.pos()
(60.00,30.00)
>>> turtle.setpos((20,80))
>>> turtle.pos()
(20.00,80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00,0.00)
```

turtle.**setx**(*x*)

**Parameters:**
- *x* a number (integer or float)

Set the turtle’s first coordinate to *x*, leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00, 240.00)
>>> turtle.setx(10)
```
turtle. \texttt{sety}(y)

\textbf{Parameters: \bullet} \hspace{1em} y \hspace{1em} a \hspace{1em} number \hspace{1em} (integer \hspace{1em} or \hspace{1em} float)

Set the turtle's first coordinate to \( y \), leave second coordinate unchanged.

```python
>>> turtle.position()
(10.00, 240.00)
```

```python
>>> turtle.sety(-10)
>>> turtle.position()
(0.00, -10.00)
```

turtle. \texttt{setheading}(to\_angle)
turtle. \texttt{seth}(to\_angle)

\textbf{Parameters: \bullet} \hspace{1em} to\_angle \hspace{1em} a \hspace{1em} number \hspace{1em} (integer \hspace{1em} or \hspace{1em} float)

Set the orientation of the turtle to \( \text{to\_angle} \). Here are some common directions in degrees:

\begin{center}
\textbf{standard mode} \hspace{1em} \textbf{logo mode}
\begin{tabular}{ll}
0 - east & 0 - north \\
90 - north & 90 - east \\
180 - west & 180 - south \\
270 - south & 270 - west \\
\end{tabular}
\end{center}

```python
>>> turtle.setheading(90)
```

```python
>>> turtle.heading()
90
```

turtle. \texttt{home}()

Move turtle to the origin – coordinates (0,0) – and set its heading
to its start-orientation (which depends on the mode, see `mode()`).

```python
turtle.circle(radius, extent=None, steps=None)
```

- `radius` a number
- **Parameters:**
  - `extent` a number (or `None`)
  - `steps` an integer (or `None`)

Draw a circle with given `radius`. The center is `radius` units left of the turtle; `extent` – an angle – determines which part of the circle is drawn. If `extent` is not given, draw the entire circle. If `extent` is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if `radius` is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of `extent`.

As the circle is approximated by an inscribed regular polygon, `steps` determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```python
>>> turtle.circle(50)
>>> turtle.circle(120, 180)  # draw a semicircle
```

```python
turtle.dot(size=None, *color)
```

- `size` an integer >= 1 (if given)
- `color` a colorstring or a numeric color tuple

Draw a circular dot with diameter `size`, using `color`. If `size` is not given, the maximum of pensize+4 and 2*pensize is used.

```python
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle.fd(50)
```

```python
turtle.stamp()
```

Stamp a copy of the turtle shape onto the canvas at the current
turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling `clearstamp(stamp_id)`.

```python
>>> turtle.color("blue")
>>> turtle.stamp()
13
>>> turtle.fd(50)
```

**turtle.clearstamp(stampid)**

**Parameters:**
- `stampid`: an integer, must be return value of previous `stamp()` call

Delete stamp with given `stampid`.

```python
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.clearstamp(astamp)
```

**turtle.clearstamps(n=None)**

**Parameters:**
- `n`: an integer (or `None`)

Delete all or first/last `n` of turtle’s stamps. If `n` is `None`, delete all stamps, if `n > 0` delete first `n` stamps, else if `n < 0` delete last `n` stamps.

```python
>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
>>> turtle.clearstamps(2)
>>> turtle.clearstamps(-2)
>>> turtle.clearstamps()
```

**turtle.undo()**

Undo (repeatedly) the last turtle action(s). Number of available
undo actions is determined by the size of the undobuffer.

```python
>>> for i in range(4):
...    turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...    turtle.undo()
```

turtle. `speed(speed=None)`

**Parameters:**
- `speed`: an integer in the range 0..10 or a speedstring (see below)

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1

Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention: `speed = 0` means that no animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```python
>>> turtle.speed(3)
```

Tell Turtle’s state
turtle.**position**()

**turtle.pos()**

Return the turtle’s current location \((x,y)\) (as a Vec2D vector).

```python
>>> turtle.pos()
(0.00, 240.00)
```

turtle.**towards**\((x, y=None)\)

- **Parameters:**
  - \(x\) a number or a pair/vector of numbers or a turtle instance
  - \(y\) a number if \(x\) is a number, else \texttt{None}

Return the angle between the line from turtle position to position specified by \((x,y)\), the vector or the other turtle. This depends on the turtle’s start orientation which depends on the mode - “standard”/”world” or “logo”).

```python
>>> turtle.pos()
(10.00, 10.00)
>>> turtle.towards(0,0)
225.0
```

turtle.**xcor**()

Return the turtle’s x coordinate.

```python
>>> reset()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.xcor())
50.0
```

turtle.**ycor**()

Return the turtle’s y coordinate.
```python
>>> reset()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print turtle.ycor()
86.6025403784
```

```python
turtle.**heading**()
```
Return the turtle's current heading (value depends on the turtle mode, see **mode**()).

```python
>>> turtle.left(67)
>>> turtle.heading()
67.0
```

```python
turtle.**distance**(*x*, *y=None*)
```
- **Parameters:**
  - *x* a number or a pair/vector of numbers or a turtle instance
  - *y* a number if *x* is a number, else **None**

Return the distance from the turtle to (*x*,*y*), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.pos()
(0.00, 0.00)
>>> turtle.distance(30,40)
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

Settings for measurement
turtle. `degrees(fullcircle=360.0)`

**Parameters:** • *fullcircle* a number

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.left(90)
>>> turtle.heading()
90
>>> turtle.degrees(400.0)  # angle measurement in gon
>>> turtle.heading()
100
```

turtle. `radians()`

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```python
>>> turtle.heading()
90
>>> turtle.radians()
>>> turtle.heading()
1.5707963267948966
```

### Pen control

#### Drawing state

turtle. `pendown()`
turtle. `pd()`
turtle. `down()`

Pull the pen down – drawing when moving.

turtle. `penup()`
turtle. `pu()`
turtle.**up**()

Pull the pen up – no drawing when moving.

turtle.**pensize**(width=**None**)
turtle.**width**(width=**None**)

**Parameters:**
- *width* a positive number

Set the line thickness to *width* or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> turtle.pensize(10)  # from here on lines of width 10 are drawn
```

turtle.**pen**(pen=**None**, ***pendict**)

**Parameters:**
- *pen* a dictionary with some or all of the below listed keys
- *pendict* one or more keyword-arguments with the below listed keys as keywords

Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number

This dictionary can be used as argument for a subsequent call to `pen()` to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
>>> turtle.pen(fillcolor="black", pencolor="red", pensize=10)
>>> turtle.pen()
{'pensize': 10, 'shown': True, 'resizemode': 'auto', 'outlin
"pencolor": 'red', 'pendown': True, 'fillcolor': 'black',
'stretchfactor': (1,1), 'speed': 3}
>>> penstate=turtle.pen()
>>> turtle.color("yellow","")
>>> turtle.penup()
>>> turtle.pen()
{'pensize': 10, 'shown': True, 'resizemode': 'auto', 'outlin
"pencolor": 'yellow', 'pendown': False, 'fillcolor': '',
'stretchfactor': (1,1), 'speed': 3}
>>> p.pen(penstate, fillcolor="green")
>>> p.pen()
{'pensize': 10, 'shown': True, 'resizemode': 'auto', 'outlin
"pencolor": 'red', 'pendown': True, 'fillcolor': 'green',
'stretchfactor': (1,1), 'speed': 3}
```

`turtle.isdown()`

Return `True` if pen is down, `False` if it’s up.

```python
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```
Color control

turtle. **pencolor**(*args*)

Return or set the pencolor.

Four input formats are allowed:

**pencolor()**

Return the current pencolor as color specification string, possibly in hex-number format (see example). May be used as input to another color/pencolor/fillcolor call.

**pencolor(colorstring)**

Set pencolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

**pencolor((r, g, b))**

Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see **colormode()**).

**pencolor(*r, g, b)*

Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```python
>>> turtle.pencolor("brown")
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
"#33cc8c"
```

turtle. **fillcolor**(*args*)
Return or set the fillcolor.

Four input formats are allowed:

```python
fillcolor()
```
Return the current fillcolor as color specification string, possibly in hex-number format (see example). May be used as input to another color/pencolor/fillcolor call.

```python
fillcolor(colorstring)
```
Set fillcolor to `colorstring`, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

```python
fillcolor((r, g, b))
```
Set fillcolor to the RGB color represented by the tuple of `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode, where colormode is either 1.0 or 255 (see `colormode()`).

```python
fillcolor(r, g, b)
```
Set fillcolor to the RGB color represented by `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

```python
>>> turtle.fillcolor("violet")
>>> col = turtle.pencolor()
>>> turtle.fillcolor(col)
>>> turtle.fillcolor(0, .5, 0)
```

```python
turtle.color(*args)
```
Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:
color()

Return the current pencolor and the current fillcolor as a pair of color specification strings as returned by `pencolor()` and `fillcolor()`.

color(colorstring), color((r,g,b)), color(r,g,b)

Inputs as in `pencolor()`, set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))

equivalent to `pencolor(colorstring1)` and `fillcolor(colorstring2)` and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

```python
>>> turtle.color("red", "green")
>>> turtle.color()
("red", "green")
>>> colormode(255)
>>> color((40, 80, 120), (160, 200, 240))
>>> color()
("#285078", "#a0c8f0")
```

See also: Screen method `colormode()`.

Filling

turtle.fill(flag)

**Parameters:** • flag True/False (or 1/0 respectively)

Call `fill(True)` before drawing the shape you want to fill, and
fill(False) when done. When used without argument: return fillstate (True if filling, False else).

```python
>>> turtle.fill(True)
>>> for _ in range(3):
...    turtle.forward(100)
...    turtle.left(120)
...
>>> turtle.fill(False)
```

turtle. **begin_fill()**
Call just before drawing a shape to be filled. Equivalent to fill(True).

```python
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(60)
>>> turtle.end_fill()
```

turtle. **end_fill()**
Fill the shape drawn after the last call to begin_fill(). Equivalent to fill(False).

**More drawing control**

turtle. **reset()**
Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.

```python
>>> turtle.position()
(0.00, -22.00)
>>> turtle.heading()
100.0
```
turtle.reset()

turtle.position()
(0.00, 0.00)

turtle.heading()
0.0

turtle.clear()
Delete the turtle’s drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.write(arg, move=False, align="left", font=("Arial", 8, "normal"))

- arg object to be written to the TurtleScreen
- move True/False
- align one of the strings “left”, “center” or right
- font a triple (fontname, fontsize, fonttype)

Write text - the string representation of arg - at the current turtle position according to align (“left”, “center” or right”) and with the given font. If move is True, the pen is moved to the bottom-right corner of the text. By default, move is False.

>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)

Turtle state

Visibility

turtle.showturtle()
turtle.st()
Make the turtle visible.
turtle.\texttt{hideturtle()}  
\texttt{turtle.ht()}  
Make the turtle invisible. It's a good idea to do this while you're in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

turtle.\texttt{isvisible()}  
Return True if the Turtle is shown, False if it's hidden.

\begin{verbatim}
>>> turtle.hideturtle()
>>> print turtle.isvisible():
False
\end{verbatim}

\section*{Appearance}

turtle.\texttt{shape(name=\texttt{None})}  
\textbf{Parameters:}  
\begin{itemize}
  \item \texttt{name} a string which is a valid shapename
\end{itemize}

Set turtle shape to shape with given \texttt{name} or, if name is not given, return name of current shape. Shape with \texttt{name} must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”, “triangle”, “classic”. To learn about how to deal with shapes see Screen method \texttt{register_shape()}.

\begin{verbatim}
>>> turtle.shape()  
"arrow"
>>> turtle.shape("turtle")
>>> turtle.shape()
\end{verbatim}
turtle. **resizemode**(*rmode=\texttt{None}* )

**Parameters:**

- \texttt{rmode} one of the strings “auto”, “user”, “noresize”

Set resizemode to one of the values: “auto”, “user”, “noresize”. If \texttt{rmode} is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by \texttt{shapesize()}.  
- “noresize”: no adaptation of the turtle’s appearance takes place.

\texttt{resizemode(“user”)} is called by \texttt{shapesize()} when used with arguments.

>>> turtle.resizemode("noresize")
>>> turtle.resizemode()
"noresize"

turtle. **shapesize**(*stretch\_wid=\texttt{None}, stretch\_len=\texttt{None}, outline=\texttt{None}*)

**Parameters:**

- \texttt{stretch\_wid} positive number
- \texttt{stretch\_len} positive number
- \texttt{outline} positive number

Return or set the pen’s attributes x/y-stretchfactors and/or outline. Set resizemode to “user”. If and only if resizemode is set to “user”, the turtle will be displayed stretched according to its stretchfactors: \texttt{stretch\_wid} is stretchfactor perpendicular to its
orientation, \textit{stretch\_len} is stretchfactor in direction of its orientation, \textit{outline} determines the width of the shapes’s outline.

\begin{Verbatim}
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize(outline=8)
\end{Verbatim}

turtle.\texttt{tilt}(\texttt{angle})

\textbf{Parameters:} \bullet \texttt{angle} a number

Rotate the turtleshape by \texttt{angle} from its current tilt-angle, but do \textit{not} change the turtle’s heading (direction of movement).

\begin{Verbatim}
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
\end{Verbatim}

turtle.\texttt{settiltangle}(\texttt{angle})

\textbf{Parameters:} \bullet \texttt{angle} a number

Rotate the turtleshape to point in the direction specified by \texttt{angle}, regardless of its current tilt-angle. \textit{Do not} change the turtle’s heading (direction of movement).

\begin{Verbatim}
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.settiltangle(45)
>>> stamp()
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> stamp()
>>> turtle.fd(50)
\end{Verbatim}
turtle.**tiltangle**()

Return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```python
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45
```

## Using events

turtle.**onclick**(fun, btn=1, add=None)

- *fun* a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- *num* number of the mouse-button, defaults to 1 (left mouse button)
- *add* True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is **None**, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```python
>>> def turn(x, y):
...     left(180)
...     ...

>>> onclick(turn)  # Now clicking into the turtle will turn
>>> onclick(None)  # event-binding will be removed
```
turtle.onrelease(fun, btn=1, add=None)

- **fun** a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** number of the mouse-button, defaults to 1 (left mouse button)
- **add** True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind **fun** to mouse-button-release events on this turtle. If **fun** is None, existing bindings are removed.

```python
>>> class MyTurtle(Turtle):
...     def glow(self, x, y):
...         self.fillcolor("red")
...     def unglow(self, x, y):
...         self.fillcolor("")
...>>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)       # clicking on turtle turns it red
>>> turtle.onrelease(turtle.unglow)  # releasing turns it to transparent
```

turtle.ondrag(fun, btn=1, add=None)

- **fun** a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** number of the mouse-button, defaults to 1 (left mouse button)
- **add** True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind **fun** to mouse-move events on this turtle. If **fun** is None,
existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```python
>>> turtle.ondrag(turtle.goto)
# Subsequently, clicking and dragging the Turtle will move it
# the screen thereby producing handdrawings (if pen is down)
```

Special Turtle methods

turtle.\texttt{begin\_poly}()
Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

turtle.\texttt{end\_poly}()
Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

turtle.\texttt{get\_poly}()
Return the last recorded polygon.

```python
>>> p = turtle.get_poly()
>>> turtle.register_shape("myFavouriteShape", p)
```

turtle.\texttt{clone}()
Create and return a clone of the turtle with same position, heading and turtle properties.

```python
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle.\texttt{getturtle}()
Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x01417350>
>>> turtles()
[turtle.Turtle object at 0x01417350>]
```

turtle.**getscreen**()

Return the **TurtleScreen** object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```python
>>> ts = turtle.getscreen()
>>> ts
<turtle.Screen object at 0x01417710>
>>> ts.bgcolor("pink")
```

turtle.**setundobuffer**(size)

**Parameters:** • *size* an integer or **None**

Set or disable undobuffer. If *size* is an integer an empty undobuffer of given size is installed. *size* gives the maximum number of turtle actions that can be undone by the **undo**() method/function. If *size* is **None**, the undobuffer is disabled.

```python
>>> turtle.setundobuffer(42)
```

turtle.undobufferentries()

Return number of entries in the undobuffer.

```python
>>> while undobufferentries():
...    undo()
```
turtle.\texttt{tracer}(\texttt{flag}=\texttt{None}, \texttt{delay}=\texttt{None})

A replica of the corresponding TurtleScreen method.

\textit{Deprecated since version 2.6.}

turtle.\texttt{window\_width}()
turtle.\texttt{window\_height}()

Both are replicas of the corresponding TurtleScreen methods.

\textit{Deprecated since version 2.6.}

\begin{tcolorbox}
\textbf{Excursus about the use of compound shapes}

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class \texttt{Shape} explicitly as described below:

1. Create an empty Shape object of type “compound”.

2. Add as many components to this object as desired, using the \texttt{addcomponent()} method.

For example:

\begin{verbatim}
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
\end{verbatim}

3. Now add the Shape to the Screen’s shapelist and use it:

\begin{verbatim}
>>> register_shape("myshape", s)
>>> shape("myshape")
\end{verbatim}
\end{tcolorbox}
**Note:** The `Shape` class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the `Shape` class *only* when using compound shapes like shown above!
Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

### Window control

**turtle.** `bgcolor(*args)`

**Parameters:**
- `args` a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```
>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"
```

**turtle.** `bgpic(picname=None)`

**Parameters:**
- `picname` a string, name of a gif-file or "nopic", Or None

Set background image or return name of current background image. If `picname` is a filename, set the corresponding image as background. If `picname` is "nopic", delete background image, if present. If `picname` is `None`, return the filename of the current background image.

```
>>> screen.bgpic()
```
turtle.\texttt{clear()}
turtle.\texttt{clearscreen()}

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

\textbf{Note: } This TurtleScreen method is available as a global function only under the name \texttt{clearscreen}. The global function \texttt{clear} is another one derived from the Turtle method \texttt{clear}.

turtle.\texttt{reset()}
turtle.\texttt{resetscreen()}

Reset all Turtles on the Screen to their initial state.

\textbf{Note: } This TurtleScreen method is available as a global function only under the name \texttt{resetscreen}. The global function \texttt{reset} is another one derived from the Turtle method \texttt{reset}.

turtle.\texttt{screensize(canvwidth=\texttt{None}, canvheight=\texttt{None}, bg=\texttt{None})}

\begin{itemize}
  \item \texttt{canvwidth} positive integer, new width of canvas in pixels
  \item \texttt{canvheight} positive integer, new height of canvas in pixels
  \item \texttt{bg} color string or color-tupel, new background color
\end{itemize}

Parameters:

If no arguments are given, return current (canvaswidth, canvashheight). Else resize the canvas the turtles are drawing on.
Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```python
>>> turtle.screensize(2000,1500)
# e.g. to search for an erroneously escaped turtle ;-)
```

**turtle. setworldcoordinates**(llx, lly, urx, ury)

- *llx*: number, x-coordinate of lower left corner of canvas
- *lly*: number, y-coordinate of lower left corner of canvas
- *urx*: number, x-coordinate of upper right corner of canvas
- *ury*: number, y-coordinate of upper right corner of canvas

**Parameters:**

Set up user-defined coordinate system and switch to mode "world" if necessary. This performs a `screen.reset()`. If mode "world" is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION:** in user-defined coordinate systems angles may appear distorted.

```python
>>> screen.reset()
>>> screen.setworldcoordinates(-50,-7.5,50,7.5)
>>> for _ in range(72):
...    left(10)
...    ...
>>> for _ in range(8):
...    left(45); fd(2)  # a regular octagon
```
Animation control

turtle. **delay**(delay=None)

**Parameters:**
- *delay*: positive integer

Set or return the drawing *delay* in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```python
>>> screen.delay(15)
>>> screen.delay()
15
```

turtle. **tracer**(n=None, delay=None)

**Parameters:**
- *n*: nonnegative integer
- *delay*: nonnegative integer

Turn turtle animation on/off and set delay for update drawings. If *n* is given, only each *n*-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) Second argument sets delay value (see `delay()`).

```python
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
    ...    fd(dist)
    ...    rt(90)
    ...    dist += 2
```

turtle. **update**()

Perform a TurtleScreen update. To be used when tracer is turned off.
See also the RawTurtle/Turtle method `speed()`.

### Using screen events

**turtle.** `listen(xdummy=None, ydummy=None)`

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass `listen()` to the onclick method.

**turtle.** `onkey(fun, key)`

- `fun` a function with no arguments or `None`

**Parameters:**
- `key` a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind `fun` to key-release event of `key`. If `fun` is `None`, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method `listen()`.)

```python
>>> def f():
...    fd(50)
...    lt(60)
...    
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

**turtle.** `onclick(fun, btn=1, add=None)`

**turtle.** `onscreenclick(fun, btn=1, add=None)`

- `fun` a function with two arguments which will be called with the coordinates of the clicked point on the canvas

**Parameters:**
- `num` number of the mouse-button, defaults to 1 (left mouse button)
- `add` `True` or `False` — if `True`, a new binding will
be added, otherwise it will replace a former binding

Bind `fun` to mouse-click events on this screen. If `fun` is `None`, existing bindings are removed.

Example for a TurtleScreen instance named `screen` and a Turtle instance named `turtle`:

```python
>>> screen.onclick(turtle.goto)
# Subsequently clicking into the TurtleScreen will
# make the turtle move to the clicked point.
>>> screen.onclick(None)  # remove event binding again
```

**Note:** This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

turtle.ontimer(`fun`, `t=0`)

**Parameters:**
- `fun` a function with no arguments
- `t` a number >= 0

Install a timer that calls `fun` after `t` milliseconds.

```python
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...     screen.ontimer(f, 250)
>>> f()  # *** makes the turtle marching around
>>> running = False
```
**Settings and special methods**

**turtle. mode**(mode=None)

**Parameters:**
- `mode` one of the strings “standard”, “logo” or “world”

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old turtle. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention:** in this mode angles appear distorted if x/y unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>“standard”</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>“logo”</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```python
>>> mode("logo")  # resets turtle heading to north
>>> mode()
"logo"
```

**turtle. colormode**(cmode=None)

**Parameters:**
- `cmode` one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently r, g, b values of color triples have to be in the range 0..`cmode`.

```python
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> turtle.pencolor(240,160,80)
```

**turtle. getcanvas()**
Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```python
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas instance at 0x010742D8>
```

turtle. `getshapes()`
Return a list of names of all currently available turtle shapes.

```python
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

turtle. `register_shape(name, shape=None)`
turtle. `addshape(name, shape=None)`
There are three different ways to call this function:

1. `name` is the name of a gif-file and `shape` is `None`: Install the corresponding image shape.

   ```python
   note: Image shapes do not rotate when turning the turtle, so they do not display the heading of the turtle!
   ```

2. `name` is an arbitrary string and `shape` is a tuple of pairs of coordinates: Install the corresponding polygon shape.

3. `name` is an arbitrary string and shape is a (compound) `Shape` object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen’s shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

```python
>>> screen.register_shape("turtle.gif")
```
turtle.register_shape("triangle", ((5,-3), (0,5), (-5,-3)))

turtle.turtles()
Return the list of turtles on the screen.

>>> for turtle in screen.turtles()
...    turtle.color("red")

turtle.window_height()
Return the height of the turtle window.

>>> screen.window_height()
480

turtle.window_width()
Return the width of the turtle window.

>>> screen.window_width()
640

Methods specific to Screen, not inherited from TurtleScreen

turtle.bye()
Shut the turtlegraphics window.

turtle.exitonclick()
Bind bye() method to mouse clicks on the Screen.

If the value "using_IDLE" in the configuration dictionary is False (default value), also enter mainloop. Remark: If IDLE with the -n switch (no subprocess) is used, this value should be set to True
in `turtle.cfg`. In this case IDLE's own mainloop is active also for the client script.

```python
turtle.setup(width=_CFG['width'], height=_CFG['height'],
startx=_CFG['leftright'], starty=_CFG['topbottom'])
```

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

- **width** if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- **height** if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen

**Parameters:**
- **startx** if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if None, center window horizontally
- **starty** if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if None, center window vertically

```python
>>> screen.setup (width=200, height=200, startx=0, starty=0)
# sets window to 200x200 pixels, in upper left of screen
>>> screen.setup(width=.75, height=0.5, startx=None, starty=None)
# sets window to 75% of screen by 50% of screen and centers
```

```python
turtle.title(titlestring)
```

**Parameters:**
- **titlestring** a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to `titlestring`.

```python
>>> screen.title("Welcome to the turtle zoo!")
```
The public classes of the module \texttt{turtle}

class \texttt{turtle.RawTurtle(canvas)}

class \texttt{turtle.RawPen(canvas)}

\begin{itemize}
\item \textit{canvas}
\end{itemize}

\begin{itemize}
\item \texttt{Tkinter.Canvas}, \texttt{ScrolledCanvas} or \texttt{TurtleScreen}
\end{itemize}

\textbf{Parameters:}

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

class \texttt{turtle.Turtle}

Subclass of RawTurtle, has the same interface but draws on a default \texttt{Screen} object created automatically when needed for the first time.

class \texttt{turtle.TurtleScreen(cv)}

\textbf{Parameters:}

\begin{itemize}
\item \texttt{cv} a \texttt{Tkinter.Canvas}
\end{itemize}

Provides screen oriented methods like \texttt{setbg()} etc. that are described above.

class \texttt{turtle.Screen}

Subclass of TurtleScreen, with \textit{four methods added}.

class \texttt{turtle.ScrolledCanvas(master)}

\begin{itemize}
\item \textit{masters}ome \texttt{Tkinter} widget to contain the
\end{itemize}

\textbf{Parameters:}

\begin{itemize}
\item \texttt{ScrolledCanvas}, i.e. a \texttt{Tkinter}-canvas with scrollbars added
\end{itemize}

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.
class turtle.**Shape**(type\_, data)

**Parameters:**
- **type** one of the strings “polygon”, “image”, “compound”

Data structure modeling shapes. The pair \((\text{type\_}, \text{data})\) must follow this specification:

<table>
<thead>
<tr>
<th>type_</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the <strong>addcomponent</strong> method)</td>
</tr>
</tbody>
</table>

**addcomponent**(poly, fill, outline=None)

**Parameters:**
- **poly** a polygon, i.e. a tuple of pairs of numbers
- **fill** a color the poly will be filled with
- **outline** a color for the poly’s outline (if given)

Example:

```python
>>> poly = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
# .. add more components and then use register_shape()
```

See *Excursus about the use of compound shapes*.

class turtle.**Vec2D**(x, y)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics programs too. Derived from tuple, so a vector is a tuple!

Provides (for a, b vectors, k number):

- \(a + b\) vector addition
- a - b vector subtraction
- a * b inner product
- k * a and a * k multiplication with scalar
- abs(a) absolute value of a
- a.rotate(angle) rotation
Help and configuration

How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.

- Calling `help()` on methods or functions displays the docstrings:

```python
>>> help(Screenbgcolor)
Help on method bgcolor in module turtle:

bgcolor(self,*args) unbound turtle.Screen method
   Set or return backgroundcolor of the TurtleScreen.

   Arguments (if given): a color string or three numbers
   in the range 0..colormode or a 3-tuple of such numbers.

>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"
```

```python
>>> help(Turtle.penup)
Help on method penup in module turtle:
```
penup(self) unbound turtle.Turtle method

Pull the pen up -- no drawing when moving.

Aliases: penup | pu | up

No argument

>>> turtle.penup()

- The docstrings of the functions which are derived from methods have a modified form:

```python
>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers.

Example::

    >>> bgcolor("orange")
    >>> bgcolor()
"orange"
    >>> bgcolor(0.5,0,0.5)
    >>> bgcolor()
"#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
```
Pull the pen up -- no drawing when moving.

Aliases: penup | pu | up

No argument

Example:
>>> penup()

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```
turtle.write_docstringdict(filename="turtle_docstringdict")
```

**Parameters:**
- `filename` a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script `filename.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use `turtle` with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary
will be read in at import time and will replace the original English docstrings.

At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

**How to configure Screen and Turtles**

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following `turtle.cfg`:

```
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
title = Python Turtle Graphics
using_IDLE = False
```
Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg-file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the `turtle_docstringdict_turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`.
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE`: Set this to `True` if you regularly work with IDLE and its `-n` switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `demo/turtle` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos (preferably not from within the demo-viewer).
There is a set of demo scripts in the turtledemo directory located in the Demo/turtle directory in the source distribution.

It contains:

- a set of 15 demo scripts demonstrating different features of the new module turtle
- a demo viewer turtleDemo.py which can be used to view the source code of the scripts and run them at the same time. 14 of the examples can be accessed via the Examples menu; all of them can also be run standalone.
- The example turtledemo_two_canvases.py demonstrates the simultaneous use of two canvases with the turtle module. Therefore it only can be run standalone.
- There is a turtle.cfg file in this directory, which also serves as an example for how to write and use such files.

The demoscripts are:

IDLE

IDLE is the Python IDE built with the `tkinter` GUI toolkit.

IDLE has the following features:

- coded in 100% pure Python, using the `tkinter` GUI toolkit
- cross-platform: works on Windows and Unix
- multi-window text editor with multiple undo, Python colorizing and many other features, e.g. smart indent and call tips
- Python shell window (a.k.a. interactive interpreter)
- debugger (not complete, but you can set breakpoints, view and step)
Menus

File menu

New window
create a new editing window

Open...
open an existing file

Open module...
open an existing module (searches sys.path)

Class browser
show classes and methods in current file

Path browser
show sys.path directories, modules, classes and methods

Save
save current window to the associated file (unsaved windows have a * before and after the window title)

Save As...
save current window to new file, which becomes the associated file

Save Copy As...
save current window to different file without changing the associated file

Close
close current window (asks to save if unsaved)

Exit
close all windows and quit IDLE (asks to save if unsaved)

Edit menu
Undo
  Undo last change to current window (max 1000 changes)
Redo
  Redo last undone change to current window
Cut
  Copy selection into system-wide clipboard; then delete selection
Copy
  Copy selection into system-wide clipboard
Paste
  Insert system-wide clipboard into window
Select All
  Select the entire contents of the edit buffer
Find...
  Open a search dialog box with many options
Find again
  Repeat last search
Find selection
  Search for the string in the selection
Find in Files...
  Open a search dialog box for searching files
Replace...
  Open a search-and-replace dialog box
Go to line
  Ask for a line number and show that line
Indent region
  Shift selected lines right 4 spaces
Dedent region
  Shift selected lines left 4 spaces
Comment out region
   Insert ## in front of selected lines

Uncomment region
   Remove leading # or ## from selected lines

Tabify region
   Turns leading stretches of spaces into tabs

Untabify region
   Turn all tabs into the right number of spaces

Expand word
   Expand the word you have typed to match another word in the same buffer; repeat to get a different expansion

Format Paragraph
   Reformat the current blank-line-separated paragraph

Import module
   Import or reload the current module

Run script
   Execute the current file in the __main__ namespace

## Windows menu ##

Zoom Height
   toggles the window between normal size (24x80) and maximum height.

The rest of this menu lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

## Debug menu (in the Python Shell window only) ##

Go to file/line
   look around the insert point for a filename and linenumber, open the file, and show the line.
Open stack viewer
  show the stack traceback of the last exception

Debugger toggle
  Run commands in the shell under the debugger

JIT Stack viewer toggle
  Open stack viewer on traceback
Basic editing and navigation

- **Backspace** deletes to the left; **Del** deletes to the right
- **Arrow keys** and **Page Up/Page Down** to move around
- **Home/End** go to begin/end of line
- **C-Home/C-End** go to begin/end of file
- Some **Emacs** bindings may also work, including **C-B, C-P, C-A, C-E, C-D, C-L**

Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, **Backspace** deletes up to 4 spaces if they are there. **Tab** inserts 1-4 spaces (in the Python Shell window one tab). See also the indent/dedent region commands in the edit menu.

Python Shell window

- **C-c** interrupts executing command
- **C-d** sends end-of-file; closes window if typed at a >>> prompt
- **Alt-p** retrieves previous command matching what you have typed
- **Alt-n** retrieves next
- **Return** while on any previous command retrieves that command
- **Alt-/** (Expand word) is also useful here
Syntax colors

The coloring is applied in a background “thread,” so you may occasionally see uncolorized text. To change the color scheme, edit the [Colors] section in config.txt.

Python syntax colors:
  Keywords
    orange
  Strings
    green
  Comments
    red
  Definitions
    blue

Shell colors:
  Console output
    brown
  stdout
    blue
  stderr
    dark green
  stdin
    black

Command line usage

idle.py [-c command] [-d] [-e] [-s] [-t title] [arg] ...
-c command  run this command
-d enable debugger
-e edit mode; arguments are files to be edited
-s run $IDLESTARTUP or $PYTHONSTARTUP first
-t title set title of shell window

If there are arguments:

1. If \(-e\) is used, arguments are files opened for editing and
   \(\text{sys.argv}\) reflects the arguments passed to IDLE itself.
2. Otherwise, if \(-c\) is used, all arguments are placed in
   \(\text{sys.argv}[1:...]\), with \(\text{sys.argv}[0]\) set to \'-c\'.
3. Otherwise, if neither \(-e\) nor \(-c\) is used, the first argument is a
   script which is executed with the remaining arguments in
   \(\text{sys.argv}[1:...]\) and \(\text{sys.argv}[0]\) set to the script name. If the
   script name is \'\-\', no script is executed but an interactive Python
   session is started; the arguments are still available in \(\text{sys.argv}\).
Other Graphical User Interface Packages

There are an number of extension widget sets to Tkinter.

See also:

**Python megawidgets**

is a toolkit for building high-level compound widgets in Python using the Tkinter module. It consists of a set of base classes and a library of flexible and extensible megawidgets built on this foundation. These megawidgets include notebooks, comboboxes, selection widgets, paned widgets, scrolled widgets, dialog windows, etc. Also, with the Pmw.Blt interface to BLT, the busy, graph, stripchart, tabset and vector commands are be available. The initial ideas for Pmw were taken from the Tk itcl extensions [incr Tk] by Michael McLennan and [incr Widgets] by Mark Ulferts. Several of the megawidgets are direct translations from the itcl to Python. It offers most of the range of widgets that [incr Widgets] does, and is almost as complete as Tix, lacking however Tix’s fast MList widget for drawing trees.

**Tkinter3000 Widget Construction Kit (WCK)**

is a library that allows you to write new Tkinter widgets in pure Python. The WCK framework gives you full control over widget creation, configuration, screen appearance, and event handling. WCK widgets can be very fast and light-weight, since they can operate directly on Python data structures, without having to transfer data through the Tk/Tcl layer.

The major cross-platform (Windows, Mac OS X, Unix-like) GUI
toolkits that are also available for Python:

See also:

PyGTK

is a set of bindings for the GTK widget set. It provides an object oriented interface that is slightly higher level than the C one. It comes with many more widgets than Tkinter provides, and has good Python-specific reference documentation. There are also bindings to GNOME. One well known PyGTK application is PythonCAD. An online tutorial is available.

PyQt

PyQt is a sip-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. sip is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python. The PyQt3 bindings have a book, GUI Programming with Python: QT Edition by Boudewijn Rempt. The PyQt4 bindings also have a book, Rapid GUI Programming with Python and Qt, by Mark Summerfield.

wxPython

wxPython is a cross-platform GUI toolkit for Python that is built around the popular wxWidgets (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules. wxPython has a book, wxPython in Action, by Noel Rappin and Robin Dunn.
PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the GUI Programming page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
Development Tools

The modules described in this chapter help you write software. For example, the `pydoc` module takes a module and generates documentation based on the module’s contents. The `doctest` and `unittest` modules contain frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. `2to3` can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **pydoc** — Documentation generator and online help system
- **doctest** — Test interactive Python examples
  - Simple Usage: Checking Examples in Docstrings
  - Simple Usage: Checking Examples in a Text File
  - How It Works
    - Which Docstrings Are Examined?
    - How are Docstring Examples Recognized?
    - What’s the Execution Context?
    - What About Exceptions?
    - Option Flags and Directives
    - Warnings
  - Basic API
  - Unittest API
  - Advanced API
    - DocTest Objects
    - Example Objects
    - DocTestFinder objects
    - DocTestParser objects
    - DocTestRunner objects
    - OutputChecker objects
- Debugging
- Soapbox

- **unittest** — Unit testing framework
  - Basic example
  - Organizing test code
  - Re-using old test code
  - Classes and functions
  - TestCase Objects
  - TestSuite Objects
  - TestResult Objects
  - TestLoader Objects

- **2to3** - Automated Python 2 to 3 code translation
  - Using 2to3
  - `lib2to3` - 2to3’s library

- **test** — Regression tests package for Python
  - Writing Unit Tests for the `test` package
  - Running tests using `test.regrtest`

- **test.test_support** — Utility functions for tests
pydoc — Documentation generator and online help system

New in version 2.1.

The pydoc module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

The built-in function help() invokes the online help system in the interactive interpreter, which uses pydoc to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running pydoc as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the sys module, in a style similar to the manual pages shown by the Unix man command. The argument to pydoc can be the name of a function, module, or package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to pydoc looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

Specifying a -w flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a -k flag before the argument will search the synopsis
lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix `man` command. The synopsis line of a module is the first line of its documentation string.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. `pydoc -g` will start the server and additionally bring up a small `Tkinter`-based graphical interface to help you search for documentation pages.

When `pydoc` generates documentation, it uses the current environment and path to locate modules. Thus, invoking `pydoc spam` documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `http://docs.python.org/library/`. This can be overridden by setting the `PYTHONDOCS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.
doctest — Test interactive Python examples

The doctest module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
"""
This is the "example" module.

The example module supplies one function, factorial(). For example,

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.
    If the result is small enough to fit in an int, return an int.
    Else return a long.
   "
    return

>>> [factorial(n) for n in range(6)]
[1, 1, 2, 6, 24, 120]
>>> [factorial(long(n)) for n in range(6)]
[1, 1, 2, 6, 24, 120]
>>> factorial(30)
```

>>> factorial(30L)
2652528598121910586363084800000000L

>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must be an exact integer:

>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer

>>> factorial(30.0)
2652528598121910586363084800000000L

It must also not be ridiculously large:

>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

""

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result

if __name__ == "__main__":
    import doctest
doctest.testmod()

If you run example.py directly from the command line, doctest works its magic:

$ python example.py
$
There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
        ...
      OverflowError: n too large
ok
2 items passed all tests:
    1 tests in __main__
    8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$```

That's all you need to know to start making productive use of `doctest`! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the
standard test file `Lib/test/test_doctest.py`.
**Simple Usage: Checking Examples in Docstrings**

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module `M` with:

```python
if __name__ == "__main__":
    import doctest
doctest.testmod()
```

`doctest` then examines docstrings in module `M`.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```bash
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures`, where `N` is the number of examples that failed.

Run it with the `-v` switch instead:

```bash
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing `-v` or not has no effect).
Since Python 2.6, there is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section *Basic API*. 
Another simple application of doctest is testing interactive examples in a text file. This can be done with the \texttt{testfile()} function:

\begin{verbatim}
import doctest
doctest.testfile("example.txt")
\end{verbatim}

That short script executes and verifies any interactive Python examples contained in the file \texttt{example.txt}. The file content is treated as if it were a single giant docstring; the file doesn’t need to contain a Python program! For example, perhaps \texttt{example.txt} contains this:

\begin{verbatim}
The ``example`` module
======================
Using ``factorial``
-------------------
This is an example text file in reStructuredText format. First
``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
\end{verbatim}

Running \texttt{doctest.testfile("example.txt")} then finds the error in this documentation:

\begin{verbatim}
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
\end{verbatim}
As with `testmod()`, `testfile()` won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section `Basic API` for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

Since Python 2.6, there is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section `Basic API`. 
How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if \texttt{M.__test__} exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from \texttt{M.__test__} are searched, and strings are treated as if they were docstrings. In output, a key \texttt{K} in \texttt{M.__test__} appears with name

\begin{verbatim}
<name of M>.__test__.K
\end{verbatim}

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

\textit{Changed in version 2.4:} A “private name” concept is deprecated and no longer documented.

How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn’t trying to do an exact emulation of any specific Python shell. All hard tab characters are expanded to
spaces, using 8-column tab stops. If you don’t believe tabs should mean that, too bad: don’t use hard tabs, or write your own DocTestParser class.

Changed in version 2.4: Expanding tabs to spaces is new; previous versions tried to preserve hard tabs, with confusing results.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print "yes"
... else:
...     print "no"
...     print "NO"
...     print "NO!!!"
...
no
NO
NO!!!
>>> 
```

Any expected output must immediately follow the final '```' or '...' line containing the code, and the expected output (if any) extends to the next '```' or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

  Changed in version 2.4: `<BLANKLINE>` was added; there was no way to use expected output containing empty lines in previous versions.

- Output to stdout is captured, but not output to stderr (exception
tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```python
>>> def f(x):
...    r'''Backslashes in a raw docstring: m\n'''
>>> print f.__doc__
Backslashes in a raw docstring: m\n```

Otherwise, the backslash will be interpreted as part of the string. For example, the “\” above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```python
>>> def f(x):
...    '''Backslashes in a raw docstring: m\n'''
>>> print f.__doc__
Backslashes in a raw docstring: m\n```

- The starting column doesn't matter:

```python
>>> assert "Easy!"
>>> import math
    >>> math.floor(1.9)
1.0
```

and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

What’s the Execution Context?
By default, each time `doctest` finds a docstring to test, it uses a *shallow copy* of `m`'s globals, so that running tests doesn’t change the module's real globals, and so that one test in `m` can’t leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in `m`, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globs=your_dict` to `testmod()` or `testfile()` instead.

### What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:

```python
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: list.remove(x): x not in list
```

That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```
The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```python
>>> raise ValueError('multi
 line
detail')
Traceback (most recent call last):
  File "<stdin>", line 1, in 
ValueError: multi
 line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception's type and detail, and the rest are ignored.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```python
>>> raise ValueError('multi
 line
detail')
Traceback (most recent call last):
  ...
ValueError: multi
 line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's `ELLIPSIS` option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won’t need to remember:
• Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.

• Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.

• When the `IGNORE_EXCEPTION_DETAIL` doctest option is specified, everything following the leftmost colon is ignored.

• The interactive shell omits the traceback header line for some `SyntaxError`s. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.

• For some `SyntaxError`s, Python displays the character position of the syntax error, using a `^` marker:

```python
>>> 1 1
   File "<stdin>", line 1
   1 1
   ^
SyntaxError: invalid syntax
```
Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```python
>>> 1 1
Traceback (most recent call last):
  File "<stdin>", line 1
  1 1
  ^
SyntaxError: invalid syntax
```

*Changed in version 2.4:* The ability to handle a multi-line exception detail, and the `IGNORE_EXCEPTION_DETAIL` doctest option, were added.

## Option Flags and Directives

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be or'ed together and passed to various functions. The names can also be used in doctest directives (see below).

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:

- **doctest.\texttt{DONT\_ACCEPT\_TRUE\_FOR\_1}**
  
  By default, if an expected output block contains just 1, an actual output block containing just 1 or just \texttt{True} is considered to be a match, and similarly for 0 versus \texttt{False}. When \texttt{DONT\_ACCEPT\_TRUE\_FOR\_1} is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests
expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest.DONT_ACCEPT_BLANKLINE**

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When **DONT_ACCEPT_BLANKLINE** is specified, this substitution is not allowed.

**doctest.NORMALIZE_WHITESPACE**

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. **NORMALIZE_WHITESPACE** is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

**doctest.ELLIPSIS**

When specified, an ellipsis marker (…) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that `.*` is prone to in regular expressions.

**doctest.IGNORE_EXCEPTION_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.
Note that a similar effect can be obtained using `ELLIPSIS`, and `IGNORE_EXCEPTION_DETAIL` may go away when Python releases prior to 2.4 become uninteresting. Until then, `IGNORE_EXCEPTION_DETAIL` is the only clear way to write a doctest that doesn’t care about the exception detail yet continues to pass under Python releases prior to 2.4 (doctest directives appear to be comments to them). For example,

```python
>>> (1, 2)[3] = 'moo' #doctest: +IGNORE_EXCEPTION_DETAIL
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment
```

passes under Python 2.4 and Python 2.3. The detail changed in 2.4, to say “does not” instead of “doesn't”.

**doctest.SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out” examples.

**doctest.COMPARISON_FLAGS**

A bitmask or’ing together all the comparison flags above.

The second group of options controls how test failures are reported:

**doctest.REPORT_UDIFF**

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.
**doctest.REPORT_CDIFF**
When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

**doctest.REPORT_NDIFF**
When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

**doctest.REPORT_ONLY_FIRST_FAILURE**
When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When `REPORT_ONLY_FIRST_FAILURE` is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

**doctest.REPORTING_FLAGS**
A bitmask or'ing together all the reporting flags above.

“Doctest directives” may be used to modify the option flags for individual examples. Doctest directives are expressed as a special Python comment following an example’s source code:

```
directive ::= "#" "doctest:" directive_options
directive_options ::= directive_option ("," directive_option)*
directive_option ::= on_or_off directive_option_name
on_or_off ::= "+" | "-"
directive_option_name ::= "DONT_ACCEPT_BLANKLINE" | "NORMALIZ
```

Whitespace is not allowed between the + or - and the directive
option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

For example, this test passes:

```python
>>> print range(20) #doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```python
>>> print range(20) # doctest:+ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```python
>>> print range(20) # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

If multiple directive comments are used for a single example, then they are combined:

```python
>>> print range(20) # doctest: +ELLIPSIS
... # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add ... lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:
Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

*Changed in version 2.4:* Constants `DONT_ACCEPT_BLANKLINE`, `NORMALIZE_WHITESPACE`, `ELLIPSIS`, `IGNORE_EXCEPTION_DETAIL`, `REPORT_UDIFF`, `REPORT_CDIFF`, `REPORT_NDIFF`, `REPORT_ONLY_FIRST_FAILURE`, `COMPARISON_FLAGS` and `REPORTING_FLAGS` were added; by default `<BLANKLINE>` in expected output matches an empty line in actual output; and doctest directives were added.

*Changed in version 2.5:* Constant `SKIP` was added.

There's also a way to register new option flag names, although this isn't useful unless you intend to extend `doctest` internals via subclassing:

```python
doctest.register_optionflag(name)
```

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```python
MY_FLAG = register_optionflag('MY_FLAG')
```
**New in version 2.4.**

**Warnings**

**doctest** is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a dict, Python doesn't guarantee that the key-value pairs will be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = foo().items()
>>> d.sort()
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0) # certain to fail some of the time
7948648
>>> class C: pass
>>> C() # the default repr() for instances embeds an address
<__main__.C instance at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:
Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```
>>> 1./7   # risky
0.14285714285714285
>>> print 1./7 # safer
0.142857142857
>>> print round(1./7, 6) # much safer
0.142857
```

Numbers of the form \( \frac{I}{2.**J} \) are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```
>>> 3./4   # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.
Basic API

The functions `testmod()` and `testfile()` provide a simple interface to `doctest` that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

`doctest.testfile(filename[, module_relative][, name][, package][, globs][, verbose][, report][, optionflags][, extraglobs][, raise_on_error][, parser][, encoding])`

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the `filename` should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `name` gives the name of the test; by default,
or if `None`, `os.path.basename(filename)` is used.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `globs` gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument `extraglobs` gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if `globs` and `extraglobs` have a common key, the associated value in `extraglobs` appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an `extraglobs` dict mapping the generic name to the subclass to be tested.

Optional argument `verbose` prints lots of stuff if true, and prints only failures if false; by default, or if `None`, it's true if and only if `-v` is in `sys.argv`.

Optional argument `report` prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument `optionflags` or's together option flags. See
section Option Flags and Directives.

Optional argument `raise_on_error` defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode.

New in version 2.4.

Changed in version 2.5: The parameter `encoding` was added.

```python
doctest.testmod([m], name=None, globs=None, verbose=None, report=None, optionflags=None, extraglobs=None, raise_on_error=None, exclude_empty=None)
```

All arguments are optional, and all except for `m` should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module `m` (or module `__main__` if `m` is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists and is not `None`. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module `m` are searched.
Return (failure_count, test_count).

Optional argument name gives the name of the module; by default, or if None, m.__name__ is used.

Optional argument exclude_empty defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using doctest.master.summarize() in conjunction with testmod() continues to get output for objects with no tests. The exclude_empty argument to the newer DocTestFinder constructor defaults to true.

Optional arguments extraglobs, verbose, report, optionflags, raise_on_error, and globs are the same as for function testfile() above, except that globs defaults to m.__dict__.

Changed in version 2.3: The parameter optionflags was added.

Changed in version 2.4: The parameters extraglobs, raise_on_error and exclude_empty were added.

Changed in version 2.5: The optional argument isprivate, deprecated in 2.4, was removed.

There's also a function to run the doctests associated with a single object. This function is provided for backward compatibility. There are no plans to deprecate it, but it's rarely useful:

```python
doctest.run_docstring_examples(f, globs[, verbose][, name][, compileflags][, optionflags])
```

Test examples associated with object f; for example, f may be a module, function, or class object.

A shallow copy of dictionary argument globs is used for the
execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if *None*, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function *testfile()* above.
As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. Prior to Python 2.4, `doctest` had a barely documented `Tester` class that supplied a rudimentary way to combine doctests from multiple modules. `Tester` was feeble, and in practice most serious Python testing frameworks build on the `unittest` module, which supplies many flexible ways to combine tests from multiple sources. So, in Python 2.4, `doctest`'s `Tester` class is deprecated, and `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. These test suites can then be run using `unittest` test runners:

```python
import unittest
import doctest
import my_module_with_doctests, and_another

suite = unittest.TestSuite()
for mod in my_module_with_doctests, and_another:
    suite.addTest(doctest.DocTestSuite(mod))
runner = unittest.TextTestRunner()
runner.run(suite)
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

```python
doctest.DocFileSuite([module_relative], [package], [setUp],
    tearDown, [globs], [optionflags], [parser], [encoding])
```

Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs the interactive examples in each file. If an
example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument `module_relative` specifies how the filenames in `paths` should be interpreted:

- If `module_relative` is `True` (the default), then each filename specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then each filename specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `setUp` specifies a set-up function for the test suite. This is called before running the tests in each file. The `setUp` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the
test passed.

Optional argument *tearDown* specifies a tear-down function for the test suite. This is called after running the tests in each file. The *tearDown* function will be passed a DocTest object. The setUp function can access the test globals as the *globs* attribute of the test passed.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section *Option Flags and Directives*. See function set_unittest_reportflags() below for a better way to set reporting options.

Optional argument *parser* specifies a DocTestParser (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., DocTestParser()).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

*New in version 2.4.*

*Changed in version 2.5:* The global __file__ was added to the globals provided to doctests loaded from a text file using DocFileSuite().

*Changed in version 2.5:* The parameter *encoding* was added.

doctest.DoctestSuite([module][, globs][, extraglobs][, test_finder][, setUp][, tearDown][, checker])
Convert doctest tests for a module to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument `module` provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `extraglobs` specifies an extra set of global variables, which is merged into `globs`. By default, no extra globals are used.

Optional argument `test_finder` is the `DocTestFinder` object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments `setUp`, `tearDown`, and `optionflags` are the same as for function `DocFileSuite()` above.

*New in version 2.3.*

*Changed in version 2.4:* The parameters `globs`, `extraglobs`, `test_finder`, `setUp`, `tearDown`, and `optionflags` were added; this function now uses the same search technique as `testmod()`.

Under the covers, `DocTestSuite()` creates a `unittest.TestSuite` out
of doctest.DocTestCase instances, and DocTestCase is a subclass of unittest.TestCase. DocTestCase isn’t documented here (it’s an internal detail), but studying its code can answer questions about the exact details of unittest integration.

Similarly, DocFileSuite() creates a unittest.TestSuite out of doctest.DocFileCase instances, and DocFileCase is a subclass of DocTestCase.

So both ways of creating a unittest.TestSuite run instances of DocTestCase. This is important for a subtle reason: when you run doctest functions yourself, you can control the doctest options in use directly, by passing option flags to doctest functions. However, if you’re writing a unittest framework, unittest ultimately controls when and how tests get run. The framework author typically wants to control doctest reporting options (perhaps, e.g., specified by command line options), but there’s no way to pass options through unittest to doctest test runners.

For this reason, doctest also supports a notion of doctest reporting flags specific to unittest support, via this function:

doctest.set_unittest_reportflags(flags)
    Set the doctest reporting flags to use.

Argument flags or’s together option flags. See section Option Flags and Directives. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module unittest: the runTest() method of DocTestCase looks at the option flags specified for the test case when the DocTestCase instance was constructed. If no reporting flags were specified (which is the typical and expected case), doctest’s
unittest reporting flags are or’ed into the option flags, and the option flags so augmented are passed to the DocTestRunner instance created to run the doctest. If any reporting flags were specified when the DocTestCase instance was constructed, doctest's unittest reporting flags are ignored.

The value of the unittest reporting flags in effect before the function was called is returned by the function.

New in version 2.4.
Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single python `statement`, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a `DocTestParser` to create a `DocTest` from every docstring that contains interactive examples.
- **DocTestParser**: Creates a `DocTest` object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a `DocTest`, and uses an `OutputChecker` to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
class doctest.\texttt{DocTest}(\textit{examples, globs, name, filename, lineno, docstring})

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the member variables of the same names.

\textit{New in version 2.4.}

\texttt{DocTest} defines the following member variables. They are initialized by the constructor, and should not be modified directly.

\textbf{examples}

A list of \texttt{Example} objects encoding the individual interactive Python examples that should be run by this test.

\textbf{globs}

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in \texttt{globs} after the test is run.

\textbf{name}

A string name identifying the \texttt{DocTest}. Typically, this is the name of the object or file that the test was extracted from.
filename
The name of the file that this DocTest was extracted from; or None if the filename is unknown, or if the DocTest was not extracted from a file.

lineno
The line number within filename where this DocTest begins, or None if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

docstring
The string that the test was extracted from, or ‘None’ if the string is unavailable, or if the test was not extracted from a string.

Example Objects

class doctest.Example(source, want[, exc_msg][, lineno][, indent][, options])
A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the member variables of the same names.

New in version 2.4.

Example defines the following member variables. They are initialized by the constructor, and should not be modified directly.

source
A string containing the example’s source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

want
The expected output from running the example’s source code (either from stdout, or a traceback in case of exception). The output ends with a newline unless no output is expected, in which case it’s an empty string. The constructor adds a newline when necessary.

**exc_msg**

The exception message generated by the example, if the example is expected to generate an exception; or None if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. **exc_msg** ends with a newline unless it’s None. The constructor adds a newline if needed.

**lineno**

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**

A dictionary mapping from option flags to True or False, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the DocTestRunner's optionflags). By default, no options are set.

**DocTestFinder objects**

```python
class doctest.DocTestFinder([verbose][, parser][, recurse][,]
```
A processing class used to extract the DocTests that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTests can currently be extracted from the following object types: modules, functions, classes, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

New in version 2.4.

DocTestFinder defines the following method:

```
find(obj[, name][, module][, globs][, extraglobs])
```

Return a list of the DocTests that are defined by obj's docstring, or by any of its contained objects' docstrings.

The optional argument name specifies the object's name; this name will be used to construct names for the returned DocTests. If name is not specified, then obj.__name__ is used.
The optional parameter `module` is the module that contains the given object. If the module is not specified or is None, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if `globs` is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than `module` are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If `module` is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if `module` is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each `DocTest` is formed by combining `globs` and `extraglobs` (bindings in `extraglobs` override bindings in `globs`). A new shallow copy of the globals dictionary is created for each `DocTest`. If `globs` is not specified, then it defaults to the module’s `__dict__`, if specified, or `{}` otherwise. If `extraglobs` is not specified, then it defaults to `{}`.

### DocTestParser objects

```python
class doctest.DocTestParser
    A processing class used to extract interactive examples from a string, and use them to create a DocTest object.

    New in version 2.4.
```
**DocTestParser** defines the following methods:

**get_doctest**(string, globs, name, filename, lineno)

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

*globs, name, filename, and lineno* are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples**(string[, name])

Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based.

The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse**(string[, name])

Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

---

**DocTestRunner objects**

class doctest. **DocTestRunner**( [checker][, verbose][, optionflags])

A processing class used to execute and verify the interactive examples in a **DocTest**.

The comparison between expected outputs and actual outputs is done by an **OutputChecker**. This comparison may be customized with a number of option flags; see section **Option Flags and Directives** for more information. If the option flags are insufficient,
then the comparison may also be customized by passing a subclass of `OutputChecker` to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to `TestRunner.run()`; this function will be called with strings that should be displayed. It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing `DocTestRunner`, and overriding the methods `report_start()`, `report_success()`, `report_unexpected_exception()`, and `report_failure()`.

The optional keyword argument `checker` specifies the `OutputChecker` object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument `verbose` controls the `DocTestRunner`’s verbosity. If `verbose` is `True`, then information is printed about each example, as it is run. If `verbose` is `False`, then only failures are printed. If `verbose` is unspecified, or `None`, then verbose output is used iff the command-line switch `-v` is used.

The optional keyword argument `optionflags` can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section `Option Flags and Directives`.

*New in version 2.4.*

`DocTestParser` defines the following methods:

```python
report_start(out, test, example)
```

Report that the test runner is about to process the given
example. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. test is the test containing example. out is the output function that was passed to DocTestRunner.run().

report_success(out, test, example, got)
Report that the given example ran successfully. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. got is the actual output from the example. test is the test containing example. out is the output function that was passed to DocTestRunner.run().

report_failure(out, test, example, got)
Report that the given example failed. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. got is the actual output from the example. test is the test containing example. out is the output function that was passed to DocTestRunner.run().

report_unexpected_exception(out, test, example, exc_info)
Report that the given example raised an unexpected exception. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.
example is the example about to be processed. exc_info is a tuple containing information about the unexpected exception (as returned by sys.exc_info()). test is the test containing example. out is the output function that was passed to DocTestRunner.run().

run(test[, compileflags][, out][, clear_globs])
Run the examples in test (a DocTest object), and display the results using the writer function out.

The examples are run in the namespace test.globs. If clear_globs is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use clear_globs=False.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to globs.

The output of each example is checked using the DocTestRunner's output checker, and the results are formatted by the DocTestRunner.report_*() methods.

summarize([verbose])
Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple TestResults(failed, attempted).

The optional verbose argument controls how detailed the summary is. If the verbosity is not specified, then the DocTestRunner's verbosity is used.
Changed in version 2.6: Use a named tuple.

OutputChecker objects

class doctest. OutputChecker

A class used to check the whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: check_output(), which compares a given pair of outputs, and returns true if they match; and output_difference(), which returns a string describing the differences between two outputs.

New in version 2.4.

OutputChecker defines the following methods:

check_output(want, got, optionflags)

Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags and Directives for more information about option flags.

output_difference(example, got, optionflags)

Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```
""
>>> def f(x):
...    g(x*2)
>>> def g(x):
...    print x+3
...    import pdb; pdb.set_trace()
>>> f(3)
g
""
```

Then an interactive Python session may look like this:
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()--None
-> import pdb; pdb.set_trace()
(Pdb) list
    1    def g(x):
    2        print x+3
    3    --> import pdb; pdb.set_trace()
[EOF]
(Pdb) print x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()--None
-> g(x*2)
(Pdb) list
    1    def f(x):
    2    --> g(x*2)
[EOF]
(Pdb) print x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()--None
-> f(3)
(Pdb) cont
(0, 3)

*Changed in version 2.4:* The ability to use `pdb.set_trace()` usefully inside doctests was added.

Functions that convert doctests to Python code, and possibly run the
synthesized code under the debugger:

doctest.script_from_examples(s)

Convert text with examples to a script.

Argument s is a string containing doctest examples. The string is converted to a Python script, where doctest examples in s are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
print doctest.script_from_examples(r""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print x+y
    3
""
)
```

displays:

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print x+y
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.
**New in version 2.4.**

```python
import a, doctest
print doctest.testsource(a, "a.f")
```

**New in version 2.3.**

```python
import a, doctest
print doctest.testsource(a, "a.f")
```

prints a script version of function f()'s docstring, with doctests converted to code, and the rest placed in comments.
an unhandled exception. If it does, then post-mortem debugging is invoked, via `pdb.post_mortem()`, passing the traceback object from the unhandled exception. If `pm` is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate `execfile()` call to `pdb.run()`.

*New in version 2.3.*

*Changed in version 2.4:* The `pm` argument was added.

```python
doctest.debug_src(src[, pm][, globs])
```

Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.

Optional argument `pm` has the same meaning as in function `debug()` above.

Optional argument `globs` gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

*New in version 2.4.*

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest.DebugRunner([checker][, verbose][, optionflags])
```

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an
**UnexpectedException** exception is raised, containing the test, the example, and the original exception. If the output doesn’t match, then a **DocTestFailure** exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for **DocTestRunner** in section **Advanced API**.

There are two exceptions that may be raised by **DebugRunner** instances:

```
exception doctest.**DocTestFailure**(test, example, got)
```

An exception thrown by **DocTestRunner** to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the member variables of the same names.

**DocTestFailure** defines the following member variables:

- **DocTestFailure.test**
  The **DocTest** object that was being run when the example failed.

- **DocTestFailure.example**
  The **Example** that failed.

- **DocTestFailure.got**
  The example's actual output.

```
exception doctest.**UnexpectedException**(test, example, exc_info)
```

An exception thrown by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the member variables of the same names.
**UnexpectedException** defines the following member variables:

UnexpectedException.*test*

   The *DocTest* object that was being run when the example failed.

UnexpectedException.*example*

   The *Example* that failed.

UnexpectedException.*exc_info*

   A tuple containing information about the unexpected exception, as returned by *sys.exc_info()*.
As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what’s actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points
of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It’s a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `__regrtest_topic__` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

Footnotes

Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

[1]
New in version 2.1.

The Python unit testing framework, sometimes referred to as “PyUnit,” is a Python language version of JUnit, by Kent Beck and Erich Gamma. JUnit is, in turn, a Java version of Kent’s Smalltalk testing framework. Each is the de facto standard unit testing framework for its respective language.

**unittest** supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework. The **unittest** module provides classes that make it easy to support these qualities for a set of tests.

To achieve this, **unittest** supports some important concepts:

**test fixture**

A *test fixture* represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case**

A *test case* is the smallest unit of testing. It checks for a specific response to a particular set of inputs. **unittest** provides a base class, **TestCase**, which may be used to create new test cases.

**test suite**

A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner**

A *test runner* is a component which orchestrates the execution of
tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

The test case and test fixture concepts are supported through the `TestCase` and `FunctionTestCase` classes; the former should be used when creating new tests, and the latter can be used when integrating existing test code with a unittest-driven framework. When building test fixtures using `TestCase`, the `setUp()` and `tearDown()` methods can be overridden to provide initialization and cleanup for the fixture. With `FunctionTestCase`, existing functions can be passed to the constructor for these purposes. When the test is run, the fixture initialization is run first; if it succeeds, the cleanup method is run after the test has been executed, regardless of the outcome of the test. Each instance of the `TestCase` will only be used to run a single test method, so a new fixture is created for each test.

Test suites are implemented by the `TestSuite` class. This class allows individual tests and test suites to be aggregated; when the suite is executed, all tests added directly to the suite and in “child” test suites are run.

A test runner is an object that provides a single method, `run()`, which accepts a `TestCase` or `TestSuite` object as a parameter, and returns a result object. The class `TestResult` is provided for use as the result object. `unittest` provides the `TextTestRunner` as an example test runner which reports test results on the standard error stream by default. Alternate runners can be implemented for other environments (such as graphical environments) without any need to derive from a specific class.

See also:

Module `doctest`
Another test-support module with a very different flavor.

**Simple Smalltalk Testing: With Patterns**

Kent Beck’s original paper on testing frameworks using the pattern shared by unittest.
Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three functions from the `random` module:

```python
import random
import unittest

class TestSequenceFunctions(unittest.TestCase):
    def setUp(self):
        self.seq = range(10)

    def testshuffle(self):
        # make sure the shuffled sequence does not lose any elements
        random.shuffle(self.seq)
        self.seq.sort()
        self.assertEqual(self.seq, range(10))

    def testchoice(self):
        element = random.choice(self.seq)
        self.assertIn(element, self.seq)

    def testsample(self):
        self.assertRaises(ValueError, random.sample, self.seq, 20)
        for element in random.sample(self.seq, 5):
            self.assertIn(element, self.seq)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an
expected result; **assert()** to verify a condition; or **assertRaises()** to verify that an expected exception gets raised. These methods are used instead of the **assert** statement so the test runner can accumulate all test results and produce a report.

When a **setUp()** method is defined, the test runner will run that method prior to each test. Likewise, if a **tearDown()** method is defined, the test runner will invoke that method after each test. In the example, **setUp()** was used to create a fresh sequence for each test.

The final block shows a simple way to run the tests. **unittest.main()** provides a command line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```...```  
Ran 3 tests in 0.000s
OK  
```...```  

Instead of **unittest.main()**, there are other ways to run the tests with a finer level of control, less terse output, and no requirement to be run from the command line. For example, the last two lines may be replaced with:

```suite = unittest.TestLoader().loadTestsFromTestCase(TestSequenceFunctions)```  
```unittest.TextTestRunner(verbosity=2).run(suite) ```

Running the revised script from the interpreter or another script produces the following output:

```testchoice (__main__.TestSequenceFunctions) ... ok```  
```testsample (__main__.TestSequenceFunctions) ... ok```  
```testshuffle (__main__.TestSequenceFunctions) ... ok```
The above examples show the most commonly used unittest features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In unittest, test cases are represented by instances of unittest's TestCase class. To make your own test cases you must write subclasses of TestCase, or use FunctionTestCase.

An instance of a TestCase-derived class is an object that can completely run a single test method, together with optional set-up and tidy-up code.

The testing code of a TestCase instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest TestCase subclass will simply override the runTest() method in order to perform specific testing code:

```python
import unittest
class DefaultWidgetSizeTestCase(unittest.TestCase):
    def runTest(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50), 'incorrect default size')
```

Note that in order to test something, we use the one of the assert*() or fail*() methods provided by the TestCase base class. If the test fails, an exception will be raised, and unittest will identify the test case as a failure. Any other exceptions will be treated as errors. This helps you identify where the problem is: failures are caused by incorrect results - a 5 where you expected a 6. Errors are caused by incorrect code - e.g., a TypeError caused by an incorrect function call.
The way to run a test case will be described later. For now, note that to construct an instance of such a test case, we call its constructor without arguments:

```python
testCase = DefaultWidgetSizeTestCase()
```

Now, such test cases can be numerous, and their set-up can be repetitive. In the above case, constructing a `Widget` in each of 100 `Widget` test case subclasses would mean unsightly duplication.

Luckily, we can factor out such set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for us when we run the test:

```python
import unittest
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

class DefaultWidgetSizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.failUnless(self.widget.size() == (50, 50),
                        'incorrect default size')

class WidgetResizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.widget.resize(100, 150)
        self.failUnless(self.widget.size() == (100, 150),
                        'wrong size after resize')
```

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the `runTest()` method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the `runTest()` method has been run:

```python
import unittest
```
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
        self.widget = None

If setUp() succeeded, the tearDown() method will be run whether runTest() succeeded or not.

Such a working environment for the testing code is called a fixture.

Often, many small test cases will use the same fixture. In this case, we would end up subclassing SimpleWidgetTestCase into many small one-method classes such as DefaultWidgetSizeTestCase. This is time-consuming and discouraging, so in the same vein as JUnit, unittest provides a simpler mechanism:

import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
        self.widget = None

    def testDefaultSize(self):
        self.failUnless(self.widget.size() == (50, 50),
                        'incorrect default size')

    def testResize(self):
        self.widget.resize(100, 150)
        self.failUnless(self.widget.size() == (100, 150),
                        'wrong size after resize')

Here we have not provided a runTest() method, but have instead provided two different test methods. Class instances will now each run one of the test*() methods, with self.widget created and
destroyed separately for each instance. When creating an instance we must specify the test method it is to run. We do this by passing the method name in the constructor:

```python
defaultSizeTestCase = WidgetTestCase('testDefaultSize')
resizeTestCase = WidgetTestCase('testResize')
```

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the test suite, represented by `unittest`'s `TestSuite` class:

```python
widgetTestSuite = unittest.TestSuite() 
widgetTestSuite.addTest(WidgetTestCase('testDefaultSize'))
widgetTestSuite.addTest(WidgetTestCase('testResize'))
```

For the ease of running tests, as we will see later, it is a good idea to provide in each test module a callable object that returns a pre-built test suite:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('testDefaultSize'))
    suite.addTest(WidgetTestCase('testResize'))
    return suite
```

or even:

```python
def suite():
    tests = ['testDefaultSize', 'testResize']
    return unittest.TestSuite(map(WidgetTestCase, tests))
```

Since it is a common pattern to create a `TestCase` subclass with many similarly named test functions, `unittest` provides a `TestLoader` class that can be used to automate the process of creating a test suite and populating it with individual tests. For example,
will create a test suite that will run WidgetTestCase.testDefaultSize() and WidgetTestCase.testResize. TestLoader uses the 'test' method name prefix to identify test methods automatically.

Note that the order in which the various test cases will be run is determined by sorting the test function names with the built-in cmp() function.

Often it is desirable to group suites of test cases together, so as to run tests for the whole system at once. This is easy, since TestSuite instances can be added to a TestSuite just as TestCase instances can be added to a TestSuite:

```python
suite1 = module1.TheTestSuite()
suite2 = module2.TheTestSuite()
alltests = unittest.TestSuite([suite1, suite2])
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as widget.py), but there are several advantages to placing the test code in a separate module, such as test_widget.py:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.
Re-using old test code

Some users will find that they have existing test code that they would like to run from unittest, without converting every old test function to a TestCase subclass.

For this reason, unittest provides a FunctionTestCase class. This subclass of TestCase can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows:

```python
testcase = unittest.FunctionTestCase(testSomething)
```

If there are additional set-up and tear-down methods that should be called as part of the test case's operation, they can also be provided like so:

```python
testcase = unittest.FunctionTestCase(testSomething,
                                     setUp=makeSomethingDB,
                                     tearDown=deleteSomethingDB)
```

To make migrating existing test suites easier, unittest supports tests raising AssertionError to indicate test failure. However, it is recommended that you use the explicit TestCase.fail*() and TestCase.assert*() methods instead, as future versions of unittest may treat AssertionError differently.
Note: Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.
Classes and functions

class unittest.TestCase([methodName])

Instances of the `TestCase` class represent the smallest testable units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the test, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single test method: the method named `methodName`. If you remember, we had an earlier example that went something like this:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('testDefaultSize'))
    suite.addTest(WidgetTestCase('testResize'))
    return suite
```

Here, we create two instances of `WidgetTestCase`, each of which runs a single test.

`methodName` defaults to `'runTest'`.

class unittest.FunctionTestCase(testFunc[, setUp[, tearDown[, description]]]])

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to
be integrated into a unittest-based test framework.

class unittest.TestSuite([tests])

This class represents an aggregation of individual tests cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a TestSuite instance is the same as iterating over the suite, running each test individually.

If tests is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

class unittest.TestLoader

This class is responsible for loading tests according to various criteria and returning them wrapped in a TestSuite. It can load all tests within a given module or TestCase subclass.

class unittest.TestResult

This class is used to compile information about which tests have succeeded and which have failed.

unittest.defaultTestLoader

Instance of the TestLoader class intended to be shared. If no customization of the TestLoader is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.TextTestRunner([stream[, descriptions[, verbosity]]]])

A basic test runner implementation which prints results on standard error. It has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations.
unittest.main([module, defaultTest[, argv[, testRunner[, testLoader]]]])

A command-line program that runs a set of tests; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```python
if __name__ == '__main__':
    unittest.main()
```

The `testRunner` argument can either be a test runner class or an already created instance of it.

In some cases, the existing tests may have been written using the `doctest` module. If so, that module provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.

*New in version 2.3.*
**TestCase Objects**

Each `TestCase` instance represents a single test, but each concrete subclass may be used to define multiple tests — the concrete class represents a single test fixture. The fixture is created and cleaned up for each test case.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

- **testCase.**`setUp()`  
  Method called to prepare the test fixture. This is called immediately before calling the test method; any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

- **testCase.**`tearDown()`  
  Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception raised by this method will be considered an error rather than a test failure. This method will only be called if the `setUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

- **testCase.**`run([result])`  
  Run the test, collecting the result into the test result object passed as `result`. If `result` is omitted or `None`, a temporary result
object is created (by calling the `defaultTestcase()` method) and used; this result object is not returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

`TestCase.debug()`  
Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The test code can use any of the following methods to check for and report failures.

`TestCase.assert_(expr[, msg])`  
`TestCase.failUnless(expr[, msg])`  
`TestCase assertTrue(expr[, msg])`  
Signal a test failure if `expr` is false; the explanation for the error will be `msg` if given, otherwise it will be `None`.

`TestCase.assertEqual(first, second[, msg])`  
`TestCase.failUnlessEqual(first, second[, msg])`  
Test that `first` and `second` are equal. If the values do not compare equal, the test will fail with the explanation given by `msg`, or `None`. Note that using `failUnlessEqual()` improves upon doing the comparison as the first parameter to `failUnless()`: the default value for `msg` can be computed to include representations of both `first` and `second`.

`TestCase.assertNotEqual(first, second[, msg])`  
`TestCase.failIfEqual(first, second[, msg])`  
Test that `first` and `second` are not equal. If the values do compare
equal, the test will fail with the explanation given by $msg$, or \texttt{None}. Note that using \texttt{failIfEqual()} improves upon doing the comparison as the first parameter to \texttt{failUnless()} is that the default value for $msg$ can be computed to include representations of both $first$ and $second$.

\begin{verbatim}
TestCase.\texttt{assertAlmostEqual}(first, second[, places[, msg]])

Test that $first$ and $second$ are approximately equal by computing the difference, rounding to the given number of decimal $places$ (default 7), and comparing to zero. Note that comparing a given number of decimal places is not the same as comparing a given number of significant digits. If the values do not compare equal, the test will fail with the explanation given by $msg$, or \texttt{None}.

TestCase.\texttt{assertNotAlmostEqual}(first, second[, places[, msg]])

Test that $first$ and $second$ are not approximately equal by computing the difference, rounding to the given number of decimal $places$ (default 7), and comparing to zero. Note that comparing a given number of decimal places is not the same as comparing a given number of significant digits. If the values do not compare equal, the test will fail with the explanation given by $msg$, or \texttt{None}.

TestCase.\texttt{assertRaises}(exception, callable, ...)

Test that an exception is raised when $callable$ is called with any positional or keyword arguments that are also passed to \texttt{assertRaises()}. The test passes if $exception$ is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as $exception$.
\end{verbatim}
TestCase. **failIf**(expr[, msg])

TestCase. **assertFalse**(expr[, msg])

The inverse of the *failUnless()* method is the *failIf()* method. This signals a test failure if *expr* is true, with *msg* or *None* for the error message.

TestCase. **fail**([msg])

Signals a test failure unconditionally, with *msg* or *None* for the error message.

TestCase. **failureException**

This class attribute gives the exception raised by the *test()* method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is *AssertionError*.

Testing frameworks can use the following methods to collect information on the test:

TestCase. **countTestCases**()

Return the number of tests represented by this test object. For *TestCase* instances, this will always be 1.

TestCase. **defaultTestResult**()

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the *run()* method).

For *TestCase* instances, this will always be an instance of *TestResult*; subclasses of *TestCase* should override this as necessary.
**TestCase.** \texttt{id()}

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

**TestCase.** \texttt{shortDescription()}

Returns a one-line description of the test, or \texttt{None} if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or \texttt{None}. 
TestSuite Objects

TestSuite objects behave much like TestCase objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to TestSuite instances:

TestSuite.**addTest(test)**

Add a TestCase or TestSuite to the suite.

TestSuite.**addTests(tests)**

Add all the tests from an iterable of TestCase and TestSuite instances to this test suite.

This is equivalent to iterating over tests, calling addTest() for each element.

TestSuite shares the following methods with TestCase:

TestSuite.**run(result)**

Run the tests associated with this suite, collecting the result into the test result object passed as result. Note that unlike TestCase.run(), TestSuite.run() requires the result object to be passed in.

TestSuite.**debug()**

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

TestSuite.**countTestCases()**

Return the number of tests represented by this test object,
including all individual tests and sub-suites.

In the typical usage of a TestSuite object, the run() method is invoked by a TestRunner rather than by the end-user test harness.
**TestResult Objects**

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of `unittest` may want access to the `TestResult` object generated by running a set of tests for reporting purposes; a `TestResult` instance is returned by the `TestRunner.run()` method for this purpose.

`TestResult` instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

`TestResult.errors`
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

*Changed in version 2.2:* Contains formatted tracebacks instead of `sys.exc_info()` results.

`TestResult.failures`
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the `TestCase.fail*()` or `TestCase.assert*()` methods.

*Changed in version 2.2:* Contains formatted tracebacks instead of `sys.exc_info()` results.

`TestResult.testsRun`
The total number of tests run so far.
TestResult\.wasSuccessful()

Returns True if all tests run so far have passed, otherwise returns False.

TestResult\.stop()

This method can be called to signal that the set of tests being run should be aborted by setting the TestResult's shouldStop attribute to True. TestRunner objects should respect this flag and return without running any additional tests.

For example, this feature is used by the TextTestRunner class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide TestRunner implementations can use this in a similar manner.

The following methods of the TestResult class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

TestResult\.startTest(test)

Called when the test case test is about to be run.

The default implementation simply increments the instance's testsRun counter.

TestResult\.stopTest(test)

Called after the test case test has been executed, regardless of the outcome.

The default implementation does nothing.

TestResult\.addError(test, err)
Called when the test case `test` raises an unexpected exception.  
`err` is a tuple of the form returned by `sys.exc_info()`:

```
(type, value, traceback)
```

The default implementation appends a tuple `(test, formatted_err)` to the instance's `errors` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**TestResult**. `addFailure(test, err)`

Called when the test case `test` signals a failure.  `err` is a tuple of the form returned by `sys.exc_info()`:

```
(type, value, traceback)
```

The default implementation appends a tuple `(test, formatted_err)` to the instance's `failures` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**TestResult**. `addSuccess(test)`

Called when the test case `test` succeeds.

The default implementation does nothing.
TestLoader Objects

The `TestLoader` class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the `unittest` module provides an instance that can be shared as `unittest.defaultTestLoader`. Using a subclass or instance, however, allows customization of some configurable properties.

`TestLoader` objects have the following methods:

`TestLoader.loadTestsFromTestCase(testCaseClass)`

Return a suite of all tests cases contained in the `TestCase`-derived `testCaseClass`.

`TestLoader.loadTestsFromModule(module)`

Return a suite of all tests cases contained in the given module. This method searches `module` for classes derived from `TestCase` and creates an instance of the class for each test method defined for the class.

**Warning:** While using a hierarchy of `TestCase`-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

`TestLoader.loadTestsFromName(name[, module])`

Return a suite of all tests cases given a string specifier.

The specifier `name` is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case
class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`), the specifier `SampleTests.SampleTestCase` would cause this method to return a suite which will run all three test methods. Using the specifier `SampleTests.SampleTestCase.test_two` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves `name` relative to the given `module`.

`TestLoader.loadTestsFromNames(names[, module])`
Similar to `loadTestsFromName()`, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

`TestLoader.getTestCaseNames(testCaseClass)`
Return a sorted sequence of method names found within `testCaseClass`; this should be a subclass of `TestCase`.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

`TestLoader.testMethodPrefix`
String giving the prefix of method names which will be interpreted as test methods. The default value is 'test'.
This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**TestLoader.sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods. The default value is the built-in `cmp()` function; the attribute can also be set to `None` to disable the sort.

**TestLoader.suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.
2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library *lib2to3* is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. *lib2to3* could also be adapted to custom applications in which Python code needs to be edited automatically.
Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3's basic arguments are a list of files or directories to transform. The directories are to recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```python
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (Of course, a backup of the original is also be made.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```python
def greet(name):
    print("Hello, {0}!".format(name))
print("What's your name?")
name = input()
greet(name)
```

Comments and and exact indentation are preserved throughout the
By default, 2to3 runs a set of predefined fixers. The -l flag lists all available fixers. An explicit set of fixers to run can be given by use of the -f flag. The following example runs only the imports and has_key fixers:

```bash
$ 2to3 -f imports -f has_key example.py
```

Some fixers are explicit, meaning they aren’t run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

```bash
$ 2to3 -f all -f idioms example.py
```

Notice how passing all enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the -d flag. Note that only doctests will be refactored. This also doesn’t require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The -v option enables the output of more information on the translation process.

When the -p is passed, 2to3 treats print as a function instead of a statement. This is useful when from __future__ import print_function is being used. If this option is not given, the print fixer will surround print calls in an extra set of parentheses because it cannot differentiate between the and print statement with
parentheses (such as `print ("a" + "b" + "c")`) and a true function call.
Warning: The lib2to3 API should be considered unstable and may change drastically in the future.
The test package contains all regression tests for Python as well as the modules test.test_support and test.regrtest. test.test_support is used to enhance your tests while test.regrtest drives the testing suite.

Each module in the test package whose name starts with test_ is a testing suite for a specific module or feature. All new tests should be written using the unittest or doctest module. Some older tests are written using a “traditional” testing style that compares output printed to sys.stdout; this style of test is considered deprecated.

See also:

Module unittest
Writing PyUnit regression tests.

Module doctest
Tests embedded in documentation strings.
**Writing Unit Tests for the `test` package**

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import test_support

class MyTestCase1(unittest.TestCase):
    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
```

```
This boilerplate code allows the testing suite to be run by `test.regrtest` as well as on its own as a script.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.

- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.

- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
• Make sure to clean up after your tests (such as close and remove all temporary files).

• If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

• Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

• Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequences(unittest.TestCase):

    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequences):
    arg = [1,2,3]

class AcceptStrings(TestFuncAcceptsSequences):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequences):
    arg = (1,2,3)
```

See also:
Test Driven Development

A book by Kent Beck on writing tests before code.
test.regrtest can be used as a script to drive Python’s regression test suite. Running the script by itself automatically starts running all regression tests in the test package. It does this by finding all modules in the package whose name starts with test_, importing them, and executing the function test_main() if present. The names of tests to execute may also be passed to the script. Specifying a single regression test (python regrtest.py test_spam.py) will minimize output and only print whether the test passed or failed and thus minimize output.

Running test.regrtest directly allows what resources are available for tests to use to be set. You do this by using the -u command-line option. Run python regrtest.py -uall to turn on all resources; specifying all as an option for -u enables all possible resources. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after all. The command python regrtest.py -uall,-audio,-largefile will run test.regrtest with all resources except the audio and largefile resources. For a list of all resources and more command-line options, run python regrtest.py -h.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run make test at the top-level directory where Python was built. On Windows, executing rt.bat from your PCBUILD directory will run all regression tests.
Note: The `test.test_support` module has been renamed to `test.support` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The `test.test_support` module provides support for Python’s regression tests.

This module defines the following exceptions:

- **exception test.test_support.TestFailed**
  Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

- **exception test.test_support.TestSkipped**
  Subclass of `TestFailed`. Raised when a test is skipped. This occurs when a needed resource (such as a network connection) is not available at the time of testing.

- **exception test.test_support.ResourceDenied**
  Subclass of `TestSkipped`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.test_support` module defines the following constants:

- **test.test_support.verbose**
  True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`. 
test.test_support.\texttt{have_unicode}
\hspace{1cm} \texttt{True} when Unicode support is available.

test.test_support.\texttt{is_jython}
\hspace{1cm} \texttt{True} if the running interpreter is Jython.

test.test_support.\texttt{TESTFN}
\hspace{1cm} Set to the path that a temporary file may be created at. Any temporary that is created should be closed and unlinked (removed).

The \texttt{test.test_support} module defines the following functions:

test.test_support.\texttt{forget}(\texttt{module\_name})
\hspace{1cm} Removes the module named \texttt{module\_name} from \texttt{sys.modules} and deletes any byte-compiled files of the module.

test.test_support.\texttt{is\_resource\_enabled}(\texttt{resource})
\hspace{1cm} Returns \texttt{True} if \texttt{resource} is enabled and available. The list of available resources is only set when \texttt{test.regrtest} is executing the tests.

test.test_support.\texttt{requires}(\texttt{resource[, msg]})
\hspace{1cm} Raises \texttt{ResourceDenied} if \texttt{resource} is not available. \texttt{msg} is the argument to \texttt{ResourceDenied} if it is raised. Always returns true if called by a function whose \texttt{\_name\_} is \texttt{\_\_main\_\_}. Used when tests are executed by \texttt{test.regrtest}.

test.test_support.\texttt{findfile}(\texttt{filename})
\hspace{1cm} Return the path to the file named \texttt{filename}. If no match is found \texttt{filename} is returned. This does not equal a failure since it could be the path to the file.

test.test_support.\texttt{run_unittest(\*classes)}
Execute `unittest.TestCase` subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following `test_main()` function:

```python
def test_main():
    test_support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.test_support.**check_warnings**()

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised with a single assertion. It is approximately equivalent to calling `warnings.catch_warnings(record=True)`. The main difference is that on entry to the context manager, a `WarningRecorder` instance is returned instead of a simple list. The underlying warnings list is available via the recorder object's `warnings` attribute, while the attributes of the last raised warning are also accessible directly on the object. If no warning has been raised, then the latter attributes will all be `None`.

A `reset()` method is also provided on the recorder object. This method simply clears the warning list.

The context manager is used like this:

```python
with check_warnings() as w:
    warnings.simplefilter("always")
```
```
warnings.warn("foo")
assert str(w.message) == "foo"
warnings.warn("bar")
assert str(w.message) == "bar"
assert str(w.warnings[0].message) == "foo"
assert str(w.warnings[1].message) == "bar"
w.reset()
assert len(w.warnings) == 0
```

New in version 2.6.

test.test_support.captured_stdout()

This is a context manager than runs the with statement body using a `StringIO.StringIO` object as sys.stdout. That object can be retrieved using the as clause of the with statement.

Example use:

```
with captured_stdout() as s:
    print "hello"
assert s.getvalue() == "hello"
```

New in version 2.6.

The test.test_support module defines the following classes:

class test.test_support.TransientResource(exc[, **kwargs])

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.
New in version 2.6.

class test.test_support.EnvironmentVarGuard
    Class used to temporarily set or unset environment variables. Instances can be used as a context manager.

New in version 2.6.

EnvironmentVarGuard.set(envvar, value)
    Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)
    Temporarily unset the environment variable envvar.

class test.test_support.WarningsRecorder
    Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.

New in version 2.6.
Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

- Programming Interface
The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```python
exception bdb.BdbQuit
```

Exception raised by the `Bdb` class for quitting the debugger.

The `bdb` module also defines two classes:

```python
class bdb.Breakpoint(self, file, line[, temporary=0[, cond=None[, funcname=None]]]])
```

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by `(file, line)` pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a `funcname` is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

`Breakpoint` instances have the following methods:

```python
deleteMe()
```

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.
enable()
    Mark the breakpoint as enabled.

disable()
    Mark the breakpoint as disabled.

pprint([out])
    Print all the information about the breakpoint:
    
    • The breakpoint number.
    • If it is temporary or not.
    • Its file, line position.
    • The condition that causes a break.
    • If it must be ignored the next N times.
    • The breakpoint hit count.

class bdb.Bdb
    The Bdb acts as a generic Python debugger base class.

    This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (pdb.Pdb) is an example.

    The following methods of Bdb normally don’t need to be overridden.

    canonic(filename)
        Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

    reset()
        Set the botframe, stopframe, returnframe and quitting attributes with values ready to start debugging.
**trace_dispatch**(*frame, event, arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has thrown an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

For more information on trace functions, see *How It Works*. For more information on code and frame objects, refer to *The standard type hierarchy*.

**dispatch_line**(*frame*)

If the debugger should stop on the current line, invoke the *user_line()* method (which should be overridden in subclasses). Raise a *BdbQuit* exception if the *Bdb.quitting* flag is set (which can be set from *user_line()*). Return a reference to the *trace_dispatch()* method for further tracing.
in that scope.

**dispatch_call**(*frame*, *arg*)

If the debugger should stop on this function call, invoke the `user_call` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return**(*frame*, *arg*)

If the debugger should stop on this function return, invoke the `user_return` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_exception**(*frame*, *arg*)

If the debugger should stop at this exception, invokes the `user_exception` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**stop_here**(*frame*)

This method checks if the *frame* is somewhere below `botframe` in the call stack. `botframe` is the frame in which debugging started.
**break_here**(frame)

This method checks if there is a breakpoint in the filename and line belonging to `frame` or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**break_anywhere**(frame)

This method checks if there is a breakpoint in the filename of the current frame.

Derived classes should override these methods to gain control over debugger operation.

**user_call**(frame, argument_list)

This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line**(frame)

This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields True.

**user_return**(frame, return_value)

This method is called from `dispatch_return()` when `stop_here()` yields True.

**user_exception**(frame, exc_info)

This method is called from `dispatch_exception()` when `stop_here()` yields True.

**do_clear**(arg)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.
Derived classes and clients can call the following methods to affect the stepping state.

```python
set_step()
Stop after one line of code.
```

```python
set_next(frame)
Stop on the next line in or below the given frame.
```

```python
set_return(frame)
Stop when returning from the given frame.
```

```python
set_until(frame)
Stop when the line with the line no greater than the current one is reached or when returning from current frame
```

```python
set_trace([frame])
Start debugging from frame. If frame is not specified, debugging starts from caller’s frame.
```

```python
set_continue()
Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.
```

```python
set_quit()
Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*() methods.
```

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

```python
set_break(filename, lineno[, temporary=0[, cond[, funcname]]]])
Set a new breakpoint. If the lineno line doesn’t exist for the filename passed as argument, return an error message. The
filename should be in canonical form, as described in the canonic() method.

clear_break(filename, lineno)
Delete the breakpoints in filename and lineno. If none were set, an error message is returned.

clear_bpbynumber(arg)
Delete the breakpoint which has the index arg in the Breakpoint.bpbynumber. If arg is not numeric or out of range, return an error message.

clear_all_file_breaks(filename)
Delete all breakpoints in filename. If none were set, an error message is returned.

clear_all_breaks()
Delete all existing breakpoints.

get_break(filename, lineno)
Check if there is a breakpoint for lineno of filename.

get_breaks(filename, lineno)
Return all breakpoints for lineno in filename, or an empty list if none are set.

get_file_breaks(filename)
Return all breakpoints in filename, or an empty list if none are set.

get_all_breaks()
Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

get_stack(f, t)
Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

```python
format_stack_entry(frame_lineno[, lprefix=': '])
```

Return a string with information about a stack entry, identified by a `(frame, lineno)` tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a `statement`, given as a string.

```python
run(cmd[, globals[, locals]])
```

Debug a statement executed via the `exec` statement. `globals` defaults to `__main__.__dict__`, `locals` defaults to `globals`.

```python
runeval(expr[, globals[, locals]])
```

Debug an expression executed via the `eval()` function. `globals` and `locals` have the same meaning as in `run()`.

```python
runctx(cmd, globals, locals)
```

For backwards compatibility. Calls the `run()` method.

```python
runcall(func, *args, **kwds)
```

Debug a single function call, and return its result.

Finally, the module defines the following functions:

```python
bdb.checkfuncname(b, frame)
```

Check whether we should break here, depending on the way the
breakpoint \texttt{b} was set.

If it was set via line number, it checks if \texttt{b.line} is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

\texttt{bdb.effective(file, line, frame)}

Determine if there is an effective (active) breakpoint at this line of code. Return breakpoint number or 0 if none.

Called only if we know there is a breakpoint at this location. Returns the breakpoint that was triggered and a flag that indicates if it is ok to delete a temporary breakpoint.

\texttt{bdb.set_trace()}

Starts debugging with a \texttt{Bdb} instance from caller's frame.
The module \texttt{pdb} defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible — it is actually defined as the class \texttt{Pdb}. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules \texttt{bdb} (undocumented) and \texttt{cmd}.

The debugger’s prompt is \texttt{(Pdb)}. Typical usage to run a program under control of the debugger is:

\begin{verbatim}
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
\end{verbatim}

\texttt{pdb.py} can also be invoked as a script to debug other scripts. For example:

\begin{verbatim}
python -m pdb myscript.py
\end{verbatim}

When invoked as a script, \texttt{pdb} will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), \texttt{pdb} will
restart the program. Automatic restarting preserves pdb’s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program’s exit.

New in version 2.4: Restarting post-mortem behavior added.

Typical usage to inspect a crashed program is:

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
```

```
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "./mymodule.py", line 4, in test
    test2()
  File "./mymodule.py", line 3, in test2
    print spam
NameError: spam
```

```
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print spam
(Pdb)
```

The module defines the following functions; each enters the debugger in a slightly different way:

```
pdb.run(statement[, globals[, locals]])
```

Execute the statement (given as a string) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type continue, or you can step through the statement using step or next (all these commands are explained below). The optional globals and locals arguments specify the environment in which the code is executed; by default the dictionary of the module __main__ is used. (See the explanation of the exec statement or the eval() built-in function.)

```
pdb.runeval(expression[, globals[, locals]])
```

Evaluate the *expression* (given as a string) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`.

`pdb.runcall(function[, argument, ...])`

Call the *function* (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

`pdb.set_trace()`

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails).

`pdb.post_mortem([traceback])`

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

`pdb.pm()`

Enter post-mortem debugging of the traceback found in `sys.last_traceback`. 
Debugger Commands

The debugger recognizes the following commands. Most commands can be abbreviated to one or two letters; e.g. h(e1p) means that either h or help can be used to enter the help command (but not he or hel, nor H or Help or HELP). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ]) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a list command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

Multiple commands may be entered on a single line, separated by ;;. (A single ; is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first ;; pair, even if it is in the middle of a quoted string.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

If a file .pdbrc exists in the user’s home directory or in the current
directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

h(elp) [command]
   Without argument, print the list of available commands. With a command as argument, print help about that command. help pdb displays the full documentation file; if the environment variable PAGER is defined, the file is piped through that command instead. Since the command argument must be an identifier, help exec must be entered to get help on the ! command.

w(here)
   Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

d(own)
   Move the current frame one level down in the stack trace (to a newer frame).

u(p)
   Move the current frame one level up in the stack trace (to an older frame).

b(reak) [[filename:]lineno | function[, condition]]
   With a lineno argument, set a break there in the current file. With a function argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn’t been loaded yet). The file is searched on sys.path. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

   If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.
Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[filename:][lineno | function[, condition]]]
Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as break.

c(r)e[ar] [bpnumber [bpnumber ...]]
With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber [bpnumber ...]]
Disables the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber [bpnumber ...]]
Enables the breakpoints specified.

ignore bpnumber [count]
Sets the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

condition bpnumber [condition]
Condition is an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

commands [bpnumber]
Specify a list of commands for breakpoint number bpnumber. The
commands themselves appear on the following lines. Type a line containing just ‘end’ to terminate the commands. An example:

```
(Pdb) commands 1
(com) print some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with end; that is, give no commands.

With no `bpnumber` argument, commands refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the continue command, or step, or any other command that resumes execution.

Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint–which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

*New in version 2.5.*

`s(tep)`

Execute the current line, stop at the first possible occasion (either
in a function that is called or on the next line in the current function).

next
Continue execution until the next line in the current function is reached or it returns. (The difference between `next` and `step` is that `step` stops inside a called function, while `next` executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

until
Continue execution until the line with the the line number greater than the current one is reached or when returning from current frame.

*New in version 2.6.*

return
Continue execution until the current function returns.

c(ontinue)
Continue execution, only stop when a breakpoint is encountered.

jump `lineno`
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed — for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

list `[first[, last]]`
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less
than the first, it is interpreted as a count.

a(rgs)
Print the argument list of the current function.

p expression
Evaluate the expression in the current context and print its value.

Note: print can also be used, but is not a debugger command — this executes the Python print statement.

pp expression
Like the p command, except the value of the expression is pretty-printed using the pprint module.

alias [name [command]]
Creates an alias called name that executes command. The command must not be enclosed in quotes. Replaceable parameters can be indicated by %1, %2, and so on, while %* is replaced by all the parameters. If no command is given, the current alias for name is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands can be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the .pdbrc file):

#Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print "%1.",k,"=",%1.
#Print instance variables in self
alias ps pi self

unalias name
    Deletes the specified alias.

[!]statement
    Execute the (one-line) statement in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a global command on the same line, e.g.:

    (Pdb) global list_options; list_options = ['-l']
    (Pdb)

run [args ...]
    Restart the debugged python program. If an argument is supplied, it is split with “shlex” and the result is used as the new sys.argv. History, breakpoints, actions and debugger options are preserved. “restart” is an alias for “run”.

    New in version 2.6.

q(u)it
    Quit from the debugger. The program being executed is aborted.
**How It Works**

Some changes were made to the interpreter:

- `sys.settrace(func)` sets the global trace function
- there can also a local trace function (see later)

Trace functions have three arguments: `frame`, `event`, and `arg`. `frame` is the current stack frame. `event` is a string: 'call', 'line', 'return', 'exception', 'c_call', 'c_return', or 'c_exception'. `arg` depends on the event type.

The global trace function is invoked (with `event` set to 'call') whenever a new local scope is entered; it should return a reference to the local trace function to be used that scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or `None` to turn off tracing in that scope.

Instance methods are accepted (and very useful!) as trace functions.

The events have the following meaning:

- `'call'`
  A function is called (or some other code block entered). The global trace function is called; `arg` is `None`; the return value specifies the local trace function.

- `'line'`
  The interpreter is about to execute a new line of code (sometimes multiple line events on one line exist). The local trace function is called; `arg` is `None`; the return value specifies the new local trace function.
'return'
A function (or other code block) is about to return. The local trace function is called; \textit{arg} is the value that will be returned. The trace function's return value is ignored.

'exception'
An exception has occurred. The local trace function is called; \textit{arg} is a triple (\textit{exception}, \textit{value}, \textit{traceback}); the return value specifies the new local trace function.

'c_call'
A C function is about to be called. This may be an extension function or a builtin. \textit{arg} is the C function object.

'c_return'
A C function has returned. \textit{arg} is \texttt{None}.

'c_exception'
A C function has thrown an exception. \textit{arg} is \texttt{None}.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more information on code and frame objects, refer to \textit{The standard type hierarchy}.

**Introduction to the profilers**

A *profiler* is a program that describes the run time performance of a program, providing a variety of statistics. This documentation describes the profiler functionality provided in the modules `cProfile`, `profile` and `pstats`. This profiler provides *deterministic profiling* of Python programs. It also provides a series of report generation tools to allow users to rapidly examine the results of a profile operation.

The Python standard library provides three different profilers:

1. **cProfile** is recommended for most users; it’s a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on `lsprof`, contributed by Brett Rosen and Ted Czotter.

   *New in version 2.5.*

2. **profile**, a pure Python module whose interface is imitated by `cProfile`. Adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Copyright © 1994, by InfoSeek Corporation.

   *Changed in version 2.4:* Now also reports the time spent in calls to built-in functions and methods.

3. **hotshot** was an experimental C module that focused on minimizing the overhead of profiling, at the expense of longer data post-processing times. It is no longer maintained and may be dropped in a future version of Python.

   *Changed in version 2.5:* The results should be more meaningful than in the past: the timing core contained a critical bug.
The `profile` and `cProfile` modules export the same interface, so they are mostly interchangeable; `cProfile` has a much lower overhead but is newer and might not be available on all systems. `cProfile` is really a compatibility layer on top of the internal `_lsprof` module. The `hotshot` module is reserved for specialized usage.
This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile an application with a main entry point of `foo()`, you would add the following to your module:

```python
import cProfile
cProfile.run('foo()')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would cause `foo()` to be run, and a series of informative lines (the profile) to be printed. The above approach is most useful when working with the interpreter. If you would like to save the results of a profile into a file for later examination, you can supply a file name as the second argument to the `run()` function:

```python
import cProfile
cProfile.run('foo()', 'fooprof')
```

The file `cProfile.py` can also be invoked as a script to profile another script. For example:

```
python -m cProfile myscript.py
```

`cProfile.py` accepts two optional arguments on the command line:

```
cProfile.py [-o output_file] [-s sort_order]
```

`-s` only applies to standard output (`-o` is not supplied). Look in the
Stats documentation for valid sort values.

When you wish to review the profile, you should use the methods in the pstats module. Typically you would load the statistics data as follows:

```python
import pstats
p = pstats.Stats('fooprof')
```

The class stats (the above code just created an instance of this class) has a variety of methods for manipulating and printing the data that was just read into p. When you ran cProfile.run() above, what was printed was the result of three method calls:

```python
p.strip_dirs().sort_stats(-1).print_stats()
```

The first method removed the extraneous path from all the module names. The second method sorted all the entries according to the standard module/line/name string that is printed. The third method printed out all the statistics. You might try the following sort calls:

```python
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```python
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:
to sort according to time spent within each function, and then print
the statistics for the top ten functions.

You might also try:

```
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out
statistics for only the class init methods (since they are spelled with
`__init__` in them). As one final example, you could try:

```
p.sort_stats('time', 'cum').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary
key of cumulative time, and then prints out some of the statistics. To
be specific, the list is first culled down to 50% (re: `.5`) of its original
size, then only lines containing `init` are maintained, and that sub-
sub-list is printed.

If you wondered what functions called the above functions, you could
now (p is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you’re going to have to read the
manual, or guess what the following functions do:

```
p.print_callees()
p.add('fooprof')
```

Invoked as a script, the `pstats` module is a statistics browser for
reading and examining profile dumps. It has a simple line-oriented
interface (implemented using cmd) and interactive help.
What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
The primary entry point for the profiler is the global function `profile.run()` (resp. `cProfile.run()`). It is typically used to create any profile information. The reports are formatted and printed using methods of the class `pstats.Stats`. The following is a description of all of these standard entry points and functions. For a more in-depth view of some of the code, consider reading the later section on Profiler Extensions, which includes discussion of how to derive “better” profilers from the classes presented, or reading the source code for these modules.

**cProfile.run(command[, filename])**

This function takes a single argument that can be passed to the `exec` statement, and an optional file name. In all cases this routine attempts to `exec` its first argument, and gather profiling statistics from the execution. If no file name is present, then this function automatically prints a simple profiling report, sorted by the standard name string (file/line/function-name) that is presented in each line. The following is a typical output from such a call:

```
2706 function calls (2004 primitive calls) in 4.504 CPU seconds
Ordered by: standard name
ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
2    0.006    0.003    0.953    0.477  pobject.py:75(save_objects)
43/3  0.533  0.012  0.749  0.250  pobject.py:99(evaluate)
...
```

The first line indicates that 2706 calls were monitored. Of those
calls, 2004 were *primitive*. We define *primitive* to mean that the call was not induced via recursion. The next line: ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls
    for the number of calls,

tottime
    for the total time spent in the given function (and excluding time made in calls to sub-functions),

percall
    is the quotient of tottime divided by ncalls

cumtime
    is the total time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.

percall
    is the quotient of cumtime divided by primitive calls

filename:lineno(function)
    provides the respective data of each function

When there are two numbers in the first column (for example, $43/3$), then the latter is the number of primitive calls, and the former is the actual number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

cProfile.runctx(command, globals, locals[, filename])
    This function is similar to run(), with added arguments to supply the globals and locals dictionaries for the command string.
Analysis of the profiler data is done using the `stats` class.

**Note:** The `stats` class is defined in the `pstats` module.

class `pstats.Stats(filename[, stream=sys.stdout[, ...]])`  
This class constructor creates an instance of a “statistics object” from a `filename` (or set of filenames). `Stats` objects are manipulated by methods, in order to print useful reports. You may specify an alternate output stream by giving the keyword argument, `stream`.

The file selected by the above constructor must have been created by the corresponding version of `profile` or `cProfile`. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing `Stats` object, the `add()` method can be used.

*Changed in version 2.5: The `stream` parameter was added.*

**The Stats Class**

`Stats` objects have the following methods:

`Stats.strip_dirs()`  
This method for the `Stats` class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its
entries in a "random" order, as it was just after object initialization and loading. If strip_dirs() causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

Stats.add(filename[, ...])
This method of the Stats class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of profile.run() or cProfile.run(). Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

Stats.dump_stats(filename)
Save the data loaded into the Stats object to a file named filename. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the profile.Profile and cProfile.Profile classes.

New in version 2.3.

Stats.sort_stats(key[, ...])
This method modifies the Stats object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example: 'time' or 'name').

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, sort_stats('name', 'file') will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the
abbreviation is unambiguous. The following are the keys currently defined:

<table>
<thead>
<tr>
<th>Valid Arg</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'calls'</td>
<td>call count</td>
</tr>
<tr>
<td>'cumulative'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'file'</td>
<td>file name</td>
</tr>
<tr>
<td>'module'</td>
<td>file name</td>
</tr>
<tr>
<td>'pcalls'</td>
<td>primitive call count</td>
</tr>
<tr>
<td>'line'</td>
<td>line number</td>
</tr>
<tr>
<td>'name'</td>
<td>function name</td>
</tr>
<tr>
<td>'nfl'</td>
<td>name/file/line</td>
</tr>
<tr>
<td>'stdname'</td>
<td>standard name</td>
</tr>
<tr>
<td>'time'</td>
<td>internal time</td>
</tr>
</tbody>
</table>

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, `sort_stats('nfl')` is the same as `sort_stats('name', 'file', 'line')`.

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.
Stats.reverse_order()
This method for the Stats class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

Stats.print_stats([restriction, ...])
This method for the Stats class prints out a report as described in the profile.run() definition.

The order of the printing is based on the last sort_stats() operation done on the object (subject to caveats in add() and strip_dirs()).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a regular expression (to pattern match the standard name that is printed; as of Python 1.5b1, this uses the Perl-style regular expression syntax defined by the re module). If several restrictions are provided, then they are applied sequentially. For example:

```python
print_stats(.1, 'foo:')[/]
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename .*foo:. In contrast, the command:

```python
print_stats('foo:', .1)[/]
```

would limit the list to all functions having file names .*foo:, and then proceed to only print the first 10% of them.
Stats. \texttt{print_callers([restriction, ...])}

This method for the \texttt{Stats} class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by \texttt{print_stats()}, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With \texttt{profile}, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With \texttt{cProfile}, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

Stats. \texttt{print_callees([restriction, ...])}

This method for the \texttt{Stats} class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the \texttt{print_callers()} method.
Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it can accumulate and become very significant.

The problem is more important with profile than with the lower-overhead cProfile. For this reason, profile provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do not be alarmed by negative numbers in the profile. They should only appear if you have calibrated your profiler, and the results are actually better than without calibration.
Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see discussion in section Limitations above).

```python
import profile
pr = profile.Profile()
for i in range(5):
    print pr.calibrate(10000)
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on an 800 MHz Pentium running Windows 2000, and using Python’s `time.clock()` as the timer, the magical number is about 12.5e-6.

The object of this exercise is to get a fairly consistent result. If your computer is very fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it: [2]

```python
import profile

# 1. Apply computed bias to all Profile instances created here
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias
```
# 3. Specify computed bias in instance constructor.

```python
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.
The `Profile` class of both modules, `profile` and `cProfile`, were written so that derived classes could be developed to extend the profiler. The details are not described here, as doing this successfully requires an expert understanding of how the `Profile` class works internally. Study the source code of the module carefully if you want to pursue this.

If all you want to do is change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the `Profile` class constructor:

```python
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func()`.

`profile.Profile` `your_time_func()` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose. For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is pretty bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

`cProfile.Profile`
your_time_func() should return a single number. If it returns plain integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if your_integer_time_func() returns times measured in thousands of seconds, you would construct the Profile instance as follows:

```
pr = profile.Profile(your_integer_time_func, 0.001)
```

As the cProfile.Profile class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal _lsprof module.

Footnotes

[1] Updated and converted to LaTeX by Guido van Rossum. Further updated by Armin Rigo to integrate the documentation for the new cProfile module of Python 2.5. Prior to Python 2.2, it was necessary to edit the profiler source code to embed the bias as a literal number. You still can, but that method is no longer described, because no longer needed.

[2]
**hotshot — High performance logging profiler**

*New in version 2.2.*

This module provides a nicer interface to the `hotshot` C module. Hotshot is a replacement for the existing `profile` module. As it’s written mostly in C, it should result in a much smaller performance impact than the existing `profile` module.

**Note:** The `hotshot` module focuses on minimizing the overhead while profiling, at the expense of long data post-processing times. For common usage it is recommended to use `cProfile` instead. `hotshot` is not maintained and might be removed from the standard library in the future.

*Changed in version 2.5:* The results should be more meaningful than in the past: the timing core contained a critical bug.

**Warning:** The `hotshot` profiler does not yet work well with threads. It is useful to use an unthreaded script to run the profiler over the code you’re interested in measuring if at all possible.

```python
class hotshot.Profile(logfile[, lineevents[, linetimes]])
```

The profiler object. The argument `logfile` is the name of a log file to use for logged profile data. The argument `lineevents` specifies whether to generate events for every source line, or just on function call/return. It defaults to 0 (only log function call/return). The argument `linetimes` specifies whether to record timing information. It defaults to 1 (store timing information).
Profile Objects

Profile objects have the following methods:

Profile. **addinfo**(key, value)

Add an arbitrary labelled value to the profile output.

Profile. **close()**

Close the logfile and terminate the profiler.

Profile. **fileno()**

Return the file descriptor of the profiler's log file.

Profile. **run**(cmd)

Profile an exec-compatible string in the script environment. The globals from the __main__ module are used as both the globals and locals for the script.

Profile. **runcall**(func, *args, **keywords)

Profile a single call of a callable. Additional positional and keyword arguments may be passed along; the result of the call is returned, and exceptions are allowed to propagate cleanly, while ensuring that profiling is disabled on the way out.

Profile. **runcxt**(cmd, globals, locals)

Evaluate an exec-compatible string in a specific environment. The string is compiled before profiling begins.

Profile. **start()**

Start the profiler.

Profile. **stop()**

Stop the profiler.
Using hotshot data

New in version 2.2.

This module loads hotshot profiling data into the standard `pstats` Stats objects.

```
hotshot.stats.load(filename)
```

Load hotshot data from `filename`. Returns an instance of the `pstats.Stats` class.

See also:

**Module profile**
- The `profile` module’s `stats` class
Example Usage

Note that this example runs the python “benchmark” pystones. It can take some time to run, and will produce large output files.

```python
>>> import hotshot, hotshot.stats, test.pystone
>>> prof = hotshot.Profile("stones.prof")
>>> benchtime, stones = prof.runcall(test.pystone.pystones)
>>> prof.close()
>>> stats = hotshot.stats.load("stones.prof")
>>> stats.strip_dirs()
>>> stats.sort_stats('time', 'calls')
>>> stats.print_stats(20)

850004 function calls in 10.090 CPU seconds

Ordered by: internal time, call count

ncalls  tottime  percall  cumtime  percall filename:lineno(function)

...
```

**timeit — Measure execution time of small code snippets**

New in version 2.3.

This module provides a simple way to time small bits of Python code. It has both command line as well as callable interfaces. It avoids a number of common traps for measuring execution times. See also Tim Peters’ introduction to the “Algorithms” chapter in the Python Cookbook, published by O'Reilly.

The module defines the following public class:

```python
class timeit.Timer([stmt='pass', setup='pass', timer=<timer function>])
```

Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to `'pass'`; the timer function is platform-dependent (see the module doc string). The statements may contain newlines, as long as they don’t contain multi-line string literals.

To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` method is a convenience to call `timeit()` multiple times and return a list of results.

*Changed in version 2.6:* The `stmt` and `setup` parameters can now also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.
Timer.print_exc([file=None])
Helper to print a traceback from the timed code.

Typical use:

```python
t = Timer(...)  # outside the try/except
try:
    t.timeit(...)  # or t.repeat(...)
except:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in
the compiled template will be displayed. The optional file
argument directs where the traceback is sent; it defaults to
sys.stderr.

Timer.repeat([repeat=3[, number=1000000]])
Call timeit() a few times.

This is a convenience function that calls the timeit() repeatedly,
returning a list of results. The first argument specifies how many
times to call timeit(). The second argument specifies the
number argument for timeit().

Note: It's tempting to calculate mean and standard deviation
from the result vector and report these. However, this is not
very useful. In a typical case, the lowest value gives a lower
bound for how fast your machine can run the given code
snippet; higher values in the result vector are typically not
caused by variability in Python's speed, but by other processes
interfering with your timing accuracy. So the min() of the result
is probably the only number you should be interested in. After
that, you should look at the entire vector and apply common
sense rather than statistics.

Timer.timeit([number=1000000])

Time number executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

**Note:** By default, timeit() temporarily turns off garbage collection during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the setup string. For example:

```python
import timer
import gc

timeit.Timer('for i in xrange(10): oct(i)', 'gc.enable()')
```

Starting with version 2.6, the module also defines two convenience functions:

```python
import timer

timeit.repeat(stmt[, setup[, timer[, repeat=3[, number=1000000]]]]))
```

Create a Timer instance with the given statement, setup code and timer function and run its repeat() method with the given repeat count and number executions.

*New in version 2.6.*
timeit.timeit(stmt[, setup[, timer[, number=1000000]]])

Create a Timer instance with the given statement, setup code and timer function and run its timeit() method with number executions.

New in version 2.6.
Command Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-s S] [-t] [-c] [-h] [statement ...]
```

where the following options are understood:

- `-n N`/`--number=N`  
  how many times to execute 'statement'

- `-r N`/`--repeat=N`  
  how many times to repeat the timer (default 3)

- `-s S`/`--setup=S`  
  statement to be executed once initially (default 'pass')

- `-t`/`--time`  
  use `time.time()` (default on all platforms but Windows)

- `-c`/`--clock`  
  use `time.clock()` (default on Windows)

- `-v`/`--verbose`  
  print raw timing results; repeat for more digits precision

- `-h`/`--help`  
  print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.

If `-n` is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.
The default timer function is platform dependent. On Windows, `time.clock()` has microsecond granularity but `time.time()`'s granularity is 1/60th of a second; on Unix, `time.clock()` has 1/100th of a second granularity and `time.time()` is much more precise. On either platform, the default timer functions measure wall clock time, not the CPU time. This means that other processes running on the same computer may interfere with the timing. The best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 3 repetitions is probably enough in most cases. On Unix, you can use `time.clock()` to measure CPU time.

**Note:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn’t try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments.

The baseline overhead differs between Python versions! Also, to fairly compare older Python versions to Python 2.3, you may want to use Python’s `-O` option for the older versions to avoid timing `SET_LINENO` instructions.
Examples

Here are two example sessions (one using the command line, one using the module interface) that compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes.

```python
>>> import timeit
>>> s = ""
... try:
...   str.__nonzero__
... except AttributeError:
...   pass
... ""
>>> t = timeit.Timer(stmt=s)
>>> print "%.2f usec/pass" % (1000000 * t.timeit(number=100000))
17.09 usec/pass
>>> s = ""
... if hasattr(str, '__nonzero__'): pass
... ""
>>> t = timeit.Timer(stmt=s)
>>> print "%.2f usec/pass" % (1000000 * t.timeit(number=100000))
4.85 usec/pass
>>> s = ""
... try:
...   int.__nonzero__
... except AttributeError:
...   pass
... ""
>>> t = timeit.Timer(stmt=s)
>>> print "%.2f usec/pass" % (1000000 * t.timeit(number=100000))
1.97 usec/pass
>>> s = ""
... if hasattr(int, '__nonzero__'): pass
... ""
```
To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement:

```python
def test():
    "Stupid test function"
    L = []
    for i in range(100):
        L.append(i)

if __name__ == '__main__':
    from timeit import Timer
    t = Timer("test()", "from __main__ import test")
    print t.timeit()  # 3.15 usec/pass
```

```python
t = timeit.Timer(stmt=s)
print "%.2f usec/pass" % (1000000 * t.timeit(number=100000))
3.15 usec/pass
```
**trace — Trace or track Python statement execution**

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.
Command Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```python
python -m trace --count somefile.py ...
```

The above will generate annotated listings of all Python modules imported during the execution of `somefile.py`.

The following command-line arguments are supported:

--`trace`, `-t`  
Display lines as they are executed.

--`count`, `-c`  
Produce a set of annotated listing files upon program completion that shows how many times each statement was executed.

--`report`, `-r`  
Produce an annotated list from an earlier program run that used the `--count` and `--file` arguments.

--`no-report`, `-R`  
Do not generate annotated listings. This is useful if you intend to make several runs with `--count` then produce a single set of annotated listings at the end.

--`listfuncs`, `-l`  
List the functions executed by running the program.

--`trackcalls`, `-T`  
Generate calling relationships exposed by running the program.

--`file`, `-f`  
Name a file containing (or to contain) counts.

--`coverdir`, `-C`
Name a directory in which to save annotated listing files.

--missing, -m
When generating annotated listings, mark lines which were not executed with ‘>>>>>>’.

--summary, -s
When using --count or --report, write a brief summary to stdout for each file processed.

--ignore-module
Accepts comma separated list of module names. Ignore each of the named module and its submodules (if it is a package). May be given multiple times.

--ignore-dir
Ignore all modules and packages in the named directory and subdirectories (multiple directories can be joined by os.pathsep). May be given multiple times.
Programming Interface

class trace. **Trace**([`count=1`, `trace=1`, `countfuncs=0`, `countcallers=0`, `ignoremods=0`, `ignoredirs=0`, `infile=None`, `outfile=None`, `timing=False]])

Create an object to trace execution of a single statement or expression. All parameters are optional. `count` enables counting of line numbers. `trace` enables line execution tracing. `countfuncs` enables listing of the functions called during the run. `countcallers` enables call relationship tracking. `ignoremods` is a list of modules or packages to ignore. `ignoredirs` is a list of directories whose modules or packages should be ignored. `infile` is the file from which to read stored count information. `outfile` is a file in which to write updated count information. `timing` enables a timestamp relative to when tracing was started to be displayed.

**Trace. run(cmd)**

Run `cmd` under control of the Trace object with the current tracing parameters.

**Trace. runctx(cmd[, globals=None, locals=None])**

Run `cmd` under control of the Trace object with the current tracing parameters in the defined global and local environments. If not defined, `globals` and `locals` default to empty dictionaries.

**Trace. runfunc(func, *args, **kwds)**

Call `func` with the given arguments under control of the Trace object with the current tracing parameters.

This is a simple example showing the use of this module:

```python
import sys
import trace
```
# create a Trace object, telling it what to ignore, and whether
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in /tmp
r = tracer.results()
r.write_results(show_missing=True, coverdir="/tmp")
Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here’s an overview:

- **sys** — System-specific parameters and functions
- **__builtin__** — Built-in objects
- **future_builtins** — Python 3 builtins
- **__main__** — Top-level script environment
- **warnings** — Warning control
  - Warning Categories
  - The Warnings Filter
  - Temporarily Suppressing Warnings
  - Testing Warnings
  - Available Functions
  - Available Context Managers
- **contextlib** — Utilities for with-statement contexts.
- **abc** — Abstract Base Classes
- **atexit** — Exit handlers
  - atexit Example
- **traceback** — Print or retrieve a stack traceback
  - Traceback Examples
- **__future__** — Future statement definitions
• gc — Garbage Collector interface

• inspect — Inspect live objects
  ○ Types and members
  ○ Retrieving source code
  ○ Classes and functions
  ○ The interpreter stack

• site — Site-specific configuration hook

• user — User-specific configuration hook

• fpectl — Floating point exception control
  ○ Example
  ○ Limitations and other considerations
sys — System-specific parameters and functions

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

sys. **argv**

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `-c`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the `fileinput` module.

sys. **byteorder**

An indicator of the native byte order. This will have the value 'big' on big-endian (most-significant byte first) platforms, and 'little' on little-endian (least-significant byte first) platforms.

*New in version 2.0.*

sys. **subversion**

A triple (repo, branch, version) representing the Subversion information of the Python interpreter. `repo` is the name of the repository, 'CPython'. `branch` is a string of one of the forms 'trunk', 'branches/name' or 'tags/name'. `version` is the output of `svnversion`, if the interpreter was built from a Subversion checkout; it contains the revision number (range) and possibly a trailing ‘M’ if there were local modifications. If the tree was
exported (or svnversion was not available), it is the revision of
\texttt{Include/patchlevel.h} if the branch is a tag. Otherwise, it is \texttt{None}.

\textit{New in version 2.5.}

\texttt{sys.builtin\_module\_names}

A tuple of strings giving the names of all modules that are
compiled into this Python interpreter. (This information is not
available in any other way — \texttt{modules.keys()} only lists the
imported modules.)

\texttt{sys.copyright}

A string containing the copyright pertaining to the Python
interpreter.

\texttt{sys._clear\_type\_cache()}

Clear the internal type cache. The type cache is used to speed
up attribute and method lookups. Use the function \texttt{only}
to drop
unnecessary references during reference leak debugging.

This function should be used for internal and specialized
purposes only.

\textit{New in version 2.6.}

\texttt{sys._current\_frames()}

Return a dictionary mapping each thread's identifier to the
topmost stack frame currently active in that thread at the time the
function is called. Note that functions in the \texttt{traceback}
module
can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not
require the deadlocked threads’ cooperation, and such threads'
call stacks are frozen for as long as they remain deadlocked. The
frame returned for a non-deadlocked thread may bear no
relationship to that thread’s current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

*New in version 2.5.*

**sys.dllhandle**

Integer specifying the handle of the Python DLL. Availability: Windows.

**sys.displayhook(value)**

If `value` is not `None`, this function prints it to `sys.stdout`, and saves it in `__builtins__`. `sys.displayhook` is called on the result of evaluating an expression entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

**sys.excepthook(type, value, traceback)**

This function prints out a given traceback and exception to `sys.stderr`.

When an exception is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

**sys.__displayhook__**

**sys.__excepthook__**
These objects contain the original values of `displayhook` and `excepthook` at the start of the program. They are saved so that `displayhook` and `excepthook` can be restored in case they happen to get replaced with broken objects.

```python
sys.exc_info()
```

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, “handling an exception” is defined as “executing or having executed an except clause.” For any stack frame, only information about the most recently handled exception is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three `None` values is returned. Otherwise, the values returned are `(type, value, traceback)`. Their meaning is: `type` gets the exception type of the exception being handled (a class object); `value` gets the exception parameter (its `associated value` or the second argument to `raise`, which is always a class instance if the exception type is a class object); `traceback` gets a traceback object (see the Reference Manual) which encapsulates the call stack at the point where the exception originally occurred.

If `exc_clear()` is called, this function will return three `None` values until either another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

**Warning:** Assigning the `traceback` return value to a local variable in a function that is handling an exception will cause a
circular reference. This will prevent anything referenced by a local variable in the same function or by the traceback from being garbage collected. Since most functions don’t need access to the traceback, the best solution is to use something like `exctype, value = sys.exc_info()[:2]` to extract only the exception type and value. If you do need the traceback, make sure to delete it after use (best done with a `try ... finally` statement) or to call `exc_info()` in a function that does not itself handle an exception.

**Note:** Beginning with Python 2.2, such cycles are automatically reclaimed when garbage collection is enabled and they become unreachable, but it remains more efficient to avoid creating cycles.

`sys.exc_clear()`
This function clears all information relating to the current or last exception that occurred in the current thread. After calling this function, `exc_info()` will return three `None` values until another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

This function is only needed in only a few obscure situations. These include logging and error handling systems that report information on the last or current exception. This function can also be used to try to free resources and trigger object finalization, though no guarantee is made as to what objects will be freed, if any.

*New in version 2.3.*

`sys.exc_type`
`sys.exc_value`
`sys.exc_traceback`
**Deprecated since version 1.5:** Use `exc_info()` instead.

Since they are global variables, they are not specific to the current thread, so their use is not safe in a multi-threaded program. When no exception is being handled, `exc_type` is set to `None` and the other two are undefined.

**sys.exec_prefix**
A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `/usr/local`. This can be set at build time with the `--exec-prefix` argument to the `configure` script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix + '/lib/pythonversion/config'`, and shared library modules are installed in `exec_prefix + '/lib/pythonversion/lib-dynload'`, where `version` is equal to `version[:3]`.

**sys.executable**
A string giving the name of the executable binary for the Python interpreter, on systems where this makes sense.

**sys.exit([arg])**
Exit from Python. This is implemented by raising the `SystemExit` exception, so cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level. The optional argument `arg` can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and the like. Most systems require it to be in the range 0-127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally
underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, None is equivalent to passing zero, and any other object is printed to sys.stderr and results in an exit code of 1. In particular, sys.exit("some error message") is a quick way to exit a program when an error occurs.

**sys.exitfunc**

This value is not actually defined by the module, but can be set by the user (or by a program) to specify a clean-up action at program exit. When set, it should be a parameterless function. This function will be called when the interpreter exits. Only one function may be installed in this way; to allow multiple functions which will be called at termination, use the atexit module.

**Note:** The exit function is not called when the program is killed by a signal, when a Python fatal internal error is detected, or when os._exit() is called.

*Deprecated since version 2.4: Use atexit instead.*

**sys.flags**

The struct sequence flags exposes the status of command line flags. The attributes are read only.

<table>
<thead>
<tr>
<th>attribute</th>
<th>flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>-d</td>
</tr>
<tr>
<td>py3k_warning</td>
<td>-3</td>
</tr>
<tr>
<td>division_warning</td>
<td>-Q</td>
</tr>
<tr>
<td>division_new</td>
<td>-Qnew</td>
</tr>
<tr>
<td>inspect</td>
<td>-i</td>
</tr>
<tr>
<td>interactive</td>
<td>-i</td>
</tr>
<tr>
<td>optimize</td>
<td>-O or -OO</td>
</tr>
<tr>
<td>dont_write_bytecode</td>
<td>-B</td>
</tr>
</tbody>
</table>
**sys. float_info**

A structseq holding information about the float type. It contains low level information about the precision and internal representation. Please study your system’s `float.h` for more information.

<table>
<thead>
<tr>
<th>attribute</th>
<th>explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>epsilon</td>
<td>Difference between 1 and the next representable floating point number</td>
</tr>
<tr>
<td>dig</td>
<td>digits (see <code>float.h</code>)</td>
</tr>
<tr>
<td>mant_dig</td>
<td>mantissa digits (see <code>float.h</code>)</td>
</tr>
<tr>
<td>max</td>
<td>maximum representable finite float</td>
</tr>
<tr>
<td>max_exp</td>
<td>maximum int e such that radix**(e-1) is in the range of finite representable floats</td>
</tr>
<tr>
<td>max_10_exp</td>
<td>maximum int e such that 10**e is in the range of finite representable floats</td>
</tr>
<tr>
<td>min</td>
<td>Minimum positive normalizer float</td>

</tr>
<tr>
<td>radix</td>
<td>radix of exponent</td>
</tr>
<tr>
<td>rounds</td>
<td>addition rounds (see <code>float.h</code>)</td>
</tr>
</tbody>
</table>

**Note:** The information in the table is simplified.

*New in version 2.6.*
sys. `getcheckinterval()`
Return the interpreter’s “check interval”; see `setcheckinterval()`.

*New in version 2.3.*

sys. `getdefaultencoding()`
Return the name of the current default string encoding used by the Unicode implementation.

*New in version 2.0.*

sys. `getdlopenflags()`
Return the current value of the flags that are used for `dlopen` calls. The flag constants are defined in the `dl` and `DLFCN` modules. Availability: Unix.

*New in version 2.2.*

sys. `getfilesystemencoding()`
Return the name of the encoding used to convert Unicode filenames into system file names, or `None` if the system default encoding is used. The result value depends on the operating system:

- On Windows 9x, the encoding is “mbcs”.
- On Mac OS X, the encoding is “utf-8”.
- On Unix, the encoding is the user’s preference according to the result of `nl_langinfo(CODESET)`, or `None` if the `nl_langinfo(CODESET)` failed.
- On Windows NT+, file names are Unicode natively, so no conversion is performed. `getfilesystemencoding()` still returns `'mbcs'`, as this is the encoding that applications should use when they explicitly want to convert Unicode strings to byte strings that are equivalent when used as file
names.

New in version 2.3.

sys. getrefcount(object)

Return the reference count of the object. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to getrefcount().

sys. getrecursionlimit()

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by setrecursionlimit().

sys. getsizeof(object[, default])

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

The default argument allows to define a value which will be returned if the object type does not provide means to retrieve the size and would cause a TypeError.

func:getsizetof calls the object’s __sizeof__ method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

New in version 2.6.

sys. _getframe([depth])

Return a frame object from the call stack. If optional integer depth is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, ValueError is
raised. The default for depth is zero, returning the frame at the top of the call stack.

This function should be used for internal and specialized purposes only.

sys.getprofile()
Get the profiler function as set by setprofile().

New in version 2.6.

sys.gettrace()
Get the trace function as set by settrace().

Note: The gettrace() function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

New in version 2.6.

sys.getwindowsversion()
Return a tuple containing five components, describing the Windows version currently running. The elements are major, minor, build, platform, and text. text contains a string while all other values are integers.

platform may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (VER_PLATFORM_WIN32s)</td>
<td>Win32s on Windows 3.1</td>
</tr>
<tr>
<td>1 (VER_PLATFORM_WIN32_WINDOWS)</td>
<td>Windows 95/98/ME</td>
</tr>
</tbody>
</table>
This function wraps the Win32 `GetVersionEx` function; see the Microsoft documentation for more information about these fields.

**Availability:** Windows.

*New in version 2.3.*

**sys.hexversion**

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```python
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The `version_info` value may be used for a more human-friendly encoding of the same information.

*New in version 1.5.2.*

**sys.last_type**

**sys.last_value**

**sys.last_traceback**

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error
message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see chapter `pdb — The Python Debugger` for more information.)

The meaning of the variables is the same as that of the return values from `exc_info()` above. (Since there is only one interactive thread, thread-safety is not a concern for these variables, unlike for `exc_type` etc.)

**sys.maxint**

The largest positive integer supported by Python’s regular integer type. This is at least $2^{**31}-1$. The largest negative integer is $-\text{maxint-1}$ — the asymmetry results from the use of 2’s complement binary arithmetic.

**sys.maxsize**

The largest positive integer supported by the platform’s `Py_ssize_t` type, and thus the maximum size lists, strings, dicts, and many other containers can have.

**sys.maxunicode**

An integer giving the largest supported code point for a Unicode character. The value of this depends on the configuration option that specifies whether Unicode characters are stored as UCS-2 or UCS-4.

**sys.modules**

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. Note that removing a module from this dictionary is not the same as calling `reload()` on the corresponding module object.
**sys. path**
A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

As initialized upon program startup, the first item of this list, `path[0]`, is the directory containing the script that was used to invoke the Python interpreter. If the script directory is not available (e.g. if the interpreter is invoked interactively or if the script is read from standard input), `path[0]` is the empty string, which directs Python to search modules in the current directory first. Notice that the script directory is inserted before the entries inserted as a result of `PYTHONPATH`.

A program is free to modify this list for its own purposes.

*Changed in version 2.3:* Unicode strings are no longer ignored.

**sys. platform**
This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For Unix systems, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5' or 'linux2', *at the time when Python was built*. For other systems, the values are:

<table>
<thead>
<tr>
<th>System</th>
<th>platform value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>'win32'</td>
</tr>
<tr>
<td>Windows/Cygwin</td>
<td>'cygwin'</td>
</tr>
<tr>
<td>Mac OS X</td>
<td>'darwin'</td>
</tr>
<tr>
<td>Mac OS 9</td>
<td>'mac'</td>
</tr>
<tr>
<td>OS/2</td>
<td>'os2'</td>
</tr>
<tr>
<td>OS/2 EMX</td>
<td>'os2emx'</td>
</tr>
<tr>
<td></td>
<td>'riscos'</td>
</tr>
</tbody>
</table>
sys. \texttt{prefix}

A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string `/usr/local`. This can be set at build time with the \texttt{--prefix} argument to the \texttt{configure} script. The main collection of Python library modules is installed in the directory \texttt{prefix + '/lib/pythonversion'} while the platform independent header files (all except \texttt{pyconfig.h}) are stored in \texttt{prefix + '/include/pythonversion'}, where \texttt{version} is equal to \texttt{version[0:3]}.

sys. \texttt{ps1} \newline sys. \texttt{ps2}

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>> ' and `'... '. If a non-string object is assigned to either variable, its \texttt{str()} is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

sys. \texttt{py3kwarning}

Bool containing the status of the Python 3.0 warning flag. It's \texttt{True} when Python is started with the -3 option.

\textit{New in version 2.6.}

sys. \texttt{dont_write_bytecode}

If this is true, Python won't try to write \texttt{.pyc} or \texttt{.pyo} files on the import of source modules. This value is initially set to \texttt{True} or \texttt{False} depending on the \texttt{-B} command line option and the
PYTHON_DONT_WRITE_BYTECODE environment variable, but you can set it yourself to control bytecode file generation.

New in version 2.6.

def setcheckinterval(interval):
    """Set the interpreter's "check interval". This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is 100, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value <= 0 checks every virtual instruction, maximizing responsiveness as well as overhead."

sys.setcheckinterval(interval)

Set the interpreter's "check interval". This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is 100, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value <= 0 checks every virtual instruction, maximizing responsiveness as well as overhead.

sys.setdefaultencoding(name)

Set the current default string encoding used by the Unicode implementation. If name does not match any available encoding, LookupError is raised. This function is only intended to be used by the site module implementation and, where needed, by sitecustomize. Once used by the site module, it is removed from the sys module's namespace.

New in version 2.0.

sys.setdlopenflags(n)

Set the flags used by the interpreter for dlopen calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as sys.setdlopenflags(0). To share symbols across extension modules, call as sys.setdlopenflags(dl.RTLD_NOW | dl.RTLD_GLOBAL). Symbolic names for the flag modules can be either found in the dl module,
or in the `DLFCN` module. If `DLFCN` is not available, it can be generated from `/usr/include/dlfcn.h` using the `h2py` script. Availability: Unix.

*New in version 2.2.*

**sys. `setprofile(profilefunc)`**

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter *The Python Profilers* for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see `settrace()`), but it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`.

**sys. `setrecursionlimit(limit)`**

Set the maximum depth of the Python interpreter stack to `limit`. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when she has a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

**sys. `settrace(tracefunc)`**

Set the system's trace function, which allows you to implement a Python source code debugger in Python. See section *How It Works* in the chapter on the Python debugger. The function is
thread-specific; for a debugger to support multiple threads, it must be registered using `settrace()` for each thread being debugged.

**Note:** The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

```python
sys.settscdump(on_flag)
```
Activate dumping of VM measurements using the Pentium timestamp counter, if `on_flag` is true. Deactivate these dumps if `on_flag` is off. The function is available only if Python was compiled with `--with-tsc`. To understand the output of this dump, read `Python/ceval.c` in the Python sources.

*New in version 2.4.*

```python
sys.stdin
sys.stdout
sys.stderr
```
File objects corresponding to the interpreter’s standard input, output and error streams. `stdin` is used for all interpreter input except for scripts but including calls to `input()` and `raw_input()`. `stdout` is used for the output of `print` and `expression` statements and for the prompts of `input()` and `raw_input()`. The interpreter’s own prompts and (almost all of) its error messages go to `stderr`. `stdout` and `stderr` needn’t be built-in file objects: any object is acceptable as long as it has a `write()` method that takes a string argument. (Changing these objects doesn’t affect the standard I/O streams of processes executed by `os.popen()`, `os.system()` or the `exec*()` family of functions in the `os` module.)
sys.__stdin__
sys.__stdout__
sys.__stderr__

These objects contain the original values of stdin, stderr and stdout at the start of the program. They are used during finalization, and could be useful to restore the actual files to known working file objects in case they have been overwritten with a broken object.

sys.tracebacklimit

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

sys.version

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. It has a value of the form 'version (#build_number, build_date, build_time) [compiler]'. The first three characters are used to identify the version in the installation directories (where appropriate on each platform). An example:

```python
>>> import sys
>>> sys.version
'1.5.2 (#0 Apr 13 1999, 10:51:12) [MSC 32 bit (Intel)]'
```

sys.api_version

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

*New in version 2.3.*
sys. `version_info`

A tuple containing the five components of the version number: `major`, `minor`, `micro`, `releaselevel`, and `serial`. All values except `releaselevel` are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The `version_info` value corresponding to the Python version 2.0 is `(2, 0, 0, 'final', 0).

*New in version 2.0.*

sys. `warnoptions`

This is an implementation detail of the warnings framework; do not modify this value. Refer to the `warnings` module for more information on the warnings framework.

sys. `winver`

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of `version`. It is provided in the `sys` module for informational purposes; modifying this value has no effect on the registry keys used by Python. Availability: Windows.

---

See also:

**Module site**

This describes how to use .pth files to extend `sys.path`.
This module provides direct access to all ‘built-in’ identifiers of Python; for example, `__builtin__.open` is the full name for the built-in function `open()`. See chapter *Built-in Objects*.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an `open()` function that wraps the built-in `open()`, this module can be used directly:

```python
import __builtin__

def open(path):
    f = __builtin__.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

As an implementation detail, most modules have the name `__builtins__` (note the 's') made available as part of their globals. The value of `__builtins__` is normally either this module or the value of this module's `__dict__` attribute. Since this is an implementation detail, it may not be used by alternate implementations of Python.
future_builtins — Python 3 builtins

*New in version 2.6.*

This module provides functions that exist in 2.x, but have different behavior in Python 3, so they cannot be put into the 2.x builtin namespace.

Instead, if you want to write code compatible with Python 3 builtins, import them from this module, like this:

```python
from future_builtins import map, filter

... code using Python 3-style map and filter ... 
```

The `2to3` tool that ports Python 2 code to Python 3 will recognize this usage and leave the new builtins alone.

**Note:** The Python 3 `print()` function is already in the builtins, but cannot be accessed from Python 2 code unless you use the appropriate future statement:

```python
from __future__ import print_function
```

Available builtins are:

* `future_builtins.ascii(object)`
  Returns the same as `repr()`. In Python 3, `repr()` will return printable Unicode characters unescaped, while `ascii()` will always backslash-escape them. Using `future_builtins.ascii()` instead of `repr()` in 2.6 code makes it clear that you need a pure ASCII return value.

* `future_builtins.filter(function, iterable)`
Works like `itertools.ifilter()`.

`future_builtins.hex(object)`
Works like the builtin `hex()`, but instead of `__hex__()` it will use the `__index__()` method on its argument to get an integer that is then converted to hexadecimal.

`future_builtins.map(function, iterable, ...)`
Works like `itertools.imap()`.

`future_builtins.oct(object)`
Works like the builtin `oct()`, but instead of `__oct__()` it will use the `__index__()` method on its argument to get an integer that is then converted to hexadecimal.

`future_builtins.zip(*iterables)`
Works like `itertools.izip()`.
This module represents the (otherwise anonymous) scope in which the interpreter's main program executes — commands read either from standard input, from a script file, or from an interactive prompt. It is this environment in which the idiomatic "conditional script" stanza causes a script to run:

```python
if __name__ == '__main__':
    main()
```
**warnings — Warning control**

*New in version 2.1.*

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn’t warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx`; see *Exception Handling* for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category (see below), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function
formats the message by calling `formatwarning()`, which is also available for use by custom implementations.
Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings. The following warnings category classes are currently defined:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>This is the base class of all warning category classes. It is a subclass of Exception.</td>
</tr>
<tr>
<td>UserWarning</td>
<td>The default category for warn().</td>
</tr>
<tr>
<td>DeprecationWarning</td>
<td>Base category for warnings about deprecated features.</td>
</tr>
<tr>
<td>SyntaxWarning</td>
<td>Base category for warnings about dubious syntactic features.</td>
</tr>
<tr>
<td>RuntimeWarning</td>
<td>Base category for warnings about dubious runtime features.</td>
</tr>
<tr>
<td>FutureWarning</td>
<td>Base category for warnings about constructs that will change semantically in the future.</td>
</tr>
<tr>
<td>PendingDeprecationWarning</td>
<td>Base category for warnings about features that will be deprecated in the future (ignored by default).</td>
</tr>
<tr>
<td>ImportWarning</td>
<td>Base category for warnings triggered during the process of importing a module (ignored by default).</td>
</tr>
<tr>
<td>UnicodeWarning</td>
<td>Base category for warnings related to Unicode.</td>
</tr>
</tbody>
</table>

While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing
one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.
The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the match determines the disposition of the match. Each entry is a tuple of the form (action, message, category, module, lineno), where:

- **action** is one of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Disposition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;error&quot;</td>
<td>turn matching warnings into exceptions</td>
</tr>
<tr>
<td>&quot;ignore&quot;</td>
<td>never print matching warnings</td>
</tr>
<tr>
<td>&quot;always&quot;</td>
<td>always print matching warnings</td>
</tr>
<tr>
<td>&quot;default&quot;</td>
<td>print the first occurrence of matching warnings for each location where the warning is issued</td>
</tr>
<tr>
<td>&quot;module&quot;</td>
<td>print the first occurrence of matching warnings for each module where the warning is issued</td>
</tr>
<tr>
<td>&quot;once&quot;</td>
<td>print only the first occurrence of matching warnings, regardless of location</td>
</tr>
</tbody>
</table>

- **message** is a string containing a regular expression that the warning message must match (the match is compiled to always be case-insensitive)
- **category** is a class (a subclass of `Warning`) of which the warning category must be a subclass in order to match

- **module** is a string containing a regular expression that the module name must match (the match is compiled to be case-sensitive)

- **lineno** is an integer that the line number where the warning occurred must match, or 0 to match all line numbers

Since the `Warning` class is derived from the built-in `Exception` class, to turn a warning into an error we simply raise `category(message)`.

The warnings filter is initialized by `-W` options passed to the Python interpreter command line. The interpreter saves the arguments for all `-W` options without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

The warnings that are ignored by default may be enabled by passing `-Wd` to the interpreter. This enables default handling for all warnings, including those that are normally ignored by default. This is particular useful for enabling `ImportWarning` when debugging problems importing a developed package. `ImportWarning` can also be enabled explicitly in Python code using:

```python
warnings.simplefilter('default', ImportWarning)
```
Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning, then it is possible to suppress the warning using the `catch_warnings` context manager:

```python
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code.
To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```python
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert isinstance(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as
exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).
### Available Functions

**warnings.warn**(message[, category[, stacklevel]])

Issue a warning, or maybe ignore it or raise an exception. The `category` argument, if given, must be a warning category class (see above); it defaults to `UserWarning`. Alternatively `message` can be a `Warning` instance, in which case `category` will be ignored and `message.__class__` will be used. In this case the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the `warnings` filter see above. The `stacklevel` argument can be used by wrapper functions written in Python, like this:

```python
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecation()`'s caller, rather than to the source of `deprecation()` itself (since the latter would defeat the purpose of the warning message).

**warnings.warn_explicit**(message, category, filename, lineno[, module[, registry[, module_globals]]])

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `_warningregistry_` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. `message` must be a string and `category` a subclass of `Warning` or `message` may be a `Warning` instance, in which case `category` will be
ignored.

*module Globals*, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

*Changed in version 2.5:* Added the *module Globals* parameter.

```
warnings.warnpy3k(message[, category[, stacklevel]])
```

Issue a warning related to Python 3.x deprecation. Warnings are only shown when Python is started with the -3 option. Like `warn()` `message` must be a string and `category` a subclass of `Warning`. `warnpy3k()` is using `DeprecationWarning` as default warning class.

```
warnings.showwarning(message, category, filename, lineno[, file[, line]])
```

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to `file`, which defaults to `sys.stderr`. You may replace this function with an alternative implementation by assigning to `warnings.showwarning`. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `showwarning()` will try to read the line specified by `filename` and `lineno`.

*Changed in version 2.6:* Added the `line` argument. Implementations that lack the new argument will trigger a `DeprecationWarning`.

```
warnings.formatwarning(message, category, filename, lineno[, line])
```

Format a warning the standard way. This returns a string which
may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()` will try to read the line specified by *filename* and *lineno*.

*Changed in version 2.6:* Added the *line* argument.

```python
warnings.filterwarnings(action[, message[, category[, module[, lineno[, append]]]]])
```

Insert an entry into the list of warnings filters. The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the message and module regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

```python
warnings.simplefilter(action[, category[, lineno[, append]]])
```

Insert a simple entry into the list of warnings filters. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

```python
warnings.resetwarnings()
```

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`. 
class warnings.catch_warnings([*, record=False, module=None])

A context manager that copies and, upon exit, restores the warnings filter and the showwarning() function. If the record argument is False (the default) the context manager returns None on entry. If record is True, a list is returned that is progressively populated with objects as seen by a custom showwarning() function (which also suppresses output to sys.stdout). Each object in the list has attributes with the same names as the arguments to showwarning().

The module argument takes a module that will be used instead of the module returned when you import warnings whose filter will be protected. This argument exists primarily for testing the warnings module itself.

**Note:** In Python 3.0, the arguments to the constructor for catch_warnings are keyword-only arguments.

*New in version 2.6.*
contextlib — Utilities for with-statement contexts.

New in version 2.5.

This module provides utilities for common tasks involving the with statement. For more information see also Context Manager Types and With Statement Context Managers.

Functions provided:

contextlib.contextmanager(func)

This function is a decorator that can be used to define a factory function for with statement context managers, without needing to create a class or separate __enter__() and __exit__() methods.

A simple example (this is not recommended as a real way of generating HTML!):

```python
from contextlib import contextmanager

@contextmanager
def tag(name):
    print "<%s>" % name
    yield
    print "</%s>" % name

>>> with tag("h1"):
    ...
    print "foo"
...
<h1>
foo
</h1>
```
The function being decorated must return a *generator*-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the `with` statement’s `as` clause, if any.

At the point where the generator yields, the block nested in the `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

```python
contextlib.nested([mgr1, mgr2, ...])
```

Combine multiple context managers into a single nested context manager.

Code like this:

```python
from contextlib import nested

with nested(A, B, C) as (X, Y, Z):
    do_something()
```

is equivalent to this:

```python
with A as X:
    with B as Y:
        with C as Z:
            do_something()
```
Note that if the \_\_exit\_\()( ) method of one of the nested context managers indicates an exception should be suppressed, no exception information will be passed to any remaining outer context managers. Similarly, if the \_\_exit\_\()( ) method of one of the nested managers raises an exception, any previous exception state will be lost; the new exception will be passed to the \_\_exit\_\()( ) methods of any remaining outer context managers. In general, \_\_exit\_\()( ) methods should avoid raising exceptions, and in particular they should not re-raise a passed-in exception.

contextlib.\texttt{closing}(\texttt{thing})

Return a context manager that closes \texttt{thing} upon completion of the block. This is basically equivalent to:

```python
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()
```

And lets you write code like this:

```python
from contextlib import closing
import urllib

with closing(urllib.urlopen('http://www.python.org')) as page:
    for line in page:
        print line
```
without needing to explicitly close page. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

See also:

**PEP 0343 - The “with” statement**

The specification, background, and examples for the Python `with` statement.
The collections module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition the collections module has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, is it hashable or a mapping.

This module provides the following class:

```python
class abc.ABCMeta
    Metaclass for defining Abstract Base Classes (ABCs).

    Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as “virtual subclasses” – these and their descendants will be considered subclasses of the registering ABC by the built-in issubclass() function, but the registering ABC won’t show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via super()). [1]

    Classes created with a metaclass of ABCMeta have the following method:

    register(subclass)
```
Register `subclass` as a “virtual subclass” of this ABC. For example:

```python
from abc import ABCMeta

class MyABC:
    __metaclass__ = ABCMeta

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance(), MyABC)
```

You can also override this method in an abstract base class:

```
__subclasshook__(subclass)
```

(Must be defined as a class method.)

Check whether `subclass` is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the `__subclasscheck__()` method of the ABC.)

This method should return `True`, `False` or `NotImplemented`. If it returns `True`, the `subclass` is considered a subclass of this ABC. If it returns `False`, the `subclass` is not considered a subclass of this ABC, even if it would normally be one. If it returns `NotImplemented`, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:
class Foo(object):
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable:
    __metaclass__ = ABCMeta

    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
    def __subclasshook__(cls, C):
        if cls is MyIterable:
            if any("__iter__" in B.__dict__ for B in C.__mro__):
                return True
        return NotImplemented

MyIterable.register(Foo)

The ABC MyIterable defines the standard iterable method, __iter__(), as an abstract method. The implementation given here can still be called from subclasses. The get_iterator() method is also part of the MyIterable abstract base class, but it does not have to be overridden in non-abstract derived classes.
The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an `__iter__()` method (it uses the old-style iterable protocol, defined in terms of `__len__()` and `__getitem__()`). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

It also provides the following decorators:

```python
abc.abstractmethod(function)
```
A decorator indicating abstract methods.

Using this decorator requires that the class’s metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the the normal ‘super’ call mechanisms.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are not supported. The `abstractmethod()` only affects subclasses derived using regular inheritance; “virtual subclasses” registered with the ABC’s `register()` method are not affected.

Usage:

```python
class C:
    __metaclass__ = ABCMeta
    @abstractmethod
```
```python
def my_abstract_method(self, ...):
    ...
```
def getx(self): ...
def setx(self, value): ...
x = abstractproperty(getx, setx)

Footnotes

[1] C++ programmers should note that Python's virtual base class concept is not the same as C++'s.
New in version 2.0.

The `atexit` module defines a single function to register cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination.

Note: the functions registered via this module are not called when the program is killed by a signal, when a Python fatal internal error is detected, or when `os._exit()` is called.

This is an alternate interface to the functionality provided by the `sys.exitfunc` variable.

Note: This module is unlikely to work correctly when used with other code that sets `sys.exitfunc`. In particular, other core Python modules are free to use `atexit` without the programmer’s knowledge. Authors who use `sys.exitfunc` should convert their code to use `atexit` instead. The simplest way to convert code that sets `sys.exitfunc` is to import `atexit` and register the function that had been bound to `sys.exitfunc`.

```python
atexit.register(func[, *args[, **kargs]])
```

Register `func` as a function to be executed at termination. Any optional arguments that are to be passed to `func` must be passed as arguments to `register()`.

At normal program termination (for instance, if `sys.exit()` is called or the main module’s execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.
If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run the last exception to be raised is re-raised.

*Changed in version 2.6:* This function now returns `func` which makes it possible to use it as a decorator without binding the original name to `None`.

**See also:**

**Module** `readline`

Useful example of `atexit` to read and write `readline` history files.
The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter's updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```python
try:
    _count = int(open("/tmp/counter").read())
except IOError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    open("/tmp/counter", "w").write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```python
def goodbye(name, adjective):
    print 'Goodbye, %s, it was %s to meet you.' % (name, adjective)

import atexit
atexit.register(goodbye, 'Donny', 'nice')

# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Usage as a `decorator`:

```python
import atexit
```
@atexit.register
def goodbye():
    print "You are now leaving the Python sector."

This obviously only works with functions that don’t take arguments.
traceback — Print or retrieve a stack trace

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects — this is the object type that is stored in the variables `sys.exc_traceback` (deprecated) and `sys.last_traceback` and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

```python
traceback.print_tb(traceback[, limit[, file]])
```

Print up to `limit` stack trace entries from `traceback`. If `limit` is omitted or `None`, all entries are printed. If `file` is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

```python
traceback.print_exception(type, value, traceback[, limit[, file]])
```

Print exception information and up to `limit` stack trace entries from `traceback` to `file`. This differs from `print_tb()` in the following ways: (1) if `traceback` is not `None`, it prints a header `Traceback (most recent call last)`:; (2) it prints the exception `type` and `value` after the stack trace; (3) if `type` is `SyntaxError` and `value` has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.
traceback.print_exc([limit[, file]])
This is a shorthand for print_exception(sys.exc_type,
    sys.exc_value, sys.exc_traceback, limit, file). (In fact, it
uses sys.exc_info() to retrieve the same information in a thread-
safe way instead of using the deprecated variables.)

traceback.format_exc([limit])
This is like print_exc(limit) but returns a string instead of
printing to a file.

    New in version 2.4.

traceback.print_last([limit[, file]])
This is a shorthand for print_exception(sys.last_type,
    sys.last_value, sys.last_traceback, limit, file).

traceback.print_stack([f[, limit[, file]]])
This function prints a stack trace from its invocation point. The
optional f argument can be used to specify an alternate stack
frame to start. The optional limit and file arguments have the
same meaning as for print_exception().

traceback.extract_tb(traceback[, limit])
Return a list of up to limit “pre-processed” stack trace entries
extracted from the traceback object traceback. It is useful for
alternate formatting of stack traces. If limit is omitted or None, all
entries are extracted. A “pre-processed” stack trace entry is a
quadruple (filename, line number, function name, text)
representing the information that is usually printed for a stack
trace. The text is a string with leading and trailing whitespace
stripped; if the source is not available it is None.
traceback.extract_stack([f, limit])

Extract the raw traceback from the current stack frame. The return value has the same format as for extract_tb(). The optional f and limit arguments have the same meaning as for print_stack().

traceback.format_list(list)

Given a list of tuples as returned by extract_tb() or extract_stack(), return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not None.

traceback.format_exception_only(type, value)

Format the exception part of a traceback. The arguments are the exception type and value such as given by sys.last_type and sys.last_value. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for SyntaxError exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

traceback.format_exception(type, value, tb[, limit])

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to print_exception(). The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does print_exception().

traceback.format_tb(tb[, limit])
A shorthand for `format_list(extract_tb(tb, limit))`.

`traceback.format_stack([f, limit])`

A shorthand for `format_list(extract_stack(f, limit))`.

`traceback.tb_lineno(tb)`

This function returns the current line number set in the traceback object. This function was necessary because in versions of Python prior to 2.3 when the `-O` flag was passed to Python the `tb.tb_lineno` was not updated correctly. This function has no use in versions past 2.3.
Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the code module.

```python
import sys, traceback

def run_user_code(envdir):
    source = raw_input(">>> ")
    try:
        exec source in envdir
    except:
        print "Exception in user code:"
        print "-"*60
        traceback.print_exc(file=sys.stdout)
        print "-"*60

envdir = {}
while 1:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```python
import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]

try:
    lumberjack()
except:
    exceptionType, exceptionValue, exceptionTraceback = sys.exc_info()
    print "*** print_tb:"
    traceback.print_tb(exceptionTraceback, limit=1, file=sys.stdout)
    print "*** print_exception:"
    traceback.print_exception(exceptionType, exceptionValue, exceptionTraceback, limit=2, file=sys.stdout)
```
The output for the example would look similar to this:

```python
*** print_tb:
    File "<doctest>", line 9, in <module>
        lumberjack()

*** print_exception:
    Traceback (most recent call last):
    File "<doctest>", line 9, in <module>
        lumberjack()
        File "<doctest>", line 3, in lumberjack
            bright_side_of_death()
    IndexError: tuple index out of range

*** print_exc:
    Traceback (most recent call last):
    File "<doctest>", line 9, in <module>
        lumberjack()
        File "<doctest>", line 3, in lumberjack
            bright_side_of_death()
    IndexError: tuple index out of range

*** format_exc, first and last line:

*** format_exception:
['Traceback (most recent call last):
', ' File "<doctest>", line 9, in <module>
        lumberjack()
', ' File "<doctest>", line 3, in lumberjack
            bright_side_of_death()
', ' File "<doctest>", line 6, in bright_side_of_death
            return
    IndexError: tuple index out of range
]

*** extract_tb:
[('"<doctest>"', 9, '"<module>"', 'lumberjack()'),

]
The following example shows the different ways to print and format the stack:

```python
>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print repr(traceback.extract_stack())
...     print repr(traceback.format_stack())
...
>>> another_function()
File "<doctest>", line 10, in <module>
    another_function()
File "<doctest>", line 3, in another_function
    lumberstack()
File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
 ('<doctest>', 3, 'another_function', 'lumberstack()'),
 ('<doctest>', 7, 'lumberstack', 'print repr(traceback.extract_')
[ 'File "<doctest>", line 10, in <module>
    another_function()
 'File "<doctest>", line 3, in another_function
 'File "<doctest>", line 8, in lumberstack
]```

This last example demonstrates the final few formatting functions:
>>> (eggs.py', 42, 'eggs', 'return "bacon")]
[' File "spam.py", line 3, in <module>
  spam.eggs()
', ' File "eggs.py", line 42, in eggs
  return "bacon"
]

>>> theError = IndexError('tuple indx out of range')
>>> traceback.format_exception_only(type(theError), theError)
['IndexError: tuple index out of range']
__future__ — Future statement definitions

__future__ is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they're importing.
- To ensure that future_statements run under releases prior to 2.1 at least yield runtime exceptions (the import of __future__ will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing __future__ and examining its contents.

Each statement in __future__.py is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease, CompilerFlag)
```

where, normally, OptionalRelease is less than MandatoryRelease, and both are 5-tuples of the same form as sys.version_info:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; s
 PY_RELEASE_SERIAL # the 3; an int
 )
```

OptionalRelease records the first release in which the feature was accepted.
In the case of a \textit{MandatoryRelease} that has not yet occurred, \textit{MandatoryRelease} predicts the release in which the feature will become part of the language.

Else \textit{MandatoryRelease} records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

\textit{MandatoryRelease} may also be \texttt{None}, meaning that a planned feature got dropped.

Instances of class \texttt{_Feature} have two corresponding methods, getOptionalRelease() and getMandatoryRelease().

\textit{CompilerFlag} is the (bitfield) flag that should be passed in the fourth argument to the builtin function \texttt{compile()} to enable the feature in dynamically compiled code. This flag is stored in the \texttt{compiler_flag} attribute on \texttt{_Feature} instances.

No feature description will ever be deleted from \texttt{__future__}. 
This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

- `gc.enable()`
  Enable automatic garbage collection.

- `gc.disable()`
  Disable automatic garbage collection.

- `gc.isenabled()`
  Returns true if automatic collection is enabled.

- `gc.collect([generation])`
  With no arguments, run a full collection. The optional argument `generation` may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is invalid. The number of unreachable objects found is returned.

  *Changed in version 2.5:* The optional `generation` argument was
added.

Changed in version 2.6: The free lists maintained for a number of builtin types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular `int` and `float`.

gc.\_set\_debug(flags)
Set the garbage collection debugging flags. Debugging information will be written to `sys.stderr`. See below for a list of debugging flags which can be combined using bit operations to control debugging.

gc.\_get\_debug()
Return the debugging flags currently set.

gc.\_get\_objects()
Returns a list of all objects tracked by the collector, excluding the list returned.

New in version 2.2.

gc.\_set\_threshold(threshold0[, threshold1[, threshold2]])
Set the garbage collection thresholds (the collection frequency). Setting `threshold0` to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object
allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds \( \text{threshold0} \), collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than \( \text{threshold1} \) times since generation 1 has been examined, then generation 1 is examined as well. Similarly, \( \text{threshold2} \) controls the number of collections of generation 1 before collecting generation 2.

\[
gc. \text{get_count()}\]

Return the current collection counts as a tuple of \(( \text{count0}, \text{count1}, \text{count2} )\).

*New in version 2.5.*

\[
gc. \text{get_threshold()}\]

Return the current collection thresholds as a tuple of \(( \text{threshold0}, \text{threshold1}, \text{threshold2} )\).

\[
gc. \text{get_referrers(*objs)}\]

Return the list of objects that directly refer to any of objs. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call \text{collect()} before calling \text{get_referrers()}.

Care must be taken when using objects returned by \text{get_referrers()} because some of them could still be under construction and hence in a temporarily invalid state. Avoid using
get_referrers() for any purpose other than debugging.

*New in version 2.2.*

gc.get_referents(*objs)
Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level *tp_traverse* methods (if any), and may not be all objects actually directly reachable. *tp_traverse* methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

*New in version 2.3.*

The following variable is provided for read-only access (you can mutate its value but should not rebind it):

gc.garbage
A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). By default, this list contains only objects with __del__() methods. [1] Objects that have __del__() methods and are part of a reference cycle cause the entire reference cycle to be uncollectable, including objects not necessarily in the cycle but reachable only from it. Python doesn't collect such cycles automatically because, in general, it isn’t possible for Python to guess a safe order in which to run the __del__() methods. If you know a safe order, you can force the issue by examining the garbage list, and explicitly breaking cycles due to your objects within the list. Note that these objects are kept alive even so by virtue of being in the garbage list, so they should be removed from garbage too. For example, after
breaking cycles, do `del gc.garbage[:]` to empty the list. It’s generally better to avoid the issue by not creating cycles containing objects with `__del__()` methods, and `garbage` can be examined in that case to verify that no such cycles are being created.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

The following constants are provided for use with `set_debug()`:

- `gc.DEBUG_STATS`
  - Print statistics during collection. This information can be useful when tuning the collection frequency.

- `gc.DEBUG_COLLECTABLE`
  - Print information on collectable objects found.

- `gc.DEBUG_UNCOLLECTABLE`
  - Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the `garbage` list.

- `gc.DEBUG_INSTANCES`
  - When `DEBUG_COLLECTABLE` or `DEBUG_UNCOLLECTABLE` is set, print information about instance objects found.

- `gc.DEBUG_OBJECTS`
  - When `DEBUG_COLLECTABLE` or `DEBUG_UNCOLLECTABLE` is set, print information about objects other than instance objects found.

- `gc.DEBUG_SAVEALL`
  - When set, all unreachable objects found will be appended to `garbage` rather than being freed. This can be useful for debugging a leaking program.
gc.DEBUG_LEAK

The debugging flags necessary for the collector to print information about a leaking program (equal to DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_INSTANCES | DEBUG_OBJECTS | DEBUG_SAVEALL).

Footnotes

[1] Prior to Python 2.2, the list contained all instance objects in unreachable cycles, not only those with __del__() methods.
The `inspect` module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.
The `getmembers()` function retrieves the members of an object such as a class or module. The sixteen functions whose names begin with “is” are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes:

<table>
<thead>
<tr>

</table>

Note:

1. *Changed in version 2.2:* `im_class` used to refer to the class that defined the method.

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional `predicate` argument is supplied, only members for which the predicate returns a true value are included.

Note: `getmembers()` does not return metaclass attributes when the argument is a class (this behavior is inherited from the `dir()` function).

`inspect.getmoduleinfo(path)`

Return a tuple of values that describe how Python will interpret the file identified by `path` if it is a module, or `None` if it would not be identified as a module. The return tuple is `(name, suffix, mode, mtype)`, where `name` is the name of the module without the name of any enclosing package, `suffix` is the trailing part of the file
name (which may not be a dot-delimited extension), mode is the `open()` mode that would be used ('r' or 'rb'), and mtype is an integer giving the type of the module. mtype will have a value which can be compared to the constants defined in the `imp` module; see the documentation for that module for more information on module types.

*Changed in version 2.6:* Returns a named tuple `ModuleInfo(name, suffix, mode, module_type)`.

`inspect.getmodulename(path)`

Return the name of the module named by the file path, without including the names of enclosing packages. This uses the same algorithm as the interpreter uses when searching for modules. If the name cannot be matched according to the interpreter’s rules, `None` is returned.

`inspect.ismodule(object)`

Return true if the object is a module.

`inspect.isclass(object)`

Return true if the object is a class.

`inspect.ismethod(object)`

Return true if the object is a method.

`inspect.isfunction(object)`

Return true if the object is a Python function or unnamed (lambda) function.

`inspect.isgeneratorfunction(object)`

Return true if the object is a Python generator function.

*New in version 2.6.*
inspect.isgenerator(object)
    Return true if the object is a generator.

    *New in version 2.6.*

inspect.istraceback(object)
    Return true if the object is a traceback.

inspect.isframe(object)
    Return true if the object is a frame.

inspect.iscode(object)
    Return true if the object is a code.

inspect.isbuiltin(object)
    Return true if the object is a built-in function.

inspect.isroutine(object)
    Return true if the object is a user-defined or built-in function or method.

inspect.isabstract(object)
    Return true if the object is an abstract base class.

    *New in version 2.6.*

inspect.ismethoddescriptor(object)
    Return true if the object is a method descriptor, but not if
    ismethod() or isclass() or isfunction() are true.

This is new as of Python 2.2, and, for example, is true of
int.__add__. An object passing this test has a __get__ attribute
but not a __set__ attribute, but beyond that the set of attributes
varies. __name__ is usually sensible, and __doc__ often is.
Methods implemented via descriptors that also pass one of the other tests return false from the `ismethoddescriptor()` test, simply because the other tests promise more – you can, e.g., count on having the `im_func` attribute (etc) when an object passes `ismethod()`.

`inspect.isdatadescriptor(object)`
Return true if the object is a data descriptor.

Data descriptors have both a `__get__` and a `__set__` attribute. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

*New in version 2.3.*

`inspect.isgetsetdescriptor(object)`
Return true if the object is a getset descriptor.

Getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return `False`.

*New in version 2.5.*

`inspect.ismemberdescriptor(object)`
Return true if the object is a member descriptor.

Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without
such types, this method will always return \texttt{False}.

\emph{New in version 2.5.}
Retrieving source code

inspect.getdoc(object)
Get the documentation string for an object, cleaned up with cleandoc().

inspect.getcomments(object)
Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module).

inspect.getfile(object)
Return the name of the (text or binary) file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

inspect.getmodule(object)
Try to guess which module an object was defined in.

inspect.getsourcefile(object)
Return the name of the Python source file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

inspect.getsourcelines(object)
Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An IOError is raised if the source code cannot be retrieved.
inspect.getsource(object)

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An IOError is raised if the source code cannot be retrieved.

inspect.cleandoc(doc)

Clean up indentation from docstrings that are indented to line up with blocks of code. Any whitespace that can be uniformly removed from the second line onwards is removed. Also, all tabs are expanded to spaces.

New in version 2.6.
Classes and functions

inspect.getclasstree(classes[, unique])

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the unique argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

inspect.getargspec(func)

Get the names and default values of a function's arguments. A tuple of four things is returned: (args, varargs, varkw, defaults). args is a list of the argument names (it may contain nested lists). varargs and varkw are the names of the * and ** arguments or None. defaults is a tuple of default argument values or None if there are no default arguments; if this tuple has n elements, they correspond to the last n elements listed in args.

Changed in version 2.6: Returns a named tuple ArgSpec(args, varargs, keywords, defaults).

inspect.getargvalues(frame)

Get information about arguments passed into a particular frame. A tuple of four things is returned: (args, varargs, varkw, locals). args is a list of the argument names (it may contain nested lists). varargs and varkw are the names of the * and ** arguments or None. locals is the locals dictionary of the given frame.
Changed in version 2.6: Returns a named tuple `ArgInfo(args, varargs, keywords, locals)`.

```python
inspect.formatargspec(*
    args, varargs, varkw, defaults, formatarg,
    formatvarargs, formatvarkw, formatvalue, join
*)
```

Format a pretty argument spec from the four values returned by `getargspec()`. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

```python
inspect.formatargvalues(*
    args, varargs, varkw, locals, formatarg,
    formatvarargs, formatvarkw, formatvalue, join
*)
```

Format a pretty argument spec from the four values returned by `getargvalues()`. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

```python
inspect.getmro(cls)
```

Return a tuple of class cls's base classes, including cls, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on cls's type. Unless a very peculiar user-defined metatype is in use, cls will be the first element of the tuple.
The interpreter stack

When the following functions return “frame records,” each record is a tuple of six items: the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

**Warning:** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python’s optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs. Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`.

```python
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

The optional `context` argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

```python
inspect.getframeinfo(frame[, context])
```
Get information about a frame or traceback object. A 5-tuple is returned, the last five elements of the frame's frame record.

*Changed in version 2.6:* Returns a named tuple `Traceback(filename, lineno, function, code_context, index)`.

```python
inspect.getouterframes(frame[, context])
```

Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of `frame`. The first entry in the returned list represents `frame`; the last entry represents the outermost call on `frame`'s stack.

```python
inspect.getinnerframes(traceback[, context])
```

Get a list of frame records for a traceback’s frame and all inner frames. These frames represent calls made as a consequence of `frame`. The first entry in the list represents `traceback`; the last entry represents where the exception was raised.

```python
inspect.currentframe()
```

Return the frame object for the caller’s stack frame.

```python
inspect.stack([context])
```

Return a list of frame records for the caller’s stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

```python
inspect.trace([context])
```

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.
This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter’s -S option.

Importing this module will append site-specific paths to the module search path.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/python|version|/site-packages` and then `lib/site-python` (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

A path configuration file is a file whose name has the form `package.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, but no check is made that the item refers to a directory (rather than a file). No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

*Changed in version 2.6:* A space or tab is now required after the import keyword.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to
The Python X.Y library is then installed in /usr/local/lib/pythonX.Y (where only the first three characters of sys.version are used to form the installation path name). Suppose this has a subdirectory /usr/local/lib/pythonX.Y/site-packages with three subsubdirectories, foo, bar and spam, and two path configuration files, foo.pth and bar.pth. Assume foo.pth contains the following:

```python
# foo package configuration
foo
bar
bletch
```

and bar.pth contains:

```python
# bar package configuration
bar
```

Then the following version-specific directories are added to sys.path, in this order:

```python
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that bletch is omitted because it doesn’t exist; the bar directory precedes the foo directory because bar.pth comes alphabetically before foo.pth; and spam is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named sitecustomize, which can perform arbitrary site-specific customizations. If this import fails with an ImportError exception, it is silently ignored.
Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` is still attempted.

**site.PREFIXES**

A list of prefixes for site package directories

*New in version 2.6.*

**site.ENABLE_USER_SITE**

Flag showing the status of the user site directory. True means the user site directory is enabled and added to `sys.path`. When the flag is None the user site directory is disabled for security reasons.

*New in version 2.6.*

**site.USER_SITE**

Path to the user site directory for the current Python version or None

*New in version 2.6.*

**site.USER_BASE**

Path to the base directory for user site directories

*New in version 2.6.*

**PYTHONNOUSERSITE**

*New in version 2.6.*

**PYTHONUSERBASE**

*New in version 2.6.*

**site.addsitedir(sitedir, known_paths=None)**

Adds a directory to `sys.path` and processes its pth files.
XXX Update documentation XXX document python -m site –user-base –user-site
user — User-specific configuration hook

*Deprecated since version 2.6:* The `user` module has been removed in Python 3.0.

As a policy, Python doesn't run user-specified code on startup of Python programs. (Only interactive sessions execute the script specified in the `PYTHONSTARTUP` environment variable if it exists).

However, some programs or sites may find it convenient to allow users to have a standard customization file, which gets run when a program requests it. This module implements such a mechanism. A program that wishes to use the mechanism must execute the statement

```
import user
```

The `user` module looks for a file `.pythonrc.py` in the user's home directory and if it can be opened, executes it (using `execfile()`) in its own (the module `user`'s) global namespace. Errors during this phase are not caught; that's up to the program that imports the `user` module, if it wishes. The home directory is assumed to be named by the `HOME` environment variable; if this is not set, the current directory is used.

The user’s `.pythonrc.py` could conceivably test for `sys.version` if it wishes to do different things depending on the Python version.

A warning to users: be very conservative in what you place in your `.pythonrc.py` file. Since you don’t know which programs will use it, changing the behavior of standard modules or functions is generally not a good idea.
A suggestion for programmers who wish to use this mechanism: a simple way to let users specify options for your package is to have them define variables in their .pythonrc.py file that you test in your module. For example, a module spam that has a verbosity level can look for a variable user.spam_verbose, as follows:

```python
import user
verbose = bool(getattr(user, "spam_verbose", 0))
```

(The three-argument form of getattr() is used in case the user has not defined spam_verbose in their .pythonrc.py file.)

Programs with extensive customization needs are better off reading a program-specific customization file.

Programs with security or privacy concerns should not import this module; a user can easily break into a program by placing arbitrary code in the .pythonrc.py file.

Modules for general use should not import this module; it may interfere with the operation of the importing program.

Module site

Site-wide customization mechanism.
fpect1 — Floating point exception control

Platforms: Unix

**Note:** The fpect1 module is not built by default, and its usage is discouraged and may be dangerous except in the hands of experts. See also the section *Limitations and other considerations* on limitations for more details.

Most computers carry out floating point operations in conformance with the so-called IEEE-754 standard. On any real computer, some floating point operations produce results that cannot be expressed as a normal floating point value. For example, try

```python
>>> import math
>>> math.exp(1000)
inf
>>> math.exp(1000) / math.exp(1000)
nan
```

(The example above will work on many platforms. DEC Alpha may be one exception.) “Inf” is a special, non-numeric value in IEEE-754 that stands for “infinity”, and “nan” means “not a number.” Note that, other than the non-numeric results, nothing special happened when you asked Python to carry out those calculations. That is in fact the default behaviour prescribed in the IEEE-754 standard, and if it works for you, stop reading now.

In some circumstances, it would be better to raise an exception and stop processing at the point where the faulty operation was attempted. The fpect1 module is for use in that situation. It provides control over floating point units from several hardware manufacturers, allowing the user to turn on the generation of **SIGFPE**
whenever any of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid Operation occurs. In tandem with a pair of wrapper macros that are inserted into the C code comprising your python system, SIGFPE is trapped and converted into the Python FloatingPointError exception.

The fpectl module defines the following functions and may raise the given exception:

fpectl.turnon_sigfpe()
    Turn on the generation of SIGFPE, and set up an appropriate signal handler.

fpectl.turnoff_sigfpe()
    Reset default handling of floating point exceptions.

exception fpectl.FloatingPointError
    After turnon_sigfpe() has been executed, a floating point operation that raises one of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid operation will in turn raise this standard Python exception.
Example

The following example demonstrates how to start up and test operation of the fpectl module.

```python
>>> import fpectl
>>> import fpetest
>>> fpectl.turnon_sigfpe()
>>> fpetest.test()
overflow    PASS
FloatingPointError: Overflow
div by 0    PASS
FloatingPointError: Division by zero
    [ more output from test elided ]
>>> import math
>>> math.exp(1000)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
FloatingPointError: in math_1
```
Limitations and other considerations

Setting up a given processor to trap IEEE-754 floating point errors currently requires custom code on a per-architecture basis. You may have to modify `fpectl` to control your particular hardware.

Conversion of an IEEE-754 exception to a Python exception requires that the wrapper macros `PyFPE_START_PROTECT` and `PyFPE_END_PROTECT` be inserted into your code in an appropriate fashion. Python itself has been modified to support the `fpectl` module, but many other codes of interest to numerical analysts have not.

The `fpectl` module is not thread-safe.

---

**See also:** Some files in the source distribution may be interesting in learning more about how this module operates. The include file `Include/pyfpe.h` discusses the implementation of this module at some length. `Modules/fpetestmodule.c` gives several examples of use. Many additional examples can be found in `Objects/floatobject.c`. 
Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python's interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the `code` module. (The `codeop` module is lower-level, used to support compiling a possibly-incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- **code** — Interpreter base classes
  - Interactive Interpreter Objects
  - Interactive Console Objects

- **codeop** — Compile Python code
The code module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

class code. InteractiveInterpreter([locals])

This class deals with parsing and interpreter state (the user’s namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional locals argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key '__name__' set to '__console__' and key '__doc__' set to None.

class code. InteractiveConsole([locals[, filename]])

Closely emulate the behavior of the interactive Python interpreter. This class builds on InteractiveInterpreter and adds prompting using the familiar sys.ps1 and sys.ps2, and input buffering.

code. interact([banner[, readfunc[, local]]])

Convenience function to run a read-eval-print loop. This creates a new instance of InteractiveConsole and sets readfunc to be used as the raw_input() method, if provided. If local is provided, it is passed to the InteractiveConsole constructor for use as the default namespace for the interpreter loop. The interact() method of the instance is then run with banner passed as the banner to use, if provided. The console object is discarded after use.

code. compile_command(source[, filename[, symbol]])

This function is useful for programs that want to emulate Python’s
interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function almost always makes the same decision as the real interpreter main loop.

source is the source string; filename is the optional filename from which source was read, defaulting to '<input>'; and symbol is the optional grammar start symbol, which should be either 'single' (the default) or 'eval'.

Returns a code object (the same as compile(source, filename, symbol)) if the command is complete and valid; None if the command is incomplete; raises SyntaxError if the command is complete and contains a syntax error, or raises OverflowError or ValueError if the command contains an invalid literal.
Interactive Interpreter Objects

InteractiveInterpreter.runsource(source[, filename[, symbol]])

Compile and run some source in the interpreter. Arguments are the same as for compile_command(); the default for filename is '<input>', and for symbol is 'single'. One several things can happen:

- The input is incorrect; compile_command() raised an exception (SyntaxError or OverflowError). A syntax traceback will be printed by calling the showsyntaxerror() method. runsourc() returns False.
- The input is incomplete, and more input is required; compile_command() returned None. runsourc() returns True.
- The input is complete; compile_command() returned a code object. The code is executed by calling the runcode() (which also handles run-time exceptions, except for SystemExit). runsourc() returns False.

The return value can be used to decide whether to use sys.ps1 or sys.ps2 to prompt the next line.

InteractiveInterpreter.runcode(code)

Execute a code object. When an exception occurs, showtraceback() is called to display a traceback. All exceptions are caught except SystemExit, which is allowed to propagate.

A note about KeyboardInterrupt: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

InteractiveInterpreter.showsyntaxerror([filename])
Display the syntax error that just occurred. This does not display a stack trace because there isn’t one for syntax errors. If filename is given, it is stuffed into the exception instead of the default filename provided by Python’s parser, because it always uses '<string>' when reading from a string. The output is written by the write() method.

InteractiveInterpreter.showtraceback()
Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the write() method.

InteractiveInterpreter.write(data)
Write a string to the standard error stream (sys.stderr). Derived classes should override this to provide the appropriate output handling as needed.
Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact([banner])`

Closely emulate the interactive Python console. The optional banner argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it's so close!).

`InteractiveConsole.push(line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer()`

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input([prompt])`  
Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation uses the
built-in function `raw_input()`; a subclass may replace this with a different implementation.
The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don’t want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print `>>>` or `...` next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

```python
codeop.compile_command(source[, filename[, symbol]])
```

Tries to compile `source`, which should be a string of Python code and return a code object if `source` is valid Python code. In that case, the filename attribute of the code object will be `filename`, which defaults to `<input>'`. Returns `None` if `source` is not valid Python code, but is a prefix of valid Python code.

If there is a problem with `source`, an exception will be raised. `SyntaxError` is raised if there is invalid Python syntax, and `OverflowError` or `ValueError` if there is an invalid literal.

The `symbol` argument determines whether `source` is compiled as a statement (`'single'`, the default) or as an `expression` (`'eval'`).
Any other value will cause `ValueError` to be raised.

**Warning**: It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

class `codeop.Compile`
Instances of this class have `__call__()` methods identical in signature to the built-in function `compile()`, but with the difference that if the instance compiles program text containing a `__future__` statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

class `codeop.CommandCompiler`
Instances of this class have `__call__()` methods identical in signature to `compile_command()`; the difference is that if the instance compiles program text containing a `__future__` statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

A note on version compatibility: the `Compile` and `CommandCompiler` are new in Python 2.2. If you want to enable the future-tracking features of 2.2 but also retain compatibility with 2.1 and earlier versions of Python you can either write

```python
try:
    from codeop import CommandCompiler
    compile_command = CommandCompiler()
    del CommandCompiler
except ImportError:
    from codeop import compile_command
```
which is a low-impact change, but introduces possibly unwanted global state into your program, or you can write:

```python
try:
    from codeop import CommandCompiler
except ImportError:
    def CommandCompiler():
        from codeop import compile_command
        return compile_command
```

and then call `CommandCompiler` every time you need a fresh compiler object.
Restricted Execution

**Warning:** In Python 2.3 these modules have been disabled due to various known and not readily fixable security holes. The modules are still documented here to help in reading old code that uses the `rexec` and `Bastion` modules.

*Restricted execution* is the basic framework in Python that allows for the segregation of trusted and untrusted code. The framework is based on the notion that trusted Python code (a *supervisor*) can create a “padded cell” (or environment) with limited permissions, and run the untrusted code within this cell. The untrusted code cannot break out of its cell, and can only interact with sensitive system resources through interfaces defined and managed by the trusted code. The term “restricted execution” is favored over “safe-Python” since true safety is hard to define, and is determined by the way the restricted environment is created. Note that the restricted environments can be nested, with inner cells creating subcells of lesser, but never greater, privilege.

An interesting aspect of Python’s restricted execution model is that the interfaces presented to untrusted code usually have the same names as those presented to trusted code. Therefore no special interfaces need to be learned to write code designed to run in a restricted environment. And because the exact nature of the padded cell is determined by the supervisor, different restrictions can be imposed, depending on the application. For example, it might be deemed “safe” for untrusted code to read any file within a specified directory, but never to write a file. In this case, the supervisor may redefine the built-in `open()` function so that it raises an exception whenever the *mode* parameter is `'w'`. It might also perform a `chroot`-like operation on the *filename* parameter, such that root is always relative to some safe “sandbox” area of the filesystem. In this
case, the untrusted code would still see an built-in `open()` function in its environment, with the same calling interface. The semantics would be identical too, with `IOError`s being raised when the supervisor determined that an unallowable parameter is being used.

The Python run-time determines whether a particular code block is executing in restricted execution mode based on the identity of the `__builtins__` object in its global variables: if this is (the dictionary of) the standard `__builtin__` module, the code is deemed to be unrestricted, else it is deemed to be restricted.

Python code executing in restricted mode faces a number of limitations that are designed to prevent it from escaping from the padded cell. For instance, the function object attribute `func_globals` and the class and instance object attribute `__dict__` are unavailable.

Two modules provide the framework for setting up restricted execution environments:

- **reexec** — Restricted execution framework
  - RExec Objects
  - Defining restricted environments
  - An example

- **Bastion** — Restricting access to objects

See also:

**Grail Home Page**

Grail, an Internet browser written in Python, uses these modules to support Python applets. More information on the use of Python's restricted execution mode in Grail is available on the Web site.
**rexec — Restricted execution framework**

*Deprecated since version 2.6:* The `rexec` module has been removed in Python 3.0.

*Changed in version 2.3:* Disabled module.

**Warning:** The documentation has been left in place to help in reading old code that uses the module.

This module contains the `RExec` class, which supports `r_eval()`, `r_execfile()`, `r_exec()`, and `r_import()` methods, which are restricted versions of the standard Python functions `eval()`, `execfile()` and the `exec` and `import` statements. Code executed in this restricted environment will only have access to modules and functions that are deemed safe; you can subclass `RExec` to add or remove capabilities as desired.

**Warning:** While the `rexec` module is designed to perform as described below, it does have a few known vulnerabilities which could be exploited by carefully written code. Thus it should not be relied upon in situations requiring “production ready” security. In such situations, execution via sub-processes or very careful “cleansing” of both code and data to be processed may be necessary. Alternatively, help in patching known `rexec` vulnerabilities would be welcomed.

**Note:** The `RExec` class can prevent code from performing unsafe operations like reading or writing disk files, or using TCP/IP sockets. However, it does not protect against code using extremely
large amounts of memory or processor time.

class rexec.RExec([hooks[, verbose]])

Returns an instance of the RExec class.

hooks is an instance of the RHooks class or a subclass of it. If it is omitted or None, the default RHooks class is instantiated. Whenever the rexec module searches for a module (even a built-in one) or reads a module's code, it doesn't actually go out to the file system itself. Rather, it calls methods of an RHooks instance that was passed to or created by its constructor. (Actually, the RExec object doesn't make these calls — they are made by a module loader object that's part of the RExec object. This allows another level of flexibility, which can be useful when changing the mechanics of import within the restricted environment.)

By providing an alternate RHooks object, we can control the file system accesses made to import a module, without changing the actual algorithm that controls the order in which those accesses are made. For instance, we could substitute an RHooks object that passes all filesystem requests to a file server elsewhere, via some RPC mechanism such as ILU. Grail's applet loader uses this to support importing applets from a URL for a directory.

If verbose is true, additional debugging output may be sent to standard output.

It is important to be aware that code running in a restricted environment can still call the sys.exit() function. To disallow restricted code from exiting the interpreter, always protect calls that cause restricted code to run with a try/except statement that catches the SystemExit exception. Removing the sys.exit() function from the restricted environment is not sufficient — the
restricted code could still use `raise SystemExit`. Removing `SystemExit` is not a reasonable option; some library code makes use of this and would break were it not available.

See also:

**Grail Home Page**

Grail is a Web browser written entirely in Python. It uses the `rexec` module as a foundation for supporting Python applets, and can be used as an example usage of this module.
RExec objects support the following methods:

**RExec. r_eval(code)**

`code` must either be a string containing a Python expression, or a compiled code object, which will be evaluated in the restricted environment's `__main__` module. The value of the expression or code object will be returned.

**RExec. r_exec(code)**

`code` must either be a string containing one or more lines of Python code, or a compiled code object, which will be executed in the restricted environment's `__main__` module.

**RExec. r_execfile(filename)**

Execute the Python code contained in the file `filename` in the restricted environment's `__main__` module.

Methods whose names begin with `s_` are similar to the functions beginning with `r_`, but the code will be granted access to restricted versions of the standard I/O streams `sys.stdin`, `sys.stderr`, and `sys.stdout`.

**RExec. s_eval(code)**

`code` must be a string containing a Python expression, which will be evaluated in the restricted environment.

**RExec. s_exec(code)**

`code` must be a string containing one or more lines of Python code, which will be executed in the restricted environment.

**RExec. s_execfile(code)**
Execute the Python code contained in the file `filename` in the restricted environment.

`RExec` objects must also support various methods which will be implicitly called by code executing in the restricted environment. Overriding these methods in a subclass is used to change the policies enforced by a restricted environment.

`RExec.r_import(modulename[, globals[, locals[, fromlist]]]])`
Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.

`RExec.r_open(filename[, mode[, bufsize]])`
Method called when `open()` is called in the restricted environment. The arguments are identical to those of `open()`, and a file object (or a class instance compatible with file objects) should be returned. `RExec`'s default behaviour is allow opening any file for reading, but forbidding any attempt to write a file. See the example below for an implementation of a less restrictive `r_open()`.

`RExec.r_reload(module)`
Reload the module object `module`, re-parsing and re-initializing it.

`RExec.r_unload(module)`
Unload the module object `module` (remove it from the restricted environment's `sys.modules` dictionary).

And their equivalents with access to restricted standard I/O streams:

`RExec.s_import(modulename[, globals[, locals[, fromlist]]]])`
Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.
RExec. **s_reload**(module)
Reload the module object *module*, re-parsing and re-initializing it.

RExec. **s_unload**(module)
Unload the module object *module*.
Defining restricted environments

The RExec class has the following class attributes, which are used by the __init__() method. Changing them on an existing instance won’t have any effect; instead, create a subclass of RExec and assign them new values in the class definition. Instances of the new class will then use those new values. All these attributes are tuples of strings.

RExec. nok_builtin_names
Contains the names of built-in functions which will not be available to programs running in the restricted environment. The value for RExec is ('open', 'reload', '__import__'). (This gives the exceptions, because by far the majority of built-in functions are harmless. A subclass that wants to override this variable should probably start with the value from the base class and concatenate additional forbidden functions — when new dangerous built-in functions are added to Python, they will also be added to this module.)

RExec. ok_builtin_modules
Contains the names of built-in modules which can be safely imported. The value for RExec is ('audioop', 'array', 'binascii', 'cmath', 'errno', 'imageop', 'marshal', 'math', 'md5', 'operator', 'parser', 'regex', 'select', 'sha', '_sre', 'strop', 'struct', 'time'). A similar remark about overriding this variable applies — use the value from the base class as a starting point.

RExec. ok_path
Contains the directories which will be searched when an import is performed in the restricted environment. The value for RExec is the same as sys.path (at the time the module is loaded) for
unrestricted code.

**RExec.ok_posix_names**

Contains the names of the functions in the `os` module which will be available to programs running in the restricted environment. The value for `RExec` is `('error', 'fstat', 'listdir', 'lstat', 'readlink', 'stat', 'times', 'uname', 'getpid', 'getppid', 'getcwd', 'getuid', 'getgid', 'geteuid', 'getegid')`.

**RExec.ok_sys_names**

Contains the names of the functions and variables in the `sys` module which will be available to programs running in the restricted environment. The value for `RExec` is `('ps1', 'ps2', 'copyright', 'version', 'platform', 'exit', 'maxint')`.

**RExec.ok_file_types**

Contains the file types from which modules are allowed to be loaded. Each file type is an integer constant defined in the `imp` module. The meaningful values are `PY_SOURCE`, `PY_COMPILED`, and `C_EXTENSION`. The value for `RExec` is `(C_EXTENSION, PY_SOURCE)`. Adding `PY_COMPILED` in subclasses is not recommended; an attacker could exit the restricted execution mode by putting a forged byte-compiled file (`.pyc`) anywhere in your file system, for example by writing it to `/tmp` or uploading it to the `/incoming` directory of your public FTP server.
An example

Let us say that we want a slightly more relaxed policy than the standard RExec class. For example, if we’re willing to allow files in /tmp to be written, we can subclass the RExec class:

```python
class TmpWriterRExec(rexec.RExec):
    def r_open(self, file, mode='r', buf=-1):
        if mode in ('r', 'rb'):
            pass
        elif mode in ('w', 'wb', 'a', 'ab'):
            # check filename : must begin with /tmp/
            if file[:5] != '/tmp/':
                raise IOError, "can't write outside /tmp"
            elif (string.find(file, '/../') >= 0 or
                  file[:3] == '/../' or file[-3:] == '/../'):
                raise IOError, "'..' in filename forbidden"
        else: raise IOError, "Illegal open() mode"
    return open(file, mode, buf)
```

Notice that the above code will occasionally forbid a perfectly valid filename; for example, code in the restricted environment won’t be able to open a file called /tmp/foo/../bar. To fix this, the r_open() method would have to simplify the filename to /tmp/bar, which would require splitting apart the filename and performing various operations on it. In cases where security is at stake, it may be preferable to write simple code which is sometimes overly restrictive, instead of more general code that is also more complex and may harbor a subtle security hole.
Bastion — Restricting access to objects

*Deprecated since version 2.6:* The `Bastion` module has been removed in Python 3.0.

*Changed in version 2.3:* Disabled module.

**Warning:** The documentation has been left in place to help in reading old code that uses the module.

According to the dictionary, a bastion is “a fortified area or position”, or “something that is considered a stronghold.” It’s a suitable name for this module, which provides a way to forbid access to certain attributes of an object. It must always be used with the `reexec` module, in order to allow restricted-mode programs access to certain safe attributes of an object, while denying access to other, unsafe attributes.

```
Bastion( object[, filter[, name[, class]]]])
```

Protect the object `object`, returning a bastion for the object. Any attempt to access one of the object’s attributes will have to be approved by the `filter` function; if the access is denied an `AttributeError` exception will be raised.

If present, `filter` must be a function that accepts a string containing an attribute name, and returns true if access to that attribute will be permitted; if `filter` returns false, the access is denied. The default filter denies access to any function beginning with an underscore (`_`). The bastion’s string representation will be `<Bastion for name>` if a value for `name` is provided; otherwise, `repr(object)` will be used.
class, if present, should be a subclass of BastionClass; see the code in bastion.py for the details. Overriding the default BastionClass will rarely be required.

```python
class Bastion.BastionClass(getfunc, name)
    Class which actually implements bastion objects. This is the default class used by Bastion(). The getfunc parameter is a function which returns the value of an attribute which should be exposed to the restricted execution environment when called with the name of the attribute as the only parameter. name is used to construct the repr() of the BastionClass instance.
```

Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- `imp` — Access the `import` internals
  - Examples

- `imputil` — Import utilities
  - Examples

- `zipimport` — Import modules from Zip archives
  - `zipimporter` Objects
  - Examples

- `pkgutil` — Package extension utility

- `modulefinder` — Find modules used by a script
  - Example usage of `ModuleFinder`

- `runpy` — Locating and executing Python modules
imp — Access the import internals

This module provides an interface to the mechanisms used to implement the `import` statement. It defines the following constants and functions:

imp.get_magic()

Return the magic string value used to recognize byte-compiled code files (.pyc files). (This value may be different for each Python version.)

imp.get_suffixes()

Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form (suffix, mode, type), where suffix is a string to be appended to the module name to form the filename to search for, mode is the mode string to pass to the built-in open() function to open the file (this can be 'r' for text files or 'rb' for binary files), and type is the file type, which has one of the values `PY_SOURCE`, `PY_COMPILED`, or `C_EXTENSION`, described below.

imp.find_module(name[, path])

Try to find the module name on the search path path. If path is a list of directory names, each directory is searched for files with any of the suffixes returned by get_suffixes() above. Invalid names in the list are silently ignored (but all list items must be strings). If path is omitted or None, the list of directory names given by sys.path is searched, but first it searches a few special places: it tries to find a built-in module with the given name (`C_BUILTIN`), then a frozen module (`PY_FROZEN`), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).
If search is successful, the return value is a 3-element tuple `(file, pathname, description):

`file` is an open file object positioned at the beginning, `pathname` is the pathname of the file found, and `description` is a 3-element tuple as contained in the list returned by `get_suffixes()` describing the kind of module found.

If the module does not live in a file, the returned `file` is `None`, `pathname` is the empty string, and the `description` tuple contains empty strings for its suffix and mode; the module type is indicated as given in parentheses above. If the search is unsuccessful, `ImportError` is raised. Other exceptions indicate problems with the arguments or environment.

If the module is a package, `file` is `None`, `pathname` is the package path and the last item in the `description` tuple is `PKG_DIRECTORY`.

This function does not handle hierarchical module names (names containing dots). In order to find `P.*M*`, that is, submodule `M` of package `P`, use `find_module()` and `load_module()` to find and load package `P`, and then use `find_module()` with the `path` argument set to `P.__path__`. When `P` itself has a dotted name, apply this recipe recursively.

```python
imp.load_module(name, file, pathname, description)
```

Load a module that was previously found by `find_module()` (or by an otherwise conducted search yielding compatible results). This function does more than importing the module: if the module was already imported, it is equivalent to a `reload()`! The `name` argument indicates the full module name (including the package name, if this is a submodule of a package). The `file` argument is an open file, and `pathname` is the corresponding file name; these can be `None` and `'.'`, respectively, when the module is a package
or not being loaded from a file. The \textit{description} argument is a
tuple, as would be returned by \texttt{get_suffixes()}, describing what
kind of module must be loaded.

If the load is successful, the return value is the module object;
otherwise, an exception (usually \texttt{ImportError}) is raised.

\textbf{Important:} the caller is responsible for closing the \texttt{file}
argument, if it was not \texttt{None}, even when an exception is raised. This is best
done using a \texttt{try ... finally} statement.

\texttt{imp.new\_module(name)}

Return a new empty module object called \texttt{name}. This object is
\textit{not} inserted in \texttt{sys.modules}.

\texttt{imp.lock\_held()}

Return \texttt{True} if the import lock is currently held, else \texttt{False}. On
platforms without threads, always return \texttt{False}.

On platforms with threads, a thread executing an import holds an
internal lock until the import is complete. This lock blocks other
threads from doing an import until the original import completes,
which in turn prevents other threads from seeing incomplete
module objects constructed by the original thread while in the
process of completing its import (and the imports, if any, triggered
by that).

\texttt{imp.acquire\_lock()}

Acquire the interpreter’s import lock for the current thread. This
lock should be used by import hooks to ensure thread-safety
when importing modules. On platforms without threads, this
function does nothing.

Once a thread has acquired the import lock, the same thread
may acquire it again without blocking; the thread must release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

*New in version 2.3.*

**imp.** `release_lock()`

Release the interpreter’s import lock. On platforms without threads, this function does nothing.

*New in version 2.3.*

The following constants with integer values, defined in this module, are used to indicate the search result of `find_module()`.

**imp.** `PY_SOURCE`

The module was found as a source file.

**imp.** `PY_COMPILED`

The module was found as a compiled code object file.

**imp.** `C_EXTENSION`

The module was found as dynamically loadable shared library.

**imp.** `PKG_DIRECTORY`

The module was found as a package directory.

**imp.** `C_BUILTIN`

The module was found as a built-in module.

**imp.** `PY_FROZEN`

The module was found as a frozen module (see `init_frozen()`).

The following constant and functions are obsolete; their functionality is available through `find_module()` or `load_module()`. They are kept around for backward compatibility:
imp. **SEARCH_ERROR**

Unused.

**imp. init_builtin(name)**

Initialize the built-in module called *name* and return its module object along with storing it in `sys.modules`. If the module was already initialized, it will be initialized *again*. Re-initialization involves the copying of the built-in module’s `__dict__` from the cached module over the module’s entry in `sys.modules`. If there is no built-in module called *name*, *None* is returned.

**imp. init_frozen(name)**

Initialize the frozen module called *name* and return its module object. If the module was already initialized, it will be initialized *again*. If there is no frozen module called *name*, *None* is returned. (Frozen modules are modules written in Python whose compiled byte-code object is incorporated into a custom-built Python interpreter by Python’s `freeze` utility. See `Tools/freeze/` for now.)

**imp. is_builtin(name)**

Return 1 if there is a built-in module called *name* which can be initialized again. Return -1 if there is a built-in module called *name* which cannot be initialized again (see `init_builtin()`). Return 0 if there is no built-in module called *name*.

**imp. is_frozen(name)**

Return True if there is a frozen module (see `init_frozen()`) called *name*, or False if there is no such module.

**imp. load_compiled(name, pathname[, file])**

Load and initialize a module implemented as a byte-compiled code file and return its module object. If the module was already initialized, it will be initialized *again*. The *name* argument is used
to create or access a module object. The `pathname` argument points to the byte-compiled code file. The `file` argument is the byte-compiled code file, open for reading in binary mode, from the beginning. It must currently be a real file object, not a user-defined class emulating a file.

```python
def load_dynamic(name, pathname[, file])
```

Load and initialize a module implemented as a dynamically loadable shared library and return its module object. If the module was already initialized, it will be initialized *again*. Re-initialization involves copying the `__dict__` attribute of the cached instance of the module over the value used in the module cached in `sys.modules`. The `pathname` argument must point to the shared library. The `name` argument is used to construct the name of the initialization function: an external C function called `initname()` in the shared library is called. The optional `file` argument is ignored. (Note: using shared libraries is highly system dependent, and not all systems support it.)

```python
def load_source(name, pathname[, file])
```

Load and initialize a module implemented as a Python source file and return its module object. If the module was already initialized, it will be initialized *again*. The `name` argument is used to create or access a module object. The `pathname` argument points to the source file. The `file` argument is the source file, open for reading as text, from the beginning. It must currently be a real file object, not a user-defined class emulating a file. Note that if a properly matching byte-compiled file (with suffix `.pyc` or `.pyo`) exists, it will be used instead of parsing the given source file.

```python
class NullImporter(path_string)
```

The `NullImporter` type is a PEP 302 import hook that handles non-directory path strings by failing to find any modules. Calling
this type with an existing directory or empty string raises `ImportError`. Otherwise, a `NullImporter` instance is returned.

Python adds instances of this type to `sys.path_importer_cache` for any path entries that are not directories and are not handled by any other path hooks on `sys.path_hooks`. Instances have only one method:

```
find_module(fullname[, path])
```

This method always returns `None`, indicating that the requested module could not be found.

*New in version 2.5.*
Examples

The following function emulates what was the standard import statement up to Python 1.4 (no hierarchical module names). (This implementation wouldn’t work in that version, since `find_module()` has been extended and `load_module()` has been added in 1.4.)

```python
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist=None):
    # Fast path: see if the module has already been imported.
    try:
        return sys.modules[name]
    except KeyError:
        pass

    # If any of the following calls raises an exception,
    # there's a problem we can't handle -- let the caller handle it.
    fp, pathname, description = imp.find_module(name)

    try:
        return imp.load_module(name, fp, pathname, description)
    finally:
        # Since we may exit via an exception, close fp explicitly.
        if fp:
            fp.close()
```

A more complete example that implements hierarchical module names and includes a `reload()` function can be found in the module `knee`. The `knee` module can be found in `Demo/imputil/` in the Python source distribution.
**imputil — Import utilities**

*Deprecated since version 2.6:* The *imputil* module has been removed in Python 3.0.

This module provides a very handy and useful mechanism for custom `import` hooks. Compared to the older *ihooks* module, *imputil* takes a dramatically simpler and more straight-forward approach to custom `import` functions.

``` python
class imputil.ImportManager([fs_imp])
    Manage the import process.

    install([namespace])
        Install this ImportManager into the specified namespace.

    uninstall()
        Restore the previous import mechanism.

    add_suffix(suffix, importFunc)
        Undocumented.
```

``` python
class imputil.Importer
    Base class for replacing standard import functions.

    import_top(name)
        Import a top-level module.

    get_code(parent, modname, fqname)
        Find and retrieve the code for the given module.

        *parent* specifies a parent module to define a context for importing. It may be *None*, indicating no particular context for the search.
```
modname specifies a single module (not dotted) within the parent.

fqname specifies the fully-qualified module name. This is a (potentially) dotted name from the “root” of the module namespace down to the modname.

If there is no parent, then modname==fqname.

This method should return None, or a 3-tuple.

- If the module was not found, then None should be returned.
- The first item of the 2- or 3-tuple should be the integer 0 or 1, specifying whether the module that was found is a package or not.
- The second item is the code object for the module (it will be executed within the new module’s namespace). This item can also be a fully-loaded module object (e.g. loaded from a shared lib).
- The third item is a dictionary of name/value pairs that will be inserted into new module before the code object is executed. This is provided in case the module's code expects certain values (such as where the module was found). When the second item is a module object, then these names/values will be inserted after the module has been loaded/initialized.

class imputil.BuiltinImporter

    Emulate the import mechanism for builtin and frozen modules.
    This is a sub-class of the Importer class.

    get_code(parent, modname, fqname)

        Undocumented.
imputil.py_suffix_importer(filename, finfo, fqname)
   Undocumented.

class imputil.DynLoadSuffixImporter([desc])
   Undocumented.

import_file(filename, finfo, fqname)
   Undocumented.
This is a re-implementation of hierarchical module import.

This code is intended to be read, not executed. However, it does work – all you need to do to enable it is “import knee”.

(The name is a pun on the clunkier predecessor of this module, “ni”.)

```python
import sys, imp, __builtin__

# Replacement for __import__()
def import_hook(name, globals=None, locals=None, fromlist=None):
    parent = determine_parent(globals)
    q, tail = find_head_package(parent, name)
    m = load_tail(q, tail)
    if not fromlist:
        return q
    if hasattr(m, '__path__'):
        ensure_fromlist(m, fromlist)
    return m

def determine_parent(globals):
    if not globals or not globals.has_key('__name__'):
        return None
    pname = globals['__name__']
    if globals.has_key('__path__'):
        parent = sys.modules[pname]
        assert globals is parent.__dict__
        return parent
    if '.' in pname:
        i = pname.rfind('.')
        pname = pname[:i]
        parent = sys.modules[pname]
        assert parent.__name__ == pname
        return parent
    return None

def find_head_package(parent, name):
    if '.' in name:
        i = name.find('.')
        head = name[:i]
        tail = name[i+1:]
    else:
```
head = name
tail = ""

if parent:
    qname = "%s.%s" % (parent.__name__, head)
else:
    qname = head
q = import_module(head, qname, parent)
if q: return q, tail
if parent:
    qname = head
    parent = None
    q = import_module(head, qname, parent)
if q: return q, tail
raise ImportError, "No module named " + qname

def load_tail(q, tail):
    m = q
    while tail:
        i = tail.find('.
')
        if i < 0: i = len(tail)
        head, tail = tail[:i], tail[i+1:]
        mname = "%s.%s" % (m.__name__, head)
        m = import_module(head, mname, m)
        if not m:
            raise ImportError, "No module named " + mname
    return m

def ensure_fromlist(m, fromlist, recursive=0):
    for sub in fromlist:
        if sub == "*":
            if not recursive:
                try:
                    all = m.__all__
                except AttributeError:
                    pass
            else:
                ensure_fromlist(m, all, 1)
        if sub != "*" and not hasattr(m, sub):
            subname = "%s.%s" % (m.__name__, sub)
            submod = import_module(sub, subname, m)
            if not submod:
                raise ImportError, "No module named " + subname

def import_module(partname, fqname, parent):
    try:
        return sys.modules[fqname]
    except KeyError:
        pass
    try:
```python
fp, pathname, stuff = imp.find_module(partname, parent)

except ImportError:
    return None

try:
    m = imp.load_module(fqname, fp, pathname, stuff)
finally:
    if fp: fp.close()
    if parent:
        setattr(parent, partname, m)

return m

# Replacement for reload()

def reload_hook(module):
    name = module.__name__
    if '.' not in name:
        return import_module(name, name, None)
    i = name.rfind('.')
    pname = name[:i]
    parent = sys.modules[pname]
    return import_module(name[i+1:], name, parent)

# Save the original hooks
original_import = __builtin__.__import__
original_reload = __builtin__.reload

# Now install our hooks
__builtin__.__import__ = import_hook
__builtin__.reload = reload_hook
```

Also see the importers module (which can be found in Demo/imputil/ in the Python source distribution) for additional examples.
zipimport — Import modules from Zip archives

New in version 2.3.

This module adds the ability to import Python modules (*.py, *.py[co]) and packages from ZIP-format archives. It is usually not needed to use the zipimport module explicitly; it is automatically used by the built-in import mechanism for sys.path items that are paths to ZIP archives.

Typically, sys.path is a list of directory names as strings. This module also allows an item of sys.path to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path /tmp/example.zip/lib/ would only import from the lib/ subdirectory within the archive.

Any files may be present in the ZIP archive, but only files .py and .py[co] are available for import. ZIP import of dynamic modules (.pyd, .so) is disallowed. Note that if an archive only contains .py files, Python will not attempt to modify the archive by adding the corresponding .pyc or .pyo file, meaning that if a ZIP archive doesn't contain .pyc files, importing may be rather slow.

Using the built-in reload() function will fail if called on a module loaded from a ZIP archive; it is unlikely that reload() would be needed, since this would imply that the ZIP has been altered during runtime.

See also:
PKZIP Application Note

Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

PEP 0273 - Import Modules from Zip Archives

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302.

PEP 0302 - New Import Hooks

The PEP to add the import hooks that help this module work.

This module defines an exception:

```
exception zipimport.ZipImportError

Exception raised by zipimporter objects. It’s a subclass of ImportError, so it can be caught as ImportError, too.
```
zipimporter Objects

**zipimporter** is the class for importing ZIP files.

```python
class zipimport.zipimporter(archivepath)
    Create a new zipimporter instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of foo/bar.zip/lib will look for modules in the *lib* directory inside the ZIP file foo/bar.zip (provided that it exists).
```

*ZipImportError* is raised if *archivepath* doesn’t point to a valid ZIP archive.

```python
find_module(fullname[, path])
    Search for a module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or *None* if it wasn’t. The optional *path* argument is ignored—it's there for compatibility with the importer protocol.
```

```python
get_code(fullname)
    Return the code object for the specified module. Raise *ZipImportError* if the module couldn’t be found.
```

```python
get_data(pathname)
    Return the data associated with *pathname*. Raise *IOError* if the file wasn’t found.
```

```python
get_source(fullname)
    Return the source code for the specified module. Raise *ZipImportError* if the module couldn’t be found, return *None* if the archive does contain the module, but has no source for it.
```
is_package(fullname)
   Return True if the module specified by fullname is a package. Raise ZipImportError if the module couldn't be found.

load_module(fullname)
   Load the module specified by fullname. fullname must be the fully qualified (dotted) module name. It returns the imported module, or raises ZipImportError if it wasn't found.

archive
   The file name of the importer’s associated ZIP file, without a possible subpath.

prefix
   The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

The archive and prefix attributes, when combined with a slash, equal the original archivepath argument given to the zipimporter constructor.
Examples

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```bash
$ unzip -l /tmp/example.zip
Archive: /tmp/example.zip
    Length Date Time Name
     ------- ---- ---- ----
8467 11-26-02 22:30 jwzthreading.py
8467     -------
8467     1 file
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, '/tmp/example.zip')  # Add .zip file to path
>>> import jwzthreading
>>> jwzthreading.__file__
'/tmp/example.zip/jwzthreading.py'
```
pkgutil — Package extension utility

New in version 2.3.

This module provides functions to manipulate packages:

pkgutil.extend_path(path, name)

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's __init__.py:

```python
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's __path__ all subdirectories of directories on sys.path named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for *.pkg files beginning where * matches the name argument. This feature is similar to *.pth files (see the site module for more information), except that it doesn't special-case lines starting with import. A *.pkg file is trusted at face value: apart from checking for duplicates, all entries found in a *.pkg file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that sys.path is a sequence. Items of sys.path that
are not (Unicode or 8-bit) strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

```python
pkgutil.get_data(package, resource)
```

Get a resource from a package.

This is a wrapper for the PEP 302 loader `get_data()` API. The package argument should be the name of a package, in standard module format (foo.bar). The resource argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```python
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```

If the package cannot be located or loaded, or it uses a PEP 302 loader which does not support `get_data()`, then `None` is returned.
modulefinder — Find modules used by a script

New in version 2.3.

This module provides a `ModuleFinder` class that can be used to determine the set of modules imported by a script. `modulefinder.py` can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

`modulefinder.AddPackagePath(pkg_name, path)`

Record that the package named `pkg_name` can be found in the specified `path`.

`modulefinder.ReplacePackage(oldname, newname)`

Allows specifying that the module named `oldname` is in fact the package named `newname`. The most common usage would be to handle how the `_xmlplus` package replaces the `xml` package.

```python
class modulefinder.ModuleFinder([path=None, debug=0,
          excludes=[], replace_paths=[]])
```

This class provides `run_script()` and `report()` methods to determine the set of modules imported by a script. `path` can be a list of directories to search for modules; if not specified, `sys.path` is used. `debug` sets the debugging level; higher values make the class print debugging messages about what it's doing. `excludes` is a list of module names to exclude from the analysis. `replace_paths` is a list of `(oldpath, newpath)` tuples that will be replaced in module paths.

```python
report()
```
Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

run_script(pathname)

Analyze the contents of the pathname file, which must contain Python code.

modules

A dictionary mapping module names to modules. See *Example usage of ModuleFinder*
Example usage of ModuleFinder

The script that is going to get analyzed later on (bacon.py):

```python
import re, itertools
try:
    import baconhameggs
except ImportError:
    pass
try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```python
from modulefinder import ModuleFinder
finder = ModuleFinder()
finder.run_script('bacon.py')
print 'Loaded modules:
for name, mod in finder.modules.iteritems():
    print '%s: %s' % (name, ', '.join(mod.globalnames.keys()[:3]))
print '-'*50
print 'Modules not imported:'
print '\n'.join(finder.badmodules.iterkeys())
```

Sample output (may vary depending on the architecture):

```
Loaded modules:
_types:
copy_reg: _inverted_registry,_slotnames,__all__
sre_compile: isstring,_sre,_optimize_unicode
_sre:
sre_constants: REPEAT_ONE,makedict,AT_END_LINE
sys:
re: __module__,finditer,_expand
itertools:
```
__main__: re, itertools, baconhameggs
sre_parse: __getslice__, _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types: __module__, IntType, TypeError
---------------------------------------------------
Modules not imported:
guido.python.ham
baconhameggs
runpy — Locating and executing Python modules

New in version 2.5.

The runpy module is used to locate and run Python modules without importing them first. Its main use is to implement the -m command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

When executed as a script, the module effectively operates as follows:

```python
def sys.argv[0]  # Remove the runpy module from the arguments
run_module(sys.argv[0], run_name="__main__", alter_sys=True)
```

The runpy module provides a single function:

```python
runpy.run_module(mod_name[, init_globals][, run_name][, alter_sys])
```

Execute the code of the specified module and return the resulting module globals dictionary. The module’s code is first located using the standard import mechanism (refer to PEP 302 for details) and then executed in a fresh module namespace.

The optional dictionary argument init_globals may be used to pre-populate the globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by the run_module function.

The special global variables __name__, __file__, __loader__ and __builtins__ are set in the globals dictionary before the module
code is executed.

__name__ is set to run_name if this optional argument is supplied, and the mod_name argument otherwise.

__loader__ is set to the PEP 302 module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism).

__file__ is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to None.

__builtins__ is automatically initialised with a reference to the top level namespace of the __builtin__ module.

If the argument alter_sys is supplied and evaluates to True, then sys.argv[0] is updated with the value of __file__ and sys.modules[__name__] is updated with a temporary module object for the module being executed. Both sys.argv[0] and sys.modules[__name__] are restored to their original values before the function returns.

Note that this manipulation of sys is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the sys module be left alone when invoking this function from threaded code.

PEP 338 - Executing modules as scripts
PEP written and implemented by Nick Coghlan.
Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **parser** — Access Python parse trees
  - Creating ST Objects
  - Converting ST Objects
  - Queries on ST Objects
  - Exceptions and Error Handling
  - ST Objects
  - Examples
    - Emulation of `compile`
    - Information Discovery

- **Abstract Syntax Trees**
  - Node classes
  - Abstract Grammar
  - `ast` Helpers

- **symtable** — Access to the compiler’s symbol tables
  - Generating Symbol Tables
  - Examining Symbol Tables

- **symbol** — Constants used with Python parse trees

- **token** — Constants used with Python parse trees

- **keyword** — Testing for Python keywords

- **tokenize** — Tokenizer for Python source
- **tabnanny** — Detection of ambiguous indentation

- **pyclbr** — Python class browser support
  - Class Objects
  - Function Objects

- **py_compile** — Compile Python source files

- **compileall** — Byte-compile Python libraries

- **dis** — Disassembler for Python bytecode
  - Python Bytecode Instructions

- **pickletools** — Tools for pickle developers.

- **distutils** — Building and installing Python modules
The `parser` module provides an interface to Python’s internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

**Note:** From Python 2.5 onward, it’s much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the `ast` module. The `parser` module exports the names documented here also with “st” replaced by “ast”; this is a legacy from the time when there was no other AST and has nothing to do with the AST found in Python 2.5. This is also the reason for the functions’ keyword arguments being called `ast`, not `st`. The “ast” functions will be removed in Python 3.0.

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the `parser` module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to *The Python Language Reference*. The parser itself is created from a grammar specification defined in the file `Grammar/Grammar` in the standard Python distribution. The parse trees stored in the ST objects created by this module are the actual output from the internal parser when created by the `expr()` or
suite() functions, described below. The ST objects created by sequence2st() faithfully simulate those structures. Be aware that the values of the sequences which are considered “correct” will vary from one version of Python to another as the formal grammar for the language is revised. However, transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, whereas source code has always been forward-compatible.

Each element of the sequences returned by st2list() or st2tuple() has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file Include/graminit.h and the Python module symbol. Each additional element of the sequence represents a component of the production as recognized in the input string: these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword if in an if_stmt, are included in the node tree without any special treatment. For example, the if keyword is represented by the tuple (1, 'if'), where 1 is the numeric value associated with all NAME tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as (1, 'if', 12), where the 12 represents the line number at which the terminal symbol was found.

Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which
was identified. The example of the `if` keyword above is representative. The various types of terminal symbols are defined in the C header file `include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes: to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple “wrapper” class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

**See also:**

**Module symbol**

Useful constants representing internal nodes of the parse tree.

**Module token**

Useful constants representing leaf nodes of the parse tree and functions for testing node values.
Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the 'eval' and 'exec' forms.

parser. expr(source)
The `expr()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'eval')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is thrown.

parser. suite(source)
The `suite()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'exec')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is thrown.

parser. sequence2st(sequence)
This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the called. If there is a problem creating the internal representation, or if the tree cannot be validated, a `ParserError` exception is thrown. An ST object created this way should not be assumed to compile correctly; normal exceptions thrown by compilation may still be initiated when the ST object is passed to `compilest()`. This may indicate problems not related to syntax (such as a `MemoryError` exception), but may also be due to constructs such as the result of parsing `del f(0)`, which escapes the Python
parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form \((1, \text{'name'})\) or as three-element lists of the form \((1, \text{'name'}, 56)\). If the third element is present, it is assumed to be a valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

\textbf{parser.}\texttt{tuple2st(sequence)}

This is the same function as \texttt{sequence2st()}. This entry point is maintained for backward compatibility.
Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple- trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

```python
parser.st2list(ast[, line_info])
```

This function accepts an ST object from the caller in `ast` and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, `st2tuple()` should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token ends. This information is omitted if the flag is false or omitted.

```python
parser.st2tuple(ast[, line_info])
```

This function accepts an ST object from the caller in `ast` and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to `st2list()`.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the
token. This information is omitted if the flag is false or omitted.

```python
parser.compile(ast[, filename='<syntax-tree>'])
```

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of an `exec` statement or a call to the built-in `eval()` function. This function provides the interface to the compiler, passing the internal parse tree from `ast` to the parser, using the source file name specified by the `filename` parameter. The default value supplied for `filename` indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a `SyntaxError` caused by the parse tree for `del f(0)`: this statement is considered legal within the formal grammar for Python but is not a legal language construct. The `SyntaxError` raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the `parser` module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.
Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via `expr()` or `suite()` or from a parse tree via `sequence2st()`.

**parser.** `isexpr(ast)`

When `ast` represents an 'eval' form, this function returns true, otherwise it returns false. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

**parser.** `issuite(ast)`

This function mirrors `isexpr()` in that it reports whether an ST object represents an 'exec' form, commonly known as a “suite.” It is not safe to assume that this function is equivalent to `not isexpr(ast)`, as additional syntactic fragments may be supported in the future.
Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

```
exception parser.ParserError

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built in SyntaxError thrown during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to sequence2st() and an explanatory string. Calls to sequence2st() need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions compilest(), expr(), and suite() may throw exceptions which are normally thrown by the parsing and compilation process. These include the built in exceptions MemoryError, OverflowError, SyntaxError, and SystemError. In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.
```
ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the pickle module) is also supported.

parser.STType

The type of the objects returned by expr(), suite() and sequence2st().

ST objects have the following methods:

ST.compile([filename])

Same as compilest(st, filename).

ST.isexpr()

Same as isexpr(st).

ST.issuite()

Same as issuite(st).

ST.tolist([line_info])

Same as st2list(st, line_info).

ST.totuple([line_info])

Same as st2tuple(st, line_info).
Examples

The parser modules allows operations to be performed on the parse tree of Python source code before the bytecode is generated, and provides for inspection of the parse tree for information gathering purposes. Two examples are presented. The simple example demonstrates emulation of the compile() built-in function and the complex example shows the use of a parse tree for information discovery.

Emulation of compile()

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the parser module to produce an intermediate data structure is equivalent to the code

```python
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the parser module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object:

```python
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions:
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()

def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()

Information Discovery

Some applications benefit from direct access to the parse tree. The remainder of this section demonstrates how the parse tree provides access to module documentation defined in docstrings without requiring that the code being examined be loaded into a running interpreter via `import`. This can be very useful for performing analyses of untrusted code.

Generally, the example will demonstrate how the parse tree may be traversed to distill interesting information. Two functions and a set of classes are developed which provide programmatic access to high level function and class definitions provided by a module. The classes extract information from the parse tree and provide access to the information at a useful semantic level, one function provides a simple low-level pattern matching capability, and the other function defines a high-level interface to the classes by handling file operations on behalf of the caller. All source files mentioned here which are not part of the Python installation are located in the Demo/parser/ directory of the distribution.

The dynamic nature of Python allows the programmer a great deal of flexibility, but most modules need only a limited measure of this when defining classes, functions, and methods. In this example, the only definitions that will be considered are those which are defined in the top level of their context, e.g., a function defined by a `def` statement at column zero of a module, but not a function defined
within a branch of an `if ... else` construct, though there are some good reasons for doing so in some situations. Nesting of definitions will be handled by the code developed in the example.

To construct the upper-level extraction methods, we need to know what the parse tree structure looks like and how much of it we actually need to be concerned about. Python uses a moderately deep parse tree so there are a large number of intermediate nodes. It is important to read and understand the formal grammar used by Python. This is specified in the file `Grammar/Grammar` in the distribution. Consider the simplest case of interest when searching for docstrings: a module consisting of a docstring and nothing else. (See file `docstring.py`.)

"""Some documentation."
"""

Using the interpreter to take a look at the parse tree, we find a bewildering mass of numbers and parentheses, with the documentation buried deep in nested tuples.

```python
>>> import parser
>>> import pprint
>>> st = parser.suite(open('docstring.py').read())
>>> tup = st.totuple()
>>> pprint.pprint(tup)
(257,
 (264,
  (265,
   (266,
    (267,
     (307,
      (287,
       (288,
        (289,
         (290,
          (292,
           (293,
            (294,
             (295,
              (296,
```

The numbers at the first element of each node in the tree are the node types; they map directly to terminal and non-terminal symbols in the grammar. Unfortunately, they are represented as integers in the internal representation, and the Python structures generated do not change that. However, the `symbol` and `token` modules provide symbolic names for the node types and dictionaries which map from the integers to the symbolic names for the node types.

In the output presented above, the outermost tuple contains four elements: the integer 257 and three additional tuples. Node type 257 has the symbolic name `file_input`. Each of these inner tuples contains an integer as the first element; these integers, 264, 4, and 0, represent the node types `stmt`, `NEWLINE`, and `ENDMARKER`, respectively. Note that these values may change depending on the version of Python you are using; consult `symbol.py` and `token.py` for details of the mapping. It should be fairly clear that the outermost node is related primarily to the input source rather than the contents of the file, and may be disregarded for the moment. The `stmt` node is much more interesting. In particular, all docstrings are found in subtrees which are formed exactly as this node is formed, with the only difference being the string itself. The association between the docstring in a similar tree and the defined entity (class, function, or module) which it describes is given by the position of the docstring subtree within the tree defining the described structure.

By replacing the actual docstring with something to signify a variable component of the tree, we allow a simple pattern matching approach
to check any given subtree for equivalence to the general pattern for docstrings. Since the example demonstrates information extraction, we can safely require that the tree be in tuple form rather than list form, allowing a simple variable representation to be ['variable_name']. A simple recursive function can implement the pattern matching, returning a Boolean and a dictionary of variable name to value mappings. (See file example.py.)

```python
from types import ListType, TupleType

def match(pattern, data, vars=None):
    if vars is None:
        vars = {}
    if type(pattern) is ListType:
        vars[ pattern[0] ] = data
        return 1, vars
    if type(pattern) is not TupleType:
        return ( pattern == data ), vars
    if len(data) != len(pattern):
        return 0, vars
    for pattern, data in map( None, pattern, data):
        same, vars = match(pattern, data, vars)
    if not same:
        break
    return same, vars
```

Using this simple representation for syntactic variables and the symbolic node types, the pattern for the candidate docstring subtrees becomes fairly readable. (See file example.py.)

```python
import symbol
import token

DOCSTRING_STMT_PATTERN = (  
    symbol.stmt,
    (symbol.simple_stmt,  
    (symbol.small_stmt,  
    (symbol.expr_stmt,  
    (symbol.testlist,  
    (symbol.test,  
    (symbol.and_test,  
    (symbol.not_test,  
    (symbol.comparison,  
```

Using the \texttt{match()} function with this pattern, extracting the module docstring from the parse tree created previously is easy:

```python
>>> found, vars = match(DOCSYNTX_STMT_PATTERN, tup[1])
>>> found
1
>>> vars
{'docstring': '""Some documentation."

}
```

Once specific data can be extracted from a location where it is expected, the question of where information can be expected needs to be answered. When dealing with docstrings, the answer is fairly simple: the docstring is the first \texttt{stmt} node in a code block (\texttt{file_input} or \texttt{suite} node types). A module consists of a single \texttt{file_input} node, and class and function definitions each contain exactly one \texttt{suite} node. Classes and functions are readily identified as subtrees of code block nodes which start with \texttt{stmt}, \texttt{compound_stmt}, \texttt{classdef}, \ldots or \texttt{stmt}, \texttt{compound_stmt}, \texttt{funcdef}, \ldots. Note that these subtrees cannot be matched by \texttt{match()} since it does not support multiple sibling nodes to match without regard to number. A more elaborate matching function could be used to overcome this limitation, but this is sufficient for the example.

Given the ability to determine whether a statement might be a
docstring and extract the actual string from the statement, some work needs to be performed to walk the parse tree for an entire module and extract information about the names defined in each context of the module and associate any docstrings with the names. The code to perform this work is not complicated, but bears some explanation.

The public interface to the classes is straightforward and should probably be somewhat more flexible. Each “major” block of the module is described by an object providing several methods for inquiry and a constructor which accepts at least the subtree of the complete parse tree which it represents. The `ModuleInfo` constructor accepts an optional `name` parameter since it cannot otherwise determine the name of the module.

The public classes include `ClassInfo`, `FunctionInfo`, and `ModuleInfo`. All objects provide the methods `get_name()`, `get_docstring()`, `get_class_names()`, and `get_class_info()`. The `ClassInfo` objects support `get_method_names()` and `get_method_info()` while the other classes provide `get_function_names()` and `get_function_info()`.

Within each of the forms of code block that the public classes represent, most of the required information is in the same form and is accessed in the same way, with classes having the distinction that functions defined at the top level are referred to as “methods.” Since the difference in nomenclature reflects a real semantic distinction from functions defined outside of a class, the implementation needs to maintain the distinction. Hence, most of the functionality of the public classes can be implemented in a common base class, `SuiteInfoBase`, with the accessors for function and method information provided elsewhere. Note that there is only one class which represents function and method information; this parallels the use of the `def` statement to define both types of elements.
Most of the accessor functions are declared in `SuiteInfoBase` and do not need to be overridden by subclasses. More importantly, the extraction of most information from a parse tree is handled through a method called by the `SuiteInfoBase` constructor. The example code for most of the classes is clear when read alongside the formal grammar, but the method which recursively creates new information objects requires further examination. Here is the relevant part of the `SuiteInfoBase` definition from `example.py`:

```python
class SuiteInfoBase:
    _docstring = ''
    _name = ''

    def __init__(self, tree = None):
        self._class_info = {}
        self._function_info = {}
        if tree:
            self._extract_info(tree)

    def _extract_info(self, tree):
        # extract docstring
        if len(tree) == 2:
            found, vars = match(DOCSTRING_STMT_PATTERN[1], tree)
        else:
            found, vars = match(DOCSTRING_STMT_PATTERN, tree[3])
        if found:
            self._docstring = eval(vars['docstring'])
        # discover inner definitions
        for node in tree[1:]:
            found, vars = match(COMPOUND_STMT_PATTERN, node)
            if found:
                cstmt = vars['compound']
                if cstmt[0] == symbol.funcdef:
                    name = cstmt[2][1]
                    self._function_info[name] = FunctionInfo(cstmt)
                elif cstmt[0] == symbol.classdef:
                    name = cstmt[2][1]
                    self._class_info[name] = ClassInfo(cstmt)
```

After initializing some internal state, the constructor calls the `_extract_info()` method. This method performs the bulk of the information extraction which takes place in the entire example. The
extraction has two distinct phases: the location of the docstring for the parse tree passed in, and the discovery of additional definitions within the code block represented by the parse tree.

The initial `if` test determines whether the nested suite is of the “short form” or the “long form.” The short form is used when the code block is on the same line as the definition of the code block, as in

```python
def square(x): "Square an argument."; return x ** 2
```

while the long form uses an indented block and allows nested definitions:

```python
def make_power(exp):
    "Make a function that raises an argument to the exponent `e
    def raiser(x, y=exp):
        return x ** y
    return raiser
```

When the short form is used, the code block may contain a docstring as the first, and possibly only, `small_stmt` element. The extraction of such a docstring is slightly different and requires only a portion of the complete pattern used in the more common case. As implemented, the docstring will only be found if there is only one `small_stmt` node in the `simple_stmt` node. Since most functions and methods which use the short form do not provide a docstring, this may be considered sufficient. The extraction of the docstring proceeds using the `match()` function as described above, and the value of the docstring is stored as an attribute of the `SuiteInfoBase` object.

After docstring extraction, a simple definition discovery algorithm operates on the `stmt` nodes of the `suite` node. The special case of the short form is not tested; since there are no `stmt` nodes in the short form, the algorithm will silently skip the single `simple_stmt` node and correctly not discover any nested definitions.
Each statement in the code block is categorized as a class definition, function or method definition, or something else. For the definition statements, the name of the element defined is extracted and a representation object appropriate to the definition is created with the defining subtree passed as an argument to the constructor. The representation objects are stored in instance variables and may be retrieved by name using the appropriate accessor methods.

The public classes provide any accessors required which are more specific than those provided by the `SuiteInfoBase` class, but the real extraction algorithm remains common to all forms of code blocks. A high-level function can be used to extract the complete set of information from a source file. (See file `example.py`.)

```python
def get_docs(fileName):
    import os
    import parser

    source = open(fileName).read()
    basename = os.path.basename(os.path.splitext(fileName)[0])
    st = parser.suite(source)
    return ModuleInfo(st.totuple(), basename)
```

This provides an easy-to-use interface to the documentation of a module. If information is required which is not extracted by the code of this example, the code may be extended at clearly defined points to provide additional capabilities.
Abstract Syntax Trees

New in version 2.5: The low-level _ast module containing only the node classes.

New in version 2.6: The high-level ast module containing all helpers.

The ast module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programmatically what the current grammar looks like.

An abstract syntax tree can be generated by passing _ast.PyCF_ONLY_AST as a flag to the compile() builtin function, or using the parse() helper provided in this module. The result will be a tree of objects whose classes all inherit from ast.AST.

A modified abstract syntax tree can be compiled into a Python code object using the built-in compile() function.
Node classes

class ast.AST

This is the base of all AST node classes. The actual node classes are derived from the Parser/Python.asdl file, which is reproduced below. They are defined in the _ast C module and re-exported in ast.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, ast.stmt or ast.expr). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, ast.BinOp inherits from ast.expr. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

_fields

Each concrete class has an attribute _fields which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, ast.BinOp instances have an attribute left of type ast.expr.

If these attributes are marked as optional in the grammar (using a question mark), the value might be None. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with compile().
Instances of `ast.expr` and `ast.stmt` subclasses have `lineno` and `col_offset` attributes. The `lineno` is the line number of source text (1-indexed so the first line is line 1) and the `col_offset` is the UTF-8 byte offset of the first token that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

The constructor of a class `ast.T` parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in `T._fields`; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an `ast.UnaryOp` node, you could use

```python
node = ast.UnaryOp()
nodem.op = ast.USub()nnodem.operand = ast.Num()nnodem.operand.n = 5nnodem.operand.lineno = 0nnodem.operand.col_offset = 0nnodem.lineno = 0nnodem.col_offset = 0
```

or the more compact

```python
node = ast.UnaryOp(ast.USub(), ast.Num(5, lineno=0, col_offset=0))
```

*New in version 2.6:* The constructor as explained above was
added. In Python 2.5 nodes had to be created by calling the class constructor without arguments and setting the attributes afterwards.
Abstract Grammar

The module defines a string constant __version__ which is the decimal Subversion revision number of the file shown below.

The abstract grammar is currently defined as follows:

```plaintext
-- ASDL's five builtin types are identifier, int, string, object
module Python version "$Revision: 62047 $"
{
    mod = Module(stmt* body)
    | Interactive(stmt* body)
    | Expression(expr body)
    -- not really an actual node but useful in Jython's
    | Suite(stmt* body)

    stmt = FunctionDef(identifier name, arguments args,
                        stmt* body, expr* decorator_list)
    | ClassDef(identifier name, expr* bases, stmt* body,
               expr* decorator_list)
    | Return(expr? value)
    | Delete(expr* targets)
    | Assign(expr* targets, expr value)
    | AugAssign(expr target, operator op, expr value)
    -- not sure if bool is allowed, can always use in
    | Print(expr? dest, expr* values, bool nl)
    -- use 'orelse' because else is a keyword in target
    | For(expr target, expr iter, stmt* body, stmt* orelse)
    | While(expr test, stmt* body, stmt* orelse)
    | If(expr test, stmt* body, stmt* orelse)
    | With(expr context_expr, expr? optional_vars, stmt* body)
    -- 'type' is a bad name
    | Raise(expr? type, expr? inst, expr? tback)
    | TryExcept(stmt* body, excepthandler* handlers,
               expr? msg)
    | TryFinally(stmt* body, stmt* finalbody)
    | Assert(expr test, expr? msg)

    | Import(alias* names)
    | ImportFrom(identifier module, alias* names, int
```
Doesn't capture requirement that locals must be defined if globals is
still supports use as a function!

| Exec(expr body, expr? globals, expr? locals)
| Global(identifier* names)
| Expr(expr value)
| Pass | Break | Continue

XXX Jython will be different
col_offset is the byte offset in the utf8 string attributes (int lineno, int col_offset)

BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
| BinOp(expr left, operator op, expr right)
| UnaryOp(unaryop op, expr operand)
| Lambda(arguments args, expr body)
| IfExp(expr test, expr body, expr orelse)
| Dict(expr* keys, expr* values)
| ListComp(expr elt, comprehension* generators)
| GeneratorExp(expr elt, comprehension* generators)
-- the grammar constrains where yield expressions
| Yield(expr? value)
-- need sequences for compare to distinguish between
-- x < 4 < 3 and (x < 4) < 3
| Compare(expr left, cmpop* ops, expr* comparators
| Call(expr func, expr* args, keyword* keywords,
| expr? starargs, expr? kwargs)
| Repr(expr value)
| Num(object n) -- a number as a PyObject.
| Str(string s) -- need to specify raw, unicode, etc
-- other literals? bools?

the following expression can appear in assignment
| Attribute(expr value, identifier attr, expr_context
total)
| Subscript(expr value, slice slice, expr_context
total)
| Name(identifier id, expr_context ctx)
| List(expr* elts, expr_context ctx)
| Tuple(expr* elts, expr_context ctx)

-- col_offset is the byte offset in the utf8 string attributes (int lineno, int col_offset)

eexpr_context = Load | Store | Del | AugLoad | AugStore
	slice = Ellipsis | Slice(expr? lower, expr? upper, expr
| ExtSlice(slice* dims)
| Index(expr value)
boolop = And | Or
operator = Add | Sub | Mult | Div | Mod | Pow | LShift
        | RShift | BitOr | BitXor | BitAnd | FloorDiv
unaryop = Invert | Not | UAdd | USub
cmpop = Eq | NotEq | Lt | LtE | Gt | GtE | Is | IsNot |
comprehension = (expr target, expr iter, expr* ifs)
    -- not sure what to call the first argument for raise a
excepthandler = ExceptHandler(expr? type, expr? name, s
    attributes (int lineno, int col_offset)
arguments = (expr* args, identifier? vararg,
            identifier? kwarg, expr* defaults)
    -- keyword arguments supplied to call
keyword = (identifier arg, expr value)
    -- import name with optional 'as' alias.
alias = (identifier name, identifier? asname)
ast Helpers

New in version 2.6.

Apart from the node classes, ast module defines these utility functions and classes for traversing abstract syntax trees:

```python
ast.parse(expr, filename='<unknown>', mode='exec')
```

Parse an expression into an AST node. Equivalent to `compile(expr, filename, mode, PyCF_ONLY_AST)`. 

```python
ast.literal_eval(node_or_string)
```

Safely evaluate an expression node or a string containing a Python expression. The string or node provided may only consist of the following Python literal structures: strings, numbers, tuples, lists, dicts, booleans, and `None`.

This can be used for safely evaluating strings containing Python expressions from untrusted sources without the need to parse the values oneself.

```python
ast.get_docstring(node, clean=True)
```

Return the docstring of the given `node` (which must be a `FunctionDef`, `ClassDef` or `Module` node), or `None` if it has no docstring. If `clean` is true, clean up the docstring’s indentation with `inspect.cleandoc()`.

```python
ast.fix_missing_locations(node)
```

When you compile a node tree with `compile()`, the compiler expects `lineno` and `col_offset` attributes for every node that supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It
works recursively starting at \textit{node}.

\texttt{ast.increment\_lineno}(\textit{node}, n=1)

Increment the line number of each node in the tree starting at \textit{node} by \textit{n}. This is useful to “move code” to a different location in a file.

\texttt{ast.copy\_location}(\textit{new\_node}, \textit{old\_node})

Copy source location (\texttt{lineno} and \texttt{col\_offset}) from \textit{old\_node} to \textit{new\_node} if possible, and return \textit{new\_node}.

\texttt{ast.iter\_fields}(\textit{node})

Yield a tuple of (\texttt{fieldname}, \texttt{value}) for each field in \textit{node._fields} that is present on \textit{node}.

\texttt{ast.iter\_child\_nodes}(\textit{node})

Yield all direct child nodes of \textit{node}, that is, all fields that are nodes and all items of fields that are lists of nodes.

\texttt{ast.walk}(\textit{node})

Recursively yield all child nodes of \textit{node}, in no specified order. This is useful if you only want to modify nodes in place and don’t care about the context.

\texttt{class ast.NodeVisitor}

A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the \texttt{visit} method.

This class is meant to be subclassed, with the subclass adding visitor methods.

\texttt{visit}(\textit{node})

Visit a node. The default implementation calls the method called \texttt{self.visit\_classname} where \texttt{classname} is the name of
the node class, or \texttt{generic\_visit()} if that method doesn’t exist.

\textbf{\texttt{generic\_visit}(node)}

This visitor calls \texttt{visit()} on all children of the node.

Note that child nodes of nodes that have a custom visitor method won’t be visited unless the visitor calls \texttt{generic\_visit()} or visits them itself.

Don’t use the \texttt{NodeVisitor} if you want to apply changes to nodes during traversal. For this a special visitor exists (\texttt{NodeTransformer}) that allows modifications.

\textbf{class \texttt{ast.NodeTransformer}}

A \texttt{NodeVisitor} subclass that walks the abstract syntax tree and allows modification of nodes.

The \texttt{NodeTransformer} will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is \texttt{None}, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (\texttt{foo}) to \texttt{data['foo']}:

\begin{verbatim}
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return copy_location(Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Index(value=Str(s=node.id)),
            ctx=node.ctx
        )
\end{verbatim}
Keep in mind that if the node you’re operating on has child nodes you must either transform the child nodes yourself or call the `generic_visit()` method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

Usually you use the transformer like this:

```python
node = YourTransformer().visit(node)
```

```python
ast.dump(node, annotate_fields=True, include_attributes=False)
```

Return a formatted dump of the tree in `node`. This is mainly useful for debugging purposes. The returned string will show the names and the values for fields. This makes the code impossible to evaluate, so if evaluation is wanted `annotate_fields` must be set to False. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, `include_attributes` can be set to `True`. 
Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. `symtable` provides an interface to examine these tables.
Generating Symbol Tables

`symtable.symtable(code, filename, compile_type)`

Return the toplevel `SymbolTable` for the Python source `code`. `filename` is the name of the file containing the code. `compile_type` is like the `mode` argument to `compile()`.
class symtable.SymbolTable

A namespace table for a block. The constructor is not public.

get_type()
Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

get_id()
Return the table’s identifier.

get_name()
Return the table’s name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (get_type() returns 'module').

get_lineno()
Return the number of the first line in the block this table represents.

is_optimized()
Return True if the locals in this table can be optimized.

is_nested()
Return True if the block is a nested class or function.

has_children()
Return True if the block has nested namespaces within it. These can be obtained with get_children().

has_exec()
Return True if the block uses exec.
has_import_start()
    Return True if the block uses a starred from-import.

get_identifiers()
    Return a list of names of symbols in this table.

lookup(name)
    Lookup name in the table and return a Symbol instance.

get_symbols()
    Return a list of Symbol instances for names in the table.

get_children()
    Return a list of the nested symbol tables.

class symtable.Function
    A namespace for a function or method. This class inherits SymbolTable.

get_parameters()
    Return a tuple containing names of parameters to this function.

get_locals()
    Return a tuple containing names of locals in this function.

get_globals()
    Return a tuple containing names of globals in this function.

get_frees()
    Return a tuple containing names of free variables in this function.

class symtable.Class
    A namespace of a class. This class inherits SymbolTable.
get_methods()
Return a tuple containing the names of methods declared in the class.

class symtable.Symbol
An entry in a SymbolTable corresponding to an identifier in the source. The constructor is not public.

get_name()
Return the symbol's name.

is_referenced()
Return True if the symbol is used in its block.

is_imported()
Return True if the symbol is created from an import statement.

is_parameter()
Return True if the symbol is a parameter.

is_global()
Return True if the symbol is global.

is_local()
Return True if the symbol is local to its block.

is_free()
Return True if the symbol is referenced in its block, but not assigned to.

is_assigned()
Return True if the symbol is assigned to in its block.

is_namespace()
Return True if name binding introduces new namespace.
If the name is used as the target of a function or class statement, this will be true.

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

```python
get_namespaces()
```
Return a list of namespaces bound to this name.

```python
get_namespace()
```
Return the namespace bound to this name. If more than one namespace is bound, a `ValueError` is raised.
symbol — Constants used with Python parse trees

This module provides constants which represent the numeric values of internal nodes of the parse tree. Unlike most Python constants, these use lower-case names. Refer to the file Grammar/Grammar in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one additional data object:

symbol. **sym_name**

    Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

**See also:**

**Module parser**

The second example for the parser module shows how to use the symbol module.
This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file Grammar/Grammar in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one data object and some functions. The functions mirror definitions in the Python C header files.

**token.** *tok_name*

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

**token.** *ISTERMINAL(x)*

Return true for terminal token values.

**token.** *ISNONTERMINAL(x)*

Return true for non-terminal token values.

**token.** *ISEOF(x)*

Return true if x is the marker indicating the end of input.

**See also:**

**Module** *parser*

The second example for the *parser* module shows how to use the *symbol* module.
This module allows a Python program to determine if a string is a keyword.

**iskeyword(s)**

Return true if s is a Python keyword.

**kwlist**

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular \_\_future\_ statements are in effect, these will be included as well.
The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers,” including colorizers for on-screen displays.

The primary entry point is a generator:

```
tokenizer.generate_tokens(readline)
```

The `generate_tokens()` generator requires one argument, `readline`, which must be a callable object which provides the same interface as the `readline()` method of built-in file objects (see section *File Objects*). Each call to the function should return one line of input as a string.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple `(srow, scol)` of ints specifying the row and column where the token begins in the source; a 2-tuple `(erow, ecol)` of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *logical* line; continuation lines are included.

*New in version 2.2.*

An older entry point is retained for backward compatibility:

```
tokenizer.tokenize(readline[, tokeneater])
```

The `tokenize()` function accepts two parameters: one representing the input stream, and one providing an output
mechanism for \texttt{tokenize()}. 

The first parameter, \texttt{readline}, must be a callable object which provides the same interface as the \texttt{readline()} method of built-in file objects (see section \textit{File Objects}). Each call to the function should return one line of input as a string. Alternately, \texttt{readline} may be a callable object that signals completion by raising \texttt{StopIteration}.

\textit{Changed in version 2.5: Added \texttt{StopIteration} support.}

The second parameter, \texttt{tokeneater}, must also be a callable object. It is called once for each token, with five arguments, corresponding to the tuples generated by \texttt{generate_tokens()}.

All constants from the \texttt{token} module are also exported from \texttt{tokenize}, as are two additional token type values that might be passed to the \texttt{tokeneater} function by \texttt{tokenize()}:

\texttt{tokenize.COMMENT}

Token value used to indicate a comment.

\texttt{tokenize.NL}

Token value used to indicate a non-terminating newline. The NEWLINE token indicates the end of a logical line of Python code; NL tokens are generated when a logical line of code is continued over multiple physical lines.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

\texttt{tokenize.untokenize(iterable)}

Converts tokens back into Python source code. The \texttt{iterable} must return sequences with at least two elements, the token type and
the token string. Any additional sequence elements are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

*New in version 2.5.*

Example of a script re-writer that transforms float literals into Decimal objects:

```python
def decistmt(s):
    """Substitute Decimals for floats in a string of statements."
    >>> from decimal import Decimal
    >>> s = 'print +21.3e-5*-.1234/81.7'
    >>> decistmt(s)
    "print +Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7')"
    >>> exec(s)
    -3.21716034272e-007
    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7
    ""
    result = []
g = generate_tokens(StringIO(s).readline)  # tokenize the
for toknum, tokval, __, __, __ in g:
    if toknum == NUMBER and '.' in tokval:  # replace NUMBERS
        result.extend([
            (NAME, 'Decimal'),
            (OP, '('),
            (STRING, repr(tokval)),
            (OP, ')')
        ])
    else:
        result.append((toknum, tokval))
return untokenize(result)
```
tabnanny — Detection of ambiguous indentation

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

**Warning:** The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

**tabnanny.check(file_or_dir)**

If `file_or_dir` is a directory and not a symbolic link, then recursively descend the directory tree named by `file_or_dir`, checking all `.py` files along the way. If `file_or_dir` is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the `print` statement.

**tabnanny.verbose**

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

**tabnanny.filename_only**

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.

**exception tabnanny.NannyNag**

Raised by `tokeneater()` if detecting an ambiguous indent. Captured and handled in `check()`.

**tabnanny.tokener(type, token, start, end, line)**
This function is used by `check()` as a callback parameter to the function `tokenize.tokenize()`.

**See also:**

**Module** `tokenize`

Lexical scanner for Python source code.
The **pyclbr** module can be used to determine some limited information about the classes, methods and top-level functions defined in a module. The information provided is sufficient to implement a traditional three-pane class browser. The information is extracted from the source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

**pyclbr.readmodule**(module[, path=None])
Read a module and return a dictionary mapping class names to class descriptor objects. The parameter *module* should be the name of a module as a string; it may be the name of a module within a package. The *path* parameter should be a sequence, and is used to augment the value of *sys.path*, which is used to locate module source code.

**pyclbr.readmodule_ex**(module[, path=None])
Like *readmodule()*, but the returned dictionary, in addition to mapping class names to class descriptor objects, also maps top-level function names to function descriptor objects. Moreover, if the module being read is a package, the key '__path__' in the returned dictionary has as its value a list which contains the package search path.
Class Objects

The `class` objects used as values in the dictionary returned by `readmodule()` and `readmodule_ex()` provide the following data members:

**Class. module**
The name of the module defining the class described by the class descriptor.

**Class. name**
The name of the class.

**Class. super**
A list of `class` objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule()` are listed as a string with the class name instead of as `class` objects.

**Class. methods**
A dictionary mapping method names to line numbers.

**Class. file**
Name of the file containing the `class` statement defining the class.

**Class. lineno**
The line number of the `class` statement within the file named by `file`. 
Function Objects

The Function objects used as values in the dictionary returned by `readmodule_ex()` provide the following data members:

**Function.module**

The name of the module defining the function described by the function descriptor.

**Function.name**

The name of the function.

**Function.file**

Name of the file containing the `def` statement defining the function.

**Function.lineno**

The line number of the `def` statement within the file named by `file`. 
The py_compile module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

exception py_compile.\texttt{PyCompileError}

Exception raised when an error occurs while attempting to compile the file.

\begin{verbatim}
py_compile.compile(file[, cfile[, dfile[, doraise]]]])
\end{verbatim}

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file name \texttt{file}. The byte-code is written to \texttt{cfile}, which defaults to \texttt{file+’c’} (\texttt{’o’} if optimization is enabled in the current interpreter). If \texttt{dfile} is specified, it is used as the name of the source file in error messages instead of \texttt{file}. If \texttt{doraise} is true, a \texttt{PyCompileError} is raised when an error is encountered while compiling \texttt{file}. If \texttt{doraise} is false (the default), an error string is written to \texttt{sys.stderr}, but no exception is raised.

\begin{verbatim}
py_compile.main([args])
\end{verbatim}

Compile several source files. The files named in \texttt{args} (or on the command line, if \texttt{args} is not specified) are compiled and the resulting bytecode is cached in the normal manner. This function does not search a directory structure to locate source files; it only
compiles files named explicitly.

When this module is run as a script, the `main()` is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

*Changed in version 2.6*: Added the nonzero exit status when module is run as a script.

**See also:**

**Module compileall**

Utilities to compile all Python source files in a directory tree.
This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree, allowing users without permission to write to the libraries to take advantage of cached byte-code files.

This module may also be used as a script (using the -m Python flag) to compile Python sources. Directories to recursively traverse (passing -l stops the recursive behavior) for sources are listed on the command line. If no arguments are given, the invocation is equivalent to -l sys.path. Printing lists of the files compiled can be disabled with the -q flag. In addition, the -x option takes a regular expression argument. All files that match the expression will be skipped.

```
compileall.compile_dir(dir[, maxlevels[, ddir[, force[, rx[, quiet]]]]]])
```

Recursively descend the directory tree named by `dir`, compiling all `.py` files along the way. The `maxlevels` parameter is used to limit the depth of the recursion; it defaults to 10. If `ddir` is given, it is used as the base path from which the filenames used in error messages will be generated. If `force` is true, modules are re-compiled even if the timestamps are up to date.

If `rx` is given, it specifies a regular expression of file names to exclude from the search; that expression is searched for in the full path.

If `quiet` is true, nothing is printed to the standard output in normal operation.
compileall.compile_path([skip_curdir, maxlevels, force])

Byte-compile all the .py files found along sys.path. If skip_curdir is true (the default), the current directory is not included in the search. The maxlevels and force parameters default to 0 and are passed to the compile_dir() function.

To force a recompile of all the .py files in the Lib/ subdirectory and all its subdirectories:

```python
import compileall
compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn directories
import re
compileall.compile_dir('Lib/', rx=re.compile('/\.[.]svn'), force=True)
```

See also:

Module py_compile

Byte-compile a single source file.
dis — Disassembler for Python bytecode

The dis module supports the analysis of Python bytecode by disassembling it. Since there is no Python assembler, this module defines the Python assembly language. The Python bytecode which this module takes as an input is defined in the file Include/opcode.h and used by the compiler and the interpreter.

Example: Given the function myfunc():

```python
def myfunc(alist):
    return len(alist)
```

the following command can be used to get the disassembly of myfunc():

```bash
>>> dis.dis(myfunc)
  2         0 LOAD_GLOBAL               0 (len)
  3         0 LOAD_FAST                0 (alist)
  6      0 CALL_FUNCTION              1
  9      0 RETURN_VALUE
```

(The “2” is a line number).

The dis module defines the following functions and constants:

```python
dis.dis([bytesource])
```

Disassemble the bytesource object. bytesource can denote either a module, a class, a method, a function, or a code object. For a module, it disassembles all functions. For a class, it disassembles all methods. For a single code sequence, it prints one line per bytecode instruction. If no object is provided, it disassembles the last traceback.
**dis.disassemble***(code[, lasti])***
Disassembles a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`
3. a labelled instruction, indicated with `>>`
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.
The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

**dis.disco***(code[, lasti])***
A synonym for disassemble. It is more convenient to type, and kept for compatibility with earlier Python releases.

**dis.opname**
Sequence of operation names, indexable using the bytecode.

**dis.opmap**
Dictionary mapping bytecodes to operation names.

**dis.cmp_op**
Sequence of all compare operation names.

**dis.hasconst**
Sequence of bytecodes that have a constant parameter.
dis. **hasfree**
   Sequence of bytecodes that access a free variable.

dis. **hasname**
   Sequence of bytecodes that access an attribute by name.

dis. **hasjrel**
   Sequence of bytecodes that have a relative jump target.

dis. **hasjabs**
   Sequence of bytecodes that have an absolute jump target.

dis. **haslocal**
   Sequence of bytecodes that access a local variable.

dis. **hascompare**
   Sequence of bytecodes of Boolean operations.
Python Bytecode Instructions

The Python compiler currently generates the following bytecode instructions.

**STOP_CODE()**
Indicates end-of-code to the compiler, not used by the interpreter.

**NOP()**
Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP_TOP()**
Removes the top-of-stack (TOS) item.

**ROT_TWO()**
Swaps the two top-most stack items.

**ROT_THREE()**
Lifts second and third stack item one position up, moves top down to position three.

**ROT_FOUR()**
Lifts second, third and forth stack item one position up, moves top down to position four.

**DUP_TOP()**
Duplicates the reference on top of the stack.

Unary Operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY_POSITIVE()**
Implements $\text{TOS} = +\text{TOS}$. 
UNARY_NEGATIVE()
    Implements \texttt{TOS} = -\texttt{TOS}.

UNARY_NOT()
    Implements \texttt{TOS} = \texttt{not TOS}.

UNARY_CONVERT()
    Implements \texttt{TOS} = `\texttt{TOS}`.

UNARY_INVERT()
    Implements \texttt{TOS} = ~\texttt{TOS}.

GET_ITER()
    Implements \texttt{TOS} = \texttt{iter(TOS)}.

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

BINARY_POWER()
    Implements \texttt{TOS} = \texttt{TOS1 ** TOS}.

BINARY_MULTIPLY()
    Implements \texttt{TOS} = \texttt{TOS1 * TOS}.

BINARY_DIVIDE()
    Implements \texttt{TOS} = \texttt{TOS1 / TOS} when \texttt{from \_\_future\_ import division} is not in effect.

BINARY_FLOOR_DIVIDE()
    Implements \texttt{TOS} = \texttt{TOS1 // TOS}.

BINARY_TRUE_DIVIDE()
    Implements \texttt{TOS} = \texttt{TOS1 / TOS} when \texttt{from \_\_future\_ import}
division is in effect.

**BINARY_MODULO()**

Implements \( TOS = TOS1 \mod TOS \).

**BINARY_ADD()**

Implements \( TOS = TOS1 + TOS \).

**BINARY_SUBTRACT()**

Implements \( TOS = TOS1 - TOS \).

**BINARY_SUBSCR()**

Implements \( TOS = TOS1[TOS] \).

**BINARY_LSHIFT()**

Implements \( TOS = TOS1 \ll TOS \).

**BINARY_RSHIFT()**

Implements \( TOS = TOS1 \gg TOS \).

**BINARY_AND()**

Implements \( TOS = TOS1 & TOS \).

**BINARY_XOR()**

Implements \( TOS = TOS1 \oplus TOS \).

**BINARY_OR()**

Implements \( TOS = TOS1 \lor TOS \).

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.
**INPLACE_POWER()**
Implements in-place \( \text{TOS} = \text{TOS1} \times \text{TOS} \).

**INPLACE_MULTIPLY()**
Implements in-place \( \text{TOS} = \text{TOS1} \times \text{TOS} \).

**INPLACE_DIVIDE()**
Implements in-place \( \text{TOS} = \text{TOS1} / \text{TOS} \) when `from __future__ import division` is not in effect.

**INPLACE_FLOOR_DIVIDE()**
Implements in-place \( \text{TOS} = \text{TOS1} // \text{TOS} \).

**INPLACE_TRUE_DIVIDE()**
Implements in-place \( \text{TOS} = \text{TOS1} / \text{TOS} \) when `from __future__ import division` is in effect.

**INPLACE_MODULO()**
Implements in-place \( \text{TOS} = \text{TOS1} \mod \text{TOS} \).

**INPLACE_ADD()**
Implements in-place \( \text{TOS} = \text{TOS1} + \text{TOS} \).

**INPLACE_SUBTRACT()**
Implements in-place \( \text{TOS} = \text{TOS1} - \text{TOS} \).

**INPLACE_LSHIFT()**
Implements in-place \( \text{TOS} = \text{TOS1} \ll \text{TOS} \).

**INPLACE_RSHIFT()**
Implements in-place \( \text{TOS} = \text{TOS1} \gg \text{TOS} \).

**INPLACE_AND()**
Implements in-place $TOS = TOS1 \& TOS$.

**INPLACE\_XOR()**
Implements in-place $TOS = TOS1 \^ TOS$.

**INPLACE\_OR()**
Implements in-place $TOS = TOS1 \mid TOS$.

The slice opcodes take up to three parameters.

**SLICE+0()**
Implements $TOS = TOS[:]$.

**SLICE+1()**
Implements $TOS = TOS1[TOS:]$.

**SLICE+2()**
Implements $TOS = TOS1[:TOS]$.

**SLICE+3()**
Implements $TOS = TOS2[TOS1:TOS]$.

Slice assignment needs even an additional parameter. As any statement, they put nothing on the stack.

**STORE\_SLICE+0()**
Implements $TOS[:] = TOS1$.

**STORE\_SLICE+1()**
Implements $TOS1[TOS:] = TOS2$.

**STORE\_SLICE+2()**
Implements $TOS1[:TOS] = TOS2$. 
STORE_SLICE+3()
  Implements \( \text{TOS}_2[\text{TOS}_1:\text{TOS}] = \text{TOS}_3 \).  

DELETE_SLICE+0()
  Implements \( \text{del} \ \text{TOS}[:]. \)

DELETE_SLICE+1()
  Implements \( \text{del} \ \text{TOS}_1[\text{TOS}:]. \)

DELETE_SLICE+2()
  Implements \( \text{del} \ \text{TOS}_1[:\text{TOS}]. \)

DELETE_SLICE+3()
  Implements \( \text{del} \ \text{TOS}_2[\text{TOS}_1:\text{TOS}]. \)

STORE_SUBSCR()
  Implements \( \text{TOS}_1[\text{TOS}] = \text{TOS}_2. \)

DELETE_SUBSCR()
  Implements \( \text{del} \ \text{TOS}_1[\text{TOS}]. \)

Miscellaneous opcodes.

PRINT_EXPR()
  Implements the expression statement for the interactive mode. 
  TOS is removed from the stack and printed. In non-interactive 
  mode, an expression statement is terminated with POP_STACK.

PRINT_ITEM()
  Prints TOS to the file-like object bound to sys.stdout. There is 
  one such instruction for each item in the print statement.

PRINT_ITEM_TO()
  Like PRINT_ITEM, but prints the item second from TOS to the file-
like object at TOS. This is used by the extended print statement.

PRINT_NEWLINE()
Prints a new line on \texttt{sys.stdout}. This is generated as the last operation of a \texttt{print} statement, unless the statement ends with a comma.

PRINT_NEWLINE_TO()
Like \texttt{PRINT_NEWLINE}, but prints the new line on the file-like object on the TOS. This is used by the extended print statement.

BREAK_LOOP()
Terminates a loop due to a \texttt{break} statement.

CONTINUE_LOOP(\texttt{target})
Continues a loop due to a \texttt{continue} statement. \texttt{target} is the address to jump to (which should be a \texttt{FOR_ITER} instruction).

LIST_APPEND()
Calls \texttt{list.append(TOS1, TOS)}. Used to implement list comprehensions.

LOAD_LOCALS()
Pushes a reference to the locals of the current scope on the stack. This is used in the code for a class definition: After the class body is evaluated, the locals are passed to the class definition.

RETURN_VALUE()
Returns with TOS to the caller of the function.

YIELD_VALUE()
Pops \texttt{tos} and yields it from a \texttt{generator}. 
**IMPORT_STAR()**
Loads all symbols not starting with '['_'] directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

**EXEC_STMT()**
Implements `exec TOS2, TOS1, TOS`. The compiler fills missing optional parameters with `None`.

**POP_BLOCK()**
Removes one block from the block stack. Per frame, there is a stack of blocks, denoting nested loops, try statements, and such.

**END_FINALLY()**
Terminates a `finally` clause. The interpreter recalls whether the exception has to be re-raised, or whether the function returns, and continues with the outer-next block.

**BUILD_CLASS()**
Creates a new class object. TOS is the methods dictionary, TOS1 the tuple of the names of the base classes, and TOS2 the class name.

**WITH_CLEANUP()**
Cleans up the stack when a `with` statement block exits. On top of the stack are 1–3 values indicating how/why the finally clause was entered:

- TOP = `None`
- `(TOP, SECOND) = (WHY_{RETURN, CONTINUE}), retval`
- TOP = `WHY_*`; no retval below it
- `(TOP, SECOND, THIRD) = exc_info()`

Under them is EXIT, the context manager's `__exit__()` bound
method.

In the last case, \texttt{EXIT(TOP, SECOND, THIRD)} is called, otherwise \texttt{EXIT(None, None, None)}.

EXIT is removed from the stack, leaving the values above it in the same order. In addition, if the stack represents an exception, \textit{and} the function call returns a ‘true’ value, this information is “zapped”, to prevent \texttt{END_FINALLY} from re-raising the exception. (But non-local gotos should still be resumed.)

All of the following opcodes expect arguments. An argument is two bytes, with the more significant byte last.

\textbf{STORE\_NAME}(\textit{namei})

Implements \texttt{name = TOS}. \textit{namei} is the index of \textit{name} in the attribute \texttt{co\_names} of the code object. The compiler tries to use \texttt{STORE\_FAST} or \texttt{STORE\_GLOBAL} if possible.

\textbf{DELETE\_NAME}(\textit{namei})

Implements \texttt{del name}, where \textit{namei} is the index into \texttt{co\_names} attribute of the code object.

\textbf{UNPACK\_SEQUENCE}(\textit{count})

Unpacks TOS into \textit{count} individual values, which are put onto the stack right-to-left.

\textbf{DUP\_TOPX}(\textit{count})

Duplicate \textit{count} items, keeping them in the same order. Due to implementation limits, \textit{count} should be between 1 and 5 inclusive.

\textbf{STORE\_ATTR}(\textit{namei})

Implements \texttt{TOS.name = TOS1}, where \textit{namei} is the index of name in \texttt{co\_names}. 
**DELETE_ATTR**(namei)
Implements `del TOS.name`, using `namei` as index into `co_names`.

**STORE_GLOBAL**(namei)
Works as `STORE_NAME`, but stores the name as a global.

**DELETE_GLOBAL**(namei)
Works as `DELETE_NAME`, but deletes a global name.

**LOAD_CONST**(consti)
Pushes `co_consts[consti]` onto the stack.

**LOAD_NAME**(namei)
Pushes the value associated with `co_names[namei]` onto the stack.

**BUILD_TUPLE**(count)
Creates a tuple consuming `count` items from the stack, and pushes the resulting tuple onto the stack.

**BUILD_LIST**(count)
Works as `BUILD_TUPLE`, but creates a list.

**BUILD_MAP**(count)
Pushes a new dictionary object onto the stack. The dictionary is pre-sized to hold `count` entries.

**LOAD_ATTR**(namei)
Replaces TOS with `getattr(TOS, co_names[namei])`.

**COMPARE_OP**(opname)
Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`. 
**IMPORT_NAME**(namei)
Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the `fromlist` and `level` arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent `STORE_FAST` instruction modifies the namespace.

**IMPORT_FROM**(namei)
Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a `STORE_FAST` instruction.

**JUMP_FORWARD**(delta)
Increments bytecode counter by `delta`.

**JUMP_IF_TRUE**(delta)
If TOS is true, increment the bytecode counter by `delta`. TOS is left on the stack.

**JUMP_IF_FALSE**(delta)
If TOS is false, increment the bytecode counter by `delta`. TOS is not changed.

**JUMP_ABSOLUTE**(target)
Set bytecode counter to `target`.

**FOR_ITER**(delta)
TOS is an `iterator`. Call its `next()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the bytecode counter is incremented by `delta`.

**LOAD_GLOBAL**(namei)
Loads the global named `co_names[namei]` onto the stack.
SETUP_LOOP($delta$)
Pushes a block for a loop onto the block stack. The block spans from the current instruction with a size of $delta$ bytes.

SETUP_EXCEPT($delta$)
Pushes a try block from a try-except clause onto the block stack. $delta$ points to the first except block.

SETUP FINALLY($delta$)
Pushes a try block from a try-except clause onto the block stack. $delta$ points to the finally block.

STORE_MAP()
Store a key and value pair in a dictionary. Pops the key and value while leaving the dictionary on the stack.

LOAD_FAST($var\_num$)
Pushes a reference to the local $co\_varnames[var\_num]$ onto the stack.

STORE_FAST($var\_num$)
Stores TOS into the local $co\_varnames[var\_num]$.

DELETE_FAST($var\_num$)
Deletes local $co\_varnames[var\_num]$.

LOAD CLOSURE($i$)
Pushes a reference to the cell contained in slot $i$ of the cell and free variable storage. The name of the variable is $co\_cellvars[i]$ if $i$ is less than the length of $co\_cellvars$. Otherwise it is $co\_freevars[i - \text{len}(co\_cellvars)]$.

LOAD_DEREF($i$)
Loads the cell contained in slot $i$ of the cell and free variable
stores a reference to the object the cell contains on the stack.

**STORE_DEREF(i)**
Stores TOS into the cell contained in slot i of the cell and free variable storage.

**SET_LINENO(lineno)**
This opcode is obsolete.

**RAISE_VARARGS(argc)**
Raises an exception. argc indicates the number of parameters to the raise statement, ranging from 0 to 3. The handler will find the traceback as TOS2, the parameter as TOS1, and the exception as TOS.

**CALL_FUNCTION(argc)**
Calls a function. The low byte of argc indicates the number of positional parameters, the high byte the number of keyword parameters. On the stack, the opcode finds the keyword parameters first. For each keyword argument, the value is on top of the key. Below the keyword parameters, the positional parameters are on the stack, with the right-most parameter on top. Below the parameters, the function object to call is on the stack.

**MAKE_FUNCTION(argc)**
Pushes a new function object on the stack. TOS is the code associated with the function. The function object is defined to have argc default parameters, which are found below TOS.

**MAKE_CLOSURE(argc)**
Creates a new function object, sets its func_closure slot, and pushes it on the stack. TOS is the code associated with the function, TOS1 the tuple containing cells for the closure’s free
variables. The function also has `argc` default parameters, which are found below the cells.

**BUILD_SLICE**(argc)
Pushes a slice object on the stack. `argc` must be 2 or 3. If it is 2, `slice(TOS1, TOS)` is pushed; if it is 3, `slice(TOS2, TOS1, TOS)` is pushed. See the `slice()` built-in function for more information.

**EXTENDED_ARG**(ext)
Prefixes any opcode which has an argument too big to fit into the default two bytes. `ext` holds two additional bytes which, taken together with the subsequent opcode's argument, comprise a four-byte argument, `ext` being the two most-significant bytes.

**CALL_FUNCTION_VAR**(argc)
Calls a function. `argc` is interpreted as in `CALL_FUNCTION`. The top element on the stack contains the variable argument list, followed by keyword and positional arguments.

**CALL_FUNCTION_KW**(argc)
Calls a function. `argc` is interpreted as in `CALL_FUNCTION`. The top element on the stack contains the keyword arguments dictionary, followed by explicit keyword and positional arguments.

**CALL_FUNCTION_VAR_KW**(argc)
Calls a function. `argc` is interpreted as in `CALL_FUNCTION`. The top element on the stack contains the keyword arguments dictionary, followed by the variable-arguments tuple, followed by explicit keyword and positional arguments.

**HAVE_ARGUMENT**()
This is not really an opcode. It identifies the dividing line between opcodes which don't take arguments `< HAVE_ARGUMENT` and those which do `>= HAVE_ARGUMENT`.
pickletools — Tools for pickle developers.

New in version 2.3.

This module contains various constants relating to the intimate details of the pickle module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the pickle and cPickle implementations; ordinary users of the pickle module probably won’t find the pickletools module relevant.

pickletools.dis(pickle[, out=None, memo=None, indentlevel=4])

Outputs a symbolic disassembly of the pickle to the file-like object out, defaulting to sys.stdout. pickle can be a string or a file-like object. memo can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by MARK opcodes in the stream, are indented by indentlevel spaces.

pickletools.genops(pickle)

Provides an iterator over all of the opcodes in a pickle, returning a sequence of (opcode, arg, pos) triples. opcode is an instance of an OpcodeInfo class; arg is the decoded value, as a Python object, of the opcode's argument; pos is the position at which this opcode is located. pickle can be a string or a file-like object.

pickletools.optimize(picklestring)

Returns a new equivalent pickle string after eliminating unused PUT opcodes. The optimized pickle is shorter, takes less
transmission time, requires less storage space, and unpickles more efficiently.

*New in version 2.6.*
The `distutils` package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

This package is discussed in two separate chapters:

**See also:**

**Distributing Python Modules**

The manual for developers and packagers of Python modules. This describes how to prepare `distutils`-based packages so that they may be easily installed into an existing Python installation.

**Installing Python Modules**

An “administrators” manual which includes information on installing modules into an existing Python installation. You do not need to be a Python programmer to read this manual.
**Python compiler package**

*Deprecated since version 2.6:* The `compiler` package has been removed in Python 3.0.

The Python compiler package is a tool for analyzing Python source code and generating Python bytecode. The compiler contains libraries to generate an abstract syntax tree from Python source code and to generate Python *bytecode* from the tree.

The `compiler` package is a Python source to bytecode translator written in Python. It uses the built-in parser and standard `parser` module to generated a concrete syntax tree. This tree is used to generate an abstract syntax tree (AST) and then Python bytecode.

The full functionality of the package duplicates the builtin compiler provided with the Python interpreter. It is intended to match its behavior almost exactly. Why implement another compiler that does the same thing? The package is useful for a variety of purposes. It can be modified more easily than the builtin compiler. The AST it generates is useful for analyzing Python source code.

This chapter explains how the various components of the `compiler` package work. It blends reference material with a tutorial.
The basic interface

The top-level of the package defines four functions. If you import `compiler`, you will get these functions and a collection of modules contained in the package.

`compiler.parse(buf)`

Returns an abstract syntax tree for the Python source code in `buf`. The function raises `SyntaxError` if there is an error in the source code. The return value is a `compiler.ast.Module` instance that contains the tree.

`compiler.parseFile(path)`

Return an abstract syntax tree for the Python source code in the file specified by `path`. It is equivalent to `parse(open(path).read())`.

`compiler.walk(ast, visitor[, verbose])`

Do a pre-order walk over the abstract syntax tree `ast`. Call the appropriate method on the `visitor` instance for each node encountered.

`compiler.compile(source, filename, mode, flags=None, dont_inherit=None)`

Compile the string `source`, a Python module, statement or expression, into a code object that can be executed by the `exec` statement or `eval()`. This function is a replacement for the built-in `compile()` function.

The `filename` will be used for run-time error messages.

The `mode` must be ‘exec’ to compile a module, ‘single’ to compile a single (interactive) statement, or ‘eval’ to compile an
expression.

The flags and dont_inherit arguments affect future-related statements, but are not supported yet.

compiler.compileFile(source)

Compiles the file source and generates a .pyc file.

The compiler package contains the following modules: ast, consts, future, misc, pyassem, pycodegen, symbols, transformer, and visitor.
Limitations

There are some problems with the error checking of the compiler package. The interpreter detects syntax errors in two distinct phases. One set of errors is detected by the interpreter’s parser, the other set by the compiler. The compiler package relies on the interpreter’s parser, so it get the first phases of error checking for free. It implements the second phase itself, and that implementation is incomplete. For example, the compiler package does not raise an error if a name appears more than once in an argument list: 

```python
def f(x, x):
...
```

A future version of the compiler should fix these problems.
The `compiler.ast` module defines an abstract syntax for Python. In the abstract syntax tree, each node represents a syntactic construct. The root of the tree is `Module` object.

The abstract syntax offers a higher level interface to parsed Python source code. The `parser` module and the compiler written in C for the Python interpreter use a concrete syntax tree. The concrete syntax is tied closely to the grammar description used for the Python parser. Instead of a single node for a construct, there are often several levels of nested nodes that are introduced by Python's precedence rules.

The abstract syntax tree is created by the `compiler.transformer` module. The transformer relies on the builtin Python parser to generate a concrete syntax tree. It generates an abstract syntax tree from the concrete tree.

The `transformer` module was created by Greg Stein and Bill Tutt for an experimental Python-to-C compiler. The current version contains a number of modifications and improvements, but the basic form of the abstract syntax and of the transformer are due to Stein and Tutt.

### AST Nodes

The `compiler.ast` module is generated from a text file that describes each node type and its elements. Each node type is represented as a class that inherits from the abstract base class `compiler.ast.Node` and defines a set of named attributes for child nodes.

```python
class compiler.ast.Node
```

The `Node` instances are created automatically by the parser
generator. The recommended interface for specific Node instances is to use the public attributes to access child nodes. A public attribute may be bound to a single node or to a sequence of nodes, depending on the Node type. For example, the bases attribute of the class node, is bound to a list of base class nodes, and the doc attribute is bound to a single node.

Each Node instance has a lineno attribute which may be None. XXX: Not sure what the rules are for which nodes will have a useful lineno.

All Node objects offer the following methods:

getChildren()

Returns a flattened list of the child nodes and objects in the order they occur. Specifically, the order of the nodes is the order in which they appear in the Python grammar. Not all of the children are Node instances. The names of functions and classes, for example, are plain strings.

getChildNodes()

Returns a flattened list of the child nodes in the order they occur. This method is like getChildren(), except that it only returns those children that are Node instances.

Two examples illustrate the general structure of Node classes. The while statement is defined by the following grammar production:

```
while_stmt: "while" expression ":" suite
            ["else" ":" suite]
```

The While node has three attributes: test, body, and else_. (If the natural name for an attribute is also a Python reserved word, it can’t be used as an attribute name. An underscore is appended to the
word to make it a legal identifier, hence `else_` instead of `else`.)

The `if` statement is more complicated because it can include several tests.

```python
if_stmt: 'if' test ':' suite ('elif' test ':' suite)* ['else' ':' suite]
```

The `If` node only defines two attributes: `tests` and `else_`. The `tests` attribute is a sequence of test expression, consequent body pairs. There is one pair for each `if/elif` clause. The first element of the pair is the test expression. The second elements is a `Stmt` node that contains the code to execute if the test is true.

The `getChildren()` method of `If` returns a flat list of child nodes. If there are three `if/elif` clauses and no `else` clause, then `getChildren()` will return a list of six elements: the first test expression, the first `Stmt`, the second test expression, etc.

The following table lists each of the `Node` subclasses defined in `compiler.ast` and each of the public attributes available on their instances. The values of most of the attributes are themselves `Node` instances or sequences of instances. When the value is something other than an instance, the type is noted in the comment. The attributes are listed in the order in which they are returned by `getChildren()` and `getChildNodes()`.

Assignment nodes

There is a collection of nodes used to represent assignments. Each assignment statement in the source code becomes a single Assign node in the AST. The nodes attribute is a list that contains a node for each assignment target. This is necessary because assignment can be chained, e.g. `a = b = 2`. Each Node in the list will be one of the following classes: AssAttr, AssList, AssName, or AssTuple.

Each target assignment node will describe the kind of object being assigned to: AssName for a simple name, e.g. `a = 1`. AssAttr for an attribute assigned, e.g. `a.x = 1`. AssList and AssTuple for list and tuple expansion respectively, e.g. `a, b, c = a_tuple`.

The target assignment nodes also have a flags attribute that indicates whether the node is being used for assignment or in a delete statement. The AssName is also used to represent a delete
When an expression contains several attribute references, an assignment or delete statement will contain only one AssAttr node – for the final attribute reference. The other attribute references will be represented as Getattr nodes in the expr attribute of the AssAttr instance.

Examples

This section shows several simple examples of ASTs for Python source code. The examples demonstrate how to use the parse() function, what the repr of an AST looks like, and how to access attributes of an AST node.

The first module defines a single function. Assume it is stored in /tmp/doublelib.py.

```python
"""This is an example module.

This is the docstring.
"""

def double(x):
    "Return twice the argument"
    return x * 2
```

In the interactive interpreter session below, I have reformatted the long AST reprs for readability. The AST reprs use unqualified class names. If you want to create an instance from a repr, you must import the class names from the compiler.ast module.

```python
>>> import compiler
>>> mod = compiler.parseFile("/tmp/doublelib.py")
>>> mod
Module('This is an example module.

This is the docstring.
',
Stmt([Function(None, 'double', ['x'], [], 0, 'Return twice the argument',
    return x * 2,],],)
```
>>> from compiler.ast import *
>>> Module('This is an example module.

This is the docstring.

... Stmt([Function(None, 'double', ['x'], [], 0, 'Return twice the argument', Stmt([Return(Mul((Name('x'), Const(2))))])])
>>> mod.doc
'This is an example module.

This is the docstring.'
>>> for node in mod.node.nodes:
...     print node
...
Function(None, 'double', ['x'], [], 0, 'Return twice the argument'
     Stmt([Return(Mul((Name('x'), Const(2))))])
>>> func = mod.node.nodes[0]
>>> func.code
Stmt([Return(Mul((Name('x'), Const(2))))])
Using Visitors to Walk ASTs

The visitor pattern is ... The compiler package uses a variant on the visitor pattern that takes advantage of Python’s introspection features to eliminate the need for much of the visitor’s infrastructure.

The classes being visited do not need to be programmed to accept visitors. The visitor need only define visit methods for classes it is specifically interested in; a default visit method can handle the rest.

XXX The magic visit() method for visitors.

```
compiler.visitor.walk(tree, visitor[, verbose])
```

class compiler.visitor.ASTVisitor

The ASTVisitor is responsible for walking over the tree in the correct order. A walk begins with a call to preorder(). For each node, it checks the visitor argument to preorder() for a method named ‘visitNodeType,’ where NodeType is the name of the node's class, e.g. for a While node a visitWhile() would be called. If the method exists, it is called with the node as its first argument.

The visitor method for a particular node type can control how child nodes are visited during the walk. The ASTVisitor modifies the visitor argument by adding a visit method to the visitor; this method can be used to visit a particular child node. If no visitor is found for a particular node type, the default() method is called.

ASTVisitor objects have the following methods:

XXX describe extra arguments
default\((node[, \ldots])\)

dispatch\((node[, \ldots])\)

preorder\((tree, visitor)\)
Bytecode Generation

The code generator is a visitor that emits bytecodes. Each visit method can call the `emit()` method to emit a new bytecode. The basic code generator is specialized for modules, classes, and functions. An assembler converts that emitted instructions to the low-level bytecode format. It handles things like generation of constant lists of code objects and calculation of jump offsets.
Miscellaneous Services

The modules described in this chapter provide miscellaneous services that are available in all Python versions. Here’s an overview:

- **formatter** — Generic output formatting
  - The Formatter Interface
  - Formatter Implementations
  - The Writer Interface
  - Writer Implementations
This module supports two interface definitions, each with multiple implementations. The *formatter* interface is used by the *HTMLParser* class of the *httplib* module, and the *writer* interface is required by the formatter interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored; writers need not be able to handle relative changes nor any sort of “change back” operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.
Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level:

```
formatter.AS_IS
```

Value which can be used in the font specification passed to the `push_font()` method described below, or as the new value to any other `push_property()` method. Pushing the `AS_IS` value allows the corresponding `pop_property()` method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects:

```
formatter.writer
```

The writer instance with which the formatter interacts.

```
formatter.end_paragraph(blanklines)
```

Close any open paragraphs and insert at least `blanklines` before the next paragraph.

```
formatter.add_line_break()
```

Add a hard line break if one does not already exist. This does not break the logical paragraph.

```
formatter.add_hor_rule(*args, **kw)
```

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the writer’s `send_line_break()` method.
formatter.**add_flowing_data**(data)

Provide data which should be formatted with collapsed whitespace. Whitespace from preceding and successive calls to **add_flowing_data()** is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

formatter.**add_literal_data**(data)

Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of *data*.

formatter.**add_label_data**(format, counter)

Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the *format* value is a string, it is interpreted as a format specification for *counter*, which should be an integer. The result of this formatting becomes the value of the label; if *format* is not a string it is used as the label value directly. The label value is passed as the only argument to the writer's **send_label_data()** method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character **'1'** represents the counter value formatter as an Arabic number, the characters **'A'** and **'a'** represent alphabetic representations of the counter value in upper and lower case, respectively, and **'I'** and **'i'** represent the counter value in Roman numerals, in upper and lower case.
Note that the alphabetic and roman transforms require that the counter value be greater than zero.

**formatter.flush_SOFTSPACE()**

Send any pending whitespace buffered from a previous call to **add_flowin_data()** to the associated writer object. This should be called before any direct manipulation of the writer object.

**formatter.push_alignment(align)**

Push a new alignment setting onto the alignment stack. This may be **AS_IS** if no change is desired. If the alignment value is changed from the previous setting, the writer’s **new_alignment()** method is called with the **align** value.

**formatter.pop_alignment()**

Restore the previous alignment.

**formatter.push_font((size, italic, bold, teletype))**

Change some or all font properties of the writer object. Properties which are not set to **AS_IS** are set to the values passed in while others are maintained at their current settings. The writer’s **new_font()** method is called with the fully resolved font specification.

**formatter.pop_font()**

Restore the previous font.

**formatter.push_margin(margin)**

Increase the number of left margin indentations by one, associating the logical tag **margin** with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than **AS_IS** are not sufficient to change the margin.
formatter. **pop_margin()**
    
    Restore the previous margin.

formatter. **push_style(*styles)**

    Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including **AS_IS** values, is passed to the writer’s **new_styles()** method.

formatter. **pop_style([n=1])**

    Pop the last \(n\) style specifications passed to **push_style()**. A tuple representing the revised stack, including **AS_IS** values, is passed to the writer’s **new_styles()** method.

formatter. **set_spacing(spacing)**

    Set the spacing style for the writer.

formatter. **assert_line_data([flag=1])**

    Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional \(flag\) argument can be set to false if the writer manipulations produced a hard line break at the end of the output.
Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

```python
class formatter.NullFormatter([writer])
A formatter which does nothing. If writer is omitted, a NullWriter instance is created. No methods of the writer are called by NullFormatter instances. Implementations should inherit from this class if implementing a writer interface but don’t need to inherit any implementation.

class formatter.AbstractFormatter(writer)
The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.
```
The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the AbstractFormatter class as a formatter, the writer must typically be provided by the application.

writer.flush()
Flush any buffered output or device control events.

writer.new_alignment(align)
Set the alignment style. The align value can be any object, but by convention is a string or None, where None indicates that the writer’s “preferred” alignment should be used. Conventional align values are 'left', 'center', 'right', and 'justify'.

writer.new_font(font)
Set the font style. The value of font will be None, indicating that the device’s default font should be used, or a tuple of the form (size, italic, bold, teletype). Size will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The italic, bold, and teletype values are Boolean values specifying which of those font attributes should be used.

writer.new_margin(margin, level)
Set the margin level to the integer level and the logical tag to margin. Interpretation of the logical tag is at the writer’s discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of level.

writer.new_spacing(spacing)
Set the spacing style to *spacing*.

**writer.new_styles(styles)**
Set additional styles. The *styles* value is a tuple of arbitrary values; the value *AS_IS* should be ignored. The *styles* tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

**writer.send_line_break()**
Break the current line.

**writer.send_paragraph(blankline)**
Produce a paragraph separation of at least *blankline* blank lines, or the equivalent. The *blankline* value will be an integer. Note that the implementation will receive a call to **send_line_break()** before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

**writer.send_hor_rule(*args, **kw)**
Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via **send_line_break()**.

**writer.send_flow_data(data)**
Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.

**writer.sendLiteral_data(data)**
Output character data which has already been formatted for
display. Generally, this should be interpreted to mean that line breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the send_formatted_data() interface.

**writer.send_label_data(data)**

Set *data* to the left of the current left margin, if possible. The value of *data* is not restricted; treatment of non-string values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.
Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the `NullWriter` class.

```python
class formatter.NullWriter:
    A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.

class formatter.AbstractWriter:
    A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.

class formatter.DumbWriter([file[, maxcol=72]])
    Simple writer class which writes output on the file object passed in as `file` or, if `file` is omitted, on standard output. The output is simply word-wrapped to the number of columns specified by `maxcol`. This class is suitable for reflowing a sequence of paragraphs.
```
This chapter describes modules that are only available on MS Windows platforms.

- **msilib** — Read and write Microsoft Installer files
  - Database Objects
  - View Objects
  - Summary Information Objects
  - Record Objects
  - Errors
  - CAB Objects
  - Directory Objects
  - Features
  - GUI classes
  - Precomputed tables

- **msvcrt** – Useful routines from the MS VC++ runtime
  - File Operations
  - Console I/O
  - Other Functions

- **_winreg** – Windows registry access
  - Registry Handle Objects

- **winsound** — Sound-playing interface for Windows
msilib — Read and write Microsoft Installer files

Platforms: Windows

New in version 2.5.

The msilib supports the creation of Microsoft Installer (.msi) files. Because these files often contain an embedded “cabinet” file (.cab), it also exposes an API to create CAB files. Support for reading .cab files is currently not implemented; read support for the .msi database is possible.

This package aims to provide complete access to all tables in an .msi file, therefore, it is a fairly low-level API. Two primary applications of this package are the distutils command `bdist_msi`, and the creation of Python installer package itself (although that currently uses a different version of msilib).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

**msilib.FCICreate(cabname, files)**

Create a new CAB file named cabname. files must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are
currently not exposed.

**msilib.**`UuidCreate()`

Return the string representation of a new unique identifier. This wraps the Windows API functions `UuidCreate` and `UuidToString`.

**msilib.**`OpenDatabase(path, persist)`

Return a new database object by calling `MsiOpenDatabase`. _path_ is the file name of the MSI file; _persist_ can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

**msilib.**`CreateRecord(count)`

Return a new record object by calling `MSICreateRecord`. _count_ is the number of fields of the record.

**msilib.**`init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)`

Create and return a new database _name_, initialize it with _schema_, and set the properties _ProductName_, _ProductCode_, _ProductVersion_, and _Manufacturer_.

_schema_ must be a module object containing _tables_ and _Validation_records_ attributes; typically, `msilib.schema` should be used.

The database will contain just the schema and the validation records when this function returns.

**msilib.**`add_data(database, table, records)`

Add all _records_ to the table named _table_ in _database_.

The table argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

records should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, None can be passed.

Field values can be int or long numbers, strings, or instances of the Binary class.

class msilib.Binary(filename)

    Represents entries in the Binary table; inserting such an object using add_data() reads the file named filename into the table.

msilib.add_tables(database, module)

    Add all table content from module to database. module must contain an attribute tables listing all tables for which content should be added, and one attribute per table that has the actual content.

    This is typically used to install the sequence tables.

msilib.add_stream(database, name, path)

    Add the file path into the _Stream table of database, with the stream name name.

msilib.gen_uuid()

    Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).

See also: FCICreateFile UuidCreate UuidToString
Database Objects

Database.**OpenView**(*sql*)

Return a view object, by calling **MSIDatabaseOpenView**. *sql* is the SQL statement to execute.

Database.**Commit**()

Commit the changes pending in the current transaction, by calling **MSIDatabaseCommit**.

Database.**GetSummaryInformation**(*count*)

Return a new summary information object, by calling **MsiGetSummaryInformation**. *count* is the maximum number of updated values.

**See also:** MSIDatabaseOpenView MSIDatabaseCommit MSIGetSummaryInformation
View Objects

**View.Execute(params)**
Execute the SQL query of the view, through `MSIViewExecute`. If `params` is not `None`, it is a record describing actual values of the parameter tokens in the query.

**View.GetColumnInfo(kind)**
Return a record describing the columns of the view, through calling `MsiViewGetColumnInfo`. `kind` can be either `MSICOLINFO_NAMES` or `MSICOLINFO_TYPES`.

**View.Fetch()**
Return a result record of the query, through calling `MsiViewFetch`.

**View.Modify(kind, data)**
Modify the view, by calling `MsiViewModify`. `kind` can be one of `MSIMODIFY_SEEK`, `MSIMODIFY_REFRESH`, `MSIMODIFY_INSERT`, `MSIMODIFY_UPDATE`, `MSIMODIFY_ASSIGN`, `MSIMODIFY_REPLACE`, `MSIMODIFY_MERGE`, `MSIMODIFY_INSERT_TEMPORARY`, `MSIMODIFY_VALIDATE`, `MSIMODIFY_VALIDATE_NEW`, `MSIMODIFY_VALIDATE_FIELD`, or `MSIMODIFY_VALIDATE_DELETE`.

`data` must be a record describing the new data.

**View.Close()**
Close the view, through `MsiViewClose`.

**See also:** `MsiViewExecute` `MSIViewGetColumnInfo` `MsiViewFetch` `MsiViewModify` `MsiViewClose`
Summary Information Objects

**SummaryInformation.GetProperty(field)**

Return a property of the summary, through MsiSummaryInfoGetProperty. *field* is the name of the property, and can be one of the constants PID_CODEPAGE, PID_TITLE, PID_SUBJECT, PID_AUTHOR, PID_KEYWORDS, PID_COMMENTS, PID_TEMPLATE, PID_LASTAUTHOR, PID_REVNUMBER, PID_LASTPRINTED, PID_CREATE_DTM, PID_LASTSAVE_DTM, PID_PAGECOUNT, PID_WORDCOUNT, PID_CHARCOUNT, PID_APPNAME, or PID_SECURITY.

**SummaryInformation.GetPropertyCount()**

Return the number of summary properties, through MsiSummaryInfoGetPropertyCount.

**SummaryInformation.SetProperty(field, value)**

Set a property through MsiSummaryInfoSetProperty. *field* can have the same values as in GetProperty(), *value* is the new value of the property. Possible value types are integer and string.

**SummaryInformation.Persist()**

Write the modified properties to the summary information stream, using MsiSummaryInfoPersist.

See also: [MsiSummaryInfoGetProperty](#), MsiSummaryInfoGetPropertyCount, MsiSummaryInfoSetProperty, MsiSummaryInfoPersist
Record Objects

Record. **GetFieldCount()**

Return the number of fields of the record, through `MsiRecordGetFieldCount`.

Record. **GetInteger(field)**

Return the value of `field` as an integer where possible. `field` must be an integer.

Record. **GetString(field)**

Return the value of `field` as a string where possible. `field` must be an integer.

Record. **SetString(field, value)**

Set `field` to `value` through `MsiRecordSetString`. `field` must be an integer; `value` a string.

Record. **SetStream(field, value)**

Set `field` to the contents of the file named `value`, through `MsiRecordSetStream`. `field` must be an integer; `value` a string.

Record. **SetInteger(field, value)**

Set `field` to `value` through `MsiRecordSetInteger`. Both `field` and `value` must be an integer.

Record. **ClearData()**

Set all fields of the record to 0, through `MsiRecordClearData`.

**See also:** `MsiRecordGetFieldCount` `MsiRecordSetString` `MsiRecordSetStream` `MsiRecordSetInteger` `MsiRecordClear`
Errors

All wrappers around MSI functions raise `MsiError`; the string inside the exception will contain more detail.
CAB Objects

class msilib.CAB(name)

The class \texttt{CAB} represents a CAB file. During MSI construction, files will be added simultaneously to the \texttt{Files} table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

\textit{name} is the name of the CAB file in the MSI file.

\textbf{append}(full, file, logical)

Add the file with the pathname \textit{full} to the CAB file, under the name \textit{logical}. If there is already a file named \textit{logical}, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

\textbf{commit}(database)

Generate a CAB file, add it as a stream to the MSI file, put it into the \texttt{Media} table, and remove the generated file from the disk.
```python
class msilib.Directory(database, cab, basedir, physical, logical, 
default, component[, componentflags])
```

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through `start_component()`, or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be `None`), the path to the physical directory, and a logical directory name. `default` specifies the DefaultDir slot in the directory table. `componentflags` specifies the default flags that new components get.

```python
start_component([component[, feature[, flags[, keyfile[, 
uuid]]]]])
```

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no `feature` is given, the current feature is used. If no `flags` are given, the directory's default flags are used. If no `keyfile` is given, the KeyPath is left null in the Component table.

```python
add_file(file[, src[, version[, language]]])
```

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the `src` file is specified, it is interpreted relative to the current directory. Optionally, a `version` and a `language` can be specified for the entry in the File table.

```python
glob(pattern[, exclude])
```
Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the *exclude* list.

```python
remove_pyc()
```
Remove `.pyc/.pyo files on uninstall.

**See also:** Directory Table File Table Component Table FeatureComponents Table
class msilib.**Feature**(*database*, *id*, *title*, *desc*, *display*, *, level=1*, *
*parent*, *
directory*, *
*attributes=0*)

Add a new record to the **Feature** table, using the values *id*,
*parent.id*, *title*, *desc*, *display*, *level*, *directory*, and *attributes*. The
resulting feature object can be passed to the **start_component()**
method of **Directory**.

**set_current()**

Make this feature the current feature of **msilib**. New
components are automatically added to the default feature,
unless a feature is explicitly specified.

**See also:**  Feature Table
GUI classes

msilib provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use bdist_msi to create MSI files with a user-interface for installing Python packages.

class msilib.Control(dlg, name)

Base class of the dialog controls. dlg is the dialog object the control belongs to, and name is the control's name.

event(event, argument[, condition=1[, ordering]])

Make an entry into the ControlEvent table for this control.

mapping(event, attribute)

Make an entry into the EventMapping table for this control.

condition(action, condition)

Make an entry into the ControlCondition table for this control.

class msilib.RadioButtonGroup(dlg, name, property)

Create a radio button control named name. property is the installer property that gets set when a radio button is selected.

add(name, x, y, width, height, text[, value])

Add a radio button named name to the group, at the coordinates x, y, width, height, and with the label text. If value is omitted, it defaults to name.

class msilib.Dialog(db, name, x, y, w, h, attr, title, first, default, cancel)

Return a new Dialog object. An entry in the dialog table is made, with the specified coordinates, dialog attributes, title, name of the
first, default, and cancel controls.

**control**(name, type, x, y, width, height, attributes, property, text, control_next, help)

Return a new **Control** object. An entry in the **Control** table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

**text**(name, x, y, width, height, attributes, text)

Add and return a **Text** control.

**bitmap**(name, x, y, width, height, text)

Add and return a **Bitmap** control.

**line**(name, x, y, width, height)

Add and return a **Line** control.

**pushbutton**(name, x, y, width, height, attributes, text, next_control)

Add and return a **PushButton** control.

**radiogroup**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a **RadioButtonGroup** control.

**checkbox**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a **CheckBox** control.

See also: Dialog Table Control Table Control Types ControlCondition Table ControlEvent Table EventMapping Table RadioButton Table
Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

`msilib.schema`

This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `_Validation_records` providing the data for MSI validation.

`msilib.sequence`

This module contains table contents for the standard sequence tables: `AdminExecuteSequence`, `AdminUISequence`, `AdvtExecuteSequence`, `InstallExecuteSequence`, and `InstallUISequence`.

`msilib.text`

This module contains definitions for the UIText and ActionText tables, for the standard installer actions.
These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used wherever possible.
File Operations

`msvcrt.locking(fd, mode, nbytes)`
Lock part of a file based on file descriptor `fd` from the C runtime. Raises `IOError` on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

`msvcrt.LK_LOCK`
`msvcrt.LK_RLCK`
Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `IOError` is raised.

`msvcrt.LK_NBLCK`
`msvcrt.LK_NBRLCK`
Locks the specified bytes. If the bytes cannot be locked, `IOError` is raised.

`msvcrt.LK_UNLCK`
Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`
Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_osfhandle(handle, flags)`
Create a C runtime file descriptor from the file handle `handle`. The
*flags* parameter should be a bitwise OR of `os.O_APPEND`, `os.O_RDONLY`, and `os.O_TEXT`. The returned file descriptor may be used as a parameter to `os.fdopen()` to create a file object.

**msvcrt. get_osfhandle(fd)**

Return the file handle for the file descriptor *fd*. Raises *IOError* if *fd* is not recognized.
msvcrt. **kbhit()**

Return true if a keypress is waiting to be read.

msvcrt. **getch()**

Read a keypress and return the resulting character. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for Enter to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The Control-C keypress cannot be read with this function.

msvcrt. **getwch()**

Wide char variant of **getch()**, returning a Unicode value.

*New in version 2.6.*

msvcrt. **getche()**

Similar to **getch()**, but the keypress will be echoed if it represents a printable character.

msvcrt. **getwche()**

Wide char variant of **getche()**, returning a Unicode value.

*New in version 2.6.*

msvcrt. **putch(char)**

Print the character `char` to the console without buffering.

msvcrt. **putwch(unicode_char)**

Wide char variant of **putch()**, accepting a Unicode value.
New in version 2.6.

**msvcruntime.ungetch(char)**
Cause the character *char* to be “pushed back” into the console buffer; it will be the next character read by `getch()` or `getche()`.

**msvcruntime.ungetwch(unicode_char)**
Wide char variant of `ungetch()`, accepting a Unicode value.

New in version 2.6.
Other Functions

```python
msvcrt.heapmin()
```

Force the `malloc` heap to clean itself up and return unused blocks to the operating system. This only works on Windows NT. On failure, this raises `IOError`.
_winreg – Windows registry access

Platforms: Windows

Note: The _winreg module has been renamed to winreg in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

New in version 2.0.

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a handle object is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

This module exposes a very low-level interface to the Windows registry; it is expected that in the future a new winreg module will be created offering a higher-level interface to the registry API.

This module offers the following functions:

_winreg.CloseKey(hkey)
    Closes a previously opened registry key. The hkey argument specifies a previously opened key.

    Note that if hkey is not closed using this method (or via handle.Close()), it is closed when the hkey object is destroyed by Python.

_winreg.ConnectRegistry(computer_name, key)
    Establishes a connection to a predefined registry handle on another computer, and returns a handle object

    computer_name is the name of the remote computer, of the form
r"\\computername". If None, the local computer is used.

key is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an EnvironmentError exception is raised.

_winreg.CreateKey(key, sub_key)

Creates or opens the specified key, returning a handle object

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the key this method opens or creates.

If key is one of the predefined keys, sub_key may be None. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an EnvironmentError exception is raised.

_winreg.DeleteKey(key, sub_key)

Deletes the specified key.

key is an already open key, or any one of the predefined HKEY_* constants.

sub_key is a string that must be a subkey of the key identified by the key parameter. This value must not be None, and the key may not have subkeys.

This method can not delete keys with subkeys.
If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `EnvironmentError` exception is raised.

```python
_winreg.DeleteValue(key, value)
```
Removes a named value from a registry key.

`key` is an already open key, or one of the predefined `HKEY_` constants.

`value` is a string that identifies the value to remove.

```python
_winreg.EnumKey(key, index)
```
Enumerates subkeys of an open registry key, returning a string.

`key` is an already open key, or any one of the predefined `HKEY_` constants.

`index` is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an `EnvironmentError` exception is raised, indicating no more values are available.

```python
_winreg.EnumValue(key, index)
```
Enumerates values of an open registry key, returning a tuple.

`key` is an already open key, or any one of the predefined `HKEY_` constants.

`index` is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an `EnvironmentError` exception is raised, indicating no more values.
The result is a tuple of 3 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A string that identifies the value name</td>
</tr>
<tr>
<td>1</td>
<td>An object that holds the value data, and whose type depends on the underlying registry type</td>
</tr>
<tr>
<td>2</td>
<td>An integer that identifies the type of the value data</td>
</tr>
</tbody>
</table>

_winreg.**ExpandEnvironmentStrings**(unicode)
Expands environment strings %NAME% in unicode string like const:REG_EXPAND_SZ:

```python
>>> ExpandEnvironmentStrings(u"%windir%")
u"C:\\Windows"
```

*New in version 2.6.*

_winreg.**FlushKey**(key)
Writes all the attributes of a key to the registry.

*key* is an already open key, or one of the predefined HKEY_* constants.

It is not necessary to call **FlushKey()** to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike **CloseKey()**, the **FlushKey()** method returns only when all the data has been written to the registry. An application should only call **FlushKey()** if it requires absolute certainty that registry changes are on disk.

**Note**: If you don’t know whether a **FlushKey()** call is required, it probably isn’t.
_winreg. **LoadKey**(key, sub_key, file_name)

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

*key* is an already open key, or any of the predefined **HKEY_* constants.

*sub_key* is a string that identifies the sub_key to load.

*file_name* is the name of the file to load registry data from. This file must have been created with the **SaveKey()** function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to LoadKey() fails if the calling process does not have the **SE_RESTORE_PRIVILEGE** privilege. Note that privileges are different than permissions - see the Win32 documentation for more details.

If *key* is a handle returned by **ConnectRegistry()**, then the path specified in *fileName* is relative to the remote computer.

The Win32 documentation implies *key* must be in the **HKEY_USER** or **HKEY_LOCAL_MACHINE** tree. This may or may not be true.

_**winreg. OpenKey**(key, sub_key[, res=0][, sam=KEY_READ])

Opens the specified key, returning a *handle object*

*key* is an already open key, or any one of the predefined **HKEY_* constants.

*sub_key* is a string that identifies the sub_key to open.

*res* is a reserved integer, and must be zero. The default is zero.
sam is an integer that specifies an access mask that describes the desired security access for the key. Default is KEY_READ

The result is a new handle to the specified key.

If the function fails, EnvironmentError is raised.

_winreg. OpenKeyEx()

The functionality of OpenKeyEx() is provided via OpenKey(), by the use of default arguments.

_winreg. QueryInfoKey(key)

Returns information about a key, as a tuple.

key is an already open key, or one of the predefined HKEY_* constants.

The result is a tuple of 3 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>An integer giving the number of sub keys this key has.</td>
</tr>
<tr>
<td>1</td>
<td>An integer giving the number of values this key has.</td>
</tr>
<tr>
<td>2</td>
<td>A long integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1600.</td>
</tr>
</tbody>
</table>

_winreg. QueryValue(key, sub_key)

Retrieves the unnamed value for a key, as a string

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that holds the name of the subkey with which the value is associated. If this parameter is None or empty, the function retrieves the value set by the SetValue() method for the key identified by key.
Values in the registry have name, type, and data components. This method retrieves the data for a key’s first value that has a NULL name. But the underlying API call doesn’t return the type, Lame Lame Lame, DO NOT USE THIS!!

\_\_winreg. QueryValueEx(key, value\_name)

Retrieves the type and data for a specified value name associated with an open registry key.

*key* is an already open key, or one of the predefined HKEY\_* constants.

*value\_name* is a string indicating the value to query.

The result is a tuple of 2 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The value of the registry item.</td>
</tr>
<tr>
<td>1</td>
<td>An integer giving the registry type for this value.</td>
</tr>
</tbody>
</table>

\_\_winreg. SaveKey(key, file\_name)

Saves the specified key, and all its subkeys to the specified file.

*key* is an already open key, or one of the predefined HKEY\_* constants.

*file\_name* is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the LoadKey(), ReplaceKey() or RestoreKey() methods.

If *key* represents a key on a remote computer, the path described by *file\_name* is relative to the remote computer. The caller of this method must possess the SeBackupPrivilege security privilege.
Note that privileges are different than permissions - see the Win32 documentation for more details.

This function passes NULL for security_attributes to the API.

_winreg.**SetValue**(key, sub_key, type, value)

Associates a value with a specified key.

**key** is an already open key, or one of the predefined **HKEY_*** constants.

**sub_key** is a string that names the subkey with which the value is associated.

**type** is an integer that specifies the type of the data. Currently this must be **REG_SZ**, meaning only strings are supported. Use the **SetValueEx()** function for support for other data types.

**value** is a string that specifies the new value.

If the key specified by the **sub_key** parameter does not exist, the **SetValue** function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the **key** parameter must have been opened with **KEY_SET_VALUE** access.

_winreg.**SetValueEx**(key, value_name, reserved, type, value)

Stores data in the value field of an open registry key.

**key** is an already open key, or one of the predefined **HKEY_*** constants.
value_name is a string that names the subkey with which the value is associated.

type is an integer that specifies the type of the data. This should be one of the following constants defined in this module:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG_BINARY</td>
<td>Binary data in any form.</td>
</tr>
<tr>
<td>REG_DWORD</td>
<td>A 32-bit number.</td>
</tr>
<tr>
<td>REG_DWORD_LITTLE_ENDIAN</td>
<td>A 32-bit number in little-endian format.</td>
</tr>
<tr>
<td>REG_DWORD_BIG_ENDIAN</td>
<td>A 32-bit number in big-endian format.</td>
</tr>
<tr>
<td>REG_EXPAND_SZ</td>
<td>Null-terminated string containing references to environment variables (%PATH%).</td>
</tr>
<tr>
<td>REG_LINK</td>
<td>A Unicode symbolic link.</td>
</tr>
<tr>
<td>REG_MULTI_SZ</td>
<td>A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)</td>
</tr>
<tr>
<td>REG_NONE</td>
<td>No defined value type.</td>
</tr>
<tr>
<td>REG_RESOURCE_LIST</td>
<td>A device-driver resource list.</td>
</tr>
<tr>
<td>REG_SZ</td>
<td>A null-terminated string.</td>
</tr>
</tbody>
</table>

reserved can be anything - zero is always passed to the API.

value is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with KEY_SET_VALUE access.

To open the key, use the CreateKeyEx() or OpenKey() methods.

Value lengths are limited by available memory. Long values
(more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.
Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the close() method on the object, or the CloseKey() function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for __nonzero__() - thus

```python
if handle:
    print "Yes"
```

will print Yes if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the builtin int() function), in which case the underlying Windows handle value is returned. You can also use the Detach() method to return the integer handle, and also disconnect the Windows handle from the handle object.

PyHKEY.close()

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.
**PyHKEY.** *Detach()*

Detaches the Windows handle from the handle object.

The result is an integer (or long on 64 bit Windows) that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

**PyHKEY.** *__enter__()*

**PyHKEY.** *__exit__(*exc_info)*

The HKEY object implements *__enter__() and __exit__() and thus supports the context protocol for the *with* statement:

```python
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    # ... work with key ...
```

will automatically close *key* when control leaves the *with* block.

*New in version 2.6.*
**winsound — Sound-playing interface for Windows**

*Platforms:* Windows

*New in version 1.5.2.*

The *winsound* module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

*winsound.* `Beep(frequency, duration)`

Beep the PC’s speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

*New in version 1.6.*

*winsound.* `PlaySound(sound, flags)`

Call the underlying `PlaySound` function from the Platform API. The *sound* parameter may be a filename, audio data as a string, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the system indicates an error, `RuntimeError` is raised.

*winsound.* `MessageBeep([type=MB_OK])`

Call the underlying `MessageBeep` function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are `-1, MB_ICONASTERISK, MB_ICONEXCLAMATION, MB_ICONHAND`,...
MB_ICONQUESTION, and MB_OK, all described below. The value -1 produces a “simple beep”; this is the final fallback if a sound cannot be played otherwise.

*New in version 2.3.*

**winsound.SND_FILENAME**

The *sound* parameter is the name of a WAV file. Do not use with **SND_ALIAS**.

**winsound.SND_ALIAS**

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless **SND_NODEFAULT** is also specified. If no default sound is registered, raise **RuntimeError**. Do not use with **SND_FILENAME**.

All Win32 systems support at least the following; most systems support many more:

<table>
<thead>
<tr>
<th>PlaySound() <em>name</em></th>
<th>Corresponding Control Panel Sound name</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SystemAsterisk'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'SystemExclamation'</td>
<td>Exclamation</td>
</tr>
<tr>
<td>'SystemExit'</td>
<td>Exit Windows</td>
</tr>
<tr>
<td>'SystemHand'</td>
<td>Critical Stop</td>
</tr>
<tr>
<td>'SystemQuestion'</td>
<td>Question</td>
</tr>
</tbody>
</table>

For example:

```python
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered
```
winsound.snd_loop

Play the sound repeatedly. The `snd_async` flag must also be used to avoid blocking. Cannot be used with `snd_memory`.

winsound.snd_memory

The `sound` parameter to `PlaySound()` is a memory image of a WAV file, as a string.

Note: This module does not support playing from a memory image asynchronously, so a combination of this flag and `snd_async` will raise `RuntimeError`.

winsound.snd_purge

Stop playing all instances of the specified sound.

winsound.snd_async

Return immediately, allowing sounds to play asynchronously.

winsound.snd_nodefault

If the specified sound cannot be found, do not play the system default sound.

winsound.snd_nostop

Do not interrupt sounds currently playing.

winsound.snd_nowait

Return immediately if the sound driver is busy.

winsound.mb_iconasterisk

Play the SystemDefault sound.

winsound.mb_iconexclamation
Play the SystemExclamation sound.

winsound.MB_ICONHAND

Play the SystemHand sound.

winsound.MB_ICONQUESTION

Play the SystemQuestion sound.

winsound.MB_OK

Play the SystemDefault sound.
Unix Specific Services

The modules described in this chapter provide interfaces to features that are unique to the Unix operating system, or in some cases to some or many variants of it. Here's an overview:

- **posix** — The most common POSIX system calls
  - Large File Support
  - Notable Module Contents

- **pwd** — The password database

- **spwd** — The shadow password database

- **grp** — The group database

- **crypt** — Function to check Unix passwords

- **d1** — Call C functions in shared objects
  - DI Objects

- **termios** — POSIX style tty control
  - Example

- **tty** — Terminal control functions

- **pty** — Pseudo-terminal utilities

- **fcntl** — The *fcntl* and *ioctl* system calls

- **pipes** — Interface to shell pipelines
  - Template Objects

- **posixfile** — File-like objects with locking support
- **resource** — Resource usage information
  - Resource Limits
  - Resource Usage

- **nis** — Interface to Sun’s NIS (Yellow Pages)

- **syslog** — Unix syslog library routines

- **commands** — Utilities for running commands
posix — The most common POSIX system calls

Platforms: Unix

This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

Do not import this module directly. Instead, import the module `os`, which provides a portable version of this interface. On Unix, the `os` module provides a superset of the `posix` interface. On non-Unix operating systems the `posix` module is not available, but a subset is always available through the `os` interface. Once `os` is imported, there is no performance penalty in using it instead of `posix`. In addition, `os` provides some additional functionality, such as automatically calling `putenv()` when an entry in `os.environ` is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise `OSError`.
Large File Support

Several operating systems (including AIX, HP-UX, Irix and Solaris) provide support for files that are larger than 2 GB from a C programming model where `int` and `long` are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as large files.

Large file support is enabled in Python when the size of an `off_t` is larger than a `long` and the `long long` type is available and is at least as large as an `off_t`. Python longs are then used to represent file sizes, offsets and other values that can exceed the range of a Python int. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, it is enabled by default with recent versions of Irix, but with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \
./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OPT="-g -O2 $CFLAGS" \
./configure
```
In addition to many functions described in the `os` module documentation, `posix` defines the following data item:

`posix.environ`  
A dictionary representing the string environment at the time the interpreter was started. For example, `environ['HOME']` is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifying this dictionary does not affect the string environment passed on by `execv()`, `popen()` or `system()`; if you need to change the environment, pass `environ` to `execve()` or add variable assignments and export statements to the command string for `system()` or `popen()`.

**Note:** The `os` module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating `os.environ` will render this dictionary obsolete. Use of the `os` module version of this is recommended over direct access to the `posix` module.
**pwd — The password database**

*Platforms:* Unix

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>pw_name</code></td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td><code>pw_passwd</code></td>
<td>Optional encrypted password</td>
</tr>
<tr>
<td>2</td>
<td><code>pw_uid</code></td>
<td>Numerical user ID</td>
</tr>
<tr>
<td>3</td>
<td><code>pw_gid</code></td>
<td>Numerical group ID</td>
</tr>
<tr>
<td>4</td>
<td><code>pw_gecos</code></td>
<td>User name or comment field</td>
</tr>
<tr>
<td>5</td>
<td><code>pw_dir</code></td>
<td>User home directory</td>
</tr>
<tr>
<td>6</td>
<td><code>pw_shell</code></td>
<td>User command interpreter</td>
</tr>
</tbody>
</table>

The uid and gid items are integers, all others are strings. `KeyError` is raised if the entry asked for cannot be found.

**Note:** In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module `crypt`). However most modern unices use a so-called shadow password system. On those unices the `pw_passwd` field only contains an asterisk (`'*'`) or the letter `'x'` where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent. If available, the `spwd` module should be used where access to the encrypted password is required.
It defines the following items:

**pwd. getpwuid(uid)**
Return the password database entry for the given numeric user ID.

**pwd. getpwnam(name)**
Return the password database entry for the given user name.

**pwd. getpwall()**
Return a list of all available password database entries, in arbitrary order.

**See also:**

**Module grp**
An interface to the group database, similar to this.

**Module spwd**
An interface to the shadow password database, similar to this.
spwd — The shadow password database

Platforms: Unix

New in version 2.5.

This module provides access to the Unix shadow password database. It is available on various Unix versions.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the spwd structure (Attribute field below, see <shadow.h>):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>sp_nam</td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td>sp_pwd</td>
<td>Encrypted password</td>
</tr>
<tr>
<td>2</td>
<td>sp_lstchg</td>
<td>Date of last change</td>
</tr>
<tr>
<td>3</td>
<td>sp_min</td>
<td>Minimal number of days between changes</td>
</tr>
<tr>
<td>4</td>
<td>sp_max</td>
<td>Maximum number of days between changes</td>
</tr>
<tr>
<td>5</td>
<td>sp_warn</td>
<td>Number of days before password expires to warn user about it</td>
</tr>
<tr>
<td>6</td>
<td>sp_inact</td>
<td>Number of days after password expires until account is blocked</td>
</tr>
<tr>
<td>7</td>
<td>sp_expire</td>
<td>Number of days since 1970-01-01 until account is disabled</td>
</tr>
<tr>
<td>8</td>
<td>sp_flag</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
The `sp_nam` and `sp_pwd` items are strings, all others are integers. `KeyError` is raised if the entry asked for cannot be found.

It defines the following items:

```
spwd.getspnam(name)
```

Return the shadow password database entry for the given user name.

```
spwd.getspall()
```

Return a list of all available shadow password database entries, in arbitrary order.

**See also:**

**Module grp**

An interface to the group database, similar to this.

**Module pwd**

An interface to the normal password database, similar to this.
The group database

**Platforms:** Unix

This module provides access to the Unix group database. It is available on all Unix versions.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>gr_name</td>
<td>the name of the group</td>
</tr>
<tr>
<td>1</td>
<td>gr_passwd</td>
<td>the (encrypted) group password; often empty</td>
</tr>
<tr>
<td>2</td>
<td>gr_gid</td>
<td>the numerical group ID</td>
</tr>
<tr>
<td>3</td>
<td>gr_mem</td>
<td>all the group member’s user names</td>
</tr>
</tbody>
</table>

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information.)

It defines the following items:

**grp.** `getgrgid(gid)`

Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

**grp.** `getgrnam(name)`

Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.
grp. `getgrall()`

Return a list of all available group entries, in arbitrary order.

See also:

**Module pwd**

An interface to the user database, similar to this.

**Module spwd**

An interface to the shadow password database, similar to this.
This module implements an interface to the crypt(3) routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include allowing Python scripts to accept typed passwords from the user, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the crypt(3) routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

```python
import crypt, getpass, pwd

def login():
```
username = raw_input('Python login: ')
cryptedpasswd = pwd.getpwnam(username)[1]
if cryptedpasswd:
    if cryptedpasswd == 'x' or cryptedpasswd == '*':
        raise "Sorry, currently no support for shadow passwords"
    cleartext = getpass.getpass()
    return crypt.crypt(cleartext, cryptedpasswd) == cryptedpasswd
else:
    return 1
**d1 — Call C functions in shared objects**

*Platforms:* Unix

*Deprecated since version 2.6:* The d1 module has been removed in Python 3.0. Use the ctypes module instead.

The d1 module defines an interface to the dlopen function, which is the most common interface on Unix platforms for handling dynamically linked libraries. It allows the program to call arbitrary functions in such a library.

**Warning:** The d1 module bypasses the Python type system and error handling. If used incorrectly it may cause segmentation faults, crashes or other incorrect behaviour.

**Note:** This module will not work unless sizeof(int) == sizeof(long) == sizeof(char *). If this is not the case, SystemError will be raised on import.

The d1 module defines the following function:

```python
d1.open(name[, mode=RTLD_LAZY])
```

Open a shared object file, and return a handle. Mode signifies late binding (RTLD_LAZY) or immediate binding (RTLD_NOW). Default is RTLD_LAZY. Note that some systems do not support RTLD_NOW.

Return value is a d1object.

The d1 module defines the following constants:
dl.RTLD_LAZY
    Useful as an argument to open().

dl.RTLD_NOW
    Useful as an argument to open(). Note that on systems which do
    not support immediate binding, this constant will not appear in the
    module. For maximum portability, use hasattr() to determine if
    the system supports immediate binding.

The dl module defines the following exception:

exception dl.error
    Exception raised when an error has occurred inside the dynamic
    loading and linking routines.

Example:

```python
>>> import dl, time
>>> a=dl.open('/lib/libc.so.6')
>>> a.call('time'), time.time()
(929723914, 929723914.498)
```

This example was tried on a Debian GNU/Linux system, and is a
good example of the fact that using this module is usually a bad
alternative.
**DI Objects**

DI objects, as returned by `open()` above, have the following methods:

```python
dl.close()
```
Free all resources, except the memory.

```python
dl.sym(name)
```
Return the pointer for the function named `name`, as a number, if it exists in the referenced shared object, otherwise `None`. This is useful in code like:

```python
>>> if a.sym('time'):
...     a.call('time')
... else:
...     time.time()
```
(Note that this function will return a non-zero number, as zero is the `NULL` pointer)

```python
dl.call(name[, arg1[, arg2...]])
```
Call the function named `name` in the referenced shared object. The arguments must be either Python integers, which will be passed as is, Python strings, to which a pointer will be passed, or `None`, which will be passed as `NULL`. Note that strings should only be passed to functions as `const char*`, as Python will not like its string mutated.

There must be at most 10 arguments, and arguments not given will be treated as `None`. The function’s return value must be a C `long`, which is a Python integer.
termios — POSIX style tty control

Platforms: Unix

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see the POSIX or Unix manual pages. It is only available for those Unix versions that support POSIX termios style tty I/O control (and then only if configured at installation time).

All functions in this module take a file descriptor \( fd \) as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a file object, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

**termios.tcgetattr(fd)**

Return a list containing the tty attributes for file descriptor \( fd \), as follows: 
\[
[\text{iflag}, \text{oflag}, \text{cflag}, \text{lflag}, \text{ispeed}, \text{ospeed}, \text{cc}]
\]
where \( \text{cc} \) is a list of the tty special characters (each a string of length 1, except the items with indices \text{VMIN} and \text{VTIME}, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the \( \text{cc} \) array must be done using the symbolic constants defined in the termios module.

**termios.tcsetattr(fd, when, attributes)**

Set the tty attributes for file descriptor \( fd \) from the \( attributes \), which is a list like the one returned by tcgetattr(). The \( when \) argument is:

- \text{TCSANOW} to set the attributes immediately
- \text{TCSADRAIN} to flush and clear the input buffer
- \text{TCSAFLUSH} to flush and clear the input buffer, and set the attributes
- \text{TCSADONTWAIT} if \( attributes \) is a list of values to be set
- \text{TCSAUDONTWAIT} if \( attributes \) is a list of values to be set and clear
- \text{TCSAFLUSHDOTWAIT} if \( attributes \) is a list of values to be set and clear, and the attributes will be flushed and cleared

The attributes are:

- \text{cflag} -- the control file
- \text{iflag} -- the input flags
- \text{lflag} -- the line discipline
- \text{oflag} -- the output flags
- \text{ispeed} -- the input baud rate
- \text{ospeed} -- the output baud rate
- \text{cc} -- the special characters
argument determines when the attributes are changed: **TCSANOW** to change immediately, **TCSADRAIN** to change after transmitting all queued output, or **TCSAFLUSH** to change after transmitting all queued output and discarding all queued input.

**termios. tcsendbreak(fd, duration)**
Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25 – 0.5 seconds; a nonzero *duration* has a system dependent meaning.

**termios. tcdrain(fd)**
Wait until all output written to file descriptor *fd* has been transmitted.

**termios. tcflush(fd, queue)**
Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: **TCIFLUSH** for the input queue, **TCOFLUSH** for the output queue, or **TCIOFLUSH** for both queues.

**termios. tcflow(fd, action)**
Suspend or resume input or output on file descriptor *fd*. The *action* argument can be **TCOOFF** to suspend output, **TCOON** to restart output, **TCIOFF** to suspend input, or **TCION** to restart input.

**See also:**

**Module tty**
Convenience functions for common terminal control operations.
Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try ... finally` statement to ensure that the old tty attributes are restored exactly no matter what happens:

```python
def getpass(prompt = "Password: "):  
    import termios, sys  
    fd = sys.stdin.fileno()  
    old = termios.tcgetattr(fd)  
    new = termios.tcgetattr(fd)  
    try:  
        termios.tcsetattr(fd, termios.TCSADRAIN, new)  
        passwd = raw_input(prompt)  
    finally:  
        termios.tcsetattr(fd, termios.TCSADRAIN, old)  
    return passwd
```
Platforms: Unix

The `tty` module defines functions for putting the tty into cbreak and raw modes.

Because it requires the `termios` module, it will work only on Unix.

The `tty` module defines the following functions:

```python
tty.setraw(fd[, when])
Change the mode of the file descriptor `fd` to raw. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.
```

```python
tty.setcbreak(fd[, when])
Change the mode of file descriptor `fd` to cbreak. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.
```

See also:

Module `termios`
Low-level terminal control interface.
**pty — Pseudo-terminal utilities**

*Platforms*: IRIX, Linux

The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

Because pseudo-terminal handling is highly platform dependant, there is code to do it only for SGI and Linux. (The Linux code is supposed to work on other platforms, but hasn’t been tested yet.)

The `pty` module defines the following functions:

**pty.** `fork()`

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets `pid 0`, and the `fd` is *invalid*. The parent's return value is the `pid` of the child, and `fd` is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

**pty.** `openpty()`

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for SGI and generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

**pty.** `spawn([argv], [master_read], [stdin_read])`

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal.

The functions `master_read` and `stdin_read` should be functions which read from a file descriptor. The defaults try to read 1024
bytes each time they are called.
fcntl — The fcntl() and ioctl() system calls

Platforms: Unix

This module performs file control and I/O control on file descriptors. It is an interface to the fcntl and ioctl Unix routines.

All functions in this module take a file descriptor `fd` as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a file object, such as `sys.stdin` itself, which provides a `fileno()` which returns a genuine file descriptor.

The module defines the following functions:

```python
fcntl.fcntl(fd, op[, arg])
```

Perform the requested operation on file descriptor `fd` (file objects providing a `fileno()` method are accepted as well). The operation is defined by `op` and is operating system dependent. These codes are also found in the `fcntl` module. The argument `arg` is optional, and defaults to the integer value 0. When present, it can either be an integer value, or a string. With the argument missing or an integer value, the return value of this function is the integer return value of the C `fcntl` call. When the argument is a string it represents a binary structure, e.g. created by `struct.pack()`. The binary data is copied to a buffer whose address is passed to the C `fcntl` call. The return value after a successful call is the contents of the buffer, converted to a string object. The length of the returned string will be the same as the length of the `arg` argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a
segmentation violation or a more subtle data corruption.

If the `fcntl` fails, an IOError is raised.

```
fcntl.ioctl(fd, op[, arg[, mutate_flag]])
```

This function is identical to the `fcntl()` function, except that the operations are typically defined in the library module `termios` and the argument handling is even more complicated.

The op parameter is limited to values that can fit in 32-bits.

The parameter `arg` can be one of an integer, absent (treated identically to the integer 0), an object supporting the read-only buffer interface (most likely a plain Python string) or an object supporting the read-write buffer interface.

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the `mutate_flag` parameter.

If it is false, the buffer’s mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is as least as long as what the operating system wants to put there, things should work.

If `mutate_flag` is true, then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter’s return code is passed back to the calling Python, and the buffer’s new contents reflect the action of the `ioctl()`. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to `ioctl()` and copied back into the supplied buffer.
If `mutate_flag` is not supplied, then from Python 2.5 it defaults to true, which is a change from versions 2.3 and 2.4. Supply the argument explicitly if version portability is a priority.

An example:

```python
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, ''))
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
```

`fcntl.flock(fd, op)`

Perform the lock operation `op` on file descriptor `fd` (file objects providing a `fileno()` method are accepted as well). See the Unix manual `flock(3)` for details. (On some systems, this function is emulated using `fcntl`.)

`fcntl.lockf(fd, operation[, length[, start[, whence]]])`

This is essentially a wrapper around the `fcntl` locking calls. `fd` is the file descriptor of the file to lock or unlock, and `operation` is one of the following values:

- `LOCK_UN` – unlock
- `LOCK_SH` – acquire a shared lock
- `LOCK_EX` – acquire an exclusive lock

When `operation` is `LOCK_SH` or `LOCK_EX`, it can also be bitwise
ORed with \texttt{LOCK NB} to avoid blocking on lock acquisition. If \texttt{LOCK NB} is used and the lock cannot be acquired, an \texttt{IOError} will be raised and the exception will have an \texttt{errno} attribute set to \texttt{EACCES} or \texttt{EAGAIN} (depending on the operating system; for portability, check for both values). On at least some systems, \texttt{LOCK EX} can only be used if the file descriptor refers to a file opened for writing.

\textit{length} is the number of bytes to lock, \textit{start} is the byte offset at which the lock starts, relative to \textit{whence}, and \textit{whence} is as with \texttt{fileobj.seek()}, specifically:

\begin{itemize}
  \item 0 – relative to the start of the file (\texttt{SEEK_SET})
  \item 1 – relative to the current buffer position (\texttt{SEEK_CUR})
  \item 2 – relative to the end of the file (\texttt{SEEK_END})
\end{itemize}

The default for \textit{start} is 0, which means to start at the beginning of the file. The default for \textit{length} is 0 which means to lock to the end of the file. The default for \textit{whence} is also 0.

Examples (all on a SVR4 compliant system):

\begin{verbatim}
import struct, fcntl, os
f = open(...)  
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)
lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)  
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
\end{verbatim}

Note that in the first example the return value variable \textit{rv} will hold an integer value; in the second example it will hold a string value. The structure lay-out for the \textit{lockdata} variable is system dependent — therefore using the \texttt{flock()} call may be better.
Module os

If the locking flags `O_SHLOCK` and `O_EXLOCK` are present in the `os` module, the `os.open()` function provides a more platform-independent alternative to the `lockf()` and `flock()` functions.
pipes — Interface to shell pipelines

*Platforms:* Unix

The `pipes` module defines a class to abstract the concept of a *pipeline* — a sequence of converters from one file to another.

Because the module uses `/bin/sh` command lines, a POSIX or compatible shell for `os.system()` and `os.popen()` is required.

The `pipes` module defines the following class:

```python
class pipes.Template
  An abstraction of a pipeline.
```

Example:

```python
>>> import pipes
>>> t=pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f=t.open('/tmp/1', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('/tmp/1').read()
'HELLO WORLD'
```
Template Objects

Template objects following methods:

Template. `reset()`

Restore a pipeline template to its initial state.

Template. `clone()`

Return a new, equivalent, pipeline template.

Template. `debug(flag)`

If `flag` is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given `set -x` command to be more verbose.

Template. `append(cmd, kind)`

Append a new action at the end. The `cmd` variable must be a valid bourne shell command. The `kind` variable consists of two letters.

The first letter can be either of `-` (which means the command reads its standard input), `f` (which means the commands reads a given file on the command line) or `.` (which means the commands reads no input, and hence must be first.)

Similarly, the second letter can be either of `-` (which means the command writes to standard output), `f` (which means the command writes a file on the command line) or `.` (which means the command does not write anything, and hence must be last.)

Template. `prepend(cmd, kind)`

Add a new action at the beginning. See `append()` for explanations of the arguments.
Template. **open**(*file, mode*)

Return a file-like object, open to *file*, but read from or written to by the pipeline. Note that only one of `'r'`, `'w'` may be given.

Template. **copy**(*infile, outfile*)

Copy *infile* to *outfile* through the pipe.
posixfile — File-like objects with locking support

Platforms: Unix

Deprecated since version 1.5: The locking operation that this module provides is done better and more portably by the fcntl.lockf() call.

This module implements some additional functionality over the built-in file objects. In particular, it implements file locking, control over the file flags, and an easy interface to duplicate the file object. The module defines a new file object, the posixfile object. It has all the standard file object methods and adds the methods described below. This module only works for certain flavors of Unix, since it uses fcntl.fcntl() for file locking.

To instantiate a posixfile object, use the open() function in the posixfile module. The resulting object looks and feels roughly the same as a standard file object.

The posixfile module defines the following constants:

posixfile. SEEK_SET
   Offset is calculated from the start of the file.

posixfile. SEEK_CUR
   Offset is calculated from the current position in the file.

posixfile. SEEK_END
   Offset is calculated from the end of the file.

The posixfile module defines the following functions:

posixfile. open(filename[, mode[, bufsize]])
Create a new posixfile object with the given filename and mode. The `filename`, `mode` and `bufsize` arguments are interpreted the same way as by the built-in `open()` function.

**posixfile.fileopen(fileobject)**
Create a new posixfile object with the given standard file object. The resulting object has the same filename and mode as the original file object.

The posixfile object defines the following additional methods:

**posixfile.lock(fmt[, len[, start[, whence]]])**
Lock the specified section of the file that the file object is referring to. The format is explained below in a table. The `len` argument specifies the length of the section that should be locked. The default is 0. `start` specifies the starting offset of the section, where the default is 0. The `whence` argument specifies where the offset is relative to. It accepts one of the constants `SEEK_SET`, `SEEK_CUR` or `SEEK_END`. The default is `SEEK_SET`. For more information about the arguments refer to the `fcntl(2)` manual page on your system.

**posixfile.flags([flags])**
Set the specified flags for the file that the file object is referring to. The new flags are ORed with the old flags, unless specified otherwise. The format is explained below in a table. Without the `flags` argument a string indicating the current flags is returned (this is the same as the `?` modifier). For more information about the flags refer to the `fcntl(2)` manual page on your system.

**posixfile.dup()**
Duplicate the file object and the underlying file pointer and file descriptor. The resulting object behaves as if it were newly opened.
posixfile. **dup2(fd)**

Duplicate the file object and the underlying file pointer and file descriptor. The new object will have the given file descriptor. Otherwise the resulting object behaves as if it were newly opened.

posixfile. **file()**

Return the standard file object that the posixfile object is based on. This is sometimes necessary for functions that insist on a standard file object.

All methods raise **IOError** when the request fails.

Format characters for the **lock()** method have the following meaning:

<table>
<thead>
<tr>
<th>Format</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>u</td>
<td>unlock the specified region</td>
</tr>
<tr>
<td>r</td>
<td>request a read lock for the specified section</td>
</tr>
<tr>
<td>w</td>
<td>request a write lock for the specified section</td>
</tr>
</tbody>
</table>

In addition the following modifiers can be added to the format:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>l</td>
<td>wait until the lock has been granted</td>
<td></td>
</tr>
<tr>
<td>?</td>
<td>return the first lock conflicting with the requested lock, or <strong>None</strong> if there is no conflict.</td>
<td>(1)</td>
</tr>
</tbody>
</table>

Note:

1. The lock returned is in the format (*mode*, *len*, *start*, *whence*, *pid*) where *mode* is a character representing the type of lock ('r' or 'w'). This modifier prevents a request from being granted; it is for query purposes only.
Format characters for the `flags()` method have the following meanings:

<table>
<thead>
<tr>
<th>Format</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>append only flag</td>
</tr>
<tr>
<td>c</td>
<td>close on exec flag</td>
</tr>
<tr>
<td>n</td>
<td>no delay flag (also called non-blocking flag)</td>
</tr>
<tr>
<td>s</td>
<td>synchronization flag</td>
</tr>
</tbody>
</table>

In addition the following modifiers can be added to the format:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>turn the specified flags ‘off’, instead of the default ‘on’</td>
<td>(1)</td>
</tr>
<tr>
<td>=</td>
<td>replace the flags, instead of the default ‘OR’ operation</td>
<td>(1)</td>
</tr>
<tr>
<td>?</td>
<td>return a string in which the characters represent the flags that are set.</td>
<td>(2)</td>
</tr>
</tbody>
</table>

Notes:

1. The `!` and `=` modifiers are mutually exclusive.
2. This string represents the flags after they may have been altered by the same call.

Examples:

```python
import posixfile

file = posixfile.open('/tmp/test', 'w')
file.lock('w|')
...
file.lock('u')
file.close()
```
resource — Resource usage information

Platforms: Unix

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

A single exception is defined for errors:

```plaintext
exception resource.error
```

The functions described below may raise this error if the underlying system call failures unexpectedly.
Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

```
resource.getrlimit(resource)
```

Returns a tuple `(soft, hard)` with the current soft and hard limits of `resource`. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

```
resource.setrlimit(resource, limits)
```

Sets new limits of consumption of `resource`. The `limits` argument must be a tuple `(soft, hard)` of two integers describing the new limits. A value of `-1` can be used to specify the maximum possible upper limit.

Raises `ValueError` if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit (unless the process has an effective UID of super-user). Can also raise `error` if the underlying system call fails.
These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences — symbols not defined for a platform will not be available from this module on that platform.

**resource.** `RLIMIT_CORE`

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

**resource.** `RLIMIT_CPU`

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a `SIGXCPU` signal is sent to the process. (See the `signal` module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

**resource.** `RLIMITFSIZE`

The maximum size of a file which the process may create. This only affects the stack of the main thread in a multi-threaded process.

**resource.** `RLIMIT_DATA`

The maximum size (in bytes) of the process's heap.

**resource.** `RLIMIT_STACK`

The maximum size (in bytes) of the call stack for the current process.
resource. **RLIMIT_RSS**  
The maximum resident set size that should be made available to the process.

resource. **RLIMIT_NPROC**  
The maximum number of processes the current process may create.

resource. **RLIMIT_NOFILE**  
The maximum number of open file descriptors for the current process.

resource. **RLIMIT_OFILE**  
The BSD name for **RLIMIT_NOFILE**.

resource. **RLIMIT_MEMLOCK**  
The maximum address space which may be locked in memory.

resource. **RLIMIT_VMEM**  
The largest area of mapped memory which the process may occupy.

resource. **RLIMIT_AS**  
The maximum area (in bytes) of address space which may be taken by the process.
These functions are used to retrieve resource usage information:

```c
resource.getrusage(who)
```

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the `who` parameter. The `who` parameter should be specified using one of the `RUSAGE_*` constants described below.

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running is user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick internal, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the `getrusage(2)` man page for detailed information about these values. A brief summary is presented here:

<table>
<thead>
<tr>
<th>Index</th>
<th>Field</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ru_utime</td>
<td>time in user mode (float)</td>
</tr>
<tr>
<td>1</td>
<td>ru_stime</td>
<td>time in system mode (float)</td>
</tr>
<tr>
<td>2</td>
<td>ru_maxrss</td>
<td>maximum resident set size</td>
</tr>
<tr>
<td>3</td>
<td>ru_ixrss</td>
<td>shared memory size</td>
</tr>
<tr>
<td>4</td>
<td>ru_idrss</td>
<td>unshared memory size</td>
</tr>
</tbody>
</table>
This function will raise a ValueError if an invalid who parameter is specified. It may also raise error exception in unusual circumstances.

*Changed in version 2.3*: Added access to values as attributes of the returned object.*

resource.getpagesize()

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.) This function is useful for determining the number of bytes of memory a process is using. The third element of the tuple returned by getrusage() describes memory usage in pages; multiplying by page size produces number of bytes.

The following RUSAGE_* symbols are passed to the getrusage() function to specify which processes information should be provided for.

resource.RUSAGE_SELF

RUSAGE_SELF should be used to request information pertaining
only to the process itself.

**resource.** `RUSAGE_CHILDREN`

Pass to `getrusage()` to request resource information for child processes of the calling process.

**resource.** `RUSAGE_BOTH`

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.
nis — Interface to Sun’s NIS (Yellow Pages)

Platforms: Unix

The nis module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

The nis module defines the following functions:

**nis.match(key, mapname[, domain=default_domain])**

Return the match for **key** in map **mapname**, or raise an error (**nis.error**) if there is none. Both should be strings, **key** is 8-bit clean. Return value is an arbitrary array of bytes (may contain NULL and other joys).

Note that **mapname** is first checked if it is an alias to another name.

*Changed in version 2.5:* The **domain** argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

**nis.cat(mapname[, domain=default_domain])**

Return a dictionary mapping **key** to **value** such that **match(key, mapname)==value**. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that **mapname** is first checked if it is an alias to another name.
Changed in version 2.5: The domain argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

```
nis.maps([domain=default_domain])
```

Return a list of all valid maps.

Changed in version 2.5: The domain argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

```
nis.get_default_domain()
```

Return the system default NIS domain.

New in version 2.5.

The nis module defines the following exception:

```
exception nis.error
```

An error raised when a NIS function returns an error code.
**syslog — Unix syslog library routines**

*Platforms*: Unix

This module provides an interface to the Unix syslog library routines. Refer to the Unix manual pages for a detailed description of the syslog facility.

The module defines the following functions:

```c
syslog. **syslog**( [*priority*], *message*)
```

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to **LOG_INFO**, determines the message priority. If the facility is not encoded in *priority* using logical-or (**LOG_INFO** | **LOG_USER**), the value given in the **openlog()** call is used.

```c
syslog. **openlog**( [*ident*][, *logopt*][, *facility*])
```

Logging options other than the defaults can be set by explicitly opening the log file with **openlog()** prior to calling **syslog()**. The defaults are (usually) *ident* = `'syslog'`, *logopt* = 0, *facility* = **LOG_USER**. The *ident* argument is a string which is prepended to every message. The optional *logopt* argument is a bit field - see below for possible values to combine. The optional *facility* argument sets the default facility for messages which do not have a facility explicitly encoded.

```c
syslog. **closelog**()
```

Close the log file.
syslog.\texttt{setlogmask}(\textit{maskpri})

Set the priority mask to \textit{maskpri} and return the previous mask value. Calls to \texttt{syslog()} with a priority level not set in \textit{maskpri} are ignored. The default is to log all priorities. The function \texttt{LOG\_MASK(pri)} calculates the mask for the individual priority \textit{pri}. The function \texttt{LOG\_UPTO(pri)} calculates the mask for all priorities up to and including \textit{pri}.

The module defines the following constants:

Priority levels (high to low):

\begin{verbatim}
  LOG_EMERG, LOG_ALERT, LOG_CRIT, LOG_ERR, LOG_WARNING,
  LOG_NOTICE, LOG_INFO, LOG_DEBUG.
\end{verbatim}

Facilities:

\begin{verbatim}
  LOG_KERN, LOG_USER, LOG_MAIL, LOG_DAEMON, LOG_AUTH, LOG_LPR,
  LOG_NEWS, LOG_UUCP, LOG_CRON and LOG_LOCAL0 to LOG_LOCAL7.
\end{verbatim}

Log options:

\begin{verbatim}
  LOG_PID, LOG_CONS, LOG_NDELAY, LOG_NOWAIT and LOG_PERROR if
  defined in <syslog.h>.
\end{verbatim}
The `commands` module contains wrapper functions for `os.popen()` which take a system command as a string and return any output generated by the command and, optionally, the exit status.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results. Using the `subprocess` module is preferable to using the `commands` module.

**Warning:** In 3.x, `getstatus()` and two undocumented functions (`mk2arg()` and `mkarg()`) have been removed. Also, `getstatusoutput()` and `getoutput()` have been moved to the `subprocess` module.

The `commands` module defines the following functions:

**commands.** `getstatusoutput(cmd)`

Execute the string `cmd` in a shell with `os.popen()` and return a 2-tuple `(status, output)`. `cmd` is actually run as `{ cmd ; } 2>&1`, so that the returned output will contain output or error messages. A trailing newline is stripped from the output. The exit status for the command can be interpreted according to the rules for the C function `wait`.

**commands.** `getoutput(cmd)`

Like `getstatusoutput()`, except the exit status is ignored and the return value is a string containing the command's output.
**commands.getstatus(file)**

Return the output of `ls -ld file` as a string. This function uses the `getoutput()` function, and properly escapes backslashes and dollar signs in the argument.

*Deprecated since version 2.6:* This function is nonobvious and useless. The name is also misleading in the presence of `getstatusoutput()`.

Example:

```python
>>> import commands
>>> commands.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> commands.getstatusoutput('cat /bin/junk')
(256, 'cat: /bin/junk: No such file or directory')
>>> commands.getstatusoutput('/bin/junk')
(256, 'sh: /bin/junk: not found')
>>> commands.getoutput('ls /bin/ls')
'/bin/ls'
>>> commands.getstatus('/bin/ls')
'-rwxr-xr-x 1 root 13352 Oct 14 1994 /bin/ls'
```

**See also:**

**Module subprocess**

Module for spawning and managing subprocesses.
Mac OS X specific services

This chapter describes modules that are only available on the Mac OS X platform.

See the chapters *MacPython OSA Modules* and *Undocumented Mac OS modules* for more modules, and the HOWTO *Using Python on a Macintosh* for a general introduction to Mac-specific Python programming.

**Warning:** These modules are deprecated and are removed in 3.0.

- **ic** — Access to the Mac OS X Internet Config
  - IC Objects

- **MacOS** — Access to Mac OS interpreter features

- **macostools** — Convenience routines for file manipulation

- **findertools** — The **finder**'s Apple Events interface

- **EasyDialogs** — Basic Macintosh dialogs
  - ProgressBar Objects

- **FrameWork** — Interactive application framework
  - Application Objects
  - Window Objects
  - ControlsWindow Object
  - ScrolledWindow Object
  - DialogWindow Objects

- **autoGIL** — Global Interpreter Lock handling in event loops

- **Mac OS Toolbox Modules**
- **Carbon.AE** — Apple Events
- **Carbon.AH** — Apple Help
- **Carbon.App** — Appearance Manager
- **Carbon.CF** — Core Foundation
- **Carbon.CG** — Core Graphics
- **Carbon.CarbonEvt** — Carbon Event Manager
- **Carbon.Cm** — Component Manager
- **Carbon.Ctl** — Control Manager
- **Carbon.Dlg** — Dialog Manager
- **Carbon.Evt** — Event Manager
- **Carbon.Fm** — Font Manager
- **Carbon.Folder** — Folder Manager
- **Carbon.Help** — Help Manager
- **Carbon.List** — List Manager
- **Carbon.Menu** — Menu Manager
- **Carbon.Mlte** — MultiLingual Text Editor
- **Carbon.Qd** — QuickDraw
- **Carbon.Qdoffs** — QuickDraw Offscreen
- **Carbon.Qt** — QuickTime
- **Carbon.Res** — Resource Manager and Handles
- **Carbon.Scrap** — Scrap Manager
- **Carbon.Snd** — Sound Manager
- **Carbon.TE** — TextEdit
- **Carbon.Win** — Window Manager

- **ColorPicker** — Color selection dialog
Platforms: Mac

This module provides access to various internet-related preferences set through System Preferences or the Finder.

Warning: This module is removed in 3.0.

There is a low-level companion module icglue which provides the basic Internet Config access functionality. This low-level module is not documented, but the docstrings of the routines document the parameters and the routine names are the same as for the Pascal or C API to Internet Config, so the standard IC programmers' documentation can be used if this module is needed.

The ic module defines the error exception and symbolic names for all error codes Internet Config can produce; see the source for details.

exception ic.error
    Exception raised on errors in the ic module.

The ic module defines the following class and function:

class ic.ic([signature[, ic]])
    Create an Internet Config object. The signature is a 4-character creator code of the current application (default 'Pyth') which may influence some of ICs settings. The optional ic argument is a low-level icglue.icinstance created beforehand, this may be useful if you want to get preferences from a different config file, etc.
ic. launchurl(url[, hint])
ic. parseurl(data[, start[, end[, hint]]])
ic. mapfile(file)
ic. maptypecreator(type, creator[, filename])
ic. settypecreator(file)

These functions are “shortcuts” to the methods of the same name, described below.
IC Objects

IC objects have a mapping interface, hence to obtain the mail address you simply get `ic['MailAddress']`. Assignment also works, and changes the option in the configuration file.

The module knows about various datatypes, and converts the internal IC representation to a “logical” Python data structure. Running the ic module standalone will run a test program that lists all keys and values in your IC database, this will have to serve as documentation.

If the module does not know how to represent the data it returns an instance of the `ICOpaqueData` type, with the raw data in its `data` attribute. Objects of this type are also acceptable values for assignment.

Besides the dictionary interface, IC objects have the following methods:

**IC.launchurl(url[, hint])**

Parse the given URL, launch the correct application and pass it the URL. The optional `hint` can be a scheme name such as `mailto:`, in which case incomplete URLs are completed with this scheme. If `hint` is not provided, incomplete URLs are invalid.

**IC.parseurl(data[, start[, end[, hint]]])**

Find an URL somewhere in `data` and return start position, end position and the URL. The optional `start` and `end` can be used to limit the search, so for instance if a user clicks in a long text field you can pass the whole text field and the click-position in `start` and this routine will return the whole URL in which the user clicked. As above, `hint` is an optional scheme used to complete
incomplete URLs.

IC. mapfile(file)
Return the mapping entry for the given file, which can be passed as either a filename or an FSSpec() result, and which need not exist.

The mapping entry is returned as a tuple (version, type, creator, postcreator, flags, extension, appname, postappname, mimetype, entryname), where version is the entry version number, type is the 4-character filetype, creator is the 4-character creator type, postcreator is the 4-character creator code of an optional application to post-process the file after downloading, flags are various bits specifying whether to transfer in binary or ascii and such, extension is the filename extension for this file type, appname is the printable name of the application to which this file belongs, postappname is the name of the postprocessing application, mimetype is the MIME type of this file and entryname is the name of this entry.

IC. maptypecreator(type, creator[, filename])
Return the mapping entry for files with given 4-character type and creator codes. The optional filename may be specified to further help finding the correct entry (if the creator code is '????', for instance).

The mapping entry is returned in the same format as for mapfile.

IC. settypecreator(file)
Given an existing file, specified either as a filename or as an FSSpec() result, set its creator and type correctly based on its extension. The finder is told about the change, so the finder icon will be updated quickly.
MacOS — Access to Mac OS interpreter features

*Platforms*: Mac

This module provides access to MacOS specific functionality in the Python interpreter, such as how the interpreter eventloop functions and the like. Use with care.

**Warning**: This module is removed in 3.0.

Note the capitalization of the module name; this is a historical artifact.

**MacOS. runtimemodel**

Always `macho`, from Python 2.4 on. In earlier versions of Python the value could also be `ppc` for the classic Mac OS 8 runtime model or `carbon` for the Mac OS 9 runtime model.

**MacOS. linkmodel**

The way the interpreter has been linked. As extension modules may be incompatible between linking models, packages could use this information to give more decent error messages. The value is one of `static` for a statically linked Python, `framework` for Python in a Mac OS X framework, `shared` for Python in a standard Unix shared library. Older Pythons could also have the value `cfm` for Mac OS 9-compatible Python.

**exception MacOS. Error**

This exception is raised on MacOS generated errors, either from functions in this module or from other mac-specific modules like the toolbox interfaces. The arguments are the integer error code
(the `osErr` value) and a textual description of the error code. Symbolic names for all known error codes are defined in the standard module `macerrors`.

**MacOS. `GetErrorString(errno)`**

Return the textual description of MacOS error code `errno`.

**MacOS. `DebugStr(message[, object])`**

On Mac OS X the string is simply printed to stderr (on older Mac OS systems more elaborate functionality was available), but it provides a convenient location to attach a breakpoint in a low-level debugger like `gdb`.

**Note:** Not available in 64-bit mode.

**MacOS. `SysBeep()`**

Ring the bell.

**Note:** Not available in 64-bit mode.

**MacOS. `GetTicks()`**

Get the number of clock ticks (1/60th of a second) since system boot.

**MacOS. `GetCreatorAndType(file)`**

Return the file creator and file type as two four-character strings. The `file` parameter can be a pathname or an `FSSpec` or `FSRef` object.

**Note:** It is not possible to use an `FSSpec` in 64-bit mode.

**MacOS. `SetCreatorAndType(file, creator, type)`**

Set the file creator and file type. The `file` parameter can be a
pathname or an FSSpec or FSRef object. creator and type must be four character strings.

**Note:** It is not possible to use an FSSpec in 64-bit mode.

MacOS. `openrf(name[, mode])`
Open the resource fork of a file. Arguments are the same as for the built-in function `open()`. The object returned has file-like semantics, but it is not a Python file object, so there may be subtle differences.

MacOS. `WMAvailable()`
Checks whether the current process has access to the window manager. The method will return `False` if the window manager is not available, for instance when running on Mac OS X Server or when logged in via ssh, or when the current interpreter is not running from a fullblown application bundle. A script runs from an application bundle either when it has been started with `pythonw` instead of `python` or when running as an applet.

MacOS. `splash([resourceid])`
Opens a splash screen by resource id. Use resourceid 0 to close the splash screen.

**Note:** Not available in 64-bit mode.
macostools — Convenience routines for file manipulation

*Platforms:* Mac

This module contains some convenience routines for file-manipulation on the Macintosh. All file parameters can be specified as pathnames, *FSRef* or *FSSpec* objects. This module expects a filesystem which supports forked files, so it should not be used on UFS partitions.

**Warning:** This module is removed in 3.0.

The *macostools* module defines the following functions:

**macostools.copy**(*src*, *dst*, *createpath*, *copytimes*)

Copy file *src* to *dst*. If *createpath* is non-zero the folders leading to *dst* are created if necessary. The method copies data and resource fork and some finder information (creator, type, flags) and optionally the creation, modification and backup times (default is to copy them). Custom icons, comments and icon position are not copied.

**macostools.copytree**(*src*, *dst*)

Recursively copy a file tree from *src* to *dst*, creating folders as needed. *src* and *dst* should be specified as pathnames.

**macostools.mkalias**(*src*, *dst*)

Create a finder alias *dst* pointing to *src*.

**macostools.touched**(*dst*)

Tell the finder that some bits of finder-information such as creator
or type for file *dst* has changed. The file can be specified by
pathname or fsspec. This call should tell the finder to redraw the
files icon.

*Deprecated since version 2.6:* The function is a no-op on OS X.

macostools. **BUFSIZ**

The buffer size for *copy*, default 1 megabyte.

Note that the process of creating finder aliases is not specified in the
Apple documentation. Hence, aliases created with *mkalias()* could
conceivably have incompatible behaviour in some cases.
findertools — The finder‘s Apple Events interface

Platforms: Mac

This module contains routines that give Python programs access to some functionality provided by the finder. They are implemented as wrappers around the AppleEvent interface to the finder.

All file and folder parameters can be specified either as full pathnames, or as FSRef or FSSpec objects.

The findertools module defines the following functions:

findertools.**launch**(file)

Tell the finder to launch file. What launching means depends on the file: applications are started, folders are opened and documents are opened in the correct application.

findertools.**Print**(file)

Tell the finder to print a file. The behaviour is identical to selecting the file and using the print command in the finder’s file menu.

findertools.**copy**(file, destdir)

Tell the finder to copy a file or folder file to folder destdir. The function returns an Alias object pointing to the new file.

findertools.**move**(file, destdir)

Tell the finder to move a file or folder file to folder destdir. The function returns an Alias object pointing to the new file.

findertools.**sleep**()

Tell the finder to put the Macintosh to sleep, if your machine
supports it.

```
findertools.restart()
Tell the finder to perform an orderly restart of the machine.

findertools.shutdown()
Tell the finder to perform an orderly shutdown of the machine.
```
EasyDialogs — Basic Macintosh dialogs

*Platforms:* Mac

The EasyDialogs module contains some simple dialogs for the Macintosh. The dialogs get launched in a separate application which appears in the dock and must be clicked on for the dialogs be displayed. All routines take an optional resource ID parameter *id* with which one can override the **DLOG** resource used for the dialog, provided that the dialog items correspond (both type and item number) to those in the default **DLOG** resource. See source code for details.

**Warning:** This module is removed in 3.0.

The EasyDialogs module defines the following functions:

EasyDialogs. **Message**(str[, *id*, *ok*])

Displays a modal dialog with the message text *str*, which should be at most 255 characters long. The button text defaults to “OK”, but is set to the string argument *ok* if the latter is supplied. Control is returned when the user clicks the “OK” button.

EasyDialogs. **AskString**(prompt[, *default*, *id*, *ok*, *cancel*])

Asks the user to input a string value via a modal dialog. *prompt* is the prompt message, and the optional *default* supplies the initial value for the string (otherwise "" is used). The text of the “OK” and “Cancel” buttons can be changed with the *ok* and *cancel* arguments. All strings can be at most 255 bytes long. **AskString()** returns the string entered or **None** in case the user
cancelled.

**EasyDialogs.** AskPassword(*prompt*[,* default*[,* id*[,* ok*[,* cancel*]]]]*)

Asks the user to input a string value via a modal dialog. Like AskString(), but with the text shown as bullets. The arguments have the same meaning as for AskString().

**EasyDialogs.** AskYesNoCancel(*question*[,* default*[,* yes*[,* no*[,* cancel*[,* id*]]]]]*)

Presents a dialog with prompt question and three buttons labelled “Yes”, “No”, and “Cancel”. Returns 1 for “Yes”, 0 for “No” and -1 for “Cancel”. The value of default (or 0 if default is not supplied) is returned when the RETURN key is pressed. The text of the buttons can be changed with the yes, no, and cancel arguments; to prevent a button from appearing, supply "" for the corresponding argument.

**EasyDialogs.** ProgressBar(*title*[,* maxval*[,* label*[,* id*]]]]*)

Displays a modeless progress-bar dialog. This is the constructor for the ProgressBar class described below. title is the text string displayed (default “Working...”), maxval is the value at which progress is complete (default 0, indicating that an indeterminate amount of work remains to be done), and label is the text that is displayed above the progress bar itself.

**EasyDialogs.** GetArgv(*optionlist*[,* commandlist*[,* addoldfile*[,* addnewfile*[,* addfolder*[,* id*]]]]]*)

Displays a dialog which aids the user in constructing a command-line argument list. Returns the list in sys.argv format, suitable for passing as an argument to getopt.getopt(). addoldfile, addnewfile, and addfolder are boolean arguments. When nonzero, they enable the user to insert into the command line
paths to an existing file, a (possibly) not-yet-existent file, and a folder, respectively. (Note: Option arguments must appear in the command line before file and folder arguments in order to be recognized by `getopt.getopt()`.) Arguments containing spaces can be specified by enclosing them within single or double quotes. A `SystemExit` exception is raised if the user presses the “Cancel” button.

`optionlist` is a list that determines a popup menu from which the allowed options are selected. Its items can take one of two forms: `optstr` or `(optstr, descr)`. When present, `descr` is a short descriptive string that is displayed in the dialog while this option is selected in the popup menu. The correspondence between `optstrs` and command-line arguments is:

<table>
<thead>
<tr>
<th><strong>optstr format</strong></th>
<th><strong>Command-line format</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>-x (short option)</td>
</tr>
<tr>
<td>x: or x=</td>
<td>-x (short option with value)</td>
</tr>
<tr>
<td>xyz</td>
<td>--xyz (long option)</td>
</tr>
<tr>
<td>xyz: or xyz=</td>
<td>--xyz (long option with value)</td>
</tr>
</tbody>
</table>

`commandlist` is a list of items of the form `cmdstr` or `(cmdstr, descr)`, where `descr` is as above. The `cmdstr`s will appear in a popup menu. When chosen, the text of *cmdstr* will be appended to the command line as is, except that a trailing `':='` or `'='` (if present) will be trimmed off.

*New in version 2.0.*

EasyDialogs. **AskFileForOpen**(message[, typeList][, defaultLocation][, defaultOptionFlags][, location][, clientName][, windowTitle][, actionButtonLabel][, cancelButtonLabel]),
Post a dialog asking the user for a file to open, and return the file selected or None if the user cancelled. message is a text message to display, typeList is a list of 4-char filetypes allowable, defaultLocation is the pathname, FSSpec or FSRef of the folder to show initially, location is the (x, y) position on the screen where the dialog is shown, actionButtonLabel is a string to show instead of “Open” in the OK button, cancelButtonLabel is a string to show instead of “Cancel” in the cancel button, wanted is the type of value wanted as a return: str, unicode, FSSpec, FSRef and subtypes thereof are acceptable.

For a description of the other arguments please see the Apple Navigation Services documentation and the EasyDialogs source code.

EasyDialogs.AskFileForSave([message][, savedFileName][, defaultLocation][, defaultOptionFlags][, location][, clientName][, windowTitle][, actionButtonLabel][, cancelButtonLabel][, preferenceKey][, popupExtension][, filterProc][, fileCreator][, eventProc][, wanted])

Post a dialog asking the user for a file to save to, and return the file selected or None if the user cancelled. savedFileName is the default for the file name to save to (the return value). See AskFileForOpen() for a description of the other arguments.

EasyDialogs.AskFolder([message][, defaultLocation][, defaultOptionFlags][, location][, clientName][, windowTitle][, actionButtonLabel][, cancelButtonLabel][, preferenceKey][, popupExtension][, eventProc][, filterProc][, wanted])
Post a dialog asking the user to select a folder, and return the folder selected or None if the user cancelled. See AskFileForOpen() for a description of the arguments.

**Navigation Services Reference**
Programmer’s reference documentation for the Navigation Services, a part of the Carbon framework.
ProgressBar objects provide support for modeless progress-bar dialogs. Both determinate (thermometer style) and indeterminate (barber-pole style) progress bars are supported. The bar will be determinate if its maximum value is greater than zero; otherwise it will be indeterminate.

*Changed in version 2.2:* Support for indeterminate-style progress bars was added.

The dialog is displayed immediately after creation. If the dialog’s “Cancel” button is pressed, or if `Cmd-` or `ESC` is typed, the dialog window is hidden and `KeyboardInterrupt` is raised (but note that this response does not occur until the progress bar is next updated, typically via a call to `inc()` or `set()`). Otherwise, the bar remains visible until the `ProgressBar` object is discarded.

`ProgressBar` objects possess the following attributes and methods:

**`ProgressBar`**

**`.curval`**

The current value (of type integer or long integer) of the progress bar. The normal access methods coerce `curval` between 0 and `maxval`. This attribute should not be altered directly.

**`.maxval`**

The maximum value (of type integer or long integer) of the progress bar; the progress bar (thermometer style) is full when `curval` equals `maxval`. If `maxval` is 0, the bar will be indeterminate (barber-pole). This attribute should not be altered directly.

**`.title([newstr])`**

Sets the text in the title bar of the progress dialog to `newstr`. 
ProgressBar. **label**([*newstr*])

Sets the text in the progress box of the progress dialog to *newstr*.

ProgressBar. **set**(*value*, [*max]*)

Sets the progress bar’s *curval* to *value*, and also *maxval* to *max* if the latter is provided. *value* is first coerced between 0 and *maxval*. The thermometer bar is updated to reflect the changes, including a change from indeterminate to determinate or vice versa.

ProgressBar. **inc**(*n*)

Increments the progress bar’s *curval* by *n*, or by 1 if *n* is not provided. (Note that *n* may be negative, in which case the effect is a decrement.) The progress bar is updated to reflect the change. If the bar is indeterminate, this causes one “spin” of the barber pole. The resulting *curval* is coerced between 0 and *maxval* if incrementing causes it to fall outside this range.
FrameWork — Interactive application framework

*Platforms:* Mac

The FrameWork module contains classes that together provide a framework for an interactive Macintosh application. The programmer builds an application by creating subclasses that override various methods of the bases classes, thereby implementing the functionality wanted. Overriding functionality can often be done on various different levels, i.e. to handle clicks in a single dialog window in a non-standard way it is not necessary to override the complete event handling.

**Warning:** This module is removed in 3.0.

Work on the FrameWork has pretty much stopped, now that PyObjc is available for full Cocoa access from Python, and the documentation describes only the most important functionality, and not in the most logical manner at that. Examine the source or the examples for more details. The following are some comments posted on the MacPython newsgroup about the strengths and limitations of FrameWork:

The strong point of FrameWork is that it allows you to break into the control-flow at many different places. W, for instance, uses a different way to enable/disable menus and that plugs right in leaving the rest intact. The weak points of FrameWork are that it has no abstract command interface (but that shouldn’t be difficult), that its dialog support is minimal and that its control/toolbar support is non-existent.

The FrameWork module defines the following functions:
FrameWork. **Application()**

An object representing the complete application. See below for a description of the methods. The default __init__() routine creates an empty window dictionary and a menu bar with an apple menu.

FrameWork. **MenuBar()**

An object representing the menubar. This object is usually not created by the user.

FrameWork. **Menu(bar, title[, after])**

An object representing a menu. Upon creation you pass the MenuBar the menu appears in, the title string and a position (1-based) after where the menu should appear (default: at the end).

FrameWork. **MenuItem(menu, title[, shortcut, callback])**

Create a menu item object. The arguments are the menu to create, the item title string and optionally the keyboard shortcut and a callback routine. The callback is called with the arguments menu-id, item number within menu (1-based), current front window and the event record.

Instead of a callable object the callback can also be a string. In this case menu selection causes the lookup of a method in the topmost window and the application. The method name is the callback string with 'domenu_' prepended.

Calling the MenuBar fixmenudimstate() method sets the correct dimming for all menu items based on the current front window.

FrameWork. **Separator(menu)**

Add a separator to the end of a menu.

FrameWork. **SubMenu(menu, label)**
Create a submenu named *label* under menu *menu*. The menu object is returned.

**FrameWork.** `Window(parent)`

Creates a (modeless) window. *Parent* is the application object to which the window belongs. The window is not displayed until later.

**FrameWork.** `DialogWindow(parent)`

Creates a modeless dialog window.

**FrameWork.** `windowbounds(width, height)`

Return a `(left, top, right, bottom)` tuple suitable for creation of a window of given width and height. The window will be staggered with respect to previous windows, and an attempt is made to keep the whole window on-screen. However, the window will however always be the exact size given, so parts may be offscreen.

**FrameWork.** `setwatchcursor()`

Set the mouse cursor to a watch.

**FrameWork.** `setarrowcursor()`

Set the mouse cursor to an arrow.
Application Objects

Application objects have the following methods, among others:

Application. `makeusermenus()`

Override this method if you need menus in your application. Append the menus to the attribute `menubar`.

Application. `getabouttext()`

Override this method to return a text string describing your application. Alternatively, override the `do_about()` method for more elaborate “about” messages.

Application. `mainloop([mask[, wait]])`

This routine is the main event loop, call it to set your application rolling. `Mask` is the mask of events you want to handle, `wait` is the number of ticks you want to leave to other concurrent application (default 0, which is probably not a good idea). While raising `self` to exit the mainloop is still supported it is not recommended: call `self._quit()` instead.

The event loop is split into many small parts, each of which can be overridden. The default methods take care of dispatching events to windows and dialogs, handling drags and resizes, Apple Events, events for non-FrameWork windows, etc.

In general, all event handlers should return 1 if the event is fully handled and 0 otherwise (because the front window was not a FrameWork window, for instance). This is needed so that update events and such can be passed on to other windows like the Sioux console window. Calling `MacOS.HandleEvent()` is not allowed within `our_dispatch` or its callees, since this may result in an infinite loop if the code is called through the Python inner-loop
event handler.

Application.\texttt{asyncevents(onoff)}
Call this method with a nonzero parameter to enable asynchronous event handling. This will tell the inner interpreter loop to call the application event handler \texttt{async\_dispatch} whenever events are available. This will cause FrameWork window updates and the user interface to remain working during long computations, but will slow the interpreter down and may cause surprising results in non-reentrant code (such as FrameWork itself). By default \texttt{async\_dispatch} will immediately call \texttt{our\_dispatch} but you may override this to handle only certain events asynchronously. Events you do not handle will be passed to Sioux and such.

The old on/off value is returned.

Application.\texttt{\_quit()}
Terminate the running \texttt{mainloop()} call at the next convenient moment.

Application.\texttt{do\_char(c, event)}
The user typed character \texttt{c}. The complete details of the event can be found in the \texttt{event} structure. This method can also be provided in a \texttt{Window} object, which overrides the application-wide handler if the window is frontmost.

Application.\texttt{do\_dialogevent(event)}
Called early in the event loop to handle modeless dialog events. The default method simply dispatches the event to the relevant dialog (not through the \texttt{DialogWindow} object involved). Override if you need special handling of dialog events (keyboard shortcuts, etc).

Application.\texttt{idle(event)}
Called by the main event loop when no events are available. The null-event is passed (so you can look at mouse position, etc).
Window Objects

Window objects have the following methods, among others:

Window.open()

Override this method to open a window. Store the Mac OS window-id in self.wid and call the do_postopen() method to register the window with the parent application.

Window.close()

Override this method to do any special processing on window close. Call the do_postclose() method to cleanup the parent state.

Window.do_postresize(width, height, macoswindowid)

Called after the window is resized. Override if more needs to be done than calling InvalRect.

Window.do_contentclick(local, modifiers, event)

The user clicked in the content part of a window. The arguments are the coordinates (window-relative), the key modifiers and the raw event.

Window.do_update(macoswindowid, event)

An update event for the window was received. Redraw the window.

Window.do_activate(activate, event)

The window was activated (activate == 1) or deactivated (activate == 0). Handle things like focus highlighting, etc.
ControlsWindow Object

ControlsWindow objects have the following methods besides those of Window objects:

\[ \text{ControlsWindow}.\text{do\_controlhit}(\text{window}, \text{control}, \text{pcode}, \text{event}) \]

Part \textit{pcode} of control \textit{control} was hit by the user. Tracking and such has already been taken care of.
ScrolledWindow Object

ScrolledWindow objects are ControlsWindow objects with the following extra methods:

**ScrolledWindow. `scrollbars([wantx, wanty])`**

Create (or destroy) horizontal and vertical scrollbars. The arguments specify which you want (default: both). The scrollbars always have minimum 0 and maximum 32767.

**ScrolledWindow. `getscrollbarvalues()`**

You must supply this method. It should return a tuple `(x, y)` giving the current position of the scrollbars (between 0 and 32767). You can return `None` for either to indicate the whole document is visible in that direction.

**ScrolledWindow. `updatescrollbars()`**

Call this method when the document has changed. It will call `getscrollbarvalues()` and update the scrollbars.

**ScrolledWindow. `scrollbar_callback(which, what, value)`**

Supplied by you and called after user interaction. `which` will be 'x' or 'y', `what` will be '-', '--', 'set', '++' or '+'. For 'set', `value` will contain the new scrollbar position.

**ScrolledWindow. `scalebarvalues(absmin, absmax, curmin, curmax)`**

Auxiliary method to help you calculate values to return from `getscrollbarvalues()`. You pass document minimum and maximum value and topmost (leftmost) and bottommost (rightmost) visible values and it returns the correct number or `None`. 
ScrolledWindow. **do activate**(onoff, event)

Takes care of dimming/highlighting scrollbars when a window becomes frontmost. If you override this method, call this one at the end of your method.

ScrolledWindow. **do postresize**(width, height, window)

Moves scrollbars to the correct position. Call this method initially if you override it.

ScrolledWindow. **do controlhit**(window, control, pcode, event)

Handles scrollbar interaction. If you override it call this method first, a nonzero return value indicates the hit was in the scrollbars and has been handled.
DialogWindow objects have the following methods besides those of Window objects:

DialogWindow.open(*resid*)

Create the dialog window, from the DLOG resource with id *resid*. The dialog object is stored in *self.wid*.

DialogWindow.do_itemhit(*item, event*)

Item number *item* was hit. You are responsible for redrawing toggle buttons, etc.
autoGIL — Global Interpreter Lock handling in event loops

*Platforms:* Mac

The autoGIL module provides a function `installAutoGIL()` that automatically locks and unlocks Python’s *Global Interpreter Lock* when running an event loop.

**Warning:** This module has been removed in 3.0.

exception `autoGIL.AutoGILError`

Raised if the observer callback cannot be installed, for example because the current thread does not have a run loop.

`autoGIL.installAutoGIL()`

Install an observer callback in the event loop (CFRunLoop) for the current thread, that will lock and unlock the Global Interpreter Lock (GIL) at appropriate times, allowing other Python threads to run while the event loop is idle.

*Availability:* OSX 10.1 or later.
Mac OS Toolbox Modules

There are a set of modules that provide interfaces to various Mac OS toolboxes. If applicable the module will define a number of Python objects for the various structures declared by the toolbox, and operations will be implemented as methods of the object. Other operations will be implemented as functions in the module. Not all operations possible in C will also be possible in Python (callbacks are often a problem), and parameters will occasionally be different in Python (input and output buffers, especially). All methods and functions have a __doc__ string describing their arguments and return values, and for additional description you are referred to Inside Macintosh or similar works.

These modules all live in a package called carbon. Despite that name they are not all part of the Carbon framework: CF is really in the CoreFoundation framework and Qt is in the QuickTime framework. The normal use pattern is

```python
from Carbon import AE
```

**Warning:** The Carbon modules are removed in 3.0.
Platforms: Mac
Platforms: Mac
Platforms: Mac
Platforms: Mac

The **CFBase**, **CFArray**, **CFData**, **CFDictionary**, **CFString** and **CFURL** objects are supported, some only partially.

**Carbon.Scrap — Scrap Manager**

*Platforms*: Mac

This module is only fully available on Mac OS 9 and earlier under classic PPC MacPython. Very limited functionality is available under Carbon MacPython.

The Scrap Manager supports the simplest form of cut & paste operations on the Macintosh. It can be used for both inter- and intra-application clipboard operations.

The Scrap module provides low-level access to the functions of the Scrap Manager. It contains the following functions:

**Carbon.Scrap.InfoScrap()**

Return current information about the scrap. The information is encoded as a tuple containing the fields \((\text{size}, \text{handle}, \text{count}, \text{state}, \text{path})\).

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{size}</td>
<td>Size of the scrap in bytes.</td>
</tr>
<tr>
<td>\textit{handle}</td>
<td>Resource object representing the scrap.</td>
</tr>
<tr>
<td>\textit{count}</td>
<td>Serial number of the scrap contents.</td>
</tr>
<tr>
<td>\textit{state}</td>
<td>Integer; positive if in memory, 0 if on disk, negative if uninitialized.</td>
</tr>
<tr>
<td>\textit{path}</td>
<td>Filename of the scrap when stored on disk.</td>
</tr>
</tbody>
</table>

Apple's documentation for the Scrap Manager gives a lot of useful information about using the Scrap Manager in
applications.
Carbon.Snd — Sound Manager

Platforms: Mac
Platforms: Mac
Carbon.Win — Window Manager

*Platforms*: Mac
ColorPicker — Color selection dialog

Platforms: Mac

The ColorPicker module provides access to the standard color picker dialog.

Warning: This module is removed in 3.0.

ColorPicker. **getColor**(prompt, rgb)

Show a standard color selection dialog and allow the user to select a color. The user is given instruction by the *prompt* string, and the default color is set to *rgb*. *rgb* must be a tuple giving the red, green, and blue components of the color. **getColor()** returns a tuple giving the user’s selected color and a flag indicating whether they accepted the selection of cancelled.
This chapter describes the current implementation of the Open Scripting Architecture (OSA, also commonly referred to as AppleScript) for Python, allowing you to control scriptable applications from your Python program, and with a fairly pythonic interface. Development on this set of modules has stopped, and a replacement is expected for Python 2.5.

For a description of the various components of AppleScript and OSA, and to get an understanding of the architecture and terminology, you should read Apple’s documentation. The “Applescript Language Guide” explains the conceptual model and the terminology, and documents the standard suite. The “Open Scripting Architecture” document explains how to use OSA from an application programmers point of view. In the Apple Help Viewer these books are located in the Developer Documentation, Core Technologies section.

As an example of scripting an application, the following piece of AppleScript will get the name of the frontmost Finder window and print it:

```plaintext
tell application "Finder"
    get name of window 1
end tell
```

In Python, the following code fragment will do the same:

```python
import Finder
f = Finder.Finder()
print f.get(f.window(1).name)
```

As distributed the Python library includes packages that implement the standard suites, plus packages that interface to a small number
of common applications.

To send AppleEvents to an application you must first create the Python package interfacing to the terminology of the application (what Script Editor calls the “Dictionary”). This can be done from within the PythonIDE or by running the gensuitemodule.py module as a standalone program from the command line.

The generated output is a package with a number of modules, one for every suite used in the program plus an __init__ module to glue it all together. The Python inheritance graph follows the AppleScript inheritance graph, so if a program’s dictionary specifies that it includes support for the Standard Suite, but extends one or two verbs with extra arguments then the output suite will contain a module Standard_Suite that imports and re-exports everything from StdSuites.Standard_Suite but overrides the methods that have extra functionality. The output of gensuitemodule is pretty readable, and contains the documentation that was in the original AppleScript dictionary in Python docstrings, so reading it is a good source of documentation.

The output package implements a main class with the same name as the package which contains all the AppleScript verbs as methods, with the direct object as the first argument and all optional parameters as keyword arguments. AppleScript classes are also implemented as Python classes, as are comparisons and all the other thingies.

The main Python class implementing the verbs also allows access to the properties and elements declared in the AppleScript class “application”. In the current release that is as far as the object orientation goes, so in the example above we need to use f.get(f.window(1).name) instead of the more Pythonic f.window(1).name.get().
If an AppleScript identifier is not a Python identifier the name is mangled according to a small number of rules:

- spaces are replaced with underscores
- other non-alphanumeric characters are replaced with \_xx\_ where xx is the hexadecimal character value
- any Python reserved word gets an underscore appended

Python also has support for creating scriptable applications in Python, but The following modules are relevant to MacPython AppleScript support:

- *gensuitemodule* — Generate OSA stub packages
- *aetools* — OSA client support
- *aepack* — Conversion between Python variables and AppleEvent data containers
- *aetypes* — AppleEvent objects
- *MiniAEFrame* — Open Scripting Architecture server support
  - AEServer Objects

In addition, support modules have been pre-generated for Finder, Terminal, Explorer, Netscape, CodeWarrior, SystemEvents and StdSuites.
The `gensuitemodule` module creates a Python package implementing stub code for the AppleScript suites that are implemented by a specific application, according to its AppleScript dictionary.

It is usually invoked by the user through the **PythonIDE**, but it can also be run as a script from the command line (pass `--help` for help on the options) or imported from Python code. For an example of its use see `Mac/scripts/genallsuites.py` in a source distribution, which generates the stub packages that are included in the standard library.

It defines the following public functions:

```python
gensuitemodule.is_scriptable(application)
```

Returns true if `application`, which should be passed as a pathname, appears to be scriptable. Take the return value with a grain of salt: **Internet Explorer** appears not to be scriptable but definitely is.

```python
gensuitemodule.processfile(application[, output, basepkgname, edit_modnames, creatorsignature, dump, verbose])
```

Create a stub package for `application`, which should be passed as a full pathname. For a `.app` bundle this is the pathname to the bundle, not to the executable inside the bundle; for an unbundled CFM application you pass the filename of the application binary.

This function asks the application for its OSA terminology
resources, decodes these resources and uses the resultant data to create the Python code for the package implementing the client stubs.

`output` is the pathname where the resulting package is stored, if not specified a standard “save file as” dialog is presented to the user. `basepkgname` is the base package on which this package will build, and defaults to `StdSuites`. Only when generating `StdSuites` itself do you need to specify this. `edit_modnames` is a dictionary that can be used to change modulenames that are too ugly after name mangling. `creator_signature` can be used to override the 4-char creator code, which is normally obtained from the `PkgInfo` file in the package or from the CFM file creator signature. When `dump` is given it should refer to a file object, and `processfile` will stop after decoding the resources and dump the Python representation of the terminology resources to this file. `verbose` should also be a file object, and specifying it will cause `processfile` to tell you what it is doing.

```python
gensuitemodule.processfile_fromresource(application[, output, basepkgname, edit_modnames, creatorsignature, dump, verbose])
```

This function does the same as `processfile`, except that it uses a different method to get the terminology resources. It opens `application` as a resource file and reads all "aete" and "aeut" resources from this file.
The `aetools` module contains the basic functionality on which Python AppleScript client support is built. It also imports and re-exports the core functionality of the `aetypes` and `aepack` modules. The stub packages generated by `gensuitemodule` import the relevant portions of `aetools`, so usually you do not need to import it yourself. The exception to this is when you cannot use a generated suite package and need lower-level access to scripting.

The `aetools` module itself uses the AppleEvent support provided by the `Carbon.AE` module. This has one drawback: you need access to the window manager, see section _Running scripts with a GUI_ for details. This restriction may be lifted in future releases.

**Warning:** This module is removed in 3.0.

The `aetools` module defines the following functions:

```python
aetools.packevent(ae, parameters, attributes)
```
Stores parameters and attributes in a pre-created `Carbon.AE.AEDesc` object. `parameters` and `attributes` are dictionaries mapping 4-character OSA parameter keys to Python objects. The objects are packed using `aepack.pack()`.

```python
aetools.unpackevent(ae[, formodulename])
```
Recursively unpacks a `Carbon.AE.AEDesc` event to Python objects. The function returns the parameter dictionary and the attribute dictionary. The `formodulename` argument is used by generated stub packages to control where AppleScript classes are looked
aetools. **keysubst**(*arguments*, *keydict*)  
Converts a Python keyword argument dictionary *arguments* to the format required by *packevent* by replacing the keys, which are Python identifiers, by the four-character OSA keys according to the mapping specified in *keydict*. Used by the generated suite packages.

aetools. **enumsubst**(*arguments*, *key*, *edict*)  
If the *arguments* dictionary contains an entry for *key* convert the value for that entry according to dictionary *edict*. This converts human-readable Python enumeration names to the OSA 4-character codes. Used by the generated suite packages.

The *aetools* module defines the following class:

class aetools. **TalkTo**([*signature=None*, *start=0*, *timeout=0*])  
Base class for the proxy used to talk to an application. *signature* overrides the class attribute *_signature* (which is usually set by subclasses) and is the 4-char creator code defining the application to talk to. *start* can be set to true to enable running the application on class instantiation. *timeout* can be specified to change the default timeout used while waiting for an AppleEvent reply.

*TalkTo. **_start**()  
Test whether the application is running, and attempt to start it if not.*

*TalkTo. **send**(code, subcode[, parameters, attributes])  
Create the AppleEvent *Carbon.AE.AEDesc* for the verb with the OSA designation *code*, *subcode* (which are the usual 4-character
strings), pack the `parameters` and `attributes` into it, send it to the target application, wait for the reply, unpack the reply with `unpackevent` and return the reply `applevent`, the unpacked return values as a dictionary and the return attributes.
The `aepack` module defines functions for converting (packing) Python variables to AppleEvent descriptors and back (unpacking). Within Python the AppleEvent descriptor is handled by Python objects of built-in type `AEDesc`, defined in module `Carbon.AE`.

**Warning:** This module is removed in 3.0.

The `aepack` module defines the following functions:

```python
aepack.pack(x[, forctype])
```

Returns an `AEDesc` object containing a conversion of Python value `x`. If `forctype` is provided it specifies the descriptor type of the result. Otherwise, a default mapping of Python types to Apple Event descriptor types is used, as follows:

<table>
<thead>
<tr>
<th>Python type</th>
<th>descriptor type</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSSpec</td>
<td>typeFSS</td>
</tr>
<tr>
<td>FSRef</td>
<td>typeFSRef</td>
</tr>
<tr>
<td>Alias</td>
<td>typeAlias</td>
</tr>
<tr>
<td>integer</td>
<td>typeLong (32 bit integer)</td>
</tr>
<tr>
<td>float</td>
<td>typeFloat (64 bit floating point)</td>
</tr>
<tr>
<td>string</td>
<td>typeText</td>
</tr>
<tr>
<td>unicode</td>
<td>typeUnicodeText</td>
</tr>
<tr>
<td>list</td>
<td>typeAEList</td>
</tr>
</tbody>
</table>
If $x$ is a Python instance then this function attempts to call an \_\_aepack\_\_() method. This method should return an AEDesc object.

If the conversion $x$ is not defined above, this function returns the Python string representation of a value (the \_\_repr\_\_() function) encoded as a text descriptor.

\texttt{aepack.unp}ack($x$, \texttt{formodulename})

$x$ must be an object of type AEDesc. This function returns a Python object representation of the data in the Apple Event descriptor $x$. Simple AppleEvent data types (integer, text, float) are returned as their obvious Python counterparts. Apple Event lists are returned as Python lists, and the list elements are recursively unpacked. Object references (ex. line 3 of document 1) are returned as instances of \texttt{aetypes.ObjectSpecifier}, unless \texttt{formodulename} is specified. AppleEvent descriptors with descriptor type typeFSS are returned as FSSpec objects. AppleEvent record descriptors are returned as Python dictionaries, with 4-character string keys and elements recursively unpacked.

The optional \texttt{formodulename} argument is used by the stub packages generated by \texttt{gensuitemodule}, and ensures that the OSA classes for object specifiers are looked up in the correct module. This ensures that if, say, the Finder returns an object specifier for a window you get an instance of \texttt{Finder.Window} and not a generic \texttt{aetypes.Window}. The former knows about all the properties and elements a window has in the Finder, while the latter knows no such things.
See also:

**Module Carbon.AE**
Built-in access to Apple Event Manager routines.

**Module aetypes**
Python definitions of codes for Apple Event descriptor types.
Platforms: Mac

The aetypes defines classes used to represent Apple Event data descriptors and Apple Event object specifiers.

Apple Event data is contained in descriptors, and these descriptors are typed. For many descriptors the Python representation is simply the corresponding Python type: typeText in OSA is a Python string, typeFloat is a float, etc. For OSA types that have no direct Python counterpart this module declares classes. Packing and unpacking instances of these classes is handled automatically by aepack.

An object specifier is essentially an address of an object implemented in a Apple Event server. An Apple Event specifier is used as the direct object for an Apple Event or as the argument of an optional parameter. The aetypes module contains the base classes for OSA classes and properties, which are used by the packages generated by gensuitemodule to populate the classes and properties in a given suite.

For reasons of backward compatibility, and for cases where you need to script an application for which you have not generated the stub package this module also contains object specifiers for a number of common OSA classes such as Document, Window, Character, etc.

**Warning:** This module is removed in 3.0.

The AEObjects module defines the following classes to represent Apple Event descriptor data:
class aetypes. **Unknown**(type, data)

The representation of OSA descriptor data for which the aepack and aetypes modules have no support, i.e. anything that is not represented by the other classes here and that is not equivalent to a simple Python value.

class aetypes. **Enum**(enum)

An enumeration value with the given 4-character string value.

class aetypes. **InsertionLoc**(of, pos)

Position pos in object of.

class aetypes. **Boolean**(bool)

A boolean.

class aetypes. **StyledText**(style, text)

Text with style information (font, face, etc) included.

class aetypes. **AEText**(script, style, text)

Text with script system and style information included.

class aetypes. **IntlText**(script, language, text)

Text with script system and language information included.

class aetypes. **IntlWritingCode**(script, language)

Script system and language information.

class aetypes. **QDPoint**(v, h)

A quickdraw point.

class aetypes. **QDRectangle**(v0, h0, v1, h1)

A quickdraw rectangle.

class aetypes. **RGBColor**(r, g, b)
A color.

class aetypes. **Type**(type)
   An OSA type value with the given 4-character name.

class aetypes. **Keyword**(name)
   An OSA keyword with the given 4-character name.

class aetypes. **Range**(start, stop)
   A range.

class aetypes. **Ordinal**(abso)
   Non-numeric absolute positions, such as "firs", first, or "midd", middle.

class aetypes. **Logical**(logc, term)
   The logical expression of applying operator logc to term.

class aetypes. **Comparison**(obj1, relo, obj2)
   The comparison relo of obj1 to obj2.

The following classes are used as base classes by the generated stub packages to represent AppleScript classes and properties in Python:

class aetypes. **ComponentItem**(which[, fr])
   Abstract baseclass for an OSA class. The subclass should set the class attribute want to the 4-character OSA class code. Instances of subclasses of this class are equivalent to AppleScript Object Specifiers. Upon instantiation you should pass a selector in which, and optionally a parent object in fr.

class aetypes. **NProperty**(fr)
   Abstract baseclass for an OSA property. The subclass should set
the class attributes `want` and `which` to designate which property we are talking about. Instances of subclasses of this class are Object Specifiers.

class aetypes. **ObjectSpecifier**(`want`, `form`, `seld`, `fr`)  
Base class of `ComponentItem` and `NProperty`, a general OSA Object Specifier. See the Apple Open Scripting Architecture documentation for the parameters. Note that this class is not abstract.
MiniAEFrame — Open Scripting Architecture server support

*Platforms*: Mac

The module *MiniAEFrame* provides a framework for an application that can function as an Open Scripting Architecture (OSA) server, i.e. receive and process AppleEvents. It can be used in conjunction with *FrameWork* or standalone. As an example, it is used in *PythonCGISlave*.

The *MiniAEFrame* module defines the following classes:

**class MiniAEFrame.*AEServer**

A class that handles AppleEvent dispatch. Your application should subclass this class together with either *MiniApplication* or *FrameWork.Application*. Your `__init__() `method should call the `__init__() `method for both classes.

**class MiniAEFrame.*MiniApplication**

A class that is more or less compatible with *FrameWork.Application* but with less functionality. Its event loop supports the apple menu, command-dot and AppleEvents; other events are passed on to the Python interpreter and/or Sioux. Useful if your application wants to use *AEServer* but does not provide its own windows, etc.
AEserver.

**installaehandler**(classe, type, callback)

Installs an AppleEvent handler. *classe* and *type* are the four-character OSA Class and Type designators, '*****' wildcards are allowed. When a matching AppleEvent is received the parameters are decoded and your callback is invoked.

AEserver.

**callback**(object, **kwargs)

Your callback is called with the OSA Direct Object as first positional parameter. The other parameters are passed as keyword arguments, with the 4-character designator as name. Three extra keyword parameters are passed: _class and _type are the Class and Type designators and _attributes is a dictionary with the AppleEvent attributes.

The return value of your method is packed with aetools.packevent() and sent as reply.

Note that there are some serious problems with the current design. AppleEvents which have non-identifier 4-character designators for arguments are not implementable, and it is not possible to return an error to the originator. This will be addressed in a future release.
SGI IRIX Specific Services

The modules described in this chapter provide interfaces to features that are unique to SGI's IRIX operating system (versions 4 and 5).

- **a1** — Audio functions on the SGI
  - Configuration Objects
  - Port Objects
- **AL** — Constants used with the a1 module
- **cd** — CD-ROM access on SGI systems
  - Player Objects
  - Parser Objects
- **f1** — FORMS library for graphical user interfaces
  - Functions Defined in Module f1
  - Form Objects
  - FORMS Objects
- **FL** — Constants used with the f1 module
- **f1p** — Functions for loading stored FORMS designs
- **fm** — *Font Manager* interface
- **g1** — *Graphics Library* interface
- **DEVICE** — Constants used with the g1 module
- **GL** — Constants used with the g1 module
- **imgfile** — Support for SGI imglib files
- **jpeg** — Read and write JPEG files
Platforms: IRIX

Deprecated since version 2.6: The al module has been deprecated for removal in Python 3.0.

This module provides access to the audio facilities of the SGI Indy and Indigo workstations. See section 3A of the IRIX man pages for details. You’ll need to read those man pages to understand what these functions do! Some of the functions are not available in IRIX releases before 4.0.5. Again, see the manual to check whether a specific function is available on your platform.

All functions and methods defined in this module are equivalent to the C functions with al prefixed to their name.

Symbolic constants from the C header file <audio.h> are defined in the standard module al, see below.

Warning: The current version of the audio library may dump core when bad argument values are passed rather than returning an error status. Unfortunately, since the precise circumstances under which this may happen are undocumented and hard to check, the Python interface can provide no protection against this kind of problems. (One example is specifying an excessive queue size — there is no documented upper limit.)

The module defines the following functions:

al. openport(name, direction[, config])

The name and direction arguments are strings. The optional config argument is a configuration object as returned by
newconfig(). The return value is an audio port object; methods of audio port objects are described below.

al. newconfig()

The return value is a new audio configuration object; methods of audio configuration objects are described below.

al. queryparams(device)

The device argument is an integer. The return value is a list of integers containing the data returned by ALqueryparams.

al. getparams(device, list)

The device argument is an integer. The list argument is a list such as returned by queryparams(); it is modified in place (!).

al. setparams(device, list)

The device argument is an integer. The list argument is a list such as returned by queryparams().
## Configuration Objects

Configuration objects returned by `newconfig()` have the following methods:

```javascript
audio configuration.getqueuesize()
    Return the queue size.

audio configuration.setqueuesize(size)
    Set the queue size.

audio configuration.getwidth()
    Get the sample width.

audio configuration.setwidth(width)
    Set the sample width.

audio configuration.getchannels()
    Get the channel count.

audio configuration.setchannels(nchannels)
    Set the channel count.

audio configuration.getsampfmt()
    Get the sample format.

audio configuration.setsampfmt(sampfmt)
    Set the sample format.

audio configuration.getfloatmax()
    Get the maximum value for floating sample formats.

audio configuration.setfloatmax(floatmax)
    Set the maximum value for floating sample formats.
```
Port objects, as returned by `openport()`, have the following methods:

**audio port.closeport()**
Close the port.

**audio port.getfd()**
Return the file descriptor as an int.

**audio port.getfilled()**
Return the number of filled samples.

**audio port.getfillable()**
Return the number of fillable samples.

**audio port.readsamps(nsamples)**
Read a number of samples from the queue, blocking if necessary. Return the data as a string containing the raw data, (e.g., 2 bytes per sample in big-endian byte order (high byte, low byte) if you have set the sample width to 2 bytes).

**audio port.writesamps(samples)**
Write samples into the queue, blocking if necessary. The samples are encoded as described for the `readsamps()` return value.

**audio port.getfillpoint()**
Return the ‘fill point’.

**audio port.setfillpoint(fillpoint)**
Set the ‘fill point’.

**audio port.getconfig()**
Return a configuration object containing the current configuration of the port.
audio_port.setconfig(config)
    Set the configuration from the argument, a configuration object.

audio_port.getstatus(list)
    Get status information on last error.
AL — Constants used with the al module

Platforms: IRIX

Deprecated since version 2.6: The al module has been deprecated for removal in Python 3.0.

This module defines symbolic constants needed to use the built-in module al (see above); they are equivalent to those defined in the C header file `<audio.h>` except that the name prefix `AL_` is omitted. Read the module source for a complete list of the defined names. Suggested use:

```python
import al
from AL import *
```
cd — CD-ROM access on SGI systems

Platforms: IRIX

Deprecated since version 2.6: The cd module has been deprecated for removal in Python 3.0.

This module provides an interface to the Silicon Graphics CD library. It is available only on Silicon Graphics systems.

The way the library works is as follows. A program opens the CD-ROM device with `open()` and creates a parser to parse the data from the CD with `createparser()`. The object returned by `open()` can be used to read data from the CD, but also to get status information for the CD-ROM device, and to get information about the CD, such as the table of contents. Data from the CD is passed to the parser, which parses the frames, and calls any callback functions that have previously been added.

An audio CD is divided into tracks or programs (the terms are used interchangeably). Tracks can be subdivided into indices. An audio CD contains a table of contents which gives the starts of the tracks on the CD. Index 0 is usually the pause before the start of a track. The start of the track as given by the table of contents is normally the start of index 1.

Positions on a CD can be represented in two ways. Either a frame number or a tuple of three values, minutes, seconds and frames. Most functions use the latter representation. Positions can be both relative to the beginning of the CD, and to the beginning of the track.

Module cd defines the following functions and constants:
\texttt{cd.createparser()}

Create and return an opaque parser object. The methods of the parser object are described below.

\texttt{cd.msftoframe(minutes, seconds, frames)}

Converts a \texttt{(minutes, seconds, frames)} triple representing time in absolute time code into the corresponding CD frame number.

\texttt{cd.open([device[, mode]])}

Open the CD-ROM device. The return value is an opaque player object; methods of the player object are described below. The device is the name of the SCSI device file, e.g. '/dev/scsi/sc0d410', or \texttt{None}. If omitted or \texttt{None}, the hardware inventory is consulted to locate a CD-ROM drive. The \texttt{mode}, if not omitted, should be the string 'r'.

The module defines the following variables:

\texttt{exception cd.error}

Exception raised on various errors.

\texttt{cd.DATASIZE}

The size of one frame's worth of audio data. This is the size of the audio data as passed to the callback of type \texttt{audio}.

\texttt{cd.BLOCKSIZE}

The size of one uninterpreted frame of audio data.

The following variables are states as returned by \texttt{getstatus()}:

\texttt{cd.READY}

The drive is ready for operation loaded with an audio CD.

\texttt{cd.NODISC}

The drive does not have a CD loaded.
The drive is loaded with a CD-ROM. Subsequent play or read operations will return I/O errors.

An error occurred while trying to read the disc or its table of contents.

The drive is in CD player mode playing an audio CD through its audio jacks.

The drive is in CD layer mode with play paused.

The equivalent of PAUSED on older (non 3301) model Toshiba CD-ROM drives. Such drives have never been shipped by SGI.

Integer constants describing the various types of parser callbacks that can be set by the addcallback() method of CD parser objects (see below).
Player Objects

Player objects (returned by `open()`) have the following methods:

**CD player.allowremoval()**
Unlocks the eject button on the CD-ROM drive permitting the user to eject the caddy if desired.

**CD player.bestreadsize()**
Returns the best value to use for the `num_frames` parameter of the `readda()` method. Best is defined as the value that permits a continuous flow of data from the CD-ROM drive.

**CD player.close()**
Frees the resources associated with the player object. After calling `close()`, the methods of the object should no longer be used.

**CD player.eject()**
Ejects the caddy from the CD-ROM drive.

**CD player.getstatus()**
Returns information pertaining to the current state of the CD-ROM drive. The returned information is a tuple with the following values: `state`, `track`, `rtime`, `atime`, `ttme`, `first`, `last`, `scsi_audio`, `cur_block`. `rtime` is the time relative to the start of the current track; `atime` is the time relative to the beginning of the disc; `ttme` is the total time on the disc. For more information on the meaning of the values, see the man page `CDgetstatus(3dm)`. The value of `state` is one of the following: `ERROR`, `NODISC`, `READY`, `PLAYING`, `PAUSED`, `STILL`, or `CDROM`.

**CD player.gettrackinfo(track)**
Returns information about the specified track. The returned
information is a tuple consisting of two elements, the start time of
the track and the duration of the track.

**CD player.msftoblock(min, sec, frame)**
Converts a minutes, seconds, frames triple representing a time in
absolute time code into the corresponding logical block number
for the given CD-ROM drive. You should use `msftoframe()` rather
than `msftoblock()` for comparing times. The logical block number
diffs from the frame number by an offset required by certain
CD-ROM drives.

**CD player.play(start, play)**
Starts playback of an audio CD in the CD-ROM drive at the
specified track. The audio output appears on the CD-ROM drive's
headphone and audio jacks (if fitted). Play stops at the end of the
disc. *start* is the number of the track at which to start playing the
CD; if *play* is 0, the CD will be set to an initial paused state. The
method `togglepause()` can then be used to commence play.

**CD player.playabs(minutes, seconds, frames, play)**
Like `play()`, except that the start is given in minutes, seconds,
and frames instead of a track number.

**CD player.playtrack(start, play)**
Like `play()`, except that playing stops at the end of the track.

**CD player.playtrackabs(track, minutes, seconds, frames, play)**
Like `play()`, except that playing begins at the specified absolute
time and ends at the end of the specified track.

**CD player.preventremoval()**
Locks the eject button on the CD-ROM drive thus preventing the
user from arbitrarily ejecting the caddy.

**CD player.readda(num_frames)**
Reads the specified number of frames from an audio CD mounted in the CD-ROM drive. The return value is a string representing the audio frames. This string can be passed unaltered to the `parseframe()` method of the parser object.

**CD player.seek(minutes, seconds, frames)**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to an absolute time code location specified in `minutes`, `seconds`, and `frames`. The return value is the logical block number to which the pointer has been set.

**CD player.seekblock(block)**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified logical block number. The return value is the logical block number to which the pointer has been set.

**CD player.seektrack(track)**

Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified track. The return value is the logical block number to which the pointer has been set.

**CD player.stop()**

Stops the current playing operation.

**CD player.togglepause()**

Pauses the CD if it is playing, and makes it play if it is paused.
Parser Objects

Parser objects (returned by `createparser()`) have the following methods:

**CD** `parser.addcallback(type, func, arg)`

Adds a callback for the parser. The parser has callbacks for eight different types of data in the digital audio data stream. Constants for these types are defined at the `cd` module level (see above). The callback is called as follows: `func(arg, type, data)`, where `arg` is the user supplied argument, `type` is the particular type of callback, and `data` is the data returned for this `type` of callback. The type of the data depends on the `type` of callback as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>audio</td>
<td>String which can be passed unmodified to <code>al.writesamps()</code></td>
</tr>
<tr>
<td>pnum</td>
<td>Integer giving the program (track) number.</td>
</tr>
<tr>
<td>index</td>
<td>Integer giving the index number.</td>
</tr>
<tr>
<td>ptime</td>
<td>Tuple consisting of the program time in minutes, seconds, and frames.</td>
</tr>
<tr>
<td>atime</td>
<td>Tuple consisting of the absolute time in minutes, seconds, and frames.</td>
</tr>
<tr>
<td>catalog</td>
<td>String of 13 characters, giving the catalog number of the CD.</td>
</tr>
<tr>
<td>ident</td>
<td>String of 12 characters, giving the ISRC identification number of the recording. The string consists of two characters country code, three characters owner code, two characters giving the year, and five characters giving a serial number.</td>
</tr>
<tr>
<td>control</td>
<td>Integer giving the control bits from the CD subcode data</td>
</tr>
</tbody>
</table>

**CD** `parser.deleteparser()`
Deletes the parser and frees the memory it was using. The object should not be used after this call. This call is done automatically when the last reference to the object is removed.

**CD parser.parseframe(frame)**

Parses one or more frames of digital audio data from a CD such as returned by `readda()`. It determines which subcodes are present in the data. If these subcodes have changed since the last frame, then `parseframe()` executes a callback of the appropriate type passing to it the subcode data found in the frame. Unlike the C function, more than one frame of digital audio data can be passed to this method.

**CD parser.removecallback(type)**

Removes the callback for the given `type`.

**CD parser.resetparser()**

Resets the fields of the parser used for tracking subcodes to an initial state. `resetparser()` should be called after the disc has been changed.
**f1 — FORMS library for graphical user interfaces**

*Platforms:* IRIX

_Deprecated since version 2.6:* The f1 module has been deprecated for removal in Python 3.0.

This module provides an interface to the FORMS Library by Mark Overmars. The source for the library can be retrieved by anonymous ftp from host `ftp.cs.ruu.nl`, directory `SGI/FORMS`. It was last tested with version 2.0b.

Most functions are literal translations of their C equivalents, dropping the initial `f1_` from their name. Constants used by the library are defined in module `FL` described below.

The creation of objects is a little different in Python than in C: instead of the ‘current form’ maintained by the library to which new FORMS objects are added, all functions that add a FORMS object to a form are methods of the Python object representing the form. Consequently, there are no Python equivalents for the C functions `f1_addto_form` and `f1_end_form`, and the equivalent of `f1_bgn_form` is called `f1.make_form()`.

Watch out for the somewhat confusing terminology: FORMS uses the word *object* for the buttons, sliders etc. that you can place in a form. In Python, ‘object’ means any value. The Python interface to FORMS introduces two new Python object types: form objects (representing an entire form) and FORMS objects (representing one button, slider etc.). Hopefully this isn’t too confusing.

There are no ‘free objects’ in the Python interface to FORMS, nor is
there an easy way to add object classes written in Python. The FORMS interface to GL event handling is available, though, so you can mix FORMS with pure GL windows.

**Please note:** importing f1 implies a call to the GL function foreground and to the FORMS routine f1_init.
Module \texttt{f1} defines the following functions. For more information about what they do, see the description of the equivalent C function in the FORMS documentation:

\texttt{f1. make_form(type, width, height)}
Create a form with given type, width and height. This returns a \textit{form} object, whose methods are described below.

\texttt{f1. do_forms()}  
The standard FORMS main loop. Returns a Python object representing the FORMS object needing interaction, or the special value \texttt{FL.EVENT}.

\texttt{f1. check_forms()}  
Check for FORMS events. Returns what \texttt{do_forms()} above returns, or \texttt{None} if there is no event that immediately needs interaction.

\texttt{f1. set_event_call_back(function)}  
Set the event callback function.

\texttt{f1. set_graphics_mode(rgbmode, doublebuffering)}  
Set the graphics modes.

\texttt{f1. get_rgbmode()}  
Return the current rgb mode. This is the value of the C global variable \texttt{fl_rgbmode}.

\texttt{f1. show_message(str1, str2, str3)}  
Show a dialog box with a three-line message and an OK button.
fl. `show_question(str1, str2, str3)`
   Show a dialog box with a three-line message and YES and NO buttons. It returns 1 if the user pressed YES, 0 if NO.

fl. `show_choice(str1, str2, str3, but1[, but2[, but3]]))`
   Show a dialog box with a three-line message and up to three buttons. It returns the number of the button clicked by the user (1, 2 or 3).

fl. `show_input(prompt, default)`
   Show a dialog box with a one-line prompt message and text field in which the user can enter a string. The second argument is the default input string. It returns the string value as edited by the user.

fl. `show_file_selector(message, directory, pattern, default)`
   Show a dialog box in which the user can select a file. It returns the absolute filename selected by the user, or None if the user presses Cancel.

fl. `get_directory()`
fl. `get_pattern()`
fl. `get_filename()`
   These functions return the directory, pattern and filename (the tail part only) selected by the user in the last `show_file_selector()` call.

fl. `qdevice(dev)`
fl. `unqdevice(dev)`
fl. `isqueued(dev)`
fl. `qtest()`
fl. `qread()`
fl. `qreset()`
`fl.qenter(dev, val)`
`fl.get_mouse()`
`fl.tie(button, valuator1, valuator2)`

These functions are the FORMS interfaces to the corresponding GL functions. Use these if you want to handle some GL events yourself when using `fl.do_events()`. When a GL event is detected that FORMS cannot handle, `fl.do_forms()` returns the special value `FL.EVENT` and you should call `fl.qread()` to read the event from the queue. Don't use the equivalent GL functions!

`fl.color()`
`fl.mapcolor()`
`fl.getmcolor()`

See the description in the FORMS documentation of `fl_color`, `fl_mapcolor` and `fl_getmcolor`. 
Form Objects

Form objects (returned by `make_form()` above) have the following methods. Each method corresponds to a C function whose name is prefixed with `fl_`; and whose first argument is a form pointer; please refer to the official FORMS documentation for descriptions.

All the `add_*()` methods return a Python object representing the FORMS object. Methods of FORMS objects are described below. Most kinds of FORMS object also have some methods specific to that kind; these methods are listed here.

```python
form.show_form(placement, bordertype, name)
    Show the form.

form.hide_form()
    Hide the form.

form.redraw_form()
    Redraw the form.

form.set_form_position(x, y)
    Set the form's position.

form.freeze_form()
    Freeze the form.

form.unfreeze_form()
    Unfreeze the form.

form.activate_form()
    Activate the form.
```
form. **deactivate_form()**
   Deactivate the form.

form. **bgn_group()**
   Begin a new group of objects; return a group object.

form. **end_group()**
   End the current group of objects.

form. **find_first()**
   Find the first object in the form.

form. **find_last()**
   Find the last object in the form.

form. **add_box**(type, x, y, w, h, name)
   Add a box object to the form. No extra methods.

form. **add_text**(type, x, y, w, h, name)
   Add a text object to the form. No extra methods.

form. **add_clock**(type, x, y, w, h, name)
   Add a clock object to the form. — Method: get_clock().

form. **add_button**(type, x, y, w, h, name)
   Add a button object to the form. — Methods: get_button(),
            set_button().

form. **add_lightbutton**(type, x, y, w, h, name)
   Add a lightbutton object to the form. — Methods: get_button(),
            set_button().

form. **add_roundbutton**(type, x, y, w, h, name)
   Add a roundbutton object to the form. — Methods: get_button(),
set_button().

form.add_slider(type, x, y, w, h, name)
Add a slider object to the form. — Methods: set_slider_value(), get_slider_value(), set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(), set_slider_precision(), set_slider_step().

form.add_valslider(type, x, y, w, h, name)
Add a valslider object to the form. — Methods: set_slider_value(), get_slider_value(), set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(), set_slider_precision(), set_slider_step().

form.add_dial(type, x, y, w, h, name)
Add a dial object to the form. — Methods: set_dial_value(), get_dial_value(), set_dial_bounds(), get_dial_bounds().

form.add_positioner(type, x, y, w, h, name)
Add a positioner object to the form. — Methods: set_positioner_xvalue(), set_positioner_yvalue(), set_positioner_xbounds(), set_positioner_ybounds(), get_positioner_xvalue(), get_positioner_yvalue(), get_positioner_xbounds(), get_positioner_ybounds().

form.add_counter(type, x, y, w, h, name)
Add a counter object to the form. — Methods: set_counter_value(), get_counter_value(), set_counter_bounds(), set_counter_step(), set_counter_precision(), set_counter_return().

form.add_input(type, x, y, w, h, name)
Add a input object to the form. — Methods: set_input(),
get_input(), set_input_color(), set_input_return().

form. add_menu(type, x, y, w, h, name)
Add a menu object to the form. — Methods: set_menu(), get_menu(), addto_menu().

form. add_choice(type, x, y, w, h, name)
Add a choice object to the form. — Methods: set_choice(), get_choice(), clear_choice(), addto_choice(), replace_choice(), delete_choice(), get_choice_text(), set_choice_fontsize(), set_choice_fontstyle().

form. add_browser(type, x, y, w, h, name)
Add a browser object to the form. — Methods: set_browser_topline(), clear_browser(), add_browser_line(), addto_browser(), insert_browser_line(), delete_browser_line(), replace_browser_line(), get_browser_line(), load_browser(), get_browser_maxline(), select_browser_line(), deselect_browser_line(), deselect_browser(), isselected_browser_line(), get_browser(), set_browser_fontsize(), set_browser_fontstyle(), set_browser_specialkey().

form. add_timer(type, x, y, w, h, name)
Add a timer object to the form. — Methods: set_timer(), get_timer().

Form objects have the following data attributes; see the FORMS documentation:

<table>
<thead>
<tr>
<th>Name</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>window</td>
<td>int (read-only)</td>
<td>GL window id</td>
</tr>
<tr>

<td>nonzero if double buffering on</td>
</tr>
</tbody>
</table>
**FORMS Objects**

Besides methods specific to particular kinds of FORMS objects, all FORMS objects also have the following methods:

**FORMS object.set_call_back(function, argument)**
Set the object's callback function and argument. When the object needs interaction, the callback function will be called with two arguments: the object, and the callback argument. (FORMS objects without a callback function are returned by `fl.do_forms()` or `fl.check_forms()` when they need interaction.) Call this method without arguments to remove the callback function.

**FORMS object.delete_object()**
Delete the object.

**FORMS object.show_object()**
Show the object.

**FORMS object.hide_object()**
Hide the object.

**FORMS object.redraw_object()**
Redraw the object.

**FORMS object.freeze_object()**
Freeze the object.

**FORMS object.unfreeze_object()**
Unfreeze the object.

FORMS objects have these data attributes; see the FORMS documentation:

<table>
<thead>
<tr>
<th>Name</th>
<th>C Type</th>
<th>Meaning</th>

</table>
FL — Constants used with the fl module

Platforms: IRIX

Deprecation notice: The FL module has been deprecated since version 2.6. The FL module has been deprecated for removal in Python 3.0.

This module defines symbolic constants needed to use the built-in module f1 (see above); they are equivalent to those defined in the C header file `<forms.h>` except that the name prefix `FL_` is omitted. Read the module source for a complete list of the defined names. Suggested use:

```python
import fl
from FL import *
```
flp — Functions for loading stored FORMS designs

Platforms: IRIX

Deprecated since version 2.6: The flp module has been deprecated for removal in Python 3.0.

This module defines functions that can read form definitions created by the ‘form designer’ (fdesign) program that comes with the FORMS library (see module f1 above).

For now, see the file flp.doc in the Python library source directory for a description.

XXX A complete description should be inserted here!
**fm — Font Manager interface**

*Platforms: IRIX*

*Deprecated since version 2.6:* The `fm` module has been deprecated for removal in Python 3.0.

This module provides access to the IRIS Font Manager library. It is available only on Silicon Graphics machines. See also: *4Sight User’s Guide*, section 1, chapter 5: “Using the IRIS Font Manager.”

This is not yet a full interface to the IRIS Font Manager. Among the unsupported features are: matrix operations; cache operations; character operations (use string operations instead); some details of font info; individual glyph metrics; and printer matching.

It supports the following operations:

* `fm.init()`
  - Initialization function. Calls `fminit`. It is normally not necessary to call this function, since it is called automatically the first time the `fm` module is imported.

* `fm.findfont(fontname)`
  - Return a font handle object. Calls `fmfindfont(fontname)`.

* `fm.enumerate()`
  - Returns a list of available font names. This is an interface to `fmenumerate`.

* `fm.prstr(string)`
  - Render a string using the current font (see the `setfont()` font handle method below). Calls `fmprstr(string)`.
\texttt{fm.\texttt{setpath}(string)}

Sets the font search path. Calls \texttt{fmsetpath(string)}. (XXX Does not work!?!)

\texttt{fm.\texttt{fontpath}()}

Returns the current font search path.

Font handle objects support the following operations:

\texttt{font handle.\texttt{scalefont}(factor)}

Returns a handle for a scaled version of this font. Calls \texttt{fmscalefont(fh, factor)}.

\texttt{font handle.\texttt{setfont}()}

Makes this font the current font. Note: the effect is undone silently when the font handle object is deleted. Calls \texttt{fmsetfont(fh)}.

\texttt{font handle.\texttt{getfontname}()}

Returns this font's name. Calls \texttt{fmgetfontname(fh)}.

\texttt{font handle.\texttt{getcomment}()}

Returns the comment string associated with this font. Raises an exception if there is none. Calls \texttt{fmgetcomment(fh)}.

\texttt{font handle.\texttt{getfontinfo}()}

Returns a tuple giving some pertinent data about this font. This is an interface to \texttt{fmgetfontinfo()}. The returned tuple contains the following numbers: \texttt{(printermatched, fixed_width, xorig, yorig, xsize, ysize, height, nglyphs)}.

\texttt{font handle.\texttt{getstrwidth}(string)}

Returns the width, in pixels, of \texttt{string} when drawn in this font. Calls \texttt{fmgetstrwidth(fh, string)}.
Platforms: IRIX

Deprecated since version 2.6: The gl module has been deprecated for removal in Python 3.0.

This module provides access to the Silicon Graphics Graphics Library. It is available only on Silicon Graphics machines.

**Warning:** Some illegal calls to the GL library cause the Python interpreter to dump core. In particular, the use of most GL calls is unsafe before the first window is opened.

The module is too large to document here in its entirety, but the following should help you to get started. The parameter conventions for the C functions are translated to Python as follows:

- All (short, long, unsigned) int values are represented by Python integers.
  
- All float and double values are represented by Python floating point numbers. In most cases, Python integers are also allowed.
  
- All arrays are represented by one-dimensional Python lists. In most cases, tuples are also allowed.
  
- All string and character arguments are represented by Python strings, for instance, `winopen('Hi There!')` and `rotate(900, 'z')`.
  
- All (short, long, unsigned) integer arguments or return values that are only used to specify the length of an array argument are omitted. For example, the C call
lmdef(deftype, index, np, props)

is translated to Python as

lmdef(deftype, index, props)

- Output arguments are omitted from the argument list; they are transmitted as function return values instead. If more than one value must be returned, the return value is a tuple. If the C function has both a regular return value (that is not omitted because of the previous rule) and an output argument, the return value comes first in the tuple. Examples: the C call

```c
getmcolor(i, &red, &green, &blue)
```

is translated to Python as

```python
red, green, blue = getmcolor(i)
```

The following functions are non-standard or have special argument conventions:

**gl.varray(argument)**
Equivalent to but faster than a number of \texttt{v3d()} calls. The \textit{argument} is a list (or tuple) of points. Each point must be a tuple of coordinates \((x, y, z)\) or \((x, y)\). The points may be 2- or 3-dimensional but must all have the same dimension. Float and int values may be mixed however. The points are always converted to 3D double precision points by assuming \(z = 0.0\) if necessary (as indicated in the man page), and for each point \texttt{v3d()} is called.

**gl.nvarray()**
Equivalent to but faster than a number of \texttt{n3f} and \texttt{v3f} calls. The argument is an array (list or tuple) of pairs of normals and points.
Each pair is a tuple of a point and a normal for that point. Each point or normal must be a tuple of coordinates \((x, y, z)\). Three coordinates must be given. Float and int values may be mixed. For each pair, \(n3f()\) is called for the normal, and then \(v3f()\) is called for the point.

\texttt{gl.vnarray()}

Similar to \texttt{nvarray()} but the pairs have the point first and the normal second.

\texttt{gl.nurbssurface(s\_k, t\_k, ctl, s\_ord, t\_ord, type)}

Defines a nurbs surface. The dimensions of \texttt{ctl[][]} are computed as follows: \([\text{len(s\_k)} - \text{s\_ord}], [\text{len(t\_k)} - \text{t\_ord}]]\).

\texttt{gl.nurbscurve(knots, ctlpoints, order, type)}

Defines a nurbs curve. The length of \texttt{ctlpoints} is \texttt{len(knots)} - \texttt{order}.

\texttt{gl.pwlcurve(points, type)}

Defines a piecewise-linear curve. \texttt{points} is a list of points. \texttt{type} must be \texttt{N\_ST}.

\texttt{gl.pick(n)}
\texttt{gl.select(n)}

The only argument to these functions specifies the desired size of the pick or select buffer.

\texttt{gl.endpick()}
\texttt{gl.endselect()}

These functions have no arguments. They return a list of integers representing the used part of the pick/select buffer. No method is provided to detect buffer overrun.

Here is a tiny but complete example GL program in Python:
import gl, GL, time

def main():
    gl.foreground()
    gl.prefposition(500, 900, 500, 900)
    w = gl.winopen('CrissCross')
    gl.ortho2(0.0, 400.0, 0.0, 400.0)
    gl.color(GL.WHITE)
    gl.clear()
    gl.color(GL.RED)
    gl.bgnline()
    gl.v2f(0.0, 0.0)
    gl.v2f(400.0, 400.0)
    gl.endline()
    gl.bgnline()
    gl.v2f(400.0, 0.0)
    gl.v2f(0.0, 400.0)
    gl.endline()
    time.sleep(5)

main()

See also:

**PyOpenGL: The Python OpenGL Binding**

An interface to OpenGL is also available; see information about the PyOpenGL project online at [http://pyopengl.sourceforge.net/](http://pyopengl.sourceforge.net/). This may be a better option if support for SGI hardware from before about 1996 is not required.
DEVICE — Constants used with the gl module

Platforms: IRIX

Deprecated since version 2.6: The DEVICE module has been deprecated for removal in Python 3.0.

This modules defines the constants used by the Silicon Graphics Graphics Library that C programmers find in the header file `<gl/device.h>`. Read the module source file for details.
GL — Constants used with the gl module

Platforms: IRIX

Deprecated since version 2.6: The GL module has been deprecated for removal in Python 3.0.

This module contains constants used by the Silicon Graphics Graphics Library from the C header file `<gl/gl.h>`. Read the module source file for details.
Support for SGI imglib files

Platforms: IRIX

Deprecated since version 2.6: The imgfile module has been deprecated for removal in Python 3.0.

The imgfile module allows Python programs to access SGI imglib image files (also known as .rgb files). The module is far from complete, but is provided anyway since the functionality that there is enough in some cases. Currently, colormap files are not supported.

The module defines the following variables and functions:

exception imgfile.error

This exception is raised on all errors, such as unsupported file type, etc.

imgfile.getsizes(file)

This function returns a tuple (x, y, z) where x and y are the size of the image in pixels and z is the number of bytes per pixel. Only 3 byte RGB pixels and 1 byte greyscale pixels are currently supported.

imgfile.read(file)

This function reads and decodes the image on the specified file, and returns it as a Python string. The string has either 1 byte greyscale pixels or 4 byte RGBA pixels. The bottom left pixel is the first in the string. This format is suitable to pass to gl.lrectwrite(), for instance.

imgfile.readscaled(file, x, y, filter[, blur])
This function is identical to read but it returns an image that is scaled to the given \(x\) and \(y\) sizes. If the filter and blur parameters are omitted scaling is done by simply dropping or duplicating pixels, so the result will be less than perfect, especially for computer-generated images.

Alternatively, you can specify a filter to use to smooth the image after scaling. The filter forms supported are 'impulse', 'box', 'triangle', 'quadratic' and 'gaussian'. If a filter is specified blur is an optional parameter specifying the blurriness of the filter. It defaults to 1.0.

\texttt{readscaled()} makes no attempt to keep the aspect ratio correct, so that is the users' responsibility.

\texttt{imgfile.ttob(flag)}

This function sets a global flag which defines whether the scan lines of the image are read or written from bottom to top (flag is zero, compatible with SGI GL) or from top to bottom(flag is one, compatible with X). The default is zero.

\texttt{imgfile.write(file, data, x, y, z)}

This function writes the RGB or greyscale data in \textit{data} to image file \textit{file}. \textit{x} and \textit{y} give the size of the image, \textit{z} is 1 for 1 byte greyscale images or 3 for RGB images (which are stored as 4 byte values of which only the lower three bytes are used). These are the formats returned by \texttt{gl.lrectread()}.  

\textbf{Python v2.6 documentation » The Python Standard Library previous | next | modules | index}
The module **jpeg** provides access to the jpeg compressor and decompressor written by the Independent JPEG Group (IJG). JPEG is a standard for compressing pictures; it is defined in ISO 10918. For details on JPEG or the Independent JPEG Group software refer to the JPEG standard or the documentation provided with the software.

A portable interface to JPEG image files is available with the Python Imaging Library (PIL) by Fredrik Lundh. Information on PIL is available at [http://www.pythonware.com/products/pil/](http://www.pythonware.com/products/pil/).

The **jpeg** module defines an exception and some functions.

**exception jpeg.error**

Exception raised by `compress()` and `decompress()` in case of errors.

**jpeg.compress(data, w, h, b)**

Treat data as a pixmap of width `w` and height `h`, with `b` bytes per pixel. The data is in SGI GL order, so the first pixel is in the lower-left corner. This means that `gl.lrectread()` return data can immediately be passed to `compress()`. Currently only 1 byte and 4 byte pixels are allowed, the former being treated as greyscale and the latter as RGB color. `compress()` returns a string that contains the compressed picture, in JFIF format.

**jpeg.decompress(data)**
Data is a string containing a picture in JFIF format. It returns a tuple `(data, width, height, bytesperpixel)`. Again, the data is suitable to pass to `gl.irectwrite()`.

```python
jpeg.setoption(name, value)
```

Set various options. Subsequent `compress()` and `decompress()` calls will use these options. The following options are available:

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>'forcegray'</td>
<td>Force output to be grayscale, even if input is RGB.</td>
</tr>
<tr>
<td>'quality'</td>
<td>Set the quality of the compressed image to a value between 0 and 100 (default is 75). This only affects compression.</td>
</tr>
<tr>
<td>'optimize'</td>
<td>Perform Huffman table optimization. Takes longer, but results in smaller compressed image. This only affects compression.</td>
</tr>
<tr>
<td>'smooth'</td>
<td>Perform inter-block smoothing on uncompressed image. Only useful for low-quality images. This only affects decompression.</td>
</tr>
</tbody>
</table>

**JPEG Still Image Data Compression Standard**

The canonical reference for the JPEG image format, by Pennebaker and Mitchell.

**Information Technology - Digital Compression and Coding of Continuous-tone Still Images - Requirements and Guidelines**

The ISO standard for JPEG is also published as ITU T.81. This is available online in PDF form.
The modules described in this chapter provide interfaces to features that are unique to SunOS 5 (also known as Solaris version 2).

- `sunaudiodev` — Access to Sun audio hardware
  - Audio Device Objects
- `SUNAUDIODEV` — Constants used with `sunaudiodev`
sunaudiodev — Access to Sun audio hardware

Platforms: SunOS

Deprecated since version 2.6: The sunaudiodev module has been deprecated for removal in Python 3.0.

This module allows you to access the Sun audio interface. The Sun audio hardware is capable of recording and playing back audio data in u-LAW format with a sample rate of 8K per second. A full description can be found in the audio(7I) manual page.

The module SUNAUDIODEV defines constants which may be used with this module.

This module defines the following variables and functions:

element exception sunaudiodev.error

This exception is raised on all errors. The argument is a string describing what went wrong.

sunaudiodev.open(mode)

This function opens the audio device and returns a Sun audio device object. This object can then be used to do I/O on. The mode parameter is one of 'r' for record-only access, 'w' for play-only access, 'rw' for both and 'control' for access to the control device. Since only one process is allowed to have the recorder or player open at the same time it is a good idea to open the device only for the activity needed. See audio(7I) for details.

As per the manpage, this module first looks in the environment variable AUDIODEV for the base audio device filename. If not
found, it falls back to /dev/audio. The control device is calculated by appending “ctl” to the base audio device.
Audio Device Objects

The audio device objects are returned by open() define the following methods (except control objects which only provide getinfo(), setinfo(), fileno(), and drain()):

**audio device.close()**
This method explicitly closes the device. It is useful in situations where deleting the object does not immediately close it since there are other references to it. A closed device should not be used again.

**audio device.fileno()**
Returns the file descriptor associated with the device. This can be used to set up SIGPOLL notification, as described below.

**audio device.drain()**
This method waits until all pending output is processed and then returns. Calling this method is often not necessary: destroying the object will automatically close the audio device and this will do an implicit drain.

**audio device.flush()**
This method discards all pending output. It can be used avoid the slow response to a user’s stop request (due to buffering of up to one second of sound).

**audio device.getinfo()**
This method retrieves status information like input and output volume, etc. and returns it in the form of an audio status object. This object has no methods but it contains a number of attributes describing the current device status. The names and meanings of the attributes are described in `<sun/audioio.h>` and in the audio(7I) manual page. Member names are slightly different from
their C counterparts: a status object is only a single structure. Members of the play substructure have o_ prepended to their name and members of the record structure have i_. So, the C member play.sample_rate is accessed as o_sample_rate, record.gain as i_gain and monitor_gain plainly as monitor_gain.

audio device.ibufcount()
This method returns the number of samples that are buffered on the recording side, i.e. the program will not block on a read() call of so many samples.

audio device.obufcount()
This method returns the number of samples buffered on the playback side. Unfortunately, this number cannot be used to determine a number of samples that can be written without blocking since the kernel output queue length seems to be variable.

audio device.read(size)
This method reads size samples from the audio input and returns them as a Python string. The function blocks until enough data is available.

audio device.setinfo(status)
This method sets the audio device status parameters. The status parameter is an device status object as returned by getinfo() and possibly modified by the program.

audio device.write(samples)
Write is passed a Python string containing audio samples to be played. If there is enough buffer space free it will immediately return, otherwise it will block.

The audio device supports asynchronous notification of various events, through the SIGPOLL signal. Here’s an example of how you
might enable this in Python:

```python
def handle_sigpoll(signum, frame):
    print 'I got a SIGPOLL update'

import fcntl, signal, STROPTS

signal.signal(signal.SIGPOLL, handle_sigpoll)
fcntl.ioctl(audio_obj.fileno(), STROPTS.I_SETSIG, STROPTS.S_MSG)
```
SUNAUDIODEV — Constants used with sunaudiodev

Platforms: SunOS

Deprecated since version 2.6: The SUNAUDIODEV module has been deprecated for removal in Python 3.0.

This is a companion module to sunaudiodev which defines useful symbolic constants like MIN_GAIN, MAX_GAIN, SPEAKER, etc. The names of the constants are the same names as used in the C include file <sun/audioio.h>, with the leading string AUDIO_ stripped.
Undocumented Modules

Here’s a quick listing of modules that are currently undocumented, but that should be documented. Feel free to contribute documentation for them! (Send via email to docs@python.org.)

The idea and original contents for this chapter were taken from a posting by Fredrik Lundh; the specific contents of this chapter have been substantially revised.
Miscellaneous useful utilities

Some of these are very old and/or not very robust; marked with “hmm.”

**ihooks**
— Import hook support (for *reexec*; may become obsolete).

**Warning:** The *ihooks* module has been removed in Python 3.0.
Platform specific modules

These modules are used to implement the `os.path` module, and are not documented beyond this mention. There's little need to document these.

**ntpath**
— Implementation of `os.path` on Win32, Win64, WinCE, and OS/2 platforms.

**posixpath**
— Implementation of `os.path` on POSIX.

**bsddb185**
— Backwards compatibility module for systems which still use the Berkeley DB 1.85 module. It is normally only available on certain BSD Unix-based systems. It should never be used directly.
Multimedia

audiodev
— Platform-independent API for playing audio data.

**Warning**: The `audiodev` module has been removed in 3.0.

linuxaudiodev
— Play audio data on the Linux audio device. Replaced in Python 2.3 by the `ossaudiodev` module.

**Warning**: The `linuxaudiodev` module has been removed in Python 3.0.

sunaudio
— Interpret Sun audio headers (may become obsolete or a tool/demo).

**Warning**: The `sunaudio` module has been removed in Python 3.0.

toaiff
— Convert “arbitrary” sound files to AIFF files; should probably become a tool or demo. Requires the external program `sox`.

**Warning**: The `toaiff` module has been removed in 3.0.
Undocumented Mac OS modules

**applesingle — AppleSingle decoder**

*Platforms*: Mac

*Deprecated since version 2.6.*

**buildtools — Helper module for BuildApplet and Friends**

*Platforms*: Mac

*Deprecated since version 2.4.*

**cfmfile — Code Fragment Resource module**

*Platforms*: Mac

`cfmfile` is a module that understands Code Fragments and the accompanying “cfrg” resources. It can parse them and merge them, and is used by BuildApplication to combine all plugin modules to a single executable.

*Deprecated since version 2.4.*

**icopen — Internet Config replacement for open()**

*Platforms*: Mac

Importing `icopen` will replace the builtin `open()` with a version that uses Internet Config to set file type and creator for new files.
**macerrors — Mac OS Errors**

*Platforms:* Mac

`macerrors` contains constant definitions for many Mac OS error codes.

*Deprecated since version 2.6.*

**macresource — Locate script resources**

*Platforms:* Mac

`macresource` helps scripts finding their resources, such as dialogs and menus, without requiring special case code for when the script is run under MacPython, as a MacPython applet or under OSX Python.

*Deprecated since version 2.6.*

**Nav — NavServices calls**

*Platforms:* Mac

A low-level interface to Navigation Services.

*Deprecated since version 2.6.*

**PixMapWrapper — Wrapper for PixMap objects**

*Platforms:* Mac

PixMapWrapper wraps a PixMap object with a Python object that allows access to the fields by name. It also has methods to convert
to and from PIL images.

_Deprecated since version 2.6._

**videoreader — Read QuickTime movies**

_Platforms:_ Mac

videoreader reads and decodes QuickTime movies and passes a stream of images to your program. It also provides some support for audio tracks.

_Deprecated since version 2.6._

**w — Widgets built on FrameWork**

_Platforms:_ Mac

The w widgets are used extensively in the IDE.

_Deprecated since version 2.6._
These modules are not normally available for import; additional work must be done to make them available.

These extension modules written in C are not built by default. Under Unix, these must be enabled by uncommenting the appropriate lines in Modules/Setup in the build tree and either rebuilding Python if the modules are statically linked, or building and installing the shared object if using dynamically-loaded extensions.

**timing**

— Measure time intervals to high resolution (use `time.clock()` instead).

**Warning:** The **timing** module has been removed in Python 3.0.
SGI-specific Extension modules

The following are SGI specific, and may be out of touch with the current version of reality.

cl
— Interface to the SGI compression library.

sv
— Interface to the “simple video” board on SGI Indigo (obsolete hardware).

**Warning:** The sv module has been removed in Python 3.0.
Extending Python with C or C++

It is quite easy to add new built-in modules to Python, if you know how to program in C. Such extension modules can do two things that can’t be done directly in Python: they can implement new built-in object types, and they can call C library functions and system calls.

To support extensions, the Python API (Application Programmers Interface) defines a set of functions, macros and variables that provide access to most aspects of the Python run-time system. The Python API is incorporated in a C source file by including the header "Python.h".

The compilation of an extension module depends on its intended use as well as on your system setup; details are given in later chapters.
A Simple Example

Let’s create an extension module called spam (the favorite food of Monty Python fans...) and let’s say we want to create a Python interface to the C library function system. [1] This function takes a null-terminated character string as argument and returns an integer. We want this function to be callable from Python as follows:

```python
>>> import spam
>>> status = spam.system("ls -l")
```

Begin by creating a file spammodule.c. (Historically, if a module is called spam, the C file containing its implementation is called spammodule.c; if the module name is very long, like spammify, the module name can be just spammify.c.)

The first line of our file can be:

```c
#include <Python.h>
```

which pulls in the Python API (you can add a comment describing the purpose of the module and a copyright notice if you like).

**Warning:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you must include Python.h before any standard headers are included.

All user-visible symbols defined by Python.h have a prefix of Py or PY, except those defined in standard header files. For convenience, and since they are used extensively by the Python interpreter, "Python.h" includes a few standard header files: <stdio.h>, <string.h>, <errno.h>, and <stdlib.h>. If the latter header file does
not exist on your system, it declares the functions `malloc`, `free` and `realloc` directly.

The next thing we add to our module file is the C function that will be called when the Python expression `spam.system(string)` is evaluated (we’ll see shortly how it ends up being called):

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;

    sts = system(command);
    return Py_BuildValue("i", sts);
}
```

There is a straightforward translation from the argument list in Python (for example, the single expression "ls -l") to the arguments passed to the C function. The C function always has two arguments, conventionally named `self` and `args`.

The `self` argument is only used when the C function implements a built-in method, not a function. In the example, `self` will always be a `NULL` pointer, since we are defining a function, not a method. (This is done so that the interpreter doesn’t have to understand two different types of C functions.)

The `args` argument will be a pointer to a Python tuple object containing the arguments. Each item of the tuple corresponds to an argument in the call’s argument list. The arguments are Python objects — in order to do anything with them in our C function we have to convert them to C values. The function `PyArg_ParseTuple` in the Python API checks the argument types and converts them to C values. It uses a template string to determine the required types of the arguments as well as the types of the C variables into which to
store the converted values. More about this later.

`PyArg_ParseTuple` returns true (nonzero) if all arguments have the right type and its components have been stored in the variables whose addresses are passed. It returns false (zero) if an invalid argument list was passed. In the latter case it also raises an appropriate exception so the calling function can return `NULL` immediately (as we saw in the example).
An important convention throughout the Python interpreter is the following: when a function fails, it should set an exception condition and return an error value (usually a NULL pointer). Exceptions are stored in a static global variable inside the interpreter; if this variable is NULL no exception has occurred. A second global variable stores the “associated value” of the exception (the second argument to `raise`). A third variable contains the stack traceback in case the error originated in Python code. These three variables are the C equivalents of the Python variables `sys.exc_type`, `sys.exc_value` and `sys.exc_traceback` (see the section on module `sys` in the Python Library Reference). It is important to know about them to understand how errors are passed around.

The Python API defines a number of functions to set various types of exceptions.

The most common one is `PyErr_SetString`. Its arguments are an exception object and a C string. The exception object is usually a predefined object like `PyExc_ZeroDivisionError`. The C string indicates the cause of the error and is converted to a Python string object and stored as the “associated value” of the exception.

Another useful function is `PyErr_SetFromErrno`, which only takes an exception argument and constructs the associated value by inspection of the global variable `errno`. The most general function is `PyErr_SetObject`, which takes two object arguments, the exception and its associated value. You don’t need to `Py_INCREF` the objects passed to any of these functions.

You can test non-destructively whether an exception has been set with `PyErr_Occurred`. This returns the current exception object, or
if no exception has occurred. You normally don’t need to call `PyErr_Occurred` to see whether an error occurred in a function call, since you should be able to tell from the return value.

When a function $f$ that calls another function $g$ detects that the latter fails, $f$ should itself return an error value (usually `NULL` or `-1`). It should not call one of the `PyErr_*` functions — one has already been called by $g$. $f$'s caller is then supposed to also return an error indication to its caller, again without calling `PyErr_*`, and so on — the most detailed cause of the error was already reported by the function that first detected it. Once the error reaches the Python interpreter’s main loop, this aborts the currently executing Python code and tries to find an exception handler specified by the Python programmer.

(There are situations where a module can actually give a more detailed error message by calling another `PyErr_*` function, and in such cases it is fine to do so. As a general rule, however, this is not necessary, and can cause information about the cause of the error to be lost: most operations can fail for a variety of reasons.)

To ignore an exception set by a function call that failed, the exception condition must be cleared explicitly by calling `PyErr_Clear`. The only time C code should call `PyErr_Clear` is if it doesn’t want to pass the error on to the interpreter but wants to handle it completely by itself (possibly by trying something else, or pretending nothing went wrong).

Every failing `malloc` call must be turned into an exception — the direct caller of `malloc` (or `realloc`) must call `PyErr_NoMemory` and return a failure indicator itself. All the object-creating functions (for example, `PyInt_FromLong`) already do this, so this note is only relevant to those who call `malloc` directly.

Also note that, with the important exception of `PyArg_ParseTuple` and
friends, functions that return an integer status usually return a positive value or zero for success and -1 for failure, like Unix system calls.

Finally, be careful to clean up garbage (by making `Py_XDECREF` or `Py_DECREF` calls for objects you have already created) when you return an error indicator!

The choice of which exception to raise is entirely yours. There are predeclared C objects corresponding to all built-in Python exceptions, such as `PyExc_ZeroDivisionError`, which you can use directly. Of course, you should choose exceptions wisely — don’t use `PyExc_TypeError` to mean that a file couldn’t be opened (that should probably be `PyExc_IOError`). If something’s wrong with the argument list, the `PyArg_ParseTuple` function usually raises `PyExc_TypeError`. If you have an argument whose value must be in a particular range or must satisfy other conditions, `PyExc_ValueError` is appropriate.

You can also define a new exception that is unique to your module. For this, you usually declare a static object variable at the beginning of your file:

```c
static PyObject *SpamError;
```

and initialize it in your module’s initialization function (`initspam`) with an exception object (leaving out the error checking for now):

```c
PyMODINIT_FUNC
initspam(void)
{
    PyObject *m;

    m = Py_InitModule("spam", SpamMethods);
    if (m == NULL)
        return;
```
Note that the Python name for the exception object is `spam.error`. The `PyErr_NewException` function may create a class with the base class being `Exception` (unless another class is passed in instead of `NULL`), described in *Built-in Exceptions*.

Note also that the `SpamError` variable retains a reference to the newly created exception class; this is intentional! Since the exception could be removed from the module by external code, an owned reference to the class is needed to ensure that it will not be discarded, causing `SpamError` to become a dangling pointer. Should it become a dangling pointer, C code which raises the exception could cause a core dump or other unintended side effects.

We discuss the use of `PyMODINIT_FUNC` as a function return type later in this sample.
Going back to our example function, you should now be able to understand this statement:

```c
if (!PyArg_ParseTuple(args, "s", &command))
    return NULL;
```

It returns *NULL* (the error indicator for functions returning object pointers) if an error is detected in the argument list, relying on the exception set by `PyArg_ParseTuple`. Otherwise the string value of the argument has been copied to the local variable `command`. This is a pointer assignment and you are not supposed to modify the string to which it points (so in Standard C, the variable `command` should properly be declared as `const char *command`).

The next statement is a call to the Unix function `system`, passing it the string we just got from `PyArg_ParseTuple`:

```c
sts = system(command);
```

Our `spam.system()` function must return the value of `sts` as a Python object. This is done using the function `Py_BuildValue`, which is something like the inverse of `PyArg_ParseTuple`: it takes a format string and an arbitrary number of C values, and returns a new Python object. More info on `Py_BuildValue` is given later.

```c
return Py_BuildValue("i", sts);
```

In this case, it will return an integer object. (Yes, even integers are objects on the heap in Python!)

If you have a C function that returns no useful argument (a function
returning `void`), the corresponding Python function must return `None`. You need this idiom to do so (which is implemented by the `Py_RETURN_NONE` macro):

```c
Py_INCREF(Py_None);
return Py_None;
```

`Py_None` is the C name for the special Python object `None`. It is a genuine Python object rather than a `NULL` pointer, which means “error” in most contexts, as we have seen.
The Module’s Method Table and Initialization Function

I promised to show how `spam_system` is called from Python programs. First, we need to list its name and address in a “method table”:

```c
static PyMethodDef SpamMethods[] = {
    ...
    {"system", spam_system, METH_VARARGS,
     "Execute a shell command."},
    ...
    {NULL, NULL, 0, NULL} /* Sentinel */
};
```

Note the third entry (`METH_VARARGS`). This is a flag telling the interpreter the calling convention to be used for the C function. It should normally always be `METH_VARARGS` or `METH_VARARGS | METH_KEYWORDS`; a value of 0 means that an obsolete variant of `PyArg_ParseTuple` is used.

When using only `METH_VARARGS`, the function should expect the Python-level parameters to be passed in as a tuple acceptable for parsing via `PyArg_ParseTuple`; more information on this function is provided below.

The `METH_KEYWORDS` bit may be set in the third field if keyword arguments should be passed to the function. In this case, the C function should accept a third `PyObject *` parameter which will be a dictionary of keywords. Use `PyArg_ParseTupleAndKeywords` to parse the arguments to such a function.

The method table must be passed to the interpreter in the module’s initialization function. The initialization function must be named `initname`, where `name` is the name of the module, and should be the
only non-static item defined in the module file:

```python
PyMODINIT_FUNC
initspam(void)
{
    (void) Py_InitModule("spam", SpamMethods);
}
```

Note that PyMODINIT_FUNC declares the function as void return type, declares any special linkage declarations required by the platform, and for C++ declares the function as extern "C".

When the Python program imports module spam for the first time, initspam is called. (See below for comments about embedding Python.) It calls Py_InitModule, which creates a “module object” (which is inserted in the dictionary sys.modules under the key "spam"), and inserts built-in function objects into the newly created module based upon the table (an array of PyMethodDef structures) that was passed as its second argument. Py_InitModule returns a pointer to the module object that it creates (which is unused here). It may abort with a fatal error for certain errors, or return NULL if the module could not be initialized satisfactorily.

When embedding Python, the initspam function is not called automatically unless there’s an entry in the _PyImport_InitTab table. The easiest way to handle this is to statically initialize your statically-linked modules by directly calling initspam after the call to Py_Initialize:

```c
int
main(int argc, char *argv[])
{
    /* Pass argv[0] to the Python interpreter */
    Py_SetProgramName(argv[0]);

    /* Initialize the Python interpreter. Required. */
    Py_Initialize();
```
An example may be found in the file `Demo/embed/demo.c` in the Python source distribution.

**Note:** Removing entries from `sys.modules` or importing compiled modules into multiple interpreters within a process (or following a `fork` without an intervening `exec`) can create problems for some extension modules. Extension module authors should exercise caution when initializing internal data structures. Note also that the `reload()` function can be used with extension modules, and will call the module initialization function (`initspam` in the example), but will not load the module again if it was loaded from a dynamically loadable object file (.so on Unix, .dll on Windows).

A more substantial example module is included in the Python source distribution as `Modules/xxmodule.c`. This file may be used as a template or simply read as an example. The `modulator.py` script included in the source distribution or Windows install provides a simple graphical user interface for declaring the functions and objects which a module should implement, and can generate a template which can be filled in. The script lives in the `Tools/modulator/` directory; see the `README` file there for more information.
Compilation and Linkage

There are two more things to do before you can use your new extension: compiling and linking it with the Python system. If you use dynamic loading, the details may depend on the style of dynamic loading your system uses; see the chapters about building extension modules (chapter Building C and C++ Extensions with distutils) and additional information that pertains only to building on Windows (chapter Building C and C++ Extensions on Windows) for more information about this.

If you can’t use dynamic loading, or if you want to make your module a permanent part of the Python interpreter, you will have to change the configuration setup and rebuild the interpreter. Luckily, this is very simple on Unix: just place your file (spammodule.c for example) in the Modules/ directory of an unpacked source distribution, add a line to the file Modules/Setup.local describing your file:

```
spam spammodule.o
```

and rebuild the interpreter by running make in the toplevel directory. You can also run make in the Modules/ subdirectory, but then you must first rebuild Makefile there by running ‘make Makefile’. (This is necessary each time you change the Setup file.)

If your module requires additional libraries to link with, these can be listed on the line in the configuration file as well, for instance:

```
spam spammodule.o -lx11
```
Calling Python Functions from C

So far we have concentrated on making C functions callable from Python. The reverse is also useful: calling Python functions from C. This is especially the case for libraries that support so-called “callback” functions. If a C interface makes use of callbacks, the equivalent Python often needs to provide a callback mechanism to the Python programmer; the implementation will require calling the Python callback functions from a C callback. Other uses are also imaginable.

Fortunately, the Python interpreter is easily called recursively, and there is a standard interface to call a Python function. (I won’t dwell on how to call the Python parser with a particular string as input — if you’re interested, have a look at the implementation of the `-c` command line option in `Modules/main.c` from the Python source code.)

Calling a Python function is easy. First, the Python program must somehow pass you the Python function object. You should provide a function (or some other interface) to do this. When this function is called, save a pointer to the Python function object (be careful to `Py_INCREF` it!) in a global variable — or wherever you see fit. For example, the following function might be part of a module definition:

```c
static PyObject *my_callback = NULL;

static PyObject *
my_set_callback(PyObject *dummy, PyObject *args)
{
    PyObject *result = NULL;
    PyObject *temp;

    if (PyArg_ParseTuple(args, "O:set_callback", &temp)) {
        if (!PyCallable_Check(temp)) {
            PyErr_SetString(PyExc_TypeError, "parameter must be callable");
            return NULL;
        }

        // Further processing...
    }
    // Other arguments...
}
```
This function must be registered with the interpreter using the \texttt{METH_VARARGS} flag; this is described in section \textit{The Module's Method Table and Initialization Function}. The \texttt{PyArg_ParseTuple} function and its arguments are documented in section \textit{Extracting Parameters in Extension Functions}.

The macros \texttt{Py_XINCREF} and \texttt{Py_XDECREF} increment/decrement the reference count of an object and are safe in the presence of \texttt{NULL} pointers (but note that \texttt{temp} will not be \texttt{NULL} in this context). More info on them in section \textit{Reference Counts}.

Later, when it is time to call the function, you call the C function \texttt{PyEval_CallObject}. This function has two arguments, both pointers to arbitrary Python objects: the Python function, and the argument list. The argument list must always be a tuple object, whose length is the number of arguments. To call the Python function with no arguments, pass in \texttt{NULL}, or an empty tuple; to call it with one argument, pass a singleton tuple. \texttt{Py_BuildValue} returns a tuple when its format string consists of zero or more format codes between parentheses. For example:

```c
int arg;
PyObject *arglist;
PyObject *result;
...
arg = 123;
...
/* Time to call the callback */
```
PyEval_CallObject returns a Python object pointer: this is the return value of the Python function. PyEval_CallObject is "reference-count-neutral" with respect to its arguments. In the example a new tuple was created to serve as the argument list, which is Py_DECREF-ed immediately after the call.

The return value of PyEval_CallObject is "new": either it is a brand new object, or it is an existing object whose reference count has been incremented. So, unless you want to save it in a global variable, you should somehow Py_DECREF the result, even (especially!) if you are not interested in its value.

Before you do this, however, it is important to check that the return value isn’t NULL. If it is, the Python function terminated by raising an exception. If the C code that called PyEval_CallObject is called from Python, it should now return an error indication to its Python caller, so the interpreter can print a stack trace, or the calling Python code can handle the exception. If this is not possible or desirable, the exception should be cleared by calling PyErr_Clear. For example:

```c
if (result == NULL)
    return NULL; /* Pass error back */
...use result...
Py_DECREF(result);
```

Depending on the desired interface to the Python callback function, you may also have to provide an argument list to PyEval_CallObject. In some cases the argument list is also provided by the Python program, through the same interface that specified the callback function. It can then be saved and used in the same manner as the function object. In other cases, you may have to construct a new tuple to pass as the argument list. The simplest way to do this is to
call **Py_BuildValue**. For example, if you want to pass an integral event code, you might use the following code:

```c
PyObject *arglist;
...
arglist = Py_BuildValue("(l)", eventcode);
result = PyEval_CallObject(my_callback, arglist);
Py_DECREF(arglist);
if (result == NULL)
  return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

Note the placement of **Py_DECREF(arglist)** immediately after the call, before the error check! Also note that strictly speaking this code is not complete: **Py_BuildValue** may run out of memory, and this should be checked.

You may also call a function with keyword arguments by using **PyEval_CallObjectWithKeywords**. As in the above example, we use **Py_BuildValue** to construct the dictionary.

```c
PyObject *dict;
...
dict = Py_BuildValue("{s:i}", "name", val);
result = PyEval_CallObjectWithKeywords(my_callback, NULL, dict);
Py_DECREF(dict);
if (result == NULL)
  return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```
Extracting Parameters in Extension Functions

The `PyArg_ParseTuple` function is declared as follows:

```c
int PyArg_ParseTuple(PyObject *arg, char *format, ...);
```

The `arg` argument must be a tuple object containing an argument list passed from Python to a C function. The `format` argument must be a format string, whose syntax is explained in *Parsing arguments and building values* in the Python/C API Reference Manual. The remaining arguments must be addresses of variables whose type is determined by the format string.

Note that while `PyArg_ParseTuple` checks that the Python arguments have the required types, it cannot check the validity of the addresses of C variables passed to the call: if you make mistakes there, your code will probably crash or at least overwrite random bits in memory. So be careful!

Note that any Python object references which are provided to the caller are *borrowed* references; do not decrement their reference count!

Some example calls:

```c
int ok;
int i, j;
long k, l;
const char *s;
int size;
ok = PyArg_ParseTuple(args, "") ; /* No arguments */
/* Python call: f() */
ok = PyArg_ParseTuple(args, "s", &s) ; /* A string */
```
/* Possible Python call: f('whoops!') */

ok = PyArg_ParseTuple(args, "lls", &k, &l, &s); /* Two longs and a string */
/* Possible Python call: f(1, 2, 'three') */

ok = PyArg_ParseTuple(args, "(ii)s#", &i, &j, &s, &size);
/* A pair of ints and a string, whose size is also returned */
/* Possible Python call: f((1, 2), 'three') */

{ const char *file;
  const char *mode = "r";
  int bufsize = 0;
  ok = PyArg_ParseTuple(args, "s|si", &file, &mode, &bufsize);
  /* A string, and optionally another string and an integer */
  /* Possible Python calls:
    f('spam')
    f('spam', 'w')
    f('spam', 'wb', 100000) */
}

{ int left, top, right, bottom, h, v;
  ok = PyArg_ParseTuple(args, "((ii)(ii))(ii)",
                        &left, &top, &right, &bottom, &h, &v);
  /* A rectangle and a point */
  /* Possible Python call:
    f(((0, 0), (400, 300)), (10, 10)) */
}

{ Py_complex c;
  ok = PyArg_ParseTuple(args, "D:myfunction", &c);
  /* A complex, also providing a function name for errors */
  /* Possible Python call: myfunction(1+2j) */
}
Keyword Parameters for Extension Functions

The `PyArg_ParseTupleAndKeywords` function is declared as follows:

```c
int PyArg_ParseTupleAndKeywords(PyObject *arg, PyObject *kwdict, char *format, char *kwlist[], ...);
```

The `arg` and `format` parameters are identical to those of the `PyArg_ParseTuple` function. The `kwdict` parameter is the dictionary of keywords received as the third parameter from the Python runtime. The `kwlist` parameter is a `NULL`-terminated list of strings which identify the parameters; the names are matched with the type information from `format` from left to right. On success, `PyArg_ParseTupleAndKeywords` returns true, otherwise it returns false and raises an appropriate exception.

**Note:** Nested tuples cannot be parsed when using keyword arguments! Keyword parameters passed in which are not present in the `kwlist` will cause `TypeError` to be raised.

Here is an example module which uses keywords, based on an example by Geoff Philbrick (philbrick@hks.com):

```c
#include "Python.h"

static PyObject *
keywdarg_parrot(PyObject *self, PyObject *args, PyObject *keywd
{
    int voltage;
    char *state = "a stiff";
    char *action = "voom";
    char *type = "Norwegian Blue";

    static char *kwlist[] = {"voltage", "state", "action", "typ```
if (!PyArg_ParseTupleAndKeywords(args, keywds, "i|sss", kw\1
   &voltage, &state, &action, 
   return NULL;

printf("-- This parrot wouldn't %s if you put %i Volts thro\2
   action, voltage);
printf("-- Lovely plumage, the %s -- It's %s!\n", type, sta\3
   Py_INCREF(Py_None);
   return Py_None;
}

static PyMethodDef keywdarg_methods[] = {
   /* The cast of the function is necessary since PyCFunction 
   * only take two PyObject* parameters, and keywdarg_parrot( 
   * three. 
   */
   {"parrot", (PyFunction)keywdarg_parrot, METH_VARARGS | MET\4
   "Print a lovely skit to standard output."},
   {NULL, NULL, 0, NULL} /* sentinel */
};

void
initkeywdarg(void)
{
   /* Create the module and add the functions */
   Py_InitModule("keywdarg", keywdarg_methods);
}
Building Arbitrary Values

This function is the counterpart to \texttt{PyArg_ParseTuple}. It is declared as follows:

\begin{verbatim}
PyObject *Py_BuildValue(char *format, ...);
\end{verbatim}

It recognizes a set of format units similar to the ones recognized by \texttt{PyArg_ParseTuple}, but the arguments (which are input to the function, not output) must not be pointers, just values. It returns a new Python object, suitable for returning from a C function called from Python.

One difference with \texttt{PyArg_ParseTuple}: while the latter requires its first argument to be a tuple (since Python argument lists are always represented as tuples internally), \texttt{Py_BuildValue} does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns \texttt{None}; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

Examples (to the left the call, to the right the resulting Python value):

\begin{verbatim}
<table>
<thead>
<tr>
<th>Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Py_BuildValue(&quot;&quot;&quot;)</td>
<td>None</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;i&quot;, 123)</td>
<td>123</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;iii&quot;, 123, 456, 789)</td>
<td>(123, 456, 789)</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;s&quot;, &quot;hello&quot;)</td>
<td>'hello'</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;ss&quot;, &quot;hello&quot;, &quot;world&quot;)</td>
<td>('hello', 'world')</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;s#&quot;, &quot;hello&quot;, 4)</td>
<td>'hell'</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;()&quot;)</td>
<td>()</td>
</tr>
<tr>
<td>Py_BuildValue(&quot;(i)&quot;, 123)</td>
<td>(123,)</td>
</tr>
<tr>

Reference Counts

In languages like C or C++, the programmer is responsible for dynamic allocation and deallocation of memory on the heap. In C, this is done using the functions `malloc` and `free`. In C++, the operators `new` and `delete` are used with essentially the same meaning and we'll restrict the following discussion to the C case.

Every block of memory allocated with `malloc` should eventually be returned to the pool of available memory by exactly one call to `free`. It is important to call `free` at the right time. If a block's address is forgotten but `free` is not called for it, the memory it occupies cannot be reused until the program terminates. This is called a memory leak. On the other hand, if a program calls `free` for a block and then continues to use the block, it creates a conflict with re-use of the block through another `malloc` call. This is called using freed memory. It has the same bad consequences as referencing uninitialized data — core dumps, wrong results, mysterious crashes.

Common causes of memory leaks are unusual paths through the code. For instance, a function may allocate a block of memory, do some calculation, and then free the block again. Now a change in the requirements for the function may add a test to the calculation that detects an error condition and can return prematurely from the function. It's easy to forget to free the allocated memory block when taking this premature exit, especially when it is added later to the code. Such leaks, once introduced, often go undetected for a long time: the error exit is taken only in a small fraction of all calls, and most modern machines have plenty of virtual memory, so the leak only becomes apparent in a long-running process that uses the leaking function frequently. Therefore, it's important to prevent leaks from happening by having a coding convention or strategy that
minimizes this kind of errors.

Since Python makes heavy use of `malloc` and `free`, it needs a strategy to avoid memory leaks as well as the use of freed memory. The chosen method is called *reference counting*. The principle is simple: every object contains a counter, which is incremented when a reference to the object is stored somewhere, and which is decremented when a reference to it is deleted. When the counter reaches zero, the last reference to the object has been deleted and the object is freed.

An alternative strategy is called *automatic garbage collection*. (Sometimes, reference counting is also referred to as a garbage collection strategy, hence my use of “automatic” to distinguish the two.) The big advantage of automatic garbage collection is that the user doesn't need to call `free` explicitly. (Another claimed advantage is an improvement in speed or memory usage — this is no hard fact however.) The disadvantage is that for C, there is no truly portable automatic garbage collector, while reference counting can be implemented portably (as long as the functions `malloc` and `free` are available — which the C Standard guarantees). Maybe some day a sufficiently portable automatic garbage collector will be available for C. Until then, we'll have to live with reference counts.

While Python uses the traditional reference counting implementation, it also offers a cycle detector that works to detect reference cycles. This allows applications to not worry about creating direct or indirect circular references; these are the weakness of garbage collection implemented using only reference counting. Reference cycles consist of objects which contain (possibly indirect) references to themselves, so that each object in the cycle has a reference count which is non-zero. Typical reference counting implementations are not able to reclaim the memory belonging to any objects in a reference cycle, or referenced from the objects in the cycle, even
though there are no further references to the cycle itself.

The cycle detector is able to detect garbage cycles and can reclaim them so long as there are no finalizers implemented in Python (__del__() methods). When there are such finalizers, the detector exposes the cycles through the gc module (specifically, the garbage variable in that module). The gc module also exposes a way to run the detector (the collect() function), as well as configuration interfaces and the ability to disable the detector at runtime. The cycle detector is considered an optional component; though it is included by default, it can be disabled at build time using the --without-cycle-gc option to the configure script on Unix platforms (including Mac OS X) or by removing the definition of WITH_CYCLE_GC in the pyconfig.h header on other platforms. If the cycle detector is disabled in this way, the gc module will not be available.

Reference Counting in Python

There are two macros, Py_INCREF(x) and Py_DECREF(x), which handle the incrementing and decrementing of the reference count. Py_DECREF also frees the object when the count reaches zero. For flexibility, it doesn’t call free directly — rather, it makes a call through a function pointer in the object’s type object. For this purpose (and others), every object also contains a pointer to its type object.

The big question now remains: when to use Py_INCREF(x) and Py_DECREF(x)? Let’s first introduce some terms. Nobody “owns” an object; however, you can own a reference to an object. An object’s reference count is now defined as the number of owned references to it. The owner of a reference is responsible for calling Py_DECREF when the reference is no longer needed. Ownership of a reference can be transferred. There are three ways to dispose of an owned reference: pass it on, store it, or call Py_DECREF. Forgetting to dispose
of an owned reference creates a memory leak.

It is also possible to borrow [2] a reference to an object. The borrower of a reference should not call Py_DECREF. The borrower must not hold on to the object longer than the owner from which it was borrowed. Using a borrowed reference after the owner has disposed of it risks using freed memory and should be avoided completely. [3]

The advantage of borrowing over owning a reference is that you don’t need to take care of disposing of the reference on all possible paths through the code — in other words, with a borrowed reference you don’t run the risk of leaking when a premature exit is taken. The disadvantage of borrowing over leaking is that there are some subtle situations where in seemingly correct code a borrowed reference can be used after the owner from which it was borrowed has in fact disposed of it.

A borrowed reference can be changed into an owned reference by calling Py_INCREf. This does not affect the status of the owner from which the reference was borrowed — it creates a new owned reference, and gives full owner responsibilities (the new owner must dispose of the reference properly, as well as the previous owner).

Ownership Rules

Whenever an object reference is passed into or out of a function, it is part of the function’s interface specification whether ownership is transferred with the reference or not.

Most functions that return a reference to an object pass on ownership with the reference. In particular, all functions whose function it is to create a new object, such as PyInt_FromLong and Py_BuildValue, pass ownership to the receiver. Even if the object is not actually new, you still receive ownership of a new reference to
that object. For instance, `PyInt_FromLong` maintains a cache of popular values and can return a reference to a cached item.

Many functions that extract objects from other objects also transfer ownership with the reference, for instance `PyObject_GetAttrString`. The picture is less clear, here, however, since a few common routines are exceptions: `PyTuple_GetItem`, `PyList_GetItem`, `PyDict_GetItem`, and `PyDict_GetItemString` all return references that you borrow from the tuple, list or dictionary.

The function `PyImport_AddModule` also returns a borrowed reference, even though it may actually create the object it returns: this is possible because an owned reference to the object is stored in `sys.modules`.

When you pass an object reference into another function, in general, the function borrows the reference from you — if it needs to store it, it will use `Py_INCREF` to become an independent owner. There are exactly two important exceptions to this rule: `PyTuple_SetItem` and `PyList_SetItem`. These functions take over ownership of the item passed to them — even if they fail! (Note that `PyDict_SetItem` and friends don’t take over ownership — they are “normal.”)

When a C function is called from Python, it borrows references to its arguments from the caller. The caller owns a reference to the object, so the borrowed reference’s lifetime is guaranteed until the function returns. Only when such a borrowed reference must be stored or passed on, it must be turned into an owned reference by calling `Py_INCREF`.

The object reference returned from a C function that is called from Python must be an owned reference — ownership is transferred from the function to its caller.
There are a few situations where seemingly harmless use of a borrowed reference can lead to problems. These all have to do with implicit invocations of the interpreter, which can cause the owner of a reference to dispose of it.

The first and most important case to know about is using `Py_DECREF` on an unrelated object while borrowing a reference to a list item. For instance:

```c
void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);

    PyList_SetItem(list, 1, PyInt_FromLong(0L));
    PyObject_Print(item, stdout, 0); /* BUG */
}
```

This function first borrows a reference to `list[0]`, then replaces `list[1]` with the value 0, and finally prints the borrowed reference. Looks harmless, right? But it's not!

Let's follow the control flow into `PyList_SetItem`. The list owns references to all its items, so when item 1 is replaced, it has to dispose of the original item 1. Now let's suppose the original item 1 was an instance of a user-defined class, and let's further suppose that the class defined a `__del__()` method. If this class instance has a reference count of 1, disposing of it will call its `__del__()` method.

Since it is written in Python, the `__del__()` method can execute arbitrary Python code. Could it perhaps do something to invalidate the reference to `item` in `bug`? You bet! Assuming that the list passed into `bug` is accessible to the `__del__()` method, it could execute a statement to the effect of `del list[0]`, and assuming this was the
last reference to that object, it would free the memory associated with it, thereby invalidating \texttt{item}.

The solution, once you know the source of the problem, is easy: temporarily increment the reference count. The correct version of the function reads:

```c
void no_bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_INCREF(item);
    PyList_SetItem(list, 1, PyInt_FromLong(0L));
    PyObject_Print(item, stdout, 0);
    Py_DECREF(item);
}
```

This is a true story. An older version of Python contained variants of this bug and someone spent a considerable amount of time in a C debugger to figure out why his \texttt{\_\_del\_\_()} methods would fail...

The second case of problems with a borrowed reference is a variant involving threads. Normally, multiple threads in the Python interpreter can’t get in each other’s way, because there is a global lock protecting Python’s entire object space. However, it is possible to temporarily release this lock using the macro \texttt{Py\_BEGIN\_ALLOW\_THREADS}, and to re-acquire it using \texttt{Py\_END\_ALLOW\_THREADS}. This is common around blocking I/O calls, to let other threads use the processor while waiting for the I/O to complete. Obviously, the following function has the same problem as the previous one:

```c
void bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_BEGIN_ALLOW_THREADS
    ...some blocking I/O call...
    Py_END_ALLOW_THREADS
```
NULL Pointers

In general, functions that take object references as arguments do not expect you to pass them NULL pointers, and will dump core (or cause later core dumps) if you do so. Functions that return object references generally return NULL only to indicate that an exception occurred. The reason for not testing for NULL arguments is that functions often pass the objects they receive on to other function — if each function were to test for NULL, there would be a lot of redundant tests and the code would run more slowly.

It is better to test for NULL only at the “source:” when a pointer that may be NULL is received, for example, from malloc or from a function that may raise an exception.

The macros Py_INCREF and Py_DECREF do not check for NULL pointers — however, their variants Py_XINCREF and Py_XDECREF do.

The macros for checking for a particular object type (Pytype_Check()) don’t check for NULL pointers — again, there is much code that calls several of these in a row to test an object against various different expected types, and this would generate redundant tests. There are no variants with NULL checking.

The C function calling mechanism guarantees that the argument list passed to C functions (args in the examples) is never NULL — in fact it guarantees that it is always a tuple. [4]

It is a severe error to ever let a NULL pointer “escape” to the Python user.
It is possible to write extension modules in C++. Some restrictions apply. If the main program (the Python interpreter) is compiled and linked by the C compiler, global or static objects with constructors cannot be used. This is not a problem if the main program is linked by the C++ compiler. Functions that will be called by the Python interpreter (in particular, module initialization functions) have to be declared using `extern "C"`. It is unnecessary to enclose the Python header files in `extern "C" {...}` — they use this form already if the symbol `_cplusplus` is defined (all recent C++ compilers define this symbol).
Providing a C API for an Extension Module

Many extension modules just provide new functions and types to be used from Python, but sometimes the code in an extension module can be useful for other extension modules. For example, an extension module could implement a type “collection” which works like lists without order. Just like the standard Python list type has a C API which permits extension modules to create and manipulate lists, this new collection type should have a set of C functions for direct manipulation from other extension modules.

At first sight this seems easy: just write the functions (without declaring them `static`, of course), provide an appropriate header file, and document the C API. And in fact this would work if all extension modules were always linked statically with the Python interpreter. When modules are used as shared libraries, however, the symbols defined in one module may not be visible to another module. The details of visibility depend on the operating system; some systems use one global namespace for the Python interpreter and all extension modules (Windows, for example), whereas others require an explicit list of imported symbols at module link time (AIX is one example), or offer a choice of different strategies (most Unices). And even if symbols are globally visible, the module whose functions one wishes to call might not have been loaded yet!

Portability therefore requires not to make any assumptions about symbol visibility. This means that all symbols in extension modules should be declared `static`, except for the module’s initialization function, in order to avoid name clashes with other extension modules (as discussed in section The Module’s Method Table and Initialization Function). And it means that symbols that `should` be accessible from other extension modules must be exported in a different way.
Python provides a special mechanism to pass C-level information (pointers) from one extension module to another one: CObjects. A CObject is a Python data type which stores a pointer (void *). CObjects can only be created and accessed via their C API, but they can be passed around like any other Python object. In particular, they can be assigned to a name in an extension module’s namespace. Other extension modules can then import this module, retrieve the value of this name, and then retrieve the pointer from the CObject.

There are many ways in which CObjects can be used to export the C API of an extension module. Each name could get its own CObject, or all C API pointers could be stored in an array whose address is published in a CObject. And the various tasks of storing and retrieving the pointers can be distributed in different ways between the module providing the code and the client modules.

The following example demonstrates an approach that puts most of the burden on the writer of the exporting module, which is appropriate for commonly used library modules. It stores all C API pointers (just one in the example!) in an array of void pointers which becomes the value of a CObject. The header file corresponding to the module provides a macro that takes care of importing the module and retrieving its C API pointers; client modules only have to call this macro before accessing the C API.

The exporting module is a modification of the spam module from section A Simple Example. The function spam.system() does not call the C library function system directly, but a function PySpam_System, which would of course do something more complicated in reality (such as adding “spam” to every command). This function PySpam_System is also exported to other extension modules.

The function PySpam_System is a plain C function, declared static
like everything else:

```c
static int
PySpam_System(const char *command)
{
    return system(command);
}
```

The function `spam_system` is modified in a trivial way:

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = PySpam_System(command);
    return Py_BuildValue("i", sts);
}
```

In the beginning of the module, right after the line

```c
#include "Python.h"
```

two more lines must be added:

```c
#define SPAM_MODULE
#include "spammodule.h"
```

The `#define` is used to tell the header file that it is being included in the exporting module, not a client module. Finally, the module's initialization function must take care of initializing the C API pointer array:

```c
PyMODINIT_FUNC
initspam(void)
{
    PyObject *m;
    static void *PySpam_API[PySpam_API_pointers];
    PyObject *c_api_object;
```
m = Py_InitModule("spam", SpamMethods);
    if (m == NULL)
        return;

    /* Initialize the C API pointer array */
    PySpam_API[PySpam_System_NUM] = (void *)PySpam_System;

    /* Create a CObject containing the API pointer array's address */
    c_api_object = PyCObject_FromVoidPtr((void *)PySpam_API, NULL);
    if (c_api_object != NULL)
        PyModule_AddObject(m, "_C_API", c_api_object);
}

Note that PySpam_API is declared static; otherwise the pointer array would disappear when initspam() terminates!

The bulk of the work is in the header file spammodule.h, which looks like this:

```c
#ifndef Py_SPAMMODULE_H
#define Py_SPAMMODULE_H
#ifdef __cplusplus
extern "C"
#else
#endif

/* Header file for spammodule */

/* C API functions */
#define PySpam_System_NUM 0
#define PySpam_System_RETURN int
#define PySpam_SystemPROTO (const char *command)

/* Total number of C API pointers */
#define PySpam_API_pointers 1

#ifdef SPAM_MODULE
/* This section is used when compiling spammodule.c */

static PySpam_System_RETURN PySpam_System PySpam_System_PROTO;
#else
/* This section is used in modules that use spammodule's API */
```
static void **PySpam_API;

#define PySpam_System \
(*PySpam_System_RETURN (*PySpam_System_PROTO) PySpam_API[PySpam_System_NUM])

/* Return -1 and set exception on error, 0 on success. */
static int import_spam(void)
{
    PyObject *module = PyImport_ImportModule("spam");
    if (module != NULL) {
        PyObject *c_api_object = PyObject_GetAttrString(module, "_C_API" if (c_api_object == NULL)
        return -1;
        if (PyCObject_Check(c_api_object))
            PySpam_API = (void **)PyCObject_AsVoidPtr(c_api_object);
    }
    return 0;
}
#endif
#endif
/* !defined(Py_SPAMMODULE_H) */

All that a client module must do in order to have access to the function PySpam_System is to call the function (or rather macro) import_spam in its initialization function:

PyMODINIT_FUNC
initclient(void)
{
    PyObject *m;
    m = Py_InitModule("client", ClientMethods);
    if (m == NULL)
        return;
    if (import_spam() < 0)
        return;
    /* additional initialization can happen here */
The main disadvantage of this approach is that the file `spammodule.h` is rather complicated. However, the basic structure is the same for each function that is exported, so it has to be learned only once.

Finally it should be mentioned that CObjects offer additional functionality, which is especially useful for memory allocation and deallocation of the pointer stored in a CObject. The details are described in the Python/C API Reference Manual in the section `CObjects` and in the implementation of CObjects (files `Include/cobject.h` and `Objects/cobject.c` in the Python source code distribution).

**Footnotes**

[1] An interface for this function already exists in the standard module `os` — it was chosen as a simple and straightforward example.

[2] The metaphor of “borrowing” a reference is not completely correct: the owner still has a copy of the reference. Checking that the reference count is at least 1 does not work — the reference count itself could be in freed memory and may thus be reused for another object!

[3] These guarantees don’t hold when you use the “old” style calling convention — this is still found in much existing code.
Defining New Types

As mentioned in the last chapter, Python allows the writer of an extension module to define new types that can be manipulated from Python code, much like strings and lists in core Python.

This is not hard; the code for all extension types follows a pattern, but there are some details that you need to understand before you can get started.

**Note:** The way new types are defined changed dramatically (and for the better) in Python 2.2. This document documents how to define new types for Python 2.2 and later. If you need to support older versions of Python, you will need to refer to older versions of this documentation.
The Basics

The Python runtime sees all Python objects as variables of type `PyObject*`. A `PyObject` is not a very magnificent object - it just contains the refcount and a pointer to the object’s “type object”. This is where the action is; the type object determines which (C) functions get called when, for instance, an attribute gets looked up on an object or it is multiplied by another object. These C functions are called “type methods” to distinguish them from things like `[]`.append (which we call “object methods”).

So, if you want to define a new object type, you need to create a new type object.

This sort of thing can only be explained by example, so here's a minimal, but complete, module that defines a new type:

```c
#include <Python.h>

typedef struct {
   PyObject_HEAD
   /* Type-specific fields go here. */
} noddy_NoddyObject;

static PyTypeObject noddy_NoddyType = {
   PyObject_HEAD_INIT(NULL)
   0,                    /*ob_size*/
   "noddy.Noddy",       /*tp_name*/
   sizeof(noddy_NoddyObject), /*tp_basicsize*/
   0,                    /*tp_itemsize*/
   0,                    /*tp_dealloc*/
   0,                    /*tp_print*/
   0,                    /*tp_getattr*/
   0,                    /*tp_setattr*/
   0,                    /*tp_compare*/
   0,                    /*tp_repr*/
   0,                    /*tp_as_number*/
   0,                    /*tp_as_sequence*/
   0,                    /*tp_as_mapping*/
   0,                    /*tp_hash */
};
```
Now that's quite a bit to take in at once, but hopefully bits will seem familiar from the last chapter.

The first bit that will be new is:

```c
typedef struct {
    PyObject_HEAD
} noddy_NoddyObject;
```

This is what a Noddy object will contain—in this case, nothing more than every Python object contains, namely a refcount and a pointer to a type object. These are the fields the `PyObject_HEAD` macro brings
The reason for the macro is to standardize the layout and to enable special debugging fields in debug builds. Note that there is no semicolon after the `PyObject_HEAD` macro; one is included in the macro definition. Be wary of adding one by accident; it’s easy to do from habit, and your compiler might not complain, but someone else’s probably will! (On Windows, MSVC is known to call this an error and refuse to compile the code.)

For contrast, let’s take a look at the corresponding definition for standard Python integers:

```
typedef struct {
    PyObject_HEAD
    long ob_ival;
} PyIntObject;
```

Moving on, we come to the crunch — the type object.

```
static PyTypeObject noddy_NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0, /*ob_size*/
    "noddy.Noddy",
    sizeof(noddy_NoddyObject), /*tp_basicsize*/
    0, /*tp_itemsize*/
    0, /*tp_dealloc*/
    0, /*tp_print*/
    0, /*tp_getattr*/
    0, /*tp_setattr*/
    0, /*tp_compare*/
    0, /*tp_repr*/
    0, /*tp_as_number*/
    0, /*tp_as_sequence*/
    0, /*tp_as_mapping*/
    0, /*tp_hash */
    0, /*tp_call*/
    0, /*tp_str*/
    0, /*tp_getattro*/
    0, /*tp_setattro*/
    0, /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT, /*tp_flags*/
    "Noddy objects",
    /* tp_doc */
};
```
Now if you go and look up the definition of `PyTypeObject` in `object.h` you'll see that it has many more fields that the definition above. The remaining fields will be filled with zeros by the C compiler, and it's common practice to not specify them explicitly unless you need them.

This is so important that we're going to pick the top of it apart still further:

```c
PyObject_HEAD_INIT(NULL)
```

This line is a bit of a wart; what we'd like to write is:

```c
PyObject_HEAD_INIT(&PyType_Type)
```

as the type of a type object is “type”, but this isn’t strictly conforming C and some compilers complain. Fortunately, this member will be filled in for us by `PyType_Ready`.

```
0,       /* ob_size */
```

The `ob_size` field of the header is not used; its presence in the type structure is a historical artifact that is maintained for binary compatibility with extension modules compiled for older versions of Python. Always set this field to zero.

```
"noddy.Noddy",   /* tp_name */
```

The name of our type. This will appear in the default textual representation of our objects and in some error messages, for example:

```python
>>> "" + noddy.new_noddy()
TypeError: cannot add type "noddy.Noddy" to string
```
Note that the name is a dotted name that includes both the module name and the name of the type within the module. The module in this case is `noddy` and the type is `Noddy`, so we set the type name to `noddy.Noddy`.

```python
sizeof(noddy_NoddyObject), /* tp_basicsize */
```

This is so that Python knows how much memory to allocate when you call `PyObject_New`.

**Note:** If you want your type to be subclassable from Python, and your type has the same `tp_basicsize` as its base type, you may have problems with multiple inheritance. A Python subclass of your type will have to list your type first in its `__bases__`, or else it will not be able to call your type's `__new__()` method without getting an error. You can avoid this problem by ensuring that your type has a larger value for `tp_basicsize` than its base type does. Most of the time, this will be true anyway, because either your base type will be `object`, or else you will be adding data members to your base type, and therefore increasing its size.

```python
0, /* tp_itemsize */
```

This has to do with variable length objects like lists and strings. Ignore this for now.

Skipping a number of type methods that we don't provide, we set the class flags to `Py_TPFLAGS_DEFAULT`.

```python
Py_TPFLAGS_DEFAULT, /*tp_flags*/
```

All types should include this constant in their flags. It enables all of the members defined by the current version of Python.
We provide a doc string for the type in `tp_doc`.

```
"Noddy objects", /* tp_doc */
```

Now we get into the type methods, the things that make your objects different from the others. We aren't going to implement any of these in this version of the module. We'll expand this example later to have more interesting behavior.

For now, all we want to be able to do is to create new `Noddy` objects. To enable object creation, we have to provide a `tp_new` implementation. In this case, we can just use the default implementation provided by the API function `PyType_GenericNew`. We'd like to just assign this to the `tp_new` slot, but we can't, for portability sake. On some platforms or compilers, we can't statically initialize a structure member with a function defined in another C module, so, instead, we'll assign the `tp_new` slot in the module initialization function just before calling `PyType_Ready`:

```python
noddy_NoddyType.tp_new = PyType_GenericNew;
if (PyType_Ready(&noddy_NoddyType) < 0)
    return;
```

All the other type methods are `NULL`, so we'll go over them later — that's for a later section!

Everything else in the file should be familiar, except for some code in `initnoddy`:

```python
if (PyType_Ready(&noddy_NoddyType) < 0)
    return;
```

This initializes the `Noddy` type, filing in a number of members, including `ob_type` that we initially set to `NULL`.

```python
PyModule_AddObject(m, "Noddy", (PyObject *)&noddy_NoddyType);
```
This adds the type to the module dictionary. This allows us to create **Noddy** instances by calling the **Noddy** class:

```python
>>> import noddy
>>> mynoddy = noddy.Noddy()
```

That's it! All that remains is to build it; put the above code in a file called *noddy.c* and

```python
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
      ext_modules=[Extension("noddy", ["noddy.c"])])
```

in a file called *setup.py*; then typing

```
$ python setup.py build
```

at a shell should produce a file *noddy.so* in a subdirectory; move to that directory and fire up Python — you should be able to `import noddy` and play around with Noddy objects.

That wasn’t so hard, was it?

Of course, the current Noddy type is pretty uninteresting. It has no data and doesn’t do anything. It can’t even be subclassed.

**Adding data and methods to the Basic example**

Let’s expend the basic example to add some data and methods. Let’s also make the type usable as a base class. We’ll create a new module, **noddy2** that adds these capabilities:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
```
static PyObject *first; /* first name */
static PyObject *last; /* last name */
int number;
} Noddy;

static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("’");
        if (self->first == NULL)
            {Py_DECREF(self);
             return NULL;}

        self->last = PyString_FromString("’");
        if (self->last == NULL)
            {Py_DECREF(self);
             return NULL;}
    }

    self->number = 0;

    return (PyObject *)self;
}

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", kwlist &first, &last,
    return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }

    return 0;
}

static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0, "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0, "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0, "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }

return NULL;
}

args = Py_BuildValue("OO", self->first, self->last);
if (args == NULL)
  return NULL;

result = PyString_Format(format, args);
Py_DECREF(args);
return result;

static PyMethodDef Noddy_methods[] = {
  {"name", (PyCFunction)Noddy_name, METH_NOARGS,
   "Return the name, combining the first and last name"},
  {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
  PyObject_HEAD_INIT(NULL)
  0, /*ob_size*/
  "noddy.Noddy", /*tp_name*/
  sizeof(Noddy), /*tp_basicsize*/
  0, /*tp_itemsize*/
  (destructor)Noddy_dealloc, /*tp_dealloc*/
  0, /*tp_print*/
  0, /*tp_getattr*/
  0, /*tp_setattr*/
  0, /*tp_compare*/
  0, /*tp_repr*/
  0, /*tp_as_number*/
  0, /*tp_as_sequence*/
  0, /*tp_as_mapping*/
  0, /*tp_hash */
  0, /*tp_call*/
  0, /*tp_str*/
  0, /*tp_getattro*/
  0, /*tp_setattro*/
  0, /*tp_as_buffer*/
  Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE, /*tp_flags*/
  "Noddy objects", /* tp_doc */
  0, /* tp_traverse */
  0, /* tp_clear */
  0, /* tp_richcompare */
  0, /* tp_weaklistoffset */
  0, /* tp_iter */
  0, /* tp_iternext */
  Noddy_methods,
};
This version of the module has a number of changes.

We've added an extra include:

```c
#include "structmember.h"
```

This include provides declarations that we use to handle attributes, as described a bit later.
The name of the Noddy object structure has been shortened to Noddy. The type object name has been shortened to NoddyType.

The Noddy type now has three data attributes, first, last, and number. The first and last variables are Python strings containing first and last names. The number attribute is an integer.

The object structure is updated accordingly:

```c
typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;
```

Because we now have data to manage, we have to be more careful about object allocation and deallocation. At a minimum, we need a deallocation method:

```c
static void Noddy_dealloc(Noddy* self) {
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    self->ob_type->tp_free((PyObject*)self);
}
```

which is assigned to the `tp_dealloc` member:

```
(destructor)Noddy_dealloc, /*tp_dealloc*/
```

This method decrements the reference counts of the two Python attributes. We use `Py_XDECREF` here because the first and last members could be NULL. It then calls the `tp_free` member of the object's type to free the object's memory. Note that the object's type might not be NoddyType, because the object may be an instance of a subclass.
We want to make sure that the first and last names are initialized to empty strings, so we provide a new method:

```c
static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("");
        if (self->first == NULL)
            {Py_DECREF(self);
             return NULL;
            }

        self->last = PyString_FromString("");
        if (self->last == NULL)
            {Py_DECREF(self);
             return NULL;
            }

        self->number = 0;
    }

    return (PyObject *)self;
}
```

and install it in the `tp_new` member:

```c
Noddy_new,          /* tp_new */
```

The new member is responsible for creating (as opposed to initializing) objects of the type. It is exposed in Python as the `__new__()` method. See the paper titled “Unifying types and classes in Python” for a detailed discussion of the `__new__()` method. One reason to implement a new method is to assure the initial values of instance variables. In this case, we use the new method to make sure that the initial values of the members `first` and `last` are not `NULL`. If we didn’t care whether the initial values were `NULL`, we
could have used `PyType_GenericNew` as our new method, as we did before. `PyType_GenericNew` initializes all of the instance variable members to `NULL`.

The new method is a static method that is passed the type being instantiated and any arguments passed when the type was called, and that returns the new object created. New methods always accept positional and keyword arguments, but they often ignore the arguments, leaving the argument handling to initializer methods. Note that if the type supports subclassing, the type passed may not be the type being defined. The new method calls the `tp_alloc` slot to allocate memory. We don’t fill the `tp_alloc` slot ourselves. Rather `PyType_Ready` fills it for us by inheriting it from our base class, which is `object` by default. Most types use the default allocation.

**Note:** If you are creating a co-operative `tp_new` (one that calls a base type’s `tp_new` or `__new__()`), you must *not* try to determine what method to call using method resolution order at runtime. Always statically determine what type you are going to call, and call its `tp_new` directly, or via `type->tp_base->tp_new`. If you do not do this, Python subclasses of your type that also inherit from other Python-defined classes may not work correctly. (Specifically, you may not be able to create instances of such subclasses without getting a `TypeError`.)

We provide an initialization function:

```c
static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {
"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
            kwlist &first, &last,
```
self->number))

    return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }

    return 0;
}

by filling the **tp_init** slot.

(initproc)Noddy_init,        /* tp_init */

The **tp_init** slot is exposed in Python as the **__init__()** method. It is used to initialize an object after it’s created. Unlike the new method, we can’t guarantee that the initializer is called. The initializer isn’t called when unpickling objects and it can be overridden. Our initializer accepts arguments to provide initial values for our instance. Initializers always accept positional and keyword arguments.

Initializers can be called multiple times. Anyone can call the **__init__()** method on our objects. For this reason, we have to be extra careful when assigning the new values. We might be tempted, for example to assign the first member like this:

    if (first) {
        Py_XDECREF(self->first);
        Py_INCREF(first);
        self->first = first;
    }
But this would be risky. Our type doesn’t restrict the type of the first member, so it could be any kind of object. It could have a destructor that causes code to be executed that tries to access the first member. To be paranoid and protect ourselves against this possibility, we almost always reassign members before decrementing their reference counts. When don’t we have to do this?

- when we absolutely know that the reference count is greater than 1
- when we know that deallocation of the object [1] will not cause any calls back into our type’s code
- when decrementing a reference count in a `tp_dealloc` handler when garbage-collections is not supported [2]

We want to expose our instance variables as attributes. There are a number of ways to do that. The simplest way is to define member definitions:

```c
static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
     "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,
     "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};
```

and put the definitions in the `tp_members` slot:

```c
Noddy_members, /* tp_members */
```

Each member definition has a member name, type, offset, access flags and documentation string. See the “Generic Attribute Management” section below for details.

A disadvantage of this approach is that it doesn’t provide a way to
restrict the types of objects that can be assigned to the Python attributes. We expect the first and last names to be strings, but any Python objects can be assigned. Further, the attributes can be deleted, setting the C pointers to NULL. Even though we can make sure the members are initialized to non-NULL values, the members can be set to NULL if the attributes are deleted.

We define a single method, `name()`, that outputs the objects name as the concatenation of the first and last names.

```c
static PyObject *
Noddy_name(Noddy * self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }

    args = Py_BuildValue("OO", self->first, self->last);
    if (args == NULL)
        return NULL;

    result = PyString_Format(format, args);
    Py_DECREF(args);

    return result;
}
```

The method is implemented as a C function that takes a `Noddy` (or `Noddy` subclass) instance as the first argument. Methods always take
an instance as the first argument. Methods often take positional and keyword arguments as well, but in this case we don't take any and don't need to accept a positional argument tuple or keyword argument dictionary. This method is equivalent to the Python method:

```python
def name(self):
    return "%s %s" % (self.first, self.last)
```

Note that we have to check for the possibility that our first and last members are NULL. This is because they can be deleted, in which case they are set to NULL. It would be better to prevent deletion of these attributes and to restrict the attribute values to be strings. We'll see how to do that in the next section.

Now that we've defined the method, we need to create an array of method definitions:

```python
static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS, "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};
```

and assign them to the `tp_methods` slot:

```python
Noddy_methods,  /* tp_methods */
```

Note that we used the `METH_NOARGS` flag to indicate that the method is passed no arguments.

Finally, we'll make our type usable as a base class. We've written our methods carefully so far so that they don't make any assumptions about the type of the object being created or used, so all we need to do is to add the `Py_TPFLAGS_BASETYPE` to our class flag definition:
We rename `initnoddy` to `initnoddy2` and update the module name passed to `Py_InitModule3`.

Finally, we update our `setup.py` file to build the new module:

```python
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
      ext_modules=[
        Extension("noddy", ["noddy.c"]),
        Extension("noddy2", ["noddy2.c"]),
      ])
```

### Providing finer control over data attributes

In this section, we’ll provide finer control over how the `first` and `last` attributes are set in the Noddy example. In the previous version of our module, the instance variables `first` and `last` could be set to non-string values or even deleted. We want to make sure that these attributes always contain strings.

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
```
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("");
        if (self->first == NULL)
            {Py_DECREF(self);
             return NULL;
            }

        self->last = PyString_FromString("");
        if (self->last == NULL)
            {Py_DECREF(self);
             return NULL;
            }

        self->number = 0;
    }

    return (PyObject *)self;
}

static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi", kwlist
                                       &first, &last,
                                       &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }
}

```c
return 0;
}

static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
        "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_getfirst(Noddy *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the first attribute");
        return -1;
    }

    if (!PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The first attribute value must be a string");
        return -1;
    }

    Py_DECREF(self->first);
    Py_INCREF(value);
    self->first = value;

    return 0;
}

static PyObject *
Noddy_getlast(Noddy *self, void *closure)
{
    Py_INCREF(self->last);
    return self->last;
}

static int
Noddy_setlast(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the last attribute");
        return -1;
    }

    if (!PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The last attribute value must be a string");
        return -1;
    }

    Py_DECREF(self->last);
    Py_INCREF(value);
    self->last = value;

    return 0;
}
```
PyErr_SetString(PyExc_TypeError, "Cannot delete the last attribute");

return -1;

if (!PyString_Check(value)) {
    PyErr_SetString(PyExc_TypeError,
                    "The last attribute value must be a string");
    return -1;
}

Py_DECREF(self->last);
Py_INCREF(value);
self->last = value;

return 0;

static PyGetSetDef Noddy_getseters[] = {
    {"first",
     (getter)Noddy_getfirst, (setter)Noddy_setfirst,
     "first name",
     NULL},
    {"last",
     (getter)Noddy_getlast, (setter)Noddy_setlast,
     "last name",
     NULL},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    args = Py_BuildValue("OO", self->first, self->last);
    if (args == NULL)
        return NULL;

    result = PyString_Format(format, args);
    Py_DECREF(args);

    return result;
}
```c
static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0,           /*ob_size*/
    "noddy.Noddy",          /*tp_name*/
    sizeof(Noddy),         /*tp_basicsize*/
    0,          /*tp_itemsize*/
    (destructor)Noddy_dealloc, /*tp_dealloc*/
    0,          /*tp_print*/
    0,          /*tp_getattr*/
    0,          /*tp_setattr*/
    0,          /*tp_compare*/
    0,          /*tp_repr*/
    0,          /*tp_as_number*/
    0,          /*tp_as_sequence*/
    0,          /*tp_as_mapping*/
    0,          /*tp_hash */
    0,          /*tp_call*/
    0,          /*tp_str*/
    0,          /*tp_getattro*/
    0,          /*tp_setattro*/
    0,          /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE, /*tp_flags*/
    "Noddy objects",            /* tp_doc */
    0,          /* tp_traverse */
    0,          /* tp_clear */
    0,          /* tp_richcompare */
    0,          /* tp_weaklistoffset */
    0,          /* tp_iter */
    0,          /* tp_iternext */
    Noddy_methods,    /* tp_methods */
    Noddy_members,    /* tp_members */
    Noddy_getseters,  /* tp_getset */
    0,          /* tp_base */
    0,          /* tp_dict */
    0,          /* tp_descr_get */
    0,          /* tp_descr_set */
    0,          /* tp_dictoffset */
    (initproc)Noddy_init,  /* tp_init */
    0,          /* tp_alloc */
    Noddy_new,   /* tp_new */
};
```
To provide greater control, over the **first** and **last** attributes, we’ll use custom getter and setter functions. Here are the functions for getting and setting the **first** attribute:

```c
static PyMethodDef module_methods[] = {
    {NULL}  /* Sentinel */
};

#ifndef PyMODINIT_FUNC /* declarations for DLL import/export */
define PyMODINIT_FUNC void
#endif
PyMODINIT_FUNC initnoddy3(void)
{
    PyObject* m;
    if (PyType_Ready(&NoddyType) < 0)
        return;
    m = Py_InitModule3("noddy3", module_methods,
                      "Example module that creates an extension.
                      
                      To provide greater control, over the first and last attributes, we’ll use custom getter and setter functions. Here are the functions for getting and setting the first attribute:

```c
Noddy_getfirst(Noddy *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the first attribute.");
        return -1;
    }
    if (!PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The first attribute value must be a string.");
```
The getter function is passed a Noddy object and a “closure”, which is void pointer. In this case, the closure is ignored. (The closure supports an advanced usage in which definition data is passed to the getter and setter. This could, for example, be used to allow a single set of getter and setter functions that decide the attribute to get or set based on data in the closure.)

The setter function is passed the Noddy object, the new value, and the closure. The new value may be NULL, in which case the attribute is being deleted. In our setter, we raise an error if the attribute is deleted or if the attribute value is not a string.

We create an array of PyGetSetDef structures:

```c
static PyGetSetDef Noddy_getseters[] = {
    {"first",
        (getter)Noddy_getfirst, (setter)Noddy_setfirst,
        "first name",
        NULL},
    {"last",
        (getter)Noddy_getlast, (setter)Noddy_setlast,
        "last name",
        NULL},
    {NULL}  /* Sentinel */
};
```

and register it in the tp_getset slot:

```c
Noddy_getseters,    /* tp_getset */
```
to register our attribute getters and setters.

The last item in a **PyGetSetDef** structure is the closure mentioned above. In this case, we aren’t using the closure, so we just pass **NULL**.

We also remove the member definitions for these attributes:

```c
static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};
```

We also need to update the **tp_init** handler to only allow strings [3] to be passed:

```c
static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi", kwlist
        &first, &last,
        &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }

    return 0;
}
```
With these changes, we can assure that the first and last members are never NULL so we can remove checks for NULL values in almost all cases. This means that most of the \texttt{Py\_XDECREF} calls can be converted to \texttt{Py\_DECREF} calls. The only place we can’t change these calls is in the deallocator, where there is the possibility that the initialization of these members failed in the constructor.

We also rename the module initialization function and module name in the initialization function, as we did before, and we add an extra definition to the \texttt{setup.py} file.

### Supporting cyclic garbage collection

Python has a cyclic-garbage collector that can identify unneeded objects even when their reference counts are not zero. This can happen when objects are involved in cycles. For example, consider:

```python
>>> l = []
>>> l.append(l)
>>> del l
```

In this example, we create a list that contains itself. When we delete it, it still has a reference from itself. Its reference count doesn’t drop to zero. Fortunately, Python’s cyclic-garbage collector will eventually figure out that the list is garbage and free it.

In the second version of the \texttt{Noddy} example, we allowed any kind of object to be stored in the first or last attributes. \cite{4} This means that \texttt{Noddy} objects can participate in cycles:

```python
>>> import noddy2
>>> n = noddy2.Noddy()
>>> l = [n]
>>> n.first = l
```
This is pretty silly, but it gives us an excuse to add support for the cyclic-garbage collector to the Noddy example. To support cyclic garbage collection, types need to fill two slots and set a class flag that enables these slots:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static int Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    int vret;
    
    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }
    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }
    return 0;
}

static int Noddy_clear(Noddy *self)
{
    PyObject *tmp;
    
    tmp = self->first;
    self->first = NULL;
    Py_XDECREF(tmp);
    
    tmp = self->last;
    self->last = NULL;
    Py_XDECREF(tmp);
```
return 0;
}

static void Noddy_dealloc(Noddy* self)
{
    Noddy_clear(self);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;
    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyString_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *)self;
}

static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;
    static char *kwlist[] = {"first", "last", "number", NULL};
    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", kwlist
                                           &first, &last,
                                           &self->number))
        return -1;
    if (first) {
        }
tmp = self->first;
Py_INCREF(first);
self->first = first;
Py_XDECREF(tmp);

if (last) {
    tmp = self->last;
    Py_INCREF(last);
    self->last = last;
    Py_XDECREF(tmp);
}

return 0;

static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
     "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,
     "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }

    args = Py_BuildValue("OO", self->first, self->last);
if (args == NULL)
    return NULL;

result = PyString_Format(format, args);
Py_DECREF(args);

    return result;
}

static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyObject_HEAD_INIT(NULL) /*ob_size*/
    "noddy.Noddy", /*tp_name*/
    sizeof(Noddy), /*tp_basicsize*/
    0, /*tp_itemsize*/
    (destructor)Noddy_dealloc, /*tp_dealloc*/
    0, /*tp_print*/
    0, /*tp_getattr*/
    0, /*tp_setattr*/
    0, /*tp_compare*/
    0, /*tp_repr*/
    0, /*tp_as_number*/
    0, /*tp_as_sequence*/
    0, /*tp_as_mapping*/
    0, /*tp_hash */
    0, /*tp_call*/
    0, /*tp_str*/
    0, /*tp_getattro*/
    0, /*tp_setattro*/
    0, /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | Py_TPFLAGS_HAVE_GC,
    "Noddy objects", /*tp_doc*/
    (traverseproc)Noddy_traverse, /*tp_traverse*/
    (inquiry)Noddy_clear, /*tp_clear*/
    0, /*tp_richcompare*/
    0, /*tp_weaklistoffset*/
    0, /*tp_iter*/
    0, /*tp_iternext*/
    Noddy_methods, /*tp_methods*/
    Noddy_members, /*tp_members*/
    0, /*tp_getset*/
    0, /*tp_base*/
    0, /*tp_dict*/
};
The traversal method provides access to subobjects that could participate in cycles:

```python
static int Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    int vret;

    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }

    if (self->last) {
```

vret = visit(self->last, arg);
if (vret != 0)
    return vret;
return 0;

For each subobject that can participate in cycles, we need to call the visit function, which is passed to the traversal method. The visit function takes as arguments the subobject and the extra argument arg passed to the traversal method. It returns an integer value that must be returned if it is non-zero.

Python 2.4 and higher provide a Py_VISIT macro that automates calling visit functions. With Py_VISIT, Noddy_traverse can be simplified:

```
static int Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}
```

**Note:** Note that the tp_traverse implementation must name its arguments exactly visit and arg in order to use Py_VISIT. This is to encourage uniformity across these boring implementations.

We also need to provide a method for clearing any subobjects that can participate in cycles. We implement the method and reimplement the deallocator to use it:

```
static int Noddy_clear(Noddy *self)
{
    PyObject *tmp;
    tmp = self->first;
```
Notice the use of a temporary variable in `Noddy_clear`. We use the temporary variable so that we can set each member to `NULL` before decrementing its reference count. We do this because, as was discussed earlier, if the reference count drops to zero, we might cause code to run that calls back into the object. In addition, because we now support garbage collection, we also have to worry about code being run that triggers garbage collection. If garbage collection is run, our `tp_traverse` handler could get called. We can't take a chance of having `Noddy_traverse` called when a member's reference count has dropped to zero and its value hasn't been set to `NULL`.

Python 2.4 and higher provide a `Py_CLEAR` that automates the careful decrementing of reference counts. With `Py_CLEAR`, the `Noddy_clear` function can be simplified:
Finally, we add the `Py_TPFLAGS_HAVE_GC` flag to the class flags:

```plaintext
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | Py_TPFLAGS_HAVE_GC,
```

That’s pretty much it. If we had written custom `tp_alloc` or `tp_free` slots, we’d need to modify them for cyclic-garbage collection. Most extensions will use the versions automatically provided.

## Subclassing other types

It is possible to create new extension types that are derived from existing types. It is easiest to inherit from the built in types, since an extension can easily use the `PyTypeObject` it needs. It can be difficult to share these `PyTypeObject` structures between extension modules.

In this example we will create a `Shoddy` type that inherits from the builtin `list` type. The new type will be completely compatible with regular lists, but will have an additional `increment()` method that increases an internal counter.

```python
>>> import shoddy
>>> s = shoddy.Shoddy(range(3))
>>> s.extend(s)
>>> print len(s)
6
>>> print s.increment()
1
>>> print s.increment()
2
```

```c
#include <Python.h>

typedef struct {
    PyListObject list;
    int state;
} Shoddy;

static PyObject *
```
Shoddy_increment(Shoddy *self, PyObject *unused)
{
    self->state++;
    return PyInt_FromLong(self->state);
}

static PyMethodDef Shoddy_methods[] = {
    {"increment", (PyCFunction)Shoddy_increment, METH_NOARGS,
    PyDoc_STR("increment state counter")},
    {NULL, NULL},
};

static int
Shoddy_init(Shoddy *self, PyObject *args, PyObject *kwds)
{
    if (PyList_Type.tp_init((PyObject *)self, args, kwds) < 0)
        return -1;
    self->state = 0;
    return 0;
}

static PyTypeObject ShoddyType = {
    PyObject_HEAD_INIT(NULL)
    0,           /* ob_size */
    "shoddy.Shoddy",    /* tp_name */
    sizeof(Shoddy),    /* tp_basicsize */
    0,               /* tp_itemsize */
    0,               /* tp_dealloc */
    0,               /* tp_print */
    0,               /* tp_getattr */
    0,               /* tp_setattr */
    0,               /* tp_compare */
    0,               /* tp_repr */
    0,               /* tp_as_number */
    0,               /* tp_as_sequence */
    0,               /* tp_as_mapping */
    0,               /* tp_hash */
    0,               /* tp_call */
    0,               /* tp_str */
    0,               /* tp_getattro */
    0,               /* tp_setattro */
    0,               /* tp_as_buffer */
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,        /* tp_flags */
    0,               /* tp_doc */
    0,               /* tp_traverse */
    0,               /* tp_clear */
    0,               /* tp_richcompare */
    0,
};
As you can see, the source code closely resembles the Noddy examples in previous sections. We will break down the main differences between them.

typedef struct {
    PyListObject list;
    int    state;
} Shoddy;

The primary difference for derived type objects is that the base type's object structure must be the first value. The base type will already include the PyObject_HEAD at the beginning of its structure.
When a Python object is a `Shoddy` instance, its `PyObject*` pointer can be safely cast to both `PyListObject*` and `Shoddy*`.

```c
static int
Shoddy_init(Shoddy *self, PyObject *args, PyObject *kwds)
{
    if (PyList_Type.tp_init((PyObject *)self, args, kwds) < 0)
        return -1;
    self->state = 0;
    return 0;
}
```

In the `__init__` method for our type, we can see how to call through to the `__init__` method of the base type.

This pattern is important when writing a type with custom `new` and `dealloc` methods. The `new` method should not actually create the memory for the object with `tp_alloc`, that will be handled by the base class when calling its `tp_new`.

When filling out the `PyTypeObject` for the `Shoddy` type, you see a slot for `tp_base`. Due to cross platform compiler issues, you can’t fill that field directly with the `PyList_Type`; it can be done later in the module's `init` function.

```c
PyMODINIT_FUNC
initshoddy(void)
{
    PyObject *m;

    ShoddyType.tp_base = &PyList_Type;
    if (PyType_Ready(&ShoddyType) < 0)
        return;

    m = Py_InitModule3("shoddy", NULL, "Shoddy module");
    if (m == NULL)
        return;

    Py_INCREF(&ShoddyType);
    PyModule_AddObject(m, "Shoddy", (PyObject *) &ShoddyType);
```
Before calling `PyType_Ready`, the type structure must have the `tp_base` slot filled in. When we are deriving a new type, it is not necessary to fill out the `tp Alloc` slot with `PyType_GenericNew` – the allocate function from the base type will be inherited.

After that, calling `PyType_Ready` and adding the type object to the module is the same as with the basic `Noddy` examples.
This section aims to give a quick fly-by on the various type methods you can implement and what they do.

Here is the definition of `PyTypeObject`, with some fields only used in debug builds omitted:

```c
typedef struct _typeobject {
    PyObject_VAR_HEAD
    char   *tp_name; /* For printing, in format "<module>.<name>" */
    int    tp_basicsize, tp_itemsize; /* For allocation */

    /* Methods to implement standard operations */
    destructor tp_dealloc;
    printfunc tp_print;
    getattfunc tp_getattr;
    setattfunc tp_setattr;
    cmpfunc tp_compare;
    reprfunc tp_repr;

    /* Method suites for standard classes */
    PyNumberMethods       *tp_as_number;
    PySequenceMethods     *tp_as_sequence;
    PyMappingMethods      *tp_as_mapping;

    /* More standard operations (here for binary compatibility) */
    hashfunc tp_hash;
    ternaryfunc tp_call;
    reprfunc tp_str;
    getattrofunc tp_getattro;
    setattrofunc tp_setattro;

    /* Functions to access object as input/output buffer */
    PyBufferProcs *tp_as_buffer;

    /* Flags to define presence of optional/expanded features */
    long    tp_flags;
    char    *tp_doc; /* Documentation string */
} PyTypeObject;
```
/* Assigned meaning in release 2.0 */
/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* Assigned meaning in release 2.1 */
/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
long tp_weaklistoffset;

/* Added in release 2.2 */
/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;
descrsetfunc tp_descr_set;
long tp_dictoffset;
initproc tp_init;
allocfunc tp_alloc;
newfunc tp_new;
freefunc tp_free; /* Low-level free-memory routine */
inquiry tp_is_gc; /* For PyObject_IS_GC */
PyObject *tp_bases;
PyObject *tp_mro; /* method resolution order */
PyObject *tp_cache;
PyObject *tp_subclasses;
PyObject *tp_weaklist;

} PyTypeObject;

Now that's a lot of methods. Don't worry too much though - if you have a type you want to define, the chances are very good that you will only implement a handful of these.

As you probably expect by now, we're going to go over this and give
more information about the various handlers. We won’t go in the order they are defined in the structure, because there is a lot of historical baggage that impacts the ordering of the fields; be sure your type initialization keeps the fields in the right order! It’s often easiest to find an example that includes all the fields you need (even if they’re initialized to \texttt{0}) and then change the values to suit your new type.

```c
char *tp_name; /* For printing */
```

The name of the type - as mentioned in the last section, this will appear in various places, almost entirely for diagnostic purposes. Try to choose something that will be helpful in such a situation!

```c
int tp_basicsize, tp_itemsize; /* For allocation */
```

These fields tell the runtime how much memory to allocate when new objects of this type are created. Python has some built-in support for variable length structures (think: strings, lists) which is where the \texttt{tp_itemsize} field comes in. This will be dealt with later.

```c
char *tp_doc;
```

Here you can put a string (or its address) that you want returned when the Python script references \texttt{obj.__doc__} to retrieve the doc string.

Now we come to the basic type methods—the ones most extension types will implement.

**Finalization and De-allocation**

```c
Destructor tp_dealloc;
```

This function is called when the reference count of the instance of
your type is reduced to zero and the Python interpreter wants to reclaim it. If your type has memory to free or other clean-up to perform, put it here. The object itself needs to be freed here as well. Here is an example of this function:

```c
static void
cnewdatatype_dealloc(newdatatypeobject * obj)
{
    free(obj->obj_UnderlyingDatatypePtr);
    obj->ob_type->tp_free(obj);
}
```

One important requirement of the deallocator function is that it leaves any pending exceptions alone. This is important since deallocators are frequently called as the interpreter unwinds the Python stack; when the stack is unwound due to an exception (rather than normal returns), nothing is done to protect the deallocators from seeing that an exception has already been set. Any actions which a deallocator performs which may cause additional Python code to be executed may detect that an exception has been set. This can lead to misleading errors from the interpreter. The proper way to protect against this is to save a pending exception before performing the unsafe action, and restoring it when done. This can be done using the `PyErr_Fetch` and `PyErr_Restore` functions:

```c
static void
my_dealloc(PyObject *obj)
{
    MyObject  *self = (MyObject *) obj;
    PyObject *cbresult;

    if (self->my_callback != NULL) {
        PyObject *err_type, *err_value, *err_traceback;
        int  have_error = PyErr_Occurred() ? 1 : 0;

        if (have_error)
            PyErr_Fetch(&err_type, &err_value, &err_traceback);

        cbresult = PyObject_CallObject(self->my_callback, NULL)
        if (cbresult == NULL)
            PyErr_WriteUnraisable(self->my_callback);
```
else
    Py_DECREF(cbresult);
if (have_error)
    PyErr_Restore(err_type, err_value, err_traceback);
Py_DECREF(self->my_callback);
}
obj->ob_type->tp_free((PyObject*)self);
}

Object Presentation

In Python, there are three ways to generate a textual representation of an object: the `repr()` function (or equivalent back-tick syntax), the `str()` function, and the `print` statement. For most objects, the `print` statement is equivalent to the `str()` function, but it is possible to special-case printing to a `FILE*` if necessary; this should only be done if efficiency is identified as a problem and profiling suggests that creating a temporary string object to be written to a file is too expensive.

These handlers are all optional, and most types at most need to implement the `tp_str` and `tp_repr` handlers.

```python
reprfunc tp_repr;
reprfunc tp_str;
printfunc tp_print;
```

The `tp_repr` handler should return a string object containing a representation of the instance for which it is called. Here is a simple example:

```python
static PyObject *
newdatatype_repr(newdatatypeobject * obj)
{
    return PyString_FromFormat("Repr-ified_newdatatype{{size:\%s
    obj->obj_UnderlyingDatatypePtr->
}
```
If no `tp_repr` handler is specified, the interpreter will supply a representation that uses the type's `tp_name` and a uniquely-identifying value for the object.

The `tp_str` handler is to `str()` what the `tp_repr` handler described above is to `repr()`; that is, it is called when Python code calls `str()` on an instance of your object. Its implementation is very similar to the `tp_repr` function, but the resulting string is intended for human consumption. If `tp_str` is not specified, the `tp_repr` handler is used instead.

Here is a simple example:

```c
static PyObject *
newdatatype_str(newdatatypeobject * obj)
{
    return PyString_FromFormat("Stringified_newdatatype{{size:\nobj->obj_UnderlyingDatatypePtr->

```

The print function will be called whenever Python needs to “print” an instance of the type. For example, if ‘node’ is an instance of type `TreeNode`, then the print function is called when Python code calls:

```c
print node
```

There is a flags argument and one flag, `Py_PRINT_RAW`, and it suggests that you print without string quotes and possibly without interpreting escape sequences.

The print function receives a file object as an argument. You will likely want to write to that file object.

Here is a sample print function:
static int newdatatype_print(newdatatypeobject *obj, FILE *fp, int flags) {
    if (flags & Py_PRINT_RAW) {
        fprintf(fp, "<{newdatatype object--size: %d}>",
                obj->obj_UnderlyingDatatypePtr->size);
    } else {
        fprintf(fp, ""<{newdatatype object--size: %d}>",
                obj->obj_UnderlyingDatatypePtr->size);
    }
    return 0;
}

Attribute Management

For every object which can support attributes, the corresponding type must provide the functions that control how the attributes are resolved. There needs to be a function which can retrieve attributes (if any are defined), and another to set attributes (if setting attributes is allowed). Removing an attribute is a special case, for which the new value passed to the handler is NULL.

Python supports two pairs of attribute handlers; a type that supports attributes only needs to implement the functions for one pair. The difference is that one pair takes the name of the attribute as a char*, while the other accepts a PyObject*. Each type can use whichever pair makes more sense for the implementation’s convenience.

getattrfunc  tp_getattr;        /* char * version */
setattrfunc  tp_setattr;
/* ... */
getattrofunc tp_getattrofunc;    /* PyObject * version */
setattrofunc tp_setattrofunc;

If accessing attributes of an object is always a simple operation (this will be explained shortly), there are generic implementations which can be used to provide the PyObject* version of the attribute management functions. The actual need for type-specific attribute
handlers almost completely disappeared starting with Python 2.2, though there are many examples which have not been updated to use some of the new generic mechanism that is available.

Generic Attribute Management

*New in version 2.2.*

Most extension types only use *simple* attributes. So, what makes the attributes simple? There are only a couple of conditions that must be met:

1. The name of the attributes must be known when `PyType_Ready` is called.
2. No special processing is needed to record that an attribute was looked up or set, nor do actions need to be taken based on the value.

Note that this list does not place any restrictions on the values of the attributes, when the values are computed, or how relevant data is stored.

When `PyType_Ready` is called, it uses three tables referenced by the type object to create *descriptors* which are placed in the dictionary of the type object. Each descriptor controls access to one attribute of the instance object. Each of the tables is optional; if all three are `NULL`, instances of the type will only have attributes that are inherited from their base type, and should leave the `tp_getattro` and `tp_setattro` fields `NULL` as well, allowing the base type to handle attributes.

The tables are declared as three fields of the type object:

```c
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
```
If `tp_methods` is not `NULL`, it must refer to an array of `PyMethodDef` structures. Each entry in the table is an instance of this structure:

```c
typedef struct PyMethodDef {
    char *ml_name;  /* method name */
    PyCFunction ml_meth;  /* implementation function */
    int ml_flags;  /* flags */
    char *ml_doc;  /* docstring */
} PyMethodDef;
```

One entry should be defined for each method provided by the type; no entries are needed for methods inherited from a base type. One additional entry is needed at the end; it is a sentinel that marks the end of the array. The `ml_name` field of the sentinel must be `NULL`.

XXX Need to refer to some unified discussion of the structure fields, shared with the next section.

The second table is used to define attributes which map directly to data stored in the instance. A variety of primitive C types are supported, and access may be read-only or read-write. The structures in the table are defined as:

```c
typedef struct PyMemberDef {
    char *name;
    int type;
    int offset;
    int flags;
    char *doc;
} PyMemberDef;
```

For each entry in the table, a `descriptor` will be constructed and added to the type which will be able to extract a value from the instance structure. The `type` field should contain one of the type codes defined in the `structmember.h` header; the value will be used to determine how to convert Python values to and from C values. The `flags` field is used to store flags which control how the attribute can be accessed.
XXX Need to move some of this to a shared section!

The following flag constants are defined in `structmember.h`; they may be combined using bitwise-OR.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>READONLY</td>
<td>Never writable.</td>
</tr>
<tr>
<td>RO</td>
<td>Shorthand for <code>READONLY</code>.</td>
</tr>
<tr>
<td>READ_RESTRICTED</td>
<td>Not readable in restricted mode.</td>
</tr>
<tr>
<td>WRITE_RESTRICTED</td>
<td>Not writable in restricted mode.</td>
</tr>
<tr>
<td>RESTRICTED</td>
<td>Not readable or writable in restricted mode.</td>
</tr>
</tbody>
</table>

An interesting advantage of using the `tp_members` table to build descriptors that are used at runtime is that any attribute defined this way can have an associated doc string simply by providing the text in the table. An application can use the introspection API to retrieve the descriptor from the class object, and get the doc string using its `__doc__` attribute.

As with the `tp_methods` table, a sentinel entry with a `name` value of `NULL` is required.

**Type-specific Attribute Management**

For simplicity, only the `char*` version will be demonstrated here; the type of the name parameter is the only difference between the `char*` and `PyObject*` flavors of the interface. This example effectively does the same thing as the generic example above, but does not use the generic support added in Python 2.2. The value in showing this is two-fold: it demonstrates how basic attribute management can be done in a way that is portable to older versions of Python, and explains how the handler functions are called, so that if you do need to extend their functionality, you’ll understand what needs to be
done.

The `tp_getattr` handler is called when the object requires an attribute look-up. It is called in the same situations where the `__getattr__()` method of a class would be called.

A likely way to handle this is (1) to implement a set of functions (such as `newdatatype_getSize` and `newdatatype_setSize` in the example below), (2) provide a method table listing these functions, and (3) provide a getattr function that returns the result of a lookup in that table. The method table uses the same structure as the `tp_methods` field of the type object.

Here is an example:

```c
static PyMethodDef newdatatype_methods[] = {
    {"getSize", (PyCFunction)newdatatype_getSize, METH_VARARGS,
     "Return the current size."},
    {"setSize", (PyCFunction)newdatatype_setSize, METH_VARARGS,
     "Set the size."},
    {NULL, NULL, 0, NULL} /* sentinel */
};

static PyObject *
newdatatype_getattr(newdatatypeobject *obj, char *name)
{
    return Py_FindMethod(newdatatype_methods, (PyObject *)obj,
}
```

The `tp_setattr` handler is called when the `__setattr__()`, or `__delattr__()` method of a class instance would be called. When an attribute should be deleted, the third parameter will be `NULL`. Here is an example that simply raises an exception; if this were really all you wanted, the `tp_setattr` handler should be set to `NULL`.

```c
static int
newdatatype_setattr(newdatatypeobject *obj, char *name, PyObject *v)
{
    (void)PyErr_Format(PyExc_RuntimeError, "Read-only attribute
```
Object Comparison

cmpfunc tp_compare;

The `tp_compare` handler is called when comparisons are needed and the object does not implement the specific rich comparison method which matches the requested comparison. (It is always used if defined and the `PyObject_Compare` or `PyObject_Cmp` functions are used, or if `cmp()` is used from Python.) It is analogous to the `__cmp__()` method. This function should return `-1` if `obj1` is less than `obj2`, `0` if they are equal, and `1` if `obj1` is greater than `obj2`. (It was previously allowed to return arbitrary negative or positive integers for less than and greater than, respectively; as of Python 2.2, this is no longer allowed. In the future, other return values may be assigned a different meaning.)

A `tp_compare` handler may raise an exception. In this case it should return a negative value. The caller has to test for the exception using `PyErr_Occurred`.

Here is a sample implementation:

```c
static int newdatatype_compare(newdatatypeobject * obj1, newdatatypeobject * obj2) {
    long result;

    if (obj1->obj_UnderlyingDatatypePtr->size <
        obj2->obj_UnderlyingDatatypePtr->size) {
        result = -1;
    } else if (obj1->obj_UnderlyingDatatypePtr->size >
              obj2->obj_UnderlyingDatatypePtr->size) {
        result = 1;
    }
    return -1;
}
```
Abstract Protocol Support

Python supports a variety of abstract ‘protocols;’ the specific interfaces provided to use these interfaces are documented in Abstract Objects Layer.

A number of these abstract interfaces were defined early in the development of the Python implementation. In particular, the number, mapping, and sequence protocols have been part of Python since the beginning. Other protocols have been added over time. For protocols which depend on several handler routines from the type implementation, the older protocols have been defined as optional blocks of handlers referenced by the type object. For newer protocols there are additional slots in the main type object, with a flag bit being set to indicate that the slots are present and should be checked by the interpreter. (The flag bit does not indicate that the slot values are non-\texttt{NULL}. The flag may be set to indicate the presence of a slot, but a slot may still be unfilled.)

\begin{verbatim}
PyNumberMethods    tp_as_number;
PySequenceMethods  tp_as_sequence;
PyMappingMethods   tp_as_mapping;
\end{verbatim}

If you wish your object to be able to act like a number, a sequence, or a mapping object, then you place the address of a structure that implements the C type \texttt{PyNumberMethods}, \texttt{PySequenceMethods}, or \texttt{PyMappingMethods}, respectively. It is up to you to fill in this structure with appropriate values. You can find examples of the use of each of these in the \texttt{Objects} directory of the Python source distribution.
This function, if you choose to provide it, should return a hash number for an instance of your data type. Here is a moderately pointless example:

```c
static long
typedatatype_hash(typedatatypeobject *obj)
{
    long result;
    result = obj->obj_UnderlyingDatatypePtr->size;
    result = result * 3;
    return result;
}
```

This function is called when an instance of your data type is “called”, for example, if `obj1` is an instance of your data type and the Python script contains `obj1('hello')`, the `tp_call` handler is invoked.

This function takes three arguments:

1. `arg1` is the instance of the data type which is the subject of the call. If the call is `obj1('hello')`, then `arg1` is `obj1`.
2. `arg2` is a tuple containing the arguments to the call. You can use `PyArg_ParseTuple` to extract the arguments.
3. `arg3` is a dictionary of keyword arguments that were passed. If this is non-`NULL` and you support keyword arguments, use `PyArg_ParseTupleAndKeywords` to extract the arguments. If you do not want to support keyword arguments and this is non-`NULL`, raise a `TypeError` with a message saying that keyword arguments are not supported.

Here is a desultory example of the implementation of the call function.
/* Implement the call function. 
*  obj1 is the instance receiving the call. 
*  obj2 is a tuple containing the arguments to the call, in 
*  case 3 strings. 
*/
static PyObject *
newdatatype_call(newdatatypeobject *obj, PyObject *args, PyObject {
    PyObject *result;
    char *arg1;
    char *arg2;
    char *arg3;

    if (!PyArg_ParseTuple(args, "sss:call", &arg1, &arg2, &arg3
        return NULL;
    }
        obj->obj_UnderlyingDatatypePtr->size, 
        arg1, arg2, arg3);
    printf("%s", PyString_AS_STRING(result));
    return result;
}

XXX some fields need to be added here...

/* Added in release 2.2 */
/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

These functions provide support for the iterator protocol. Any object 
which wishes to support iteration over its contents (which may be 
generated during iteration) must implement the tp_iter handler. 
Objects which are returned by a tp_iter handler must implement 
both the tp_iter and tp_iternext handlers. Both handlers take 
exactly one parameter, the instance for which they are being called, 
and return a new reference. In the case of an error, they should set 
an exception and return NULL.

For an object which represents an iterable collection, the tp_iter
handler must return an iterator object. The iterator object is responsible for maintaining the state of the iteration. For collections which can support multiple iterators which do not interfere with each other (as lists and tuples do), a new iterator should be created and returned. Objects which can only be iterated over once (usually due to side effects of iteration) should implement this handler by returning a new reference to themselves, and should also implement the \texttt{tp\_iternext} handler. File objects are an example of such an iterator.

Iterator objects should implement both handlers. The \texttt{tp\_iter} handler should return a new reference to the iterator (this is the same as the \texttt{tp\_iter} handler for objects which can only be iterated over destructively). The \texttt{tp\_iternext} handler should return a new reference to the next object in the iteration if there is one. If the iteration has reached the end, it may return \texttt{NULL} without setting an exception or it may set \texttt{StopIteration}; avoiding the exception can yield slightly better performance. If an actual error occurs, it should set an exception and return \texttt{NULL}.

**Weak Reference Support**

One of the goals of Python's weak-reference implementation is to allow any type to participate in the weak reference mechanism without incurring the overhead on those objects which do not benefit by weak referencing (such as numbers).

For an object to be weakly referencable, the extension must include a \texttt{PyObject*} field in the instance structure for the use of the weak reference mechanism; it must be initialized to \texttt{NULL} by the object's constructor. It must also set the \texttt{tp\_weaklistoffset} field of the corresponding type object to the offset of the field. For example, the instance type is defined with the following structure:
typedef struct {
    PyObject_HEAD
    PyClassObject *in_class;  /* The class object */
    PyObject *in_dict;        /* A dictionary */
    PyObject *in_weakreflist; /* List of weak references */
} PyInstanceObject;

The statically-declared type object for instances is defined this way:

PyTypeObject PyInstance_Type = {
    PyObject_HEAD_INIT(&PyType_Type),
    0,
    "module.instance",
    /* Lots of stuff omitted for brevity... */
    Py_TPFLAGS_DEFAULT,        /* tp_flags */
    0,                          /* tp_doc */
    0,                          /* tp_traverse */
    0,                          /* tp_clear */
    0,                          /* tp_richcompare */
    offsetof(PyInstanceObject, in_weakreflist), /* tp_weaklistoffset */
};

The type constructor is responsible for initializing the weak reference list to NULL:

static PyObject *
instance_new() {
    /* Other initialization stuff omitted for brevity */

    self->in_weakreflist = NULL;

    return (PyObject *) self;
}

The only further addition is that the destructor needs to call the weak reference manager to clear any weak references. This should be done before any other parts of the destruction have occurred, but is only required if the weak reference list is non-NULL:

static void
instance_dealloc(PyInstanceObject *inst) {
    /* Allocate temporaries if needed, but do not begin
    destruction just yet. */

    if (inst->in_weakreflist != NULL)
        PyObject_ClearWeakRefs((PyObject *) inst);

    /* Proceed with object destruction normally. */
}

More Suggestions

Remember that you can omit most of these functions, in which case you provide 0 as a value. There are type definitions for each of the functions you must provide. They are in object.h in the Python include directory that comes with the source distribution of Python.

In order to learn how to implement any specific method for your new data type, do the following: Download and unpack the Python source distribution. Go the objects directory, then search the C source files for tp_ plus the function you want (for example, tp_print or tp_compare). You will find examples of the function you want to implement.

When you need to verify that an object is an instance of the type you are implementing, use the PyObject_TypeCheck function. A sample of its use might be something like the following:

    if (!PyObject_TypeCheck(some_object, &MyType)) {
        PyErr_SetString(PyExc_TypeError, "arg #1 not a mything");
        return NULL;
    }

Footnotes

This is true when we know that the object is a basic type, like a
string or a float.

We relied on this in the `tp_dealloc` handler in this example, because our type doesn’t support garbage collection. Even if a type supports garbage collection, there are calls that can be made to “untrack” the object from garbage collection, however, these calls are advanced and not covered here.

We now know that the first and last members are strings, so perhaps we could be less careful about decrementing their reference counts, however, we accept instances of string subclasses. Even though deallocating normal strings won’t call back into our objects, we can’t guarantee that deallocating an instance of a string subclass won’t call back into our objects.

Even in the third version, we aren’t guaranteed to avoid cycles.

Instances of string subclasses are allowed and string subclasses could allow cycles even if normal strings don’t.
Building C and C++ Extensions with distutils

Starting in Python 1.4, Python provides, on Unix, a special make file for building make files for building dynamically-linked extensions and custom interpreters. Starting with Python 2.0, this mechanism (known as related to Makefile.pre.in, and Setup files) is no longer supported. Building custom interpreters was rarely used, and extension modules can be built using distutils.

Building an extension module using distutils requires that distutils is installed on the build machine, which is included in Python 2.x and available separately for Python 1.5. Since distutils also supports creation of binary packages, users don’t necessarily need a compiler and distutils to install the extension.

A distutils package contains a driver script, setup.py. This is a plain Python file, which, in the most simple case, could look like this:

```
from distutils.core import setup, Extension

module1 = Extension('demo',
                     sources = ['demo.c'])

setup (name = 'PackageName',
       version = '1.0',
       description = 'This is a demo package',
       ext_modules = [module1])
```

With this setup.py, and a file demo.c, running

```
python setup.py build
```

will compile demo.c, and produce an extension module named demo in the build directory. Depending on the system, the module file will
end up in a subdirectory build/lib.system, and may have a name like demo.so or demo.pyd.

In the setup.py, all execution is performed by calling the setup function. This takes a variable number of keyword arguments, of which the example above uses only a subset. Specifically, the example specifies meta-information to build packages, and it specifies the contents of the package. Normally, a package will contain of addition modules, like Python source modules, documentation, subpackages, etc. Please refer to the distutils documentation in Distributing Python Modules to learn more about the features of distutils; this section explains building extension modules only.

It is common to pre-compute arguments to setup(), to better structure the driver script. In the example above, the ext_modules argument to setup() is a list of extension modules, each of which is an instance of the Extension. In the example, the instance defines an extension named demo which is build by compiling a single source file, demo.c.

In many cases, building an extension is more complex, since additional preprocessor defines and libraries may be needed. This is demonstrated in the example below.

```python
from distutils.core import setup, Extension

module1 = Extension('demo',
    define_macros = [('MAJOR_VERSION', '1'), ('MINOR_VERSION', '0')],
    include_dirs = ['/usr/local/include'],
    libraries = ['tcl83'],
    library_dirs = ['/usr/local/lib'],
    sources = ['demo.c'])

setup (name = 'Package.Name',
    version = '1.0',
    description = 'This is a demo package',
)
In this example, `setup()` is called with additional meta-information, which is recommended when distribution packages have to be built. For the extension itself, it specifies preprocessor defines, include directories, library directories, and libraries. Depending on the compiler, distutils passes this information in different ways to the compiler. For example, on Unix, this may result in the compilation commands

```bash
gcc -DNDEBUG -g -O3 -Wall -Wstrict-prototypes -fPIC -DMAJOR_VERSION
gcc -shared build/temp.linux-i686-2.2/demo.o -L/usr/local/lib -L/usr/lib
```

These lines are for demonstration purposes only; distutils users should trust that distutils gets the invocations right.
Distributing your extension modules

When an extension has been successfully build, there are three ways to use it.

End-users will typically want to install the module, they do so by running

```python
python setup.py install
```

Module maintainers should produce source packages; to do so, they run

```python
python setup.py sdist
```

In some cases, additional files need to be included in a source distribution; this is done through a `MANIFEST.in` file; see the `distutils` documentation for details.

If the source distribution has been build successfully, maintainers can also create binary distributions. Depending on the platform, one of the following commands can be used to do so.

```python
python setup.py bdist_wininst
python setup.py bdist_rpm
python setup.py bdist_dumb
```
Building C and C++ Extensions on Windows

This chapter briefly explains how to create a Windows extension module for Python using Microsoft Visual C++, and follows with more detailed background information on how it works. The explanatory material is useful for both the Windows programmer learning to build Python extensions and the Unix programmer interested in producing software which can be successfully built on both Unix and Windows.

Module authors are encouraged to use the distutils approach for building extension modules, instead of the one described in this section. You will still need the C compiler that was used to build Python; typically Microsoft Visual C++.

Note: This chapter mentions a number of filenames that include an encoded Python version number. These filenames are represented with the version number shown as \texttt{XY}; in practice, \texttt{'X'} will be the major version number and \texttt{'Y'} will be the minor version number of the Python release you’re working with. For example, if you are using Python 2.2.1, \texttt{XY} will actually be \texttt{22}. 
A Cookbook Approach

There are two approaches to building extension modules on Windows, just as there are on Unix: use the distutils package to control the build process, or do things manually. The distutils approach works well for most extensions; documentation on using distutils to build and package extension modules is available in Distributing Python Modules. This section describes the manual approach to building Python extensions written in C or C++.

To build extensions using these instructions, you need to have a copy of the Python sources of the same version as your installed Python. You will need Microsoft Visual C++ “Developer Studio”; project files are supplied for VC++ version 7.1, but you can use older versions of VC++. Notice that you should use the same version of VC++ that was used to build Python itself. The example files described here are distributed with the Python sources in the PC\example_nt\ directory.

1. **Copy the example files** — The example_nt directory is a subdirectory of the pc directory, in order to keep all the PC-specific files under the same directory in the source distribution. However, the example_nt directory can’t actually be used from this location. You first need to copy or move it up one level, so that example_nt is a sibling of the pc and Include directories. Do all your work from within this new location.

2. **Open the project** — From VC++, use the File ▶ Open Solution dialog (not File ▶ Open!). Navigate to and select the file example.sln, in the copy of the example_nt directory you made above. Click Open.

3. **Build the example DLL** — In order to check that everything is
set up right, try building:

4. Select a configuration. This step is optional. Choose Build ▶ Configuration Manager ▶ Active Solution Configuration and select either Release or Debug. If you skip this step, VC++ will use the Debug configuration by default.

5. Build the DLL. Choose Build ▶ Build Solution. This creates all intermediate and result files in a subdirectory called either Debug or Release, depending on which configuration you selected in the preceding step.

6. Testing the debug-mode DLL — Once the Debug build has succeeded, bring up a DOS box, and change to the `example_nt\Debug` directory. You should now be able to repeat the following session (c> is the DOS prompt, >>> is the Python prompt; note that build information and various debug output from Python may not match this screen dump exactly):

```
C> ..\..\PCbuild\python_d
Adding parser accelerators ...
Done.
Python 2.2 (#28, Dec 19 2001, 23:26:37) [MSC 32 bit (Intel)]
Type "copyright", "credits" or "license" for more information.
>>> import example
[4897 refs]
>>> example.foo()
Hello, world
[4903 refs]
>>>
```

Congratulations! You’ve successfully built your first Python extension module.
7. **Creating your own project** — Choose a name and create a directory for it. Copy your C sources into it. Note that the module source file name does not necessarily have to match the module name, but the name of the initialization function should match the module name — you can only import a module *spam* if its initialization function is called `initspam`, and it should call `Py_InitModule` with the string "spam" as its first argument (use the minimal `example.c` in this directory as a guide). By convention, it lives in a file called `spam.c` or `spammodule.c`. The output file should be called `spam.pyd` (in Release mode) or `spam_d.pyd` (in Debug mode). The extension `.pyd` was chosen to avoid confusion with a system library `spam.dll` to which your module could be a Python interface.

*Changed in version 2.5:* Previously, file names like `spam.dll` (in release mode) or `spam_d.dll` (in debug mode) were also recognized.

Now your options are:

8. Copy `example.sln` and `example.vcproj`, rename them to `spam.*`, and edit them by hand, or

9. Create a brand new project; instructions are below.

   In either case, copy `example_nt\example.def` to `spam\spam.def`, and edit the new `spam.def` so its second line contains the string ‘*initspam*’. If you created a new project yourself, add the file `spam.def` to the project now. (This is an annoying little file with only two lines. An alternative approach is to forget about the `.def` file, and add the option `/export:initspam` somewhere to the Link settings, by manually editing the setting in Project Properties dialog).
10. **Creating a brand new project** — Use the *File ‣ New ‣ Project* dialog to create a new Project Workspace. Select *Visual C++ Projects/Win32/ Win32 Project*, enter the name (*spam*), and make sure the Location is set to parent of the *spam* directory you have created (which should be a direct subdirectory of the Python build tree, a sibling of *Include* and *PC*). Select Win32 as the platform (in my version, this is the only choice). Make sure the Create new workspace radio button is selected. Click OK.

You should now create the file *spam.def* as instructed in the previous section. Add the source files to the project, using *Project ‣ Add Existing Item*. Set the pattern to *.* and select both *spam.c* and *spam.def* and click OK. (Inserting them one by one is fine too.)

Now open the *Project ‣ spam properties* dialog. You only need to change a few settings. Make sure *All Configurations* is selected from the *Settings for:* dropdown list. Select the C/C++ tab. Choose the General category in the popup menu at the top. Type the following text in the entry box labeled *Additional Include Directories*:

```plaintext
..\Include,..\PC
```

Then, choose the General category in the Linker tab, and enter

```plaintext
..\PC\build
```

in the text box labelled *Additional library Directories*.

Now you need to add some mode-specific settings:

Select *Release* in the *Configuration* dropdown list. Choose the *Link* tab, choose the *Input* category, and append *pythonXY.lib*
to the list in the **Additional Dependencies** box.

Select **Debug** in the **Configuration** dropdown list, and append `pythonXY_d.lib` to the list in the **Additional Dependencies** box. Then click the C/C++ tab, select **Code Generation**, and select **Multi-threaded Debug DLL** from the **Runtime library** dropdown list.

Select **Release** again from the **Configuration** dropdown list. Select **Multi-threaded DLL** from the **Runtime library** dropdown list.

If your module creates a new type, you may have trouble with this line:

```python
PyObject_HEAD_INIT(&PyType_Type)
```

Change it to:

```python
PyObject_HEAD_INIT(NULL)
```

and add the following to the module initialization function:

```c
MyObject_Type.ob_type = &PyType_Type;
```

Refer to section 3 of the **Python FAQ** for details on why you must do this.
Differences Between Unix and Windows

Unix and Windows use completely different paradigms for run-time loading of code. Before you try to build a module that can be dynamically loaded, be aware of how your system works.

In Unix, a shared object (.so) file contains code to be used by the program, and also the names of functions and data that it expects to find in the program. When the file is joined to the program, all references to those functions and data in the file's code are changed to point to the actual locations in the program where the functions and data are placed in memory. This is basically a link operation.

In Windows, a dynamic-link library (.dll) file has no dangling references. Instead, an access to functions or data goes through a lookup table. So the DLL code does not have to be fixed up at runtime to refer to the program's memory; instead, the code already uses the DLL's lookup table, and the lookup table is modified at runtime to point to the functions and data.

In Unix, there is only one type of library file (.a) which contains code from several object files (.o). During the link step to create a shared object file (.so), the linker may find that it doesn't know where an identifier is defined. The linker will look for it in the object files in the libraries; if it finds it, it will include all the code from that object file.

In Windows, there are two types of library, a static library and an import library (both called .lib). A static library is like a Unix .a file; it contains code to be included as necessary. An import library is basically used only to reassure the linker that a certain identifier is legal, and will be present in the program when the DLL is loaded. So the linker uses the information from the import library to build the lookup table for using identifiers that are not included in the DLL.
When an application or a DLL is linked, an import library may be generated, which will need to be used for all future DLLs that depend on the symbols in the application or DLL.

Suppose you are building two dynamic-load modules, B and C, which should share another block of code A. On Unix, you would not pass `A.a` to the linker for `B.so` and `C.so`; that would cause it to be included twice, so that B and C would each have their own copy. In Windows, building `A.dll` will also build `A.lib`. You do pass `A.lib` to the linker for B and C. `A.lib` does not contain code; it just contains information which will be used at runtime to access A’s code.

In Windows, using an import library is sort of like using `import spam`; it gives you access to spam’s names, but does not create a separate copy. On Unix, linking with a library is more like `from spam import *`; it does create a separate copy.
Using DLLs in Practice

Windows Python is built in Microsoft Visual C++; using other compilers may or may not work (though Borland seems to). The rest of this section is MSVC++ specific.

When creating DLLs in Windows, you must pass `pythonXY.lib` to the linker. To build two DLLs, spam and ni (which uses C functions found in spam), you could use these commands:

```
c1 /LD /I/python/include spam.c ..:/libs/pythonXY.lib
cl /LD /I/python/include ni.c spam.lib ..:/libs/pythonXY.lib
```

The first command created three files: spam.obj, spam.dll and spam.lib. Spam.dll does not contain any Python functions (such as `PyArg_ParseTuple`), but it does know how to find the Python code thanks to `pythonXY.lib`.

The second command created ni.dll (and .obj and .lib), which knows how to find the necessary functions from spam, and also from the Python executable.

Not every identifier is exported to the lookup table. If you want any other modules (including Python) to be able to see your identifiers, you have to say `__declspec(dllexport)`, as in `void __declspec(dllexport) initspam(void)` or `PyObject __declspec(dllexport) *NiGetSpamData(void)`.

Developer Studio will throw in a lot of import libraries that you do not really need, adding about 100K to your executable. To get rid of them, use the Project Settings dialog, Link tab, to specify `ignore default libraries`. Add the correct `msvcrtxx.lib` to the list of libraries.
Embedding Python in Another Application

The previous chapters discussed how to extend Python, that is, how to extend the functionality of Python by attaching a library of C functions to it. It is also possible to do it the other way around: enrich your C/C++ application by embedding Python in it. Embedding provides your application with the ability to implement some of the functionality of your application in Python rather than C or C++. This can be used for many purposes; one example would be to allow users to tailor the application to their needs by writing some scripts in Python. You can also use it yourself if some of the functionality can be written in Python more easily.

Embedding Python is similar to extending it, but not quite. The difference is that when you extend Python, the main program of the application is still the Python interpreter, while if you embed Python, the main program may have nothing to do with Python — instead, some parts of the application occasionally call the Python interpreter to run some Python code.

So if you are embedding Python, you are providing your own main program. One of the things this main program has to do is initialize the Python interpreter. At the very least, you have to call the function `Py_Initialize`. There are optional calls to pass command line arguments to Python. Then later you can call the interpreter from any part of the application.

There are several different ways to call the interpreter: you can pass a string containing Python statements to `PyRun_SimpleString`, or you can pass a stdio file pointer and a file name (for identification in error messages only) to `PyRun_SimpleFile`. You can also call the lower-level operations described in the previous chapters to construct and
use Python objects.

A simple demo of embedding Python can be found in the directory `Demo/embed/` of the source distribution.

**See also:**

*Python/C API Reference Manual*

The details of Python’s C interface are given in this manual. A great deal of necessary information can be found here.
Very High Level Embedding

The simplest form of embedding Python is the use of the very high level interface. This interface is intended to execute a Python script without needing to interact with the application directly. This can for example be used to perform some operation on a file.

```c
#include <Python.h>

int main(int argc, char *argv[])
{
    Py_Initialize();
    PyRun_SimpleString("from time import time,ctime\n" "print 'Today is',ctime(time())\n");
    Py_Finalize();
    return 0;
}
```

The above code first initializes the Python interpreter with `Py_Initialize`, followed by the execution of a hard-coded Python script that print the date and time. Afterwards, the `Py_Finalize` call shuts the interpreter down, followed by the end of the program. In a real program, you may want to get the Python script from another source, perhaps a text-editor routine, a file, or a database. Getting the Python code from a file can better be done by using the `PyRun_SimpleFile` function, which saves you the trouble of allocating memory space and loading the file contents.
Beyond Very High Level Embedding: An overview

The high level interface gives you the ability to execute arbitrary pieces of Python code from your application, but exchanging data values is quite cumbersome to say the least. If you want that, you should use lower level calls. At the cost of having to write more C code, you can achieve almost anything.

It should be noted that extending Python and embedding Python is quite the same activity, despite the different intent. Most topics discussed in the previous chapters are still valid. To show this, consider what the extension code from Python to C really does:

1. Convert data values from Python to C,
2. Perform a function call to a C routine using the converted values, and
3. Convert the data values from the call from C to Python.

When embedding Python, the interface code does:

1. Convert data values from C to Python,
2. Perform a function call to a Python interface routine using the converted values, and
3. Convert the data values from the call from Python to C.

As you can see, the data conversion steps are simply swapped to accommodate the different direction of the cross-language transfer. The only difference is the routine that you call between both data conversions. When extending, you call a C routine, when embedding, you call a Python routine.

This chapter will not discuss how to convert data from Python to C and vice versa. Also, proper use of references and dealing with
errors is assumed to be understood. Since these aspects do not differ from extending the interpreter, you can refer to earlier chapters for the required information.
The first program aims to execute a function in a Python script. Like in the section about the very high level interface, the Python interpreter does not directly interact with the application (but that will change in the next section).

The code to run a function defined in a Python script is:

```c
#include <Python.h>

int main(int argc, char *argv[]) {
    PyObject *pName, *pModule, *pDict, *pFunc;
    PyObject *pArgs, *pValue;
    int i;

    if (argc < 3) {
        fprintf(stderr, "Usage: call pythonfile funcname [args]\n        return 1;
    }

    Py_Initialize();
    pName = PyString_FromString(argv[1]);
    /* Error checking of pName left out */
    pModule = PyImport_Import(pName);
    Py_DECREF(pName);

    if (pModule != NULL) {
        pFunc = PyObject_GetAttrString(pModule, argv[2]);
        /* pFunc is a new reference */

        if (pFunc && PyCallable_Check(pFunc)) {
            pArgs = PyTuple_New(argc - 3);
            for (i = 0; i < argc - 3; ++i) {
                pValue = PyInt_FromLong(atoi(argv[i + 3]));
                if (!pValue) {
                    Py_DECREF(pArgs);
                    Py_DECREF(pModule);
                    fprintf(stderr, "Cannot convert argument\n                    return 1;
                }
            }
        }
    }
```
/* pValue reference stolen here: */
PyTuple_SetItem(pArgs, i, pValue);
}
pValue = PyObject_CallObject(pFunc, pArgs);
Py_DECREF(pArgs);
if (pValue != NULL) {
    printf("Result of call: %ld\n", PyInt_AsLong(pV
    Py_DECREF(pValue);
} else {
    Py_DECREF(pFunc);
    Py_DECREF(pModule);
    PyErr_Print();
    fprintf(stderr,"Call failed\n");
    return 1;
}
else {
    if (PyErr_Occurred())
        PyErr_Print();
    fprintf(stderr, "Cannot find function \"%s\"\n", ar
    Py_XDECREF(pFunc);
    Py_DECREF(pModule);
}
else {
    PyErr_Print();
    fprintf(stderr, "Failed to load \"%s\"\n", argv[1]);
    return 1;
}
Py_Finalize();
return 0;

This code loads a Python script using argv[1], and calls the function named in argv[2]. Its integer arguments are the other values of the argv array. If you compile and link this program (let's call the finished executable call), and use it to execute a Python script, such as:

```python
def multiply(a,b):
    print "Will compute", a, "times", b
    c = 0
    for i in range(0, a):
        c = c + b
    return c
```
then the result should be:

```
$ call multiply multiply 3 2
Will compute 3 times 2
Result of call: 6
```

Although the program is quite large for its functionality, most of the code is for data conversion between Python and C, and for error reporting. The interesting part with respect to embedding Python starts with

```python
Py_Initialize();
pName = PyString_FromString(argv[1]);
/* Error checking of pName left out */
pModule = PyImport_Import(pName);
```

After initializing the interpreter, the script is loaded using `PyImport_Import`. This routine needs a Python string as its argument, which is constructed using the `PyString_FromString` data conversion routine.

```python
pFunc = PyObject_GetAttrString(pModule, argv[2]);
/* pFunc is a new reference */
if (pFunc && PyCallable_Check(pFunc)) {
    ...
}
Py_XDECREF(pFunc);
```

Once the script is loaded, the name we're looking for is retrieved using `PyObject_GetAttrString`. If the name exists, and the object returned is callable, you can safely assume that it is a function. The program then proceeds by constructing a tuple of arguments as normal. The call to the Python function is then made with:

```python
pValue = PyObject_CallObject(pFunc, pArgs);
```

Upon return of the function, `pValue` is either `NULL` or it contains a
reference to the return value of the function. Be sure to release the reference after examining the value.
Extending Embedded Python

Until now, the embedded Python interpreter had no access to functionality from the application itself. The Python API allows this by extending the embedded interpreter. That is, the embedded interpreter gets extended with routines provided by the application. While it sounds complex, it is not so bad. Simply forget for a while that the application starts the Python interpreter. Instead, consider the application to be a set of subroutines, and write some glue code that gives Python access to those routines, just like you would write a normal Python extension. For example:

```c
static int numargs=0;

/* Return the number of arguments of the application command line */
static PyObject *
emb_numargs(PyObject *self, PyObject *args)
{
    if(!PyArg_ParseTuple(args, "::numargs"))
        return NULL;
    return Py_BuildValue("i", numargs);
}

static PyMethodDef EmbMethods[] = {
    {"numargs", emb_numargs, METH_VARARGS,
    "Return the number of arguments received by the process."}
    {NULL, NULL, 0, NULL}
};
```

Insert the above code just above the `main` function. Also, insert the following two statements directly after `Py_Initialize`:

```c
numargs = argc;
Py_InitModule("emb", EmbMethods);
```

These two lines initialize the `numargs` variable, and make the `emb.numargs()` function accessible to the embedded Python
interpreter. With these extensions, the Python script can do things like

```python
import emb
print "Number of arguments", emb.numargs()
```

In a real application, the methods will expose an API of the application to Python.
Embedding Python in C++

It is also possible to embed Python in a C++ program; precisely how this is done will depend on the details of the C++ system used; in general you will need to write the main program in C++, and use the C++ compiler to compile and link your program. There is no need to recompile Python itself using C++.
Linking Requirements

While the `configure` script shipped with the Python sources will correctly build Python to export the symbols needed by dynamically linked extensions, this is not automatically inherited by applications which embed the Python library statically, at least on Unix. This is an issue when the application is linked to the static runtime library (`libpython.a`) and needs to load dynamic extensions (implemented as `.so` files).

The problem is that some entry points are defined by the Python runtime solely for extension modules to use. If the embedding application does not use any of these entry points, some linkers will not include those entries in the symbol table of the finished executable. Some additional options are needed to inform the linker not to remove these symbols.

Determining the right options to use for any given platform can be quite difficult, but fortunately the Python configuration already has those values. To retrieve them from an installed Python interpreter, start an interactive interpreter and have a short session like this:

```python
>>> import distutils.sysconfig
>>> distutils.sysconfig.get_config_var('LINKFORSHARED')
'-Xlinker -export-dynamic'
```

The contents of the string presented will be the options that should be used. If the string is empty, there’s no need to add any additional options. The `LINKFORSHARED` definition corresponds to the variable of the same name in Python’s top-level `Makefile`. 
using Sphinx 0.5.
Introduction

The Application Programmer’s Interface to Python gives C and C++ programmers access to the Python interpreter at a variety of levels. The API is equally usable from C++, but for brevity it is generally referred to as the Python/C API. There are two fundamentally different reasons for using the Python/C API. The first reason is to write extension modules for specific purposes; these are C modules that extend the Python interpreter. This is probably the most common use. The second reason is to use Python as a component in a larger application; this technique is generally referred to as embedding Python in an application.

Writing an extension module is a relatively well-understood process, where a “cookbook” approach works well. There are several tools that automate the process to some extent. While people have embedded Python in other applications since its early existence, the process of embedding Python is less straightforward than writing an extension.

Many API functions are useful independent of whether you’re embedding or extending Python; moreover, most applications that embed Python will need to provide a custom extension as well, so it’s probably a good idea to become familiar with writing an extension before attempting to embed Python in a real application.
Include Files

All function, type and macro definitions needed to use the Python/C API are included in your code by the following line:

```
#include "Python.h"
```

This implies inclusion of the following standard headers: `<stdio.h>`, `<string.h>`, `<errno.h>`, `<limits.h>`, and `<stdlib.h>` (if available).

**Warning:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you must include `Python.h` before any standard headers are included.

All user visible names defined by Python.h (except those defined by the included standard headers) have one of the prefixes `Py` or `_Py`. Names beginning with `_Py` are for internal use by the Python implementation and should not be used by extension writers. Structure member names do not have a reserved prefix.

**Important:** user code should never define names that begin with `Py` or `_Py`. This confuses the reader, and jeopardizes the portability of the user code to future Python versions, which may define additional names beginning with one of these prefixes.

The header files are typically installed with Python. On Unix, these are located in the directories `prefix/include/pythonversion/` and `exec_prefix/include/pythonversion/`, where `prefix` and `exec_prefix` are defined by the corresponding parameters to Python's `configure` script and `version` is `sys.version[:3]`. On Windows, the headers are installed in `prefix/include`, where `prefix` is the installation directory
specified to the installer.

To include the headers, place both directories (if different) on your compiler’s search path for includes. Do not place the parent directories on the search path and then use \#include <pythonX.Y/Python.h>; this will break on multi-platform builds since the platform independent headers under prefix include the platform specific headers from exec_prefix.

C++ users should note that though the API is defined entirely using C, the header files do properly declare the entry points to be extern "c", so there is no need to do anything special to use the API from C++. 
Objects, Types and Reference Counts

Most Python/C API functions have one or more arguments as well as a return value of type `PyObject*`. This type is a pointer to an opaque data type representing an arbitrary Python object. Since all Python object types are treated the same way by the Python language in most situations (e.g., assignments, scope rules, and argument passing), it is only fitting that they should be represented by a single C type. Almost all Python objects live on the heap: you never declare an automatic or static variable of type `PyObject`, only pointer variables of type `PyObject*` can be declared. The sole exception are the type objects; since these must never be deallocated, they are typically static `PyTypeObject` objects.

All Python objects (even Python integers) have a type and a reference count. An object’s type determines what kind of object it is (e.g., an integer, a list, or a user-defined function; there are many more as explained in *The standard type hierarchy*). For each of the well-known types there is a macro to check whether an object is of that type; for instance, `PyList_Check(a)` is true if (and only if) the object pointed to by `a` is a Python list.

Reference Counts

The reference count is important because today’s computers have a finite (and often severely limited) memory size; it counts how many different places there are that have a reference to an object. Such a place could be another object, or a global (or static) C variable, or a local variable in some C function. When an object’s reference count becomes zero, the object is deallocated. If it contains references to other objects, their reference count is decremented. Those other objects may be deallocated in turn, if this decrement makes their
reference count become zero, and so on. (There's an obvious problem with objects that reference each other here; for now, the solution is “don’t do that.”)

Reference counts are always manipulated explicitly. The normal way is to use the macro `Py_INCREF` to increment an object’s reference count by one, and `Py_DECREF` to decrement it by one. The `Py_DECREF` macro is considerably more complex than the incref one, since it must check whether the reference count becomes zero and then cause the object’s deallocator to be called. The deallocator is a function pointer contained in the object’s type structure. The type-specific deallocator takes care of decrementing the reference counts for other objects contained in the object if this is a compound object type, such as a list, as well as performing any additional finalization that’s needed. There's no chance that the reference count can overflow; at least as many bits are used to hold the reference count as there are distinct memory locations in virtual memory (assuming `sizeof(Py_ssize_t) >= sizeof(void*)`). Thus, the reference count increment is a simple operation.

It is not necessary to increment an object’s reference count for every local variable that contains a pointer to an object. In theory, the object's reference count goes up by one when the variable is made to point to it and it goes down by one when the variable goes out of scope. However, these two cancel each other out, so at the end the reference count hasn't changed. The only real reason to use the reference count is to prevent the object from being deallocated as long as our variable is pointing to it. If we know that there is at least one other reference to the object that lives at least as long as our variable, there is no need to increment the reference count temporarily. An important situation where this arises is in objects that are passed as arguments to C functions in an extension module that are called from Python; the call mechanism guarantees to hold a reference to every argument for the duration of the call.
However, a common pitfall is to extract an object from a list and hold on to it for a while without incrementing its reference count. Some other operation might conceivably remove the object from the list, decrementing its reference count and possible deallocating it. The real danger is that innocent-looking operations may invoke arbitrary Python code which could do this; there is a code path which allows control to flow back to the user from a `Py_DECREF`, so almost any operation is potentially dangerous.

A safe approach is to always use the generic operations (functions whose name begins with `PyObject_`, `PyNumber_`, `PySequence_` or `PyMapping_`). These operations always increment the reference count of the object they return. This leaves the caller with the responsibility to call `Py_DECREF` when they are done with the result; this soon becomes second nature.

### Reference Count Details

The reference count behavior of functions in the Python/C API is best explained in terms of *ownership of references*. Ownership pertains to references, never to objects (objects are not owned: they are always shared). “Owning a reference” means being responsible for calling `Py_DECREF` on it when the reference is no longer needed. Ownership can also be transferred, meaning that the code that receives ownership of the reference then becomes responsible for eventually decref’ing it by calling `Py_DECREF` or `Py_XDECREF` when it’s no longer needed—or passing on this responsibility (usually to its caller). When a function passes ownership of a reference on to its caller, the caller is said to receive a *new reference*. When no ownership is transferred, the caller is said to *borrow* the reference. Nothing needs to be done for a borrowed reference.

Conversely, when a calling function passes it a reference to an object, there are two possibilities: the function *steals* a reference to
the object, or it does not. *Stealing a reference* means that when you pass a reference to a function, that function assumes that it now owns that reference, and you are not responsible for it any longer.

Few functions steal references; the two notable exceptions are `PyList_SetItem` and `PyTuple_SetItem`, which steal a reference to the item (but not to the tuple or list into which the item is put!). These functions were designed to steal a reference because of a common idiom for populating a tuple or list with newly created objects; for example, the code to create the tuple `(1, 2, "three")` could look like this (forgetting about error handling for the moment; a better way to code this is shown below):

```c
PyObject *t;

int r;
PyInt_FromLong(1L));
PyInt_FromLong(2L));
PyString_FromString("three");
```

Here, `PyInt_FromLong` returns a new reference which is immediately stolen by `PyTuple_SetItem`. When you want to keep using an object although the reference to it will be stolen, use `Py_INCREF` to grab another reference before calling the reference-stealing function.

Incidentally, `PyTuple_SetItem` is the only way to set tuple items; `PySequence_SetItem` and `PyObject_SetItem` refuse to do this since tuples are an immutable data type. You should only use `PyTuple_SetItem` for tuples that you are creating yourself.

Equivalent code for populating a list can be written using `PyList_New` and `PyList_SetItem`.

However, in practice, you will rarely use these ways of creating and populating a tuple or list. There's a generic function, `Py_BuildValue`, that can create most common objects from C values, directed by a
format string. For example, the above two blocks of code could be replaced by the following (which also takes care of the error checking):

```c
PyObject *tuple, *list;
tuple = Py_BuildValue("(iis)", 1, 2, "three");
list = Py_BuildValue("[iis]", 1, 2, "three");
```

It is much more common to use `PyObject_SetItem` and friends with items whose references you are only borrowing, like arguments that were passed in to the function you are writing. In that case, their behaviour regarding reference counts is much saner, since you don’t have to increment a reference count so you can give a reference away (“have it be stolen”). For example, this function sets all items of a list (actually, any mutable sequence) to a given item:

```c
int set_all(PyObject *target, PyObject *item)
{
    int i, n;

    n = PyObject_Length(target);
    if (n < 0)
        return -1;
    for (i = 0; i < n; i++) {
        PyObject *index = PyInt_FromLong(i);
        if (!index)
            return -1;
        if (PyObject_SetItem(target, index, item) < 0)
            return -1;
        Py_DECREF(index);
    }
    return 0;
}
```

The situation is slightly different for function return values. While passing a reference to most functions does not change your ownership responsibilities for that reference, many functions that return a reference to an object give you ownership of the reference. The reason is simple: in many cases, the returned object is created
on the fly, and the reference you get is the only reference to the object. Therefore, the generic functions that return object references, like `PyObject_GetItem` and `PySequence_GetItem`, always return a new reference (the caller becomes the owner of the reference).

It is important to realize that whether you own a reference returned by a function depends on which function you call only — *the plumage* (the type of the object passed as an argument to the function) *doesn’t enter into it!* Thus, if you extract an item from a list using `PyList_GetItem`, you don’t own the reference — but if you obtain the same item from the same list using `PySequence_GetItem` (which happens to take exactly the same arguments), you do own a reference to the returned object.

Here is an example of how you could write a function that computes the sum of the items in a list of integers; once using `PyList_GetItem`, and once using `PySequence_GetItem`.

```c
long sum_list(PyObject *list)
{
    int i, n;
    long total = 0;
    PyObject *item;

    n = PyList_Size(list);
    if (n < 0)
        return -1; /* Not a list */
    for (i = 0; i < n; i++) {
        item = PyList_GetItem(list, i); /* Can't fail */
        if (!PyInt_Check(item)) continue; /* Skip non-integers */
        total += PyInt_AsLong(item);
    }
    return total;
}
```

```c
long sum_sequence(PyObject *sequence)
{
    int i, n;
```
Types

There are few other data types that play a significant role in the Python/C API; most are simple C types such as `int`, `long`, `double` and `char*`. A few structure types are used to describe static tables used to list the functions exported by a module or the data attributes of a new object type, and another is used to describe the value of a complex number. These will be discussed together with the functions that use them.
Exceptions

The Python programmer only needs to deal with exceptions if specific error handling is required; unhandled exceptions are automatically propagated to the caller, then to the caller’s caller, and so on, until they reach the top-level interpreter, where they are reported to the user accompanied by a stack traceback.

For C programmers, however, error checking always has to be explicit. All functions in the Python/C API can raise exceptions, unless an explicit claim is made otherwise in a function's documentation. In general, when a function encounters an error, it sets an exception, discards any object references that it owns, and returns an error indicator — usually $NULL$ or $-1$. A few functions return a Boolean true/false result, with false indicating an error. Very few functions return no explicit error indicator or have an ambiguous return value, and require explicit testing for errors with $PyErr_Occurred$.

Exception state is maintained in per-thread storage (this is equivalent to using global storage in an unthreaded application). A thread can be in one of two states: an exception has occurred, or not. The function $PyErr_Occurred$ can be used to check for this: it returns a borrowed reference to the exception type object when an exception has occurred, and $NULL$ otherwise. There are a number of functions to set the exception state: $PyErr_SetString$ is the most common (though not the most general) function to set the exception state, and $PyErr_Clear$ clears the exception state.

The full exception state consists of three objects (all of which can be $NULL$): the exception type, the corresponding exception value, and the traceback. These have the same meanings as the Python objects $sys.exc_type$, $sys.exc_value$, and $sys.exc_traceback$;
however, they are not the same: the Python objects represent the last exception being handled by a Python `try ... except` statement, while the C level exception state only exists while an exception is being passed on between C functions until it reaches the Python bytecode interpreter's main loop, which takes care of transferring it to `sys.exc_type` and friends.

Note that starting with Python 1.5, the preferred, thread-safe way to access the exception state from Python code is to call the function `sys.exc_info()`, which returns the per-thread exception state for Python code. Also, the semantics of both ways to access the exception state have changed so that a function which catches an exception will save and restore its thread's exception state so as to preserve the exception state of its caller. This prevents common bugs in exception handling code caused by an innocent-looking function overwriting the exception being handled; it also reduces the often unwanted lifetime extension for objects that are referenced by the stack frames in the traceback.

As a general principle, a function that calls another function to perform some task should check whether the called function raised an exception, and if so, pass the exception state on to its caller. It should discard any object references that it owns, and return an error indicator, but it should not set another exception — that would overwrite the exception that was just raised, and lose important information about the exact cause of the error.

A simple example of detecting exceptions and passing them on is shown in the `sum_sequence` example above. It so happens that that example doesn't need to clean up any owned references when it detects an error. The following example function shows some error cleanup. First, to remind you why you like Python, we show the equivalent Python code:

```python
def incr_item(dict, key):
```

try:
    item = dict[key]
except KeyError:
    item = 0
    dict[key] = item + 1

Here is the corresponding C code, in all its glory:

```c
int incr_item(PyObject *dict, PyObject *key)
{
    /* Objects all initialized to NULL for Py_XDECREF */
    PyObject *item = NULL, *const_one = NULL, *incremented_item
    int rv = -1; /* Return value initialized to -1 (failure) */
    item = PyObject_GetItem(dict, key);
    if (item == NULL) {
        /* Handle KeyError only: */
        PyErr_Clear();
        item = PyInt_FromLong(0L);
        if (item == NULL)
            goto error;
    }
    const_one = PyInt_FromLong(1L);
    if (const_one == NULL)
        goto error;
    incremented_item = PyNumber_Add(item, const_one);
    if (incremented_item == NULL)
        goto error;
    if (PyObject_SetItem(dict, key, incremented_item) < 0)
        goto error;
    rv = 0; /* Success */
    /* Continue with cleanup code */
}
```

error:
    /* Cleanup code, shared by success and failure path */
    /* Use Py_XDECREF() to ignore NULL references */
    Py_XDECREF(item);
    Py_XDECREF(const_one);
    Py_XDECREF(incremented_item);
```
This example represents an endorsed use of the `goto` statement in C! It illustrates the use of `PyErr_ExceptionMatches` and `PyErr_Clear` to handle specific exceptions, and the use of `Py_XDECREF` to dispose of owned references that may be `NULL` (note the 'x' in the name; `Py_DECREF` would crash when confronted with a `NULL` reference). It is important that the variables used to hold owned references are initialized to `NULL` for this to work; likewise, the proposed return value is initialized to `-1` (failure) and only set to success after the final call made is successful.
Embedding Python

The one important task that only embedders (as opposed to extension writers) of the Python interpreter have to worry about is the initialization, and possibly the finalization, of the Python interpreter. Most functionality of the interpreter can only be used after the interpreter has been initialized.

The basic initialization function is `Py_Initialize`. This initializes the table of loaded modules, and creates the fundamental modules `__builtin__`, `__main__`, `sys`, and `exceptions`. It also initializes the module search path (`sys.path`).

`Py_Initialize` does not set the “script argument list” (`sys.argv`). If this variable is needed by Python code that will be executed later, it must be set explicitly with a call to `PySys_SetArgv(argc, argv)` subsequent to the call to `Py_Initialize`.

On most systems (in particular, on Unix and Windows, although the details are slightly different), `Py_Initialize` calculates the module search path based upon its best guess for the location of the standard Python interpreter executable, assuming that the Python library is found in a fixed location relative to the Python interpreter executable. In particular, it looks for a directory named `lib/pythonX.Y` relative to the parent directory where the executable named `python` is found on the shell command search path (the environment variable `PATH`).

For instance, if the Python executable is found in `/usr/local/bin/python`, it will assume that the libraries are in `/usr/local/lib/pythonX.Y`. (In fact, this particular path is also the “fallback” location, used when no executable file named `python` is
found along **PATH**. The user can override this behavior by setting the environment variable **PYTHONHOME**, or insert additional directories in front of the standard path by setting **PYTHONPATH**.

The embedding application can steer the search by calling `Py_SetProgramName(file)` before calling `Py_Initialize`. Note that **PYTHONHOME** still overrides this and **PYTHONPATH** is still inserted in front of the standard path. An application that requires total control has to provide its own implementation of **Py_GetPath**, **Py_GetPrefix**, **Py_GetExecPrefix**, and **Py_GetProgramFullPath** (all defined in `Modules/getpath.c`).

Sometimes, it is desirable to “uninitialize” Python. For instance, the application may want to start over (make another call to `Py_Initialize`) or the application is simply done with its use of Python and wants to free memory allocated by Python. This can be accomplished by calling `Py_Finalize`. The function `Py_IsInitialized` returns true if Python is currently in the initialized state. More information about these functions is given in a later chapter. Notice that `Py_Finalize` does *not* free all memory allocated by the Python interpreter, e.g. memory allocated by extension modules currently cannot be released.
Python can be built with several macros to enable extra checks of the interpreter and extension modules. These checks tend to add a large amount of overhead to the runtime so they are not enabled by default.

A full list of the various types of debugging builds is in the file Misc/SpecialBuilds.txt in the Python source distribution. Builds are available that support tracing of reference counts, debugging the memory allocator, or low-level profiling of the main interpreter loop. Only the most frequently-used builds will be described in the remainder of this section.

Compiling the interpreter with the Py_DEBUG macro defined produces what is generally meant by “a debug build” of Python. Py_DEBUG is enabled in the Unix build by adding --with-pydebug to the configure command. It is also implied by the presence of the not-Python-specific _DEBUG macro. When Py_DEBUG is enabled in the Unix build, compiler optimization is disabled.

In addition to the reference count debugging described below, the following extra checks are performed:

- Extra checks are added to the object allocator.
- Extra checks are added to the parser and compiler.
- Downcasts from wide types to narrow types are checked for loss of information.
- A number of assertions are added to the dictionary and set implementations. In addition, the set object acquires a test_c_api() method.
- Sanity checks of the input arguments are added to frame creation.
• The storage for long ints is initialized with a known invalid pattern to catch reference to uninitialized digits.
• Low-level tracing and extra exception checking are added to the runtime virtual machine.
• Extra checks are added to the memory arena implementation.
• Extra debugging is added to the thread module.

There may be additional checks not mentioned here.

Defining `Py_TRACE_REFS` enables reference tracing. When defined, a circular doubly linked list of active objects is maintained by adding two extra fields to every `PyObject`. Total allocations are tracked as well. Upon exit, all existing references are printed. (In interactive mode this happens after every statement run by the interpreter.) Implied by `Py_DEBUG`.

Please refer to Misc/SpecialBuilds.txt in the Python source distribution for more detailed information.
The Very High Level Layer

The functions in this chapter will let you execute Python source code given in a file or a buffer, but they will not let you interact in a more detailed way with the interpreter.

Several of these functions accept a start symbol from the grammar as a parameter. The available start symbols are `Py_eval_input`, `Py_file_input`, and `Py_single_input`. These are described following the functions which accept them as parameters.

Note also that several of these functions take `FILE*` parameters. On particular issue which needs to be handled carefully is that the `FILE` structure for different C libraries can be different and incompatible. Under Windows (at least), it is possible for dynamically linked extensions to actually use different libraries, so care should be taken that `FILE*` parameters are only passed to these functions if it is certain that they were created by the same library that the Python runtime is using.

```
int Py_Main(int argc, char **argv)
The main program for the standard interpreter. This is made available for programs which embed Python. The `argc` and `argv` parameters should be prepared exactly as those which are passed to a C program's `main` function. It is important to note that the argument list may be modified (but the contents of the strings pointed to by the argument list are not). The return value will be the integer passed to the `sys.exit()` function, 1 if the interpreter exits due to an exception, or 2 if the parameter list does not represent a valid Python command line.
```

```
int PyRun_AnyFile(FILE *fp, const char *filename)
This is a simplified interface to `PyRun_AnyFileExFlags` below,
```
leaving closeit set to 0 and flags set to NULL.

int PyRun_AnyFileFlags(FILE *fp, const char *filename,
PyCompilerFlags *flags)
This is a simplified interface to PyRun_AnyFileExFlags below,
leaving the closeit argument set to 0.

int PyRun_AnyFileEx(FILE *fp, const char *filename, int closeit)
This is a simplified interface to PyRun_AnyFileExFlags below,
leaving the flags argument set to NULL.

int PyRun_AnyFileExFlags(FILE *fp, const char *filename, int closeit,
PyCompilerFlags *flags)
If fp refers to a file associated with an interactive device (console
or terminal input or Unix pseudo-terminal), return the value of
PyRun_InteractiveLoop, otherwise return the result of
PyRun_SimpleFile. If filename is NULL, this function uses "???"
as the filename.

int PyRun_SimpleString(const char *command)
This is a simplified interface to PyRun_SimpleStringFlags below,
leaving the PyCompilerFlags* argument set to NULL.

int PyRun_SimpleStringFlags(const char *command,
PyCompilerFlags *flags)
Executes the Python source code from command in the __main__
module according to the flags argument. If __main__ does not
already exist, it is created. Returns 0 on success or -1 if an
exception was raised. If there was an error, there is no way to get
the exception information. For the meaning of flags, see below.

int PyRun_SimpleFile(FILE *fp, const char *filename)
This is a simplified interface to PyRun_SimpleFileExFlags below,
leaving closeit set to 0 and flags set to NULL.

```c
int PyRun_SimpleFileFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
```

This is a simplified interface to `PyRun_SimpleFileExFlags` below, leaving closeit set to 0.

```c
int PyRun_SimpleFileEx(FILE *fp, const char *filename, int closeit)
```

This is a simplified interface to `PyRun_SimpleFileExFlags` below, leaving flags set to NULL.

```c
int PyRun_SimpleFileExFlags(FILE *fp, const char *filename, int closeit, PyCompilerFlags *flags)
```

Similar to `PyRun_SimpleStringFlags`, but the Python source code is read from fp instead of an in-memory string. filename should be the name of the file. If closeit is true, the file is closed before PyRun_SimpleFileExFlags returns.

```c
int PyRun_InteractiveOne(FILE *fp, const char *filename)
```

This is a simplified interface to `PyRun_InteractiveOneFlags` below, leaving flags set to NULL.

```c
int PyRun_InteractiveOneFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
```

Read and execute a single statement from a file associated with an interactive device according to the flags argument. If filename is NULL, "???" is used instead. The user will be prompted using sys.ps1 and sys.ps2. Returns 0 when the input was executed successfully, -1 if there was an exception, or an error code from the errcode.h include file distributed as part of Python if there was a parse error. (Note that errcode.h is not included by Python.h, so must be included specifically if needed.)
int PyRun_InteractiveLoop(FILE *fp, const char *filename)
    This is a simplified interface to PyRun_InteractiveLoopFlags below, leaving flags set to NULL.

int PyRun_InteractiveLoopFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
    Read and execute statements from a file associated with an interactive device until EOF is reached. If filename is NULL, "???" is used instead. The user will be prompted using sys.ps1 and sys.ps2. Returns 0 at EOF.

struct _node* PyParser_SimpleParseString(const char *str, int start)
    This is a simplified interface to PyParser_SimpleParseStringFlagsFilename below, leaving filename set to NULL and flags set to 0.

struct _node* PyParser_SimpleParseStringFlags(const char *str, int start, int flags)
    This is a simplified interface to PyParser_SimpleParseStringFlagsFilename below, leaving filename set to NULL.

struct _node* PyParser_SimpleParseStringFlagsFilename(const char *str, const char *filename, int start, int flags)
    Parse Python source code from str using the start token start according to the flags argument. The result can be used to create a code object which can be evaluated efficiently. This is useful if a code fragment must be evaluated many times.

struct _node* PyParser_SimpleParseFile(FILE *fp, const char *filename, int start)
    This is a simplified interface to PyParser_SimpleParseFileFlags
below, leaving flags set to 0

struct _node* PyParser_SimpleParseFileFlags(FILE *fp, const char *filename, int start, int flags)

Similar to PyParser_SimpleParseStringFlagsFilename, but the Python source code is read from fp instead of an in-memory string.

PyObject* PyRun_String(const char *str, int start, PyObject *globals, PyObject *locals)

This is a simplified interface to PyRun_StringFlags below, leaving flags set to NULL.

PyObject* PyRun_StringFlags(const char *str, int start, PyObject *globals, PyObject *locals, PyCompilerFlags *flags)

Execute Python source code from str in the context specified by the dictionaries globals and locals with the compiler flags specified by flags. The parameter start specifies the start token that should be used to parse the source code.

Returns the result of executing the code as a Python object, or NULL if an exception was raised.

PyObject* PyRun_File(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals)

This is a simplified interface to PyRun_FileExFlags below, leaving closeit set to 0 and flags set to NULL.

PyObject* PyRun_FileEx(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, int closeit)

This is a simplified interface to PyRun_FileExFlags below, leaving flags set to NULL.

PyObject* PyRun_FileFlags(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, PyCompilerFlags *flags)

This is a simplified interface to PyRun_FileExFlags below, leaving closeit set to 0.

PyObject* PyRun_FileExFlags(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, int closeit, PyCompilerFlags *flags)

Similar to PyRun_StringFlags, but the Python source code is read from fp instead of an in-memory string. filename should be the name of the file. If closeit is true, the file is closed before PyRun_FileExFlags returns.

PyObject* Py_CompileString(const char *str, const char *filename, int start)

This is a simplified interface to Py_CompileStringFlags below, leaving flags set to NULL.

PyObject* Py_CompileStringFlags(const char *str, const char *filename, int start, PyCompilerFlags *flags)

Parse and compile the Python source code in str, returning the resulting code object. The start token is given by start; this can be used to constrain the code which can be compiled and should be Py_eval_input, Py_file_input, or Py_single_input. The filename specified by filename is used to construct the code object and may appear in tracebacks or SyntaxError exception messages.
This returns \textit{NULL} if the code cannot be parsed or compiled.

\textbf{PyObject* \texttt{PyEval_EvalCode}(PyCodeObject *co, PyObject *\texttt{globals}, PyObject *\texttt{locals})}

\textit{Return value: New reference.}

This is a simplified interface to \texttt{PyEval_EvalCodeEx}, with just the code object, and the dictionaries of global and local variables. The other arguments are set to \texttt{NULL}.

\textbf{PyObject* \texttt{PyEval_EvalCodeEx}(PyCodeObject *co, PyObject *\texttt{globals}, PyObject *\texttt{locals},PyObject **\texttt{args}, int \texttt{argcount}, PyObject **\texttt{kws}, int \texttt{kwcount}, PyObject **\texttt{defs}, int \texttt{defcount}, PyObject *\texttt{closure})}

Evaluate a precompiled code object, given a particular environment for its evaluation. This environment consists of dictionaries of global and local variables, arrays of arguments, keywords and defaults, and a closure tuple of cells.

\textbf{PyObject* \texttt{PyEval_EvalFrame}(PyFrameObject *f)}

Evaluate an execution frame. This is a simplified interface to \texttt{PyEval_EvalFrameEx}, for backward compatibility.

\textbf{PyObject* \texttt{PyEval_EvalFrameEx}(PyFrameObject *f, int \texttt{throwflag})}

This is the main, unvarnished function of Python interpretation. It is literally 2000 lines long. The code object associated with the execution frame \texttt{f} is executed, interpreting bytecode and executing calls as needed. The additional \texttt{throwflag} parameter can mostly be ignored - if true, then it causes an exception to immediately be thrown; this is used for the \texttt{throw()} methods of generator objects.

\textbf{int \texttt{PyEval_MergeCompilerFlags}(PyCompilerFlags *cf)}

This function changes the flags of the current evaluation frame, and returns true on success, false on failure.

\textbf{int \texttt{Py_eval_input}}
The start symbol from the Python grammar for isolated expressions; for use with `Py_CompileString`.

```c
int Py_file_input
```

The start symbol from the Python grammar for sequences of statements as read from a file or other source; for use with `Py_CompileString`. This is the symbol to use when compiling arbitrarily long Python source code.

```c
int Py_single_input
```

The start symbol from the Python grammar for a single statement; for use with `Py_CompileString`. This is the symbol used for the interactive interpreter loop.

```c
struct PyCompilerFlags
```

This is the structure used to hold compiler flags. In cases where code is only being compiled, it is passed as `int flags`, and in cases where code is being executed, it is passed as `PyCompilerFlags *flags`. In this case, `from __future__ import can modify flags`.

Whenever `PyCompilerFlags *flags` is `NULL`, `cf_flags` is treated as equal to 0, and any modification due to `from __future__ import` is discarded.

```c
struct PyCompilerFlags {
    int cf_flags;
}
```

```c
int CO_FUTURE_DIVISION
```

This bit can be set in `flags` to cause division operator `/` to be interpreted as “true division” according to PEP 238.
Reference Counting

The macros in this section are used for managing reference counts of Python objects.

```c
void Py_INCREF(PyObject *o)
    Increment the reference count for object o. The object must not be NULL; if you aren't sure that it isn't NULL, use Py_XINCREF.

void Py_XINCREF(PyObject *o)
    Increment the reference count for object o. The object may be NULL, in which case the macro has no effect.

void Py_DECREF(PyObject *o)
    Decrement the reference count for object o. The object must not be NULL; if you aren't sure that it isn't NULL, use Py_XDECREF. If the reference count reaches zero, the object's type's deallocation function (which must not be NULL) is invoked.
```

**Warning:** The deallocation function can cause arbitrary Python code to be invoked (e.g. when a class instance with a `__del__() method is deallocated). While exceptions in such code are not propagated, the executed code has free access to all Python global variables. This means that any object that is reachable from a global variable should be in a consistent state before Py_DECREF is invoked. For example, code to delete an object from a list should copy a reference to the deleted object in a temporary variable, update the list data structure, and then call Py_DECREF for the temporary variable.

```c
void Py_XDECREF(PyObject *o)
    Decrement the reference count for object o. The object may be NULL, in which case the macro has no effect; otherwise the
effect is the same as for `Py_DECREF`, and the same warning applies.

```c
void Py_CLEAR(PyObject *o)
```

Decrement the reference count for object `o`. The object may be `NULL`, in which case the macro has no effect; otherwise the effect is the same as for `Py_DECREF`, except that the argument is also set to `NULL`. The warning for `Py_DECREF` does not apply with respect to the object passed because the macro carefully uses a temporary variable and sets the argument to `NULL` before decrementing its reference count.

It is a good idea to use this macro whenever decrementing the value of a variable that might be traversed during garbage collection.

*New in version 2.4.*

The following functions are for runtime dynamic embedding of Python: `Py_IncRef(PyObject *o)`, `Py_DecRef(PyObject *o)`. They are simply exported function versions of `Py_XINCREF` and `Py_XDECREF`, respectively.

The following functions or macros are only for use within the interpreter core: `Py_Dealloc`, `Py_ForgetReference`, `Py_NewReference`, as well as the global variable `_Py_RefTotal`. 
Exception Handling

The functions described in this chapter will let you handle and raise Python exceptions. It is important to understand some of the basics of Python exception handling. It works somewhat like the Unix *errno* variable: there is a global indicator (per thread) of the last error that occurred. Most functions don’t clear this on success, but will set it to indicate the cause of the error on failure. Most functions also return an error indicator, usually *NULL* if they are supposed to return a pointer, or -1 if they return an integer (exception: the *PyArg_* functions return 1 for success and 0 for failure).

When a function must fail because some function it called failed, it generally doesn’t set the error indicator; the function it called already set it. It is responsible for either handling the error and clearing the exception or returning after cleaning up any resources it holds (such as object references or memory allocations); it should not continue normally if it is not prepared to handle the error. If returning due to an error, it is important to indicate to the caller that an error has been set. If the error is not handled or carefully propagated, additional calls into the Python/C API may not behave as intended and may fail in mysterious ways.

The error indicator consists of three Python objects corresponding to the Python variables *sys.exc_type*, *sys.exc_value* and *sys.exc_traceback*. API functions exist to interact with the error indicator in various ways. There is a separate error indicator for each thread.

```c
void PyErr_Print()
{
    Print a standard traceback to *sys.stderr* and clear the error indicator. Call this function only when the error indicator is set. (Otherwise it will cause a fatal error!)
}
```
PyObject* PyErr_Occurred()

*Return value: Borrowed reference.*

Test whether the error indicator is set. If set, return the exception type (the first argument to the last call to one of the PyErr_Set* functions or to PyErr_Restore). If not set, return NULL. You do not own a reference to the return value, so you do not need to Py_DECREF it.

**Note:** Do not compare the return value to a specific exception; use PyErr_ExceptionMatches instead, shown below. (The comparison could easily fail since the exception may be an instance instead of a class, in the case of a class exception, or it may be the a subclass of the expected exception.)

int PyErr_ExceptionMatches(PyObject *exc)

Equivalent to PyErr_GivenExceptionMatches(PyErr_Occurred(), exc). This should only be called when an exception is actually set; a memory access violation will occur if no exception has been raised.

int PyErr_GivenExceptionMatches(PyObject *given, PyObject *exc)

Return true if the given exception matches the exception in exc. If exc is a class object, this also returns true when given is an instance of a subclass. If exc is a tuple, all exceptions in the tuple (and recursively in subtuples) are searched for a match. If given is NULL, a memory access violation will occur.

void PyErr_NormalizeException(PyObject**exc, PyObject**val, PyObject**tb)

Under certain circumstances, the values returned by PyErr_Fetch below can be “unnormalized”, meaning that *exc is a class object but *val is not an instance of the same class. This function can
be used to instantiate the class in that case. If the values are already normalized, nothing happens. The delayed normalization is implemented to improve performance.

```c
void PyErr_Clear()
{
    Clear the error indicator. If the error indicator is not set, there is no effect.
}
```

```c
void PyErr_Fetch(PyObject **ptype, PyObject **pvalue, PyObject **ptraceback)
{
    Retrieve the error indicator into three variables whose addresses are passed. If the error indicator is not set, set all three variables to NULL. If it is set, it will be cleared and you own a reference to each object retrieved. The value and traceback object may be NULL even when the type object is not.
}
```

Note: This function is normally only used by code that needs to handle exceptions or by code that needs to save and restore the error indicator temporarily.

```c
void PyErr_Restore(PyObject *type, PyObject *value, PyObject *traceback)
{
    Set the error indicator from the three objects. If the error indicator is already set, it is cleared first. If the objects are NULL, the error indicator is cleared. Do not pass a NULL type and non-NULL value or traceback. The exception type should be a class. Do not pass an invalid exception type or value. (Violating these rules will cause subtle problems later.) This call takes away a reference to each object: you must own a reference to each object before the call and after the call you no longer own these references. (If you don’t understand this, don’t use this function. I warned you.)
}
```

Note: This function is normally only used by code that needs to save and restore the error indicator temporarily; use
void PyErr_SetString(PyObject *type, const char *message)
This is the most common way to set the error indicator. The first argument specifies the exception type; it is normally one of the standard exceptions, e.g. PyExc_RuntimeError. You need not increment its reference count. The second argument is an error message; it is converted to a string object.

void PyErr_SetObject(PyObject *type, PyObject *value)
This function is similar to PyErr_SetString but lets you specify an arbitrary Python object for the “value” of the exception.

PyObject* PyErr_Format(PyObject *exception, const char *format, ...)

Return value: Always NULL.
This function sets the error indicator and returns NULL. exception should be a Python exception (class, not an instance). format should be a string, containing format codes, similar to printf. The width.precision before a format code is parsed, but the width part is ignored.

</tbody>
</table>

An unrecognized format character causes all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

void PyErr_SetNone(PyObject *type)
This is a shorthand for PyErr_SetObject(type, Py_None).

int PyErr_BadArgument()
This is a shorthand for PyErr_SetString(PyExc_TypeError, message), where message indicates that a built-in operation was invoked with an illegal argument. It is mostly for internal use.

PyObject* PyErr_NoMemory()
Return value: Always NULL.
This is a shorthand for PyErr_SetNone(PyExc_MemoryError); it returns NULL so an object allocation function can write return PyErr_NoMemory(); when it runs out of memory.
PyObject* PyErr_SetFromErrno(PyObject *type)

*Return value: Always NULL.*
This is a convenience function to raise an exception when a C library function has returned an error and set the C variable `errno`. It constructs a tuple object whose first item is the integer `errno` value and whose second item is the corresponding error message (gotten from `strerror`), and then calls `PyErr_SetObject(type, object)`. On Unix, when the `errno` value is `EINTR`, indicating an interrupted system call, this calls `PyErr_CheckSignals`, and if that set the error indicator, leaves it set to that. The function always returns `NULL`, so a wrapper function around a system call can write `return PyErr_SetFromErrno(type);` when the system call returns an error.

PyObject* PyErr_SetFromErrnoWithFilename(PyObject *type, const char *filename)

*Return value: Always NULL.*
Similar to `PyErr_SetFromErrno`, with the additional behavior that if `filename` is not `NULL`, it is passed to the constructor of `type` as a third parameter. In the case of exceptions such as `IOError` and `OSError`, this is used to define the `filename` attribute of the exception instance.

PyObject* PyErr_SetFromWindowsErr(int ierr)

*Return value: Always NULL.*
This is a convenience function to raise `WindowsError`. If called with `ierr` of 0, the error code returned by a call to `GetLastError` is used instead. It calls the Win32 function `FormatMessage` to retrieve the Windows description of error code given by `ierr` or `GetLastError`, then it constructs a tuple object whose first item is the `ierr` value and whose second item is the corresponding error message (gotten from `FormatMessage`), and then calls
PyErr_SetObject(PyExc_WindowsError, object). This function always returns NULL. Availability: Windows.

PyObject* PyErr_SetExcFromWindowsErr(PyObject *type, int ierr)
Return value: Always NULL.
Similar to PyErr_SetFromWindowsErr, with an additional parameter specifying the exception type to be raised. Availability: Windows.

New in version 2.3.

PyObject* PyErr_SetFromWindowsErrWithFilename(int ierr, const char *filename)
Return value: Always NULL.
Similar to PyErr_SetFromWindowsErr, with the additional behavior that if filename is not NULL, it is passed to the constructor of WindowsError as a third parameter. Availability: Windows.

PyObject* PyErr_SetExcFromWindowsErrWithFilename(PyObject *type, int ierr, char *filename)
Return value: Always NULL.
Similar to PyErr_SetFromWindowsErrWithFilename, with an additional parameter specifying the exception type to be raised. Availability: Windows.

New in version 2.3.

void PyErr_BadInternalCall()
This is a shorthand for PyErr_SetString(PyExc_TypeError, message), where message indicates that an internal operation (e.g. a Python/C API function) was invoked with an illegal argument. It is mostly for internal use.

int PyErr_WarnEx(PyObject *category, char *message, int stacklevel)
Issue a warning message. The `category` argument is a warning category (see below) or `NULL`; the `message` argument is a message string. `stacklevel` is a positive number giving a number of stack frames; the warning will be issued from the currently executing line of code in that stack frame. A `stacklevel` of 1 is the function calling `PyErr_WarnEx`, 2 is the function above that, and so forth.

This function normally prints a warning message to `sys.stderr`; however, it is also possible that the user has specified that warnings are to be turned into errors, and in that case this will raise an exception. It is also possible that the function raises an exception because of a problem with the warning machinery (the implementation imports the `warnings` module to do the heavy lifting). The return value is 0 if no exception is raised, or -1 if an exception is raised. (It is not possible to determine whether a warning message is actually printed, nor what the reason is for the exception; this is intentional.) If an exception is raised, the caller should do its normal exception handling (for example, `Py_DecREF` owned references and return an error value).

Warning categories must be subclasses of `Warning`; the default warning category is `RuntimeWarning`. The standard Python warning categories are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. Their names are `PyExc_Warning`, `PyExc_UserWarning`, `PyExc_UnicodeWarning`, `PyExc_DeprecationWarning`, `PyExc_SyntaxWarning`, `PyExc_RuntimeWarning`, and `PyExc_FutureWarning`. `PyExc_Warning` is a subclass of `PyExc_Exception`; the other warning categories are subclasses of `PyExc_Warning`.

For information about warning control, see the documentation for
the `warnings` module and the `-W` option in the command line documentation. There is no C API for warning control.

```c
int PyErr_Warn(PyObject *category, char *message)
```

Issue a warning message. The `category` argument is a warning category (see below) or `NULL`; the `message` argument is a message string. The warning will appear to be issued from the function calling `PyErr_Warn`, equivalent to calling `PyErr_WarnEx` with a `stacklevel` of 1.

Deprecated; use `PyErr_WarnEx` instead.

```c
int PyErr_WarnExplicit(PyObject *category, const char *message, const char *filename, int lineno, const char *module, PyObject *registry)
```

Issue a warning message with explicit control over all warning attributes. This is a straightforward wrapper around the Python function `warnings.warn_explicit()`, see there for more information. The `module` and `registry` arguments may be set to `NULL` to get the default effect described there.

```c
int PyErr_WarnPy3k(char *message, int stacklevel)
```

Issue a `DeprecationWarning` with the given `message` and `stacklevel` if the `Py_Py3kWarningFlag` flag is enabled.

_ENew in version 2.6._

```c
int PyErr_CheckSignals()
```

This function interacts with Python’s signal handling. It checks whether a signal has been sent to the processes and if so, invokes the corresponding signal handler. If the `signal` module is supported, this can invoke a signal handler written in Python. In all cases, the default effect for `SIGINT` is to raise the `KeyboardInterrupt` exception. If an exception is raised the error
indicator is set and the function returns -1; otherwise the function returns 0. The error indicator may or may not be cleared if it was previously set.

void PyErr_SetInterrupt()
This function simulates the effect of a SIGINT signal arriving — the next time PyErr_CheckSignals is called, KeyboardInterrupt will be raised. It may be called without holding the interpreter lock.

int PySignal_SetWakeupFd(int fd)
This utility function specifies a file descriptor to which a \n byte will be written whenever a signal is received. It returns the previous such file descriptor. The value -1 disables the feature; this is the initial state. This is equivalent to signal.set_wakeup_fd() in Python, but without any error checking. fd should be a valid file descriptor. The function should only be called from the main thread.

PyObject* PyErr_NewException(char *name, PyObject *base, PyObject *dict)

This utility function creates and returns a new exception object. The name argument must be the name of the new exception, a C string of the form module.class. The base and dict arguments are normally NULL. This creates a class object derived from Exception (accessible in C as PyExc_Exception).

The __module__ attribute of the new class is set to the first part (up to the last dot) of the name argument, and the class name is set to the last part (after the last dot). The base argument can be used to specify alternate base classes; it can either be only one class or a tuple of classes. The dict argument can be used to
specify a dictionary of class variables and methods.

`void PyErr_WriteUnraisable(PyObject *obj)`

This utility function prints a warning message to `sys.stderr` when an exception has been set but it is impossible for the interpreter to actually raise the exception. It is used, for example, when an exception occurs in an `__del__()` method.

The function is called with a single argument `obj` that identifies the context in which the unraisable exception occurred. The `repr` of `obj` will be printed in the warning message.
Standard Exceptions

All standard Python exceptions are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. For completeness, here are all the variables:

<table>
<thead>
<tr>
<th>C Name</th>
<th>Python Name</th>
<th>Notes</th>

<td>RuntimeError</td>
<td></td>
</tr>
<tr>
<td>PyExc_SyntaxError</td>
<td>SyntaxError</td>
<td></td>
</tr>
</tbody>
</table>
Notes:

1. This is a base class for other standard exceptions.

2. This is the same as `weakref.ReferenceError`.

3. Only defined on Windows; protect code that uses this by testing that the preprocessor macro `MS_WINDOWS` is defined.

4. *New in version 2.5.*
Deprecation of String Exceptions

All exceptions built into Python or provided in the standard library are derived from `BaseException`.

String exceptions are still supported in the interpreter to allow existing code to run unmodified, but this will also change in a future release.
Utilities

The functions in this chapter perform various utility tasks, ranging from helping C code be more portable across platforms, using Python modules from C, and parsing function arguments and constructing Python values from C values.

- Operating System Utilities
- System Functions
- Process Control

- Importing Modules
- Data marshalling support
- Parsing arguments and building values
- String conversion and formatting
- Reflection
Operating System Utilities

int **Py_FdIsInteractive**(FILE *fp, const char *filename)

Return true (nonzero) if the standard I/O file fp with name filename is deemed interactive. This is the case for files for which isatty(fileno(fp)) is true. If the global flag Py_InteractiveFlag is true, this function also returns true if the filename pointer is NULL or if the name is equal to one of the strings '<stdin>' or '???'.

long **PyOS_GetLastModificationTime**(char *filename)

Return the time of last modification of the file filename. The result is encoded in the same way as the timestamp returned by the standard C library function time.

void **PyOS_AfterFork**()

Function to update some internal state after a process fork; this should be called in the new process if the Python interpreter will continue to be used. If a new executable is loaded into the new process, this function does not need to be called.

int **PyOS_CheckStack**()

Return true when the interpreter runs out of stack space. This is a reliable check, but is only available when USE_STACKCHECK is defined (currently on Windows using the Microsoft Visual C++ compiler). USE_STACKCHECK will be defined automatically; you should never change the definition in your own code.

**PyOS_sighandler_t PyOS_getsig**(int i)

Return the current signal handler for signal i. This is a thin wrapper around either sigaction or signal. Do not call those functions directly! PyOS_sighandler_t is a typedef alias for void
PyOS_sighandler_t PyOS_setsig(int i, PyOS_sighandler_t h)

Set the signal handler for signal i to be h; return the old signal handler. This is a thin wrapper around either sigaction or signal. Do not call those functions directly! PyOS_sighandler_t is a typedef alias for void (*)(int).
System Functions

These are utility functions that make functionality from the `sys` module accessible to C code. They all work with the current interpreter thread’s `sys` module’s dict, which is contained in the internal thread state structure.

`PyObject *PySys_GetObject(char *name)`

*Return value: Borrowed reference.*

Return the object `name` from the `sys` module or `NULL` if it does not exist, without setting an exception.

`FILE *PySys_GetFile(char *name, FILE *def)`

Return the `FILE*` associated with the object `name` in the `sys` module, or `def` if `name` is not in the module or is not associated with a `FILE*`.

`int PySys_SetObject(char *name, PyObject *v)`

Set `name` in the `sys` module to `v` unless `v` is `NULL`, in which case `name` is deleted from the `sys` module. Returns 0 on success, -1 on error.

`void PySys_ResetWarnOptions(void)`

Reset `sys.warnoptions` to an empty list.

`void PySys_AddWarnOption(char *s)`

Append `s` to `sys.warnoptions`.

`void PySys_SetPath(char *path)`

Set `sys.path` to a list object of paths found in `path` which should be a list of paths separated with the platform’s search path delimiter (; on Unix, ; on Windows).
void **PySys_WriteStdout** (const char *format, ...)

Write the output string described by format to *sys.stdout*. No exceptions are raised, even if truncation occurs (see below).

*format* should limit the total size of the formatted output string to 1000 bytes or less – after 1000 bytes, the output string is truncated. In particular, this means that no unrestricted “%s” formats should occur; these should be limited using “%.<N>s” where <N> is a decimal number calculated so that <N> plus the maximum size of other formatted text does not exceed 1000 bytes. Also watch out for “%f”, which can print hundreds of digits for very large numbers.

If a problem occurs, or *sys.stdout* is unset, the formatted message is written to the real (C level) *stdout*.

void **PySys_WriteStderr** (const char *format, ...)

As above, but write to *sys.stderr* or *stderr* instead.
Process Control

void Py_FatalError(const char *message)
Print a fatal error message and kill the process. No cleanup is performed. This function should only be invoked when a condition is detected that would make it dangerous to continue using the Python interpreter; e.g., when the object administration appears to be corrupted. On Unix, the standard C library function abort is called which will attempt to produce a core file.

void Py_Exit(int status)
Exit the current process. This calls Py_Finalize and then calls the standard C library function exit(status).

int Py_AtExit(void (*func) ())
Register a cleanup function to be called by Py_Finalize. The cleanup function will be called with no arguments and should return no value. At most 32 cleanup functions can be registered. When the registration is successful, Py_AtExit returns 0; on failure, it returns -1. The cleanup function registered last is called first. Each cleanup function will be called at most once. Since Python’s internal finalization will have completed before the cleanup function, no Python APIs should be called by func.
Importing Modules

**PyObject** `PyImport_ImportModule(const char *name)`

*Return value: New reference.*

This is a simplified interface to `PyImport_ImportModuleEx` below, leaving the `globals` and `locals` arguments set to `NULL` and `level` set to 0. When the `name` argument contains a dot (when it specifies a submodule of a package), the `fromlist` argument is set to the list `[*]` so that the return value is the named module rather than the top-level package containing it as would otherwise be the case. (Unfortunately, this has an additional side effect when `name` in fact specifies a subpackage instead of a submodule: the submodules specified in the package's `__all__` variable are loaded.) Return a new reference to the imported module, or `NULL` with an exception set on failure. Before Python 2.4, the module may still be created in the failure case — examine `sys.modules` to find out. Starting with Python 2.4, a failing import of a module no longer leaves the module in `sys.modules`.

*Changed in version 2.4:* failing imports remove incomplete module objects.

*Changed in version 2.6:* always use absolute imports

**PyObject** `PyImport_ImportModuleNoBlock(const char *name)`

This version of `PyImport_ImportModule` does not block. It's intended to be used in C functions that import other modules to execute a function. The import may block if another thread holds the import lock. The function `PyImport_ImportModuleNoBlock` never blocks. It first tries to fetch the module from `sys.modules` and falls back to `PyImport_ImportModule` unless the lock is held, in which case the function will raise an `ImportError`. 
New in version 2.6.

PyObject* PyImport_ImportModuleEx(char *name, PyObject *globals, PyObject *locals, PyObject *fromlist)

Import a module. This is best described by referring to the built-in Python function __import__(), as the standard __import__() function calls this function directly.

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure (before Python 2.4, the module may still be created in this case). Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.

Changed in version 2.4: failing imports remove incomplete module objects.

Changed in version 2.6: The function is an alias for PyImport_ImportModuleLevel with -1 as level, meaning relative import.

PyObject* PyImport_ImportModuleLevel(char *name, PyObject *globals, PyObject *locals, PyObject *fromlist, int level)

Import a module. This is best described by referring to the built-in Python function __import__(), as the standard __import__() function calls this function directly.

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure. Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.
New in version 2.5.

PyObject* PyImport_Import(PyObject *name)

*Return value: New reference.*
This is a higher-level interface that calls the current “import hook function”. It invokes the __import__() function from the __builtins__ of the current globals. This means that the import is done using whatever import hooks are installed in the current environment, e.g. by rexec or ihooks.

Changed in version 2.6: always use absolute imports

PyObject* PyImport_ReloadModule(PyObject *m)

*Return value: New reference.*
Reload a module. This is best described by referring to the built-in Python function reload(), as the standard reload() function calls this function directly. Return a new reference to the reloaded module, or NULL with an exception set on failure (the module still exists in this case).

PyObject* PyImport_AddModule(const char *name)

*Return value: Borrowed reference.*
Return the module object corresponding to a module name. The name argument may be of the form package.module. First check the modules dictionary if there’s one there, and if not, create a new one and insert it in the modules dictionary. Return NULL with an exception set on failure.

Note: This function does not load or import the module; if the module wasn’t already loaded, you will get an empty module object. Use PyImport_ImportModule or one of its variants to import a module. Package structures implied by a dotted name for name are not created if not already present.
PyObject* PyImport_ExecCodeModule(char *name, PyObject *co)

*Return value: New reference.*

Given a module name (possibly of the form `package.module`) and a code object read from a Python bytecode file or obtained from the built-in function `compile()`, load the module. Return a new reference to the module object, or `NULL` with an exception set if an error occurred. Before Python 2.4, the module could still be created in error cases. Starting with Python 2.4, `name` is removed from `sys.modules` in error cases, and even if `name` was already in `sys.modules` on entry to `PyImport_ExecCodeModule`. Leaving incompletely initialized modules in `sys.modules` is dangerous, as imports of such modules have no way to know that the module object is an unknown (and probably damaged with respect to the module author’s intents) state.

This function will reload the module if it was already imported. See `PyImport_ReloadModule` for the intended way to reload a module.

If `name` points to a dotted name of the form `package.module`, any package structures not already created will still not be created.

*Changed in version 2.4: `name` is removed from `sys.modules` in error cases.*

long PyImport_GetMagicNumber()

Return the magic number for Python bytecode files (a.k.a. `.pyc` and `.pyo` files). The magic number should be present in the first four bytes of the bytecode file, in little-endian byte order.

PyObject* PyImport_GetModuleDict()

*Return value: Borrowed reference.*

Return the dictionary used for the module administration (a.k.a. `sys.modules`). Note that this is a per-interpreter variable.
PyObject* PyImport_GetImporter(PyObject *path)

Return an importer object for a sys.path/pkg.__path__ item path, possibly by fetching it from the sys.path_importer_cache dict. If it wasn’t yet cached, traverse sys.path_hooks until a hook is found that can handle the path item. Return None if no hook could; this tells our caller it should fall back to the builtin import mechanism. Cache the result in sys.path_importer_cache. Return a new reference to the importer object.

*New in version 2.6.*

void _PyImport_Init()

Initialize the import mechanism. For internal use only.

void PyImport_Cleanup()

Empty the module table. For internal use only.

void _PyImport_Fini()

Finalize the import mechanism. For internal use only.

PyObject* _PyImport_FindExtension(char *, char *)

For internal use only.

PyObject* _PyImport_FixupExtension(char *, char *)

For internal use only.

int PyImport_ImportFrozenModule(char *name)

Load a frozen module named name. Return 1 for success, 0 if the module is not found, and -1 with an exception set if the initialization failed. To access the imported module on a successful load, use PyImport_ImportModule. (Note the misnomer — this function would reload the module if it was already imported.)
struct _frozen
This is the structure type definition for frozen module descriptors, as generated by the freeze utility (see Tools/freeze/ in the Python source distribution). Its definition, found in Include/import.h, is:

```c
struct _frozen {
    char *name;
    unsigned char *code;
    int size;
};
```

struct _frozen* PyImport_FrozenModules
This pointer is initialized to point to an array of struct _frozen records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

int PyImport_AppendInittab(char *name, void (*initfunc)(void))
Add a single module to the existing table of built-in modules. This is a convenience wrapper around PyImport_ExtendInittab, returning -1 if the table could not be extended. The new module can be imported by the name name, and uses the function initfunc as the initialization function called on the first attempted import. This should be called before Py_Initialize.

struct _inittab
Structure describing a single entry in the list of built-in modules. Each of these structures gives the name and initialization function for a module built into the interpreter. Programs which embed Python may use an array of these structures in conjunction with PyImport_ExtendInittab to provide additional built-in modules.
The structure is defined in `include/import.h` as:

```c
struct _inittab {
    char  *name;
    void (*initfunc)(void);
};
```

```c
int PyImport_ExtendInittab(struct _inittab *newtab)
```

Add a collection of modules to the table of built-in modules. The `newtab` array must end with a sentinel entry which contains `NULL` for the `name` field; failure to provide the sentinel value can result in a memory fault. Returns `0` on success or `-1` if insufficient memory could be allocated to extend the internal table. In the event of failure, no modules are added to the internal table. This should be called before `Py_Initialize`. 

```c
```
Data marshalling support

These routines allow C code to work with serialized objects using the same data format as the marshal module. There are functions to write data into the serialization format, and additional functions that can be used to read the data back. Files used to store marshalled data must be opened in binary mode.

Numeric values are stored with the least significant byte first.

The module supports two versions of the data format: version 0 is the historical version, version 1 (new in Python 2.4) shares interned strings in the file, and upon unmarshalling. Version 2 (new in Python 2.5) uses a binary format for floating point numbers. Py_MARSHAL_VERSION indicates the current file format (currently 2).

void PyMarshal_WriteLongToFile(long value, FILE *file, int version)
    Marshal a long integer, value, to file. This will only write the least-significant 32 bits of value; regardless of the size of the native long type.

    Changed in version 2.4: version indicates the file format.

void PyMarshal_WriteObjectToFile(PyObject *value, FILE *file, int version)
    Marshal a Python object, value, to file.

    Changed in version 2.4: version indicates the file format.

PyObject* PyMarshal_WriteObjectToString(PyObject *value, int version)
Return a string object containing the marshalled representation of value.

*Changed in version 2.4: version* indicates the file format.

The following functions allow marshalled values to be read back in.

XXX What about error detection? It appears that reading past the end of the file will always result in a negative numeric value (where that's relevant), but it's not clear that negative values won't be handled properly when there's no error. What's the right way to tell? Should only non-negative values be written using these routines?

```c
long PyMarshal_ReadLongFromFile(FILE *file)
    Return a C long from the data stream in a FILE* opened for reading. Only a 32-bit value can be read in using this function, regardless of the native size of long.
```

```c
int PyMarshal_ReadShortFromFile(FILE *file)
    Return a C short from the data stream in a FILE* opened for reading. Only a 16-bit value can be read in using this function, regardless of the native size of short.
```

```c
PyObject* PyMarshal_ReadObjectFromFile(FILE *file)
    Return a Python object from the data stream in a FILE* opened for reading. On error, sets the appropriate exception (EOFError or TypeError) and returns NULL.
```

```c
PyObject* PyMarshal_ReadLastObjectFromFile(FILE *file)
    Return a Python object from the data stream in a FILE* opened for reading. Unlike PyMarshal_ReadObjectFromFile, this function assumes that no further objects will be read from the file, allowing
it to aggressively load file data into memory so that the de-
serializaon can operate from data in memory rather than reading
a byte at a time from the ﬁle. Only use these variant if you are
certain that you won’t be reading anything else from the ﬁle. On
error, sets the appropriate exception (\texttt{EOFError} or \texttt{TypeError}) and
returns \texttt{NULL}.

\begin{verbatim}
PyObject* PyMarshal_ReadObjectFromString(char *string,
Py_ssize_t len)
    Return a Python object from the data stream in a character buffer
    containing \texttt{len} bytes pointed to by \texttt{string}. On error, sets the
    appropriate exception (\texttt{EOFError} or \texttt{TypeError}) and returns \texttt{NULL}.
\end{verbatim}
Parsing arguments and building values

These functions are useful when creating your own extensions functions and methods. Additional information and examples are available in *Extending and Embedding the Python Interpreter*.

The first three of these functions described, PyArg_ParseTuple, PyArg_ParseTupleAndKeywords, and PyArg_Parse, all use *format strings* which are used to tell the function about the expected arguments. The format strings use the same syntax for each of these functions.

A format string consists of zero or more “format units.” A format unit describes one Python object; it is usually a single character or a parenthesized sequence of format units. With a few exceptions, a format unit that is not a parenthesized sequence normally corresponds to a single address argument to these functions. In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that matches the format unit; and the entry in [square] brackets is the type of the C variable(s) whose address should be passed.

```
s (string or Unicode object) [const char *]
```

Convert a Python string or Unicode object to a C pointer to a character string. You must not provide storage for the string itself; a pointer to an existing string is stored into the character pointer variable whose address you pass. The C string is NUL-terminated. The Python string must not contain embedded NUL bytes; if it does, a *TypeError* exception is raised. Unicode objects are converted to C strings using the default encoding. If this conversion fails, a *UnicodeError* is raised.
s# (string, Unicode or any read buffer compatible object) [const char *, int]
This variant on s stores into two C variables, the first one a pointer to a character string, the second one its length. In this case the Python string may contain embedded null bytes. Unicode objects pass back a pointer to the default encoded string version of the object if such a conversion is possible. All other read-buffer compatible objects pass back a reference to the raw internal data representation.

s* (string, Unicode, or any buffer compatible object) [Py_buffer *]
Similar to s#, this code fills a Py_buffer structure provided by the caller. The buffer gets locked, so that the caller can subsequently use the buffer even inside a Py_BEGIN_ALLOW_THREADS block; the caller is responsible for calling PyBuffer_Release with the structure after it has processed the data.

New in version 2.6.

z (string or None) [const char *]
Like s, but the Python object may also be None, in which case the C pointer is set to NULL.

z# (string or None or any read buffer compatible object) [const char *, int]
This is to s# as z is to s.

z* (string or None or any buffer compatible object) [Py_buffer*]
This is to s* as z is to s.

New in version 2.6.

u (Unicode object) [Py_UNICODE *]
Convert a Python Unicode object to a C pointer to a NULL-terminated buffer of 16-bit Unicode (UTF-16) data. As with s, there is no need to provide storage for the Unicode data buffer; a
pointer to the existing Unicode data is stored into the `Py_UNICODE` pointer variable whose address you pass.

`u#` (Unicode object) `[Py_UNICODE *, int]
This variant on `u` stores into two C variables, the first one a pointer to a Unicode data buffer, the second one its length. Non-Unicode objects are handled by interpreting their read-buffer pointer as pointer to a `Py_UNICODE` array.

`es` (string, Unicode object or character buffer compatible object) 
[const char *encoding, char **buffer]
This variant on `s` is used for encoding Unicode and objects convertible to Unicode into a character buffer. It only works for encoded data without embedded NUL bytes.

This format requires two arguments. The first is only used as input, and must be a `const char*` which points to the name of an encoding as a NUL-terminated string, or `NULL`, in which case the default encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a `char**`; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument.

`PyArg_ParseTuple` will allocate a buffer of the needed size, copy the encoded data into this buffer and adjust `*buffer` to reference the newly allocated storage. The caller is responsible for calling `PyMem_Free` to free the allocated buffer after use.

`et` (string, Unicode object or character buffer compatible object) 
[const char *encoding, char **buffer]
Same as `es` except that 8-bit string objects are passed through without recoding them. Instead, the implementation assumes that the string object uses the encoding passed in as parameter.

`es#` (string, Unicode object or character buffer compatible object)
This variant on encoding is used for encoding Unicode and objects convertible to Unicode into a character buffer. Unlike the es format, this variant allows input data which contains NUL characters.

It requires three arguments. The first is only used as input, and must be a const char* which points to the name of an encoding as a NUL-terminated string, or NULL, in which case the default encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a char**; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument. The third argument must be a pointer to an integer; the referenced integer will be set to the number of bytes in the output buffer.

There are two modes of operation:

If *buffer points a NULL pointer, the function will allocate a buffer of the needed size, copy the encoded data into this buffer and set *buffer to reference the newly allocated storage. The caller is responsible for calling PyMem_Free to free the allocated buffer after usage.

If *buffer points to a non-NULL pointer (an already allocated buffer), PyArg_ParseTuple will use this location as the buffer and interpret the initial value of *buffer_length as the buffer size. It will then copy the encoded data into the buffer and NUL-terminate it. If the buffer is not large enough, a ValueError will be set.

In both cases, *buffer_length is set to the length of the encoded data without the trailing NUL byte.
[const char *encoding, char **buffer]
    Same as es# except that string objects are passed through
    without recoding them. Instead, the implementation assumes that
    the string object uses the encoding passed in as parameter.

b (integer) [char]
    Convert a Python integer to a tiny int, stored in a C char.

B (integer) [unsigned char]
    Convert a Python integer to a tiny int without overflow checking,
    stored in a C unsigned char.

    New in version 2.3.

h (integer) [short int]
    Convert a Python integer to a C short int.

H (integer) [unsigned short int]
    Convert a Python integer to a C unsigned short int, without
    overflow checking.

    New in version 2.3.

i (integer) [int]
    Convert a Python integer to a plain C int.

I (integer) [unsigned int]
    Convert a Python integer to a C unsigned int, without overflow
    checking.

    New in version 2.3.

l (integer) [long int]
    Convert a Python integer to a C long int.

k (integer) [unsigned long]
    Convert a Python integer or long integer to a C unsigned long
    without overflow checking.
New in version 2.3.

L (integer) [PY_LONG_LONG]
Convert a Python integer to a C long long. This format is only available on platforms that support long long (or _int64 on Windows).

K (integer) [unsigned PY_LONG_LONG]
Convert a Python integer or long integer to a C unsigned long long without overflow checking. This format is only available on platforms that support unsigned long long (or unsigned _int64 on Windows).

New in version 2.3.

n (integer) [Py_ssize_t]
Convert a Python integer or long integer to a C Py_ssize_t.

New in version 2.5.

c (string of length 1) [char]
Convert a Python character, represented as a string of length 1, to a C char.

f (float) [float]
Convert a Python floating point number to a C float.

d (float) [double]
Convert a Python floating point number to a C double.

p (complex) [Py_complex]
Convert a Python complex number to a C Py_complex structure.

0 (object) [PyObject *]
Store a Python object (without any conversion) in a C object pointer. The C program thus receives the actual object that was passed. The object's reference count is not increased. The
pointer stored is not NULL.

0! (object) [typeobject, PyObject *]
Store a Python object in a C object pointer. This is similar to 0, but takes two C arguments: the first is the address of a Python type object, the second is the address of the C variable (of type PyObject*) into which the object pointer is stored. If the Python object does not have the required type, TypeError is raised.

0& (object) [converter, anything]
Convert a Python object to a C variable through a converter function. This takes two arguments: the first is a function, the second is the address of a C variable (of arbitrary type), converted to void*. The converter function in turn is called as follows:

```c
status = converter(object, address);
```

where object is the Python object to be converted and address is the void* argument that was passed to the PyArg_Parse* function. The returned status should be 1 for a successful conversion and 0 if the conversion has failed. When the conversion fails, the converter function should raise an exception and leave the content of address unmodified.

s (string) [PyStringObject *]
Like 0 but requires that the Python object is a string object. Raises TypeError if the object is not a string object. The C variable may also be declared as PyObject*.

u (Unicode string) [PyUnicodeObject *]
Like 0 but requires that the Python object is a Unicode object. Raises TypeError if the object is not a Unicode object. The C variable may also be declared as PyObject*.

t# (read-only character buffer) [char *, int]
Like s#, but accepts any object which implements the read-only buffer interface. The char* variable is set to point to the first byte of the buffer, and the int is set to the length of the buffer. Only single-segment buffer objects are accepted; TypeError is raised for all others.

w (read-write character buffer) [char *]
Similar to s, but accepts any object which implements the read-write buffer interface. The caller must determine the length of the buffer by other means, or use w# instead. Only single-segment buffer objects are accepted; TypeError is raised for all others.

w# (read-write character buffer) [char *, int]
Like s#, but accepts any object which implements the read-write buffer interface. The char * variable is set to point to the first byte of the buffer, and the int is set to the length of the buffer. Only single-segment buffer objects are accepted; TypeError is raised for all others.

w* (read-write byte-oriented buffer) [Py_buffer *]
This is to w what s* is to s. .. versionadded:: 2.6

(items) (tuple) [matching-items]
The object must be a Python sequence whose length is the number of format units in items. The C arguments must correspond to the individual format units in items. Format units for sequences may be nested.

Note: Prior to Python version 1.5.2, this format specifier only accepted a tuple containing the individual parameters, not an arbitrary sequence. Code which previously caused TypeError to be raised here may now proceed without an exception. This is not expected to be a problem for existing code.

It is possible to pass Python long integers where integers are
requested; however no proper range checking is done — the most significant bits are silently truncated when the receiving field is too small to receive the value (actually, the semantics are inherited from downcasts in C — your mileage may vary).

A few other characters have a meaning in a format string. These may not occur inside nested parentheses. They are:

| Indicates that the remaining arguments in the Python argument list are optional. The C variables corresponding to optional arguments should be initialized to their default value — when an optional argument is not specified, \texttt{PyArg_ParseTuple} does not touch the contents of the corresponding C variable(s).

; The list of format units ends here; the string after the colon is used as the function name in error messages (the “associated value” of the exception that \texttt{PyArg_ParseTuple} raises).

; The list of format units ends here; the string after the semicolon is used as the error message \textit{instead} of the default error message. Clearly, | and ; mutually exclude each other.

Note that any Python object references which are provided to the caller are \textit{borrowed} references; do not decrement their reference count!

Additional arguments passed to these functions must be addresses of variables whose type is determined by the format string; these are used to store values from the input tuple. There are a few cases, as described in the list of format units above, where these parameters are used as input values; they should match what is specified for the corresponding format unit in that case.

For the conversion to succeed, the \texttt{arg} object must match the format
and the format must be exhausted. On success, the PyArg_Parse* functions return true, otherwise they return false and raise an appropriate exception. When the PyArg_Parse* functions fail due to conversion failure in one of the format units, the variables at the addresses corresponding to that and the following format units are left untouched.

```c
int PyArg_ParseTuple(PyObject *args, const char *format, ...)  
Parse the parameters of a function that takes only positional parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.
```

```c
int PyArg_VaParse(PyObject *args, const char *format, va_list vargs)  
Identical to PyArg_ParseTuple, except that it accepts a va_list rather than a variable number of arguments.
```

```c
int PyArg_ParseTupleAndKeywords(PyObject *args, PyObject *kw, const char *format, char *keywords[], ...)  
Parse the parameters of a function that takes both positional and keyword parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.
```

```c
int PyArg_VaParseTupleAndKeywords(PyObject *args, PyObject *kw, const char *format, char *keywords[], va_list vargs)  
Identical to PyArg_ParseTupleAndKeywords, except that it accepts a va_list rather than a variable number of arguments.
```

```c
int PyArg_Parse(PyObject *args, const char *format, ...)  
Function used to deconstruct the argument lists of “old-style” functions — these are functions which use the METH_OLDARGS parameter parsing method. This is not recommended for use in parameter parsing in new code, and most code in the standard
interpreter has been modified to no longer use this for that purpose. It does remain a convenient way to decompose other tuples, however, and may continue to be used for that purpose.

```c
int PyArg_UnpackTuple(PyObject *args, const char *name,
Py_ssize_t min, Py_ssize_t max, ...)```

A simpler form of parameter retrieval which does not use a format string to specify the types of the arguments. Functions which use this method to retrieve their parameters should be declared as `METH_VARARGS` in function or method tables. The tuple containing the actual parameters should be passed as `args`; it must actually be a tuple. The length of the tuple must be at least `min` and no more than `max`; `min` and `max` may be equal. Additional arguments must be passed to the function, each of which should be a pointer to a `PyObject*` variable; these will be filled in with the values from `args`; they will contain borrowed references. The variables which correspond to optional parameters not given by `args` will not be filled in; these should be initialized by the caller. This function returns true on success and false if `args` is not a tuple or contains the wrong number of elements; an exception will be set if there was a failure.

This is an example of the use of this function, taken from the sources for the `_weakref` helper module for weak references:

```c
static PyObject *
weakref_ref(PyObject *self, PyObject *args)
{
    PyObject *object;
    PyObject *callback = NULL;
    PyObject *result = NULL;

    if (PyArg_UnpackTuple(args, "ref", 1, 2, &object, &callback)
        result = PyWeakref_NewRef(object, callback);
```
The call to \texttt{PyArg_UnpackTuple} in this example is entirely equivalent to this call to \texttt{PyArg_ParseTuple}:

\begin{verbatim}
PyArg_ParseTuple(args, "O|O:ref", &object, &callback)
\end{verbatim}

\textit{New in version 2.2.}

\texttt{PyObject* \textbf{Py_BuildValue}(const char *format, ...)}

\textit{Return value: New reference.}

Create a new value based on a format string similar to those accepted by the \texttt{PyArg_Parse*} family of functions and a sequence of values. Returns the value or \texttt{NULL} in the case of an error; an exception will be raised if \texttt{NULL} is returned.

\texttt{Py_BuildValue} does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns \texttt{None}; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

When memory buffers are passed as parameters to supply data to build objects, as for the \texttt{s} and \texttt{s#} formats, the required data is copied. Buffers provided by the caller are never referenced by the objects created by \texttt{Py_BuildValue}. In other words, if your code invokes \texttt{malloc} and passes the allocated memory to \texttt{Py_BuildValue}, your code is responsible for calling \texttt{free} for that memory once \texttt{Py_BuildValue} returns.
In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that the format unit will return; and the entry in [square] brackets is the type of the C value(s) to be passed.

The characters space, tab, colon and comma are ignored in format strings (but not within format units such as s#). This can be used to make long format strings a tad more readable.

s (string) [char *]
Convert a null-terminated C string to a Python object. If the C string pointer is NULL, None is used.

s# (string) [char *, int]
Convert a C string and its length to a Python object. If the C string pointer is NULL, the length is ignored and None is returned.

z (string or None) [char *]
Same as s.

z# (string or None) [char *, int]
Same as s#.

u (Unicode string) [Py_UNICODE *]
Convert a null-terminated buffer of Unicode (UCS-2 or UCS-4) data to a Python Unicode object. If the Unicode buffer pointer is NULL, None is returned.

u# (Unicode string) [Py_UNICODE *, int]
Convert a Unicode (UCS-2 or UCS-4) data buffer and its length to a Python Unicode object. If the Unicode buffer pointer is NULL, the length is ignored and None is returned.

i (integer) [int]
Convert a plain C int to a Python integer object.
b (integer) [char]
    Convert a plain C char to a Python integer object.

h (integer) [short int]
    Convert a plain C short int to a Python integer object.

l (integer) [long int]
    Convert a C long int to a Python integer object.

B (integer) [unsigned char]
    Convert a C unsigned char to a Python integer object.

H (integer) [unsigned short int]
    Convert a C unsigned short int to a Python integer object.

I (integer/long) [unsigned int]
    Convert a C unsigned int to a Python integer object or a
    Python long integer object, if it is larger than \texttt{sys.maxint}.

K (integer/long) [unsigned long]
    Convert a C unsigned long to a Python integer object or a
    Python long integer object, if it is larger than \texttt{sys.maxint}.

L (long) [PY_LONG_LONG]
    Convert a C long long to a Python long integer object. Only
    available on platforms that support \texttt{long long}.

K (long) [unsigned PY_LONG_LONG]
    Convert a C unsigned long long to a Python long integer
    object. Only available on platforms that support \texttt{unsigned long
    long}.

n (int) [Py_ssize_t]
    Convert a C Py_ssize_t to a Python integer or long integer.

\textit{New in version 2.5.}
c (string of length 1) [char]
  Convert a C int representing a character to a Python string of length 1.

d (float) [double]
  Convert a C double to a Python floating point number.

f (float) [float]
  Same as d.

d (complex) [Py_complex *]
  Convert a C Py_complex structure to a Python complex number.

O (object) [PyObject *]
  Pass a Python object untouched (except for its reference count, which is incremented by one). If the object passed in is a NULL pointer, it is assumed that this was caused because the call producing the argument found an error and set an exception. Therefore, Py_BuildValue will return NULL but won’t raise an exception. If no exception has been raised yet, SystemError is set.

S (object) [PyObject *]
  Same as O.

N (object) [PyObject *]
  Same as O, except it doesn’t increment the reference count on the object. Useful when the object is created by a call to an object constructor in the argument list.

O& (object) [converter, anything]
  Convert anything to a Python object through a converter function. The function is called with anything (which should be compatible with void *) as its argument and should return a “new” Python object, or NULL if an error occurred.
(items) (tuple) [matching-items]

Convert a sequence of C values to a Python tuple with the same number of items.

[items] (list) [matching-items]

Convert a sequence of C values to a Python list with the same number of items.

{items} (dictionary) [matching-items]

Convert a sequence of C values to a Python dictionary. Each pair of consecutive C values adds one item to the dictionary, serving as key and value, respectively.

If there is an error in the format string, the `SystemError` exception is set and `NULL` returned.
String conversion and formatting

Functions for number conversion and formatted string output.

```c
int PyOS_snprintf(char *str, size_t size, const char *format, ...)
```

Output not more than `size` bytes to `str` according to the format string `format` and the extra arguments. See the Unix man page `snprintf(2)`.

```c
int PyOS_vsnprintf(char *str, size_t size, const char *format, va_list va)
```

Output not more than `size` bytes to `str` according to the format string `format` and the variable argument list `va`. Unix man page `vsnprintf(2)`.

`PyOS_snprintf` and `PyOS_vsnprintf` wrap the Standard C library functions `snprintf` and `vsnprintf`. Their purpose is to guarantee consistent behavior in corner cases, which the Standard C functions do not.

The wrappers ensure that `str[*(size-1)]` is always `\0` upon return. They never write more than `size` bytes (including the trailing `\0`) into `str`. Both functions require that `str != NULL, size > 0` and `format != NULL`.

If the platform doesn’t have `vsnprintf` and the buffer size needed to avoid truncation exceeds `size` by more than 512 bytes, Python aborts with a `Py_FatalError`.

The return value (`rv`) for these functions should be interpreted as follows:

- When `0 <= rv < size`, the output conversion was successful
and \(rv\) characters were written to \(str\) (excluding the trailing \'\0\' byte at \(str[\ast rv]\)).

- When \(rv \geq size\), the output conversion was truncated and a buffer with \(rv + 1\) bytes would have been needed to succeed. \(str[\ast size-1]\) is \'\0\' in this case.
- When \(rv < 0\), “something bad happened.” \(str[\ast size-1]\) is \'\0\' in this case too, but the rest of \(str\) is undefined. The exact cause of the error depends on the underlying platform.

The following functions provide locale-independent string to number conversions.

```c
double PyOS_ascii_strtod(const char *nptr, char **endptr)
```

Convert a string to a \texttt{double}. This function behaves like the Standard C function \texttt{strtd}\(d\) does in the C locale. It does this without changing the current locale, since that would not be thread-safe.

\texttt{PyOS_ascii_strtod} should typically be used for reading configuration files or other non-user input that should be locale independent.

\textit{New in version 2.4.}

See the Unix man page \texttt{strtd}(2) for details.

```c
char * PyOS_ascii_formatd(char *buffer, size_t buf_len, const char *format, double d)
```

Convert a \texttt{double} to a string using the \'\.\' as the decimal separator. \texttt{format} is a printf-style format string specifying the number format. Allowed conversion characters are \'e\', \'E\', \'f\', \'F\', \'g\' and \'G\'.

The return value is a pointer to \texttt{buffer} with the converted string or
NULL if the conversion failed.

*New in version 2.4.*

double **PyOS_ascii_atof**(const char *nptr)

Convert a string to a **double** in a locale-independent way.

*New in version 2.4.*

See the Unix man page `atof(2)` for details.

char * **PyOS_stricmp**(char *s1, char *s2)

Case insensitive comparison of strings. The function works almost identically to `strcmp` except that it ignores the case.

*New in version 2.6.*

char * **PyOS_strnicmp**(char *s1, char *s2, Py_ssize_t size)

Case insensitive comparison of strings. The function works almost identically to `strnicmp` except that it ignores the case.

*New in version 2.6.*
Reflection

PyObject* PyEval_GetBuiltins()

*Return value: Borrowed reference.*
Return a dictionary of the builtins in the current execution frame, or the interpreter of the thread state if no frame is currently executing.

PyObject* PyEval_GetLocals()

*Return value: Borrowed reference.*
Return a dictionary of the local variables in the current execution frame, or NULL if no frame is currently executing.

PyObject* PyEval_GetGlobals()

*Return value: Borrowed reference.*
Return a dictionary of the global variables in the current execution frame, or NULL if no frame is currently executing.

PyFrameObject* PyEval_GetFrame()

*Return value: Borrowed reference.*
Return the current thread state’s frame, which is NULL if no frame is currently executing.

int PyEval_GetRestricted()

If there is a current frame and it is executing in restricted mode, return true, otherwise false.

const char* PyEval_GetFuncName(PyObject *func)

Return the name of func if it is a function, class or instance object, else the name of funcs type.

const char* PyEval_GetFuncDesc(PyObject *func)

Return a description string, depending on the type of func. Return values include “()” for functions and methods, ” constructor”, ”
instance", and " object". Concatenated with the result of
\texttt{PyEval_GetFuncName}, the result will be a description of \texttt{func}.
Abstract Objects Layer

The functions in this chapter interact with Python objects regardless of their type, or with wide classes of object types (e.g. all numerical types, or all sequence types). When used on object types for which they do not apply, they will raise a Python exception.

It is not possible to use these functions on objects that are not properly initialized, such as a list object that has been created by PyList_New, but whose items have not been set to some non-NULL value yet.

**Object Protocol**

```c
int PyObject_Print(PyObject *o, FILE *fp, int flags)
```

Print an object `o`, on file `fp`. Returns `-1` on error. The flags argument is used to enable certain printing options. The only option currently supported is `Py_PRINT_RAW`; if given, the `str()` of the object is written instead of the `repr()`.

```c
int PyObject_HasAttr(PyObject *o, PyObject *attr_name)
```

Returns `1` if `o` has the attribute `attr_name`, and `0` otherwise. This is equivalent to the Python expression `hasattr(o, attr_name)`. This function always succeeds.

```c
int PyObject_HasAttrString(PyObject *o, const char *attr_name)
```

Returns `1` if `o` has the attribute `attr_name`, and `0` otherwise. This is equivalent to the Python expression `hasattr(o, attr_name)`. This function always succeeds.

```c
PyObject* PyObject_GetAttr(PyObject *o, PyObject *attr_name)
```

*Return value: New reference.*

Retrieve an attribute named `attr_name` from object `o`. Returns the attribute value on success, or `NULL` on failure. This is the equivalent of the Python expression `o.attr_name`.

```c
PyObject* PyObject_GetAttrString(PyObject *o, const char *attr_name)
```

*Return value: New reference.*

Retrieve an attribute named `attr_name` from object `o`. Returns the attribute value on success, or `NULL` on failure. This is the equivalent of the Python expression `o.attr_name`.

```c
int PyObject_SetAttr(PyObject *o, PyObject *attr_name, PyObject*
```
*\nu*

Set the value of the attribute named *attr_name*, for object *o*, to
the value \(v\). Returns -1 on failure. This is the equivalent of the
Python statement *o*.\*.\*attr_name = \(v\).

```c
int PyObject_SetAttrString(PyObject *o, const char *attr_name,
Pyobject *v)
```

Set the value of the attribute named *attr_name*, for object *o*, to
the value \(v\). Returns -1 on failure. This is the equivalent of the
Python statement *o*.\*.\*attr_name = \(v\).

```c
int PyObject_DelAttr(PyObject *o, PyObject *attr_name)
```

Delete attribute named *attr_name*, for object *o*. Returns -1 on
failure. This is the equivalent of the Python statement del
\*o.\*attr_name.

```c
int PyObject_DelAttrString(PyObject *o, const char *attr_name)
```

Delete attribute named *attr_name*, for object *o*. Returns -1 on
failure. This is the equivalent of the Python statement del
\*o.\*attr_name.

```c
Pyobject* PyObject_RichCompare(PyObject *o1, PyObject *o2, int
opid)
```

*Return value: New reference.*

Compare the values of *o1* and *o2* using the operation specified
by *opid*, which must be one of \*Py_LT*, \*Py_LE*, \*Py_EQ*, \*Py_NE*, \*Py_GT*,
or \*Py_GE*, corresponding to <, \(<=\), ==, \(!=\), >, or \(>=\) respectively.
This is the equivalent of the Python expression \*o1\* op \*o2*, where
\*op\* is the operator corresponding to *opid*. Returns the value of the
comparison on success, or \*NULL\* on failure.

```c
int PyObject_RichCompareBool(PyObject *o1, PyObject *o2, int
opid)
```
Compare the values of $o1$ and $o2$ using the operation specified by $opid$, which must be one of Py_LT, Py_LE, Py_EQ, Py_NE, Py_GT, or Py_GE, corresponding to $<$, $\leq$, $=$, $\neq$, $>$, or $\geq$ respectively. Returns -1 on error, 0 if the result is false, 1 otherwise. This is the equivalent of the Python expression $o1$ $op$ $o2$, where $op$ is the operator corresponding to $opid$.

```c
int PyObject_Cmp(PyObject *o1, PyObject *o2, int *result)
```

Compare the values of $o1$ and $o2$ using a routine provided by $o1$, if one exists, otherwise with a routine provided by $o2$. The result of the comparison is returned in $result$. Returns -1 on failure. This is the equivalent of the Python statement $result = cmp(o1, o2)$.

```c
int PyObject_Compare(PyObject *o1, PyObject *o2)
```

Compare the values of $o1$ and $o2$ using a routine provided by $o1$, if one exists, otherwise with a routine provided by $o2$. Returns the result of the comparison on success. On error, the value returned is undefined; use PyErr_Occurred to detect an error. This is equivalent to the Python expression $cmp(o1, o2)$.

```c
PyObject* PyObject_Repr(PyObject *o)
```

Compute a string representation of object $o$. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression $repr(o)$. Called by the $repr()$ built-in function and by reverse quotes.

```c
PyObject* PyObject_Str(PyObject *o)
```

Compute a string representation of object $o$. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression $str(o)$. Called by the $str()$ built-in function and by the print statement.
PyObject* PyObject_Bytes(PyObject *o)

Compute a bytes representation of object o. In 2.x, this is just a alias for PyObject_Str.

PyObject* PyObject_Ununicode(PyObject *o)

Compute a Unicode string representation of object o. Returns the Unicode string representation on success, NULL on failure. This is the equivalent of the Python expression unicode(o). Called by the unicode() built-in function.

int PyObject_IsInstance(PyObject *inst, PyObject *cls)

Returns 1 if inst is an instance of the class cls or a subclass of cls, or 0 if not. On error, returns -1 and sets an exception. If cls is a type object rather than a class object, PyObject_IsInstance returns 1 if inst is of type cls. If cls is a tuple, the check will be done against every entry in cls. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0. If inst is not a class instance and cls is neither a type object, nor a class object, nor a tuple, inst must have a __class__ attribute — the class relationship of the value of that attribute with cls will be used to determine the result of this function.

New in version 2.1.

Changed in version 2.2: Support for a tuple as the second argument added.

Subclass determination is done in a fairly straightforward way, but includes a wrinkle that implementors of extensions to the class system may want to be aware of. If A and B are class objects, B is a subclass of A if it inherits from A either directly or indirectly. If either is not a class object, a more general mechanism is used to determine
the class relationship of the two objects. When testing if $B$ is a subclass of $A$, if $A$ is $B$, `PyObject_IsSubclass` returns true. If $A$ and $B$ are different objects, $B$’s `__bases__` attribute is searched in a depth-first fashion for $A$ — the presence of the `__bases__` attribute is considered sufficient for this determination.

```c
int PyObject_IsSubclass(PyObject *derived, PyObject *cls)
```

Returns 1 if the class `derived` is identical to or derived from the class `cls`, otherwise returns 0. In case of an error, returns -1. If `cls` is a tuple, the check will be done against every entry in `cls`. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0. If either `derived` or `cls` is not an actual class object (or tuple), this function uses the generic algorithm described above.

*New in version 2.1.*

*Changed in version 2.3:* Older versions of Python did not support a tuple as the second argument.

```c
int PyCallable_Check(PyObject *o)
```

Determine if the object `o` is callable. Return 1 if the object is callable and 0 otherwise. This function always succeeds.

```c
PyObject* PyObject_Call(PyObject *callable_object, PyObject *args, PyObject *kw)
```

*Return value: New reference.*

Call a callable Python object `callable_object`, with arguments given by the tuple `args`, and named arguments given by the dictionary `kw`. If no named arguments are needed, `kw` may be `NULL`. `args` must not be `NULL`, use an empty tuple if no arguments are needed. Returns the result of the call on success, or `NULL` on failure. This is the equivalent of the Python expression `apply(callable_object, args, kw) or
callable_object(*args, **kw).

New in version 2.2.

PyObject* PyObject_CallObject(PyObject *callable_object, PyObject *args)

_Return value: New reference._
Call a callable Python object _callable_object_, with arguments given by the tuple _args_. If no arguments are needed, then _args_ may be _NULL_. Returns the result of the call on success, or _NULL_ on failure. This is the equivalent of the Python expression apply(callable_object, args) or callable_object(*args).

PyObject* PyObject_CallFunction(PyObject *callable, char *format, ...)

_Return value: New reference._
Call a callable Python object _callable_, with a variable number of C arguments. The C arguments are described using a _Py_BuildValue_ style format string. The format may be _NULL_, indicating that no arguments are provided. Returns the result of the call on success, or _NULL_ on failure. This is the equivalent of the Python expression apply(callable, args) or callable(*args). Note that if you only pass _PyObject_ * _args_, _PyObject_CallFunctionObjArgs_ is a faster alternative.

PyObject* PyObject_CallMethod(PyObject *o, char *method, char *format, ...)

_Return value: New reference._
Call the method named _method_ of object _o_ with a variable number of C arguments. The C arguments are described by a _Py_BuildValue_ format string that should produce a tuple. The format may be _NULL_, indicating that no arguments are provided. Returns the result of the call on success, or _NULL_ on failure. This is the equivalent of the Python expression _o_.method(args). Note
that if you only pass `PyObject * args`, `PyObject_CallMethodObjArgs` is a faster alternative.

`PyObject* PyObject_CallFunctionObjArgs(PyObject *callable, ..., NULL)`

*Return value: New reference.*

Call a callable Python object `callable`, with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by `NULL`. Returns the result of the call on success, or `NULL` on failure.

*New in version 2.2.*

`PyObject* PyObject_CallMethodObjArgs(PyObject *o, PyObject *name, ..., NULL)`

*Return value: New reference.*

Calls a method of the object `o`, where the name of the method is given as a Python string object in `name`. It is called with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by `NULL`. Returns the result of the call on success, or `NULL` on failure.

*New in version 2.2.*

`long PyObject_Hash(PyObject *o)`

Compute and return the hash value of an object `o`. On failure, return `-1`. This is the equivalent of the Python expression `hash(o)`.

`long PyObject_HashNotImplemented(PyObject *o)`

Set a `TypeError` indicating that `type(o)` is not hashable and return `-1`. This function receives special treatment when stored in a `tp_hash` slot, allowing a type to explicitly indicate to the interpreter that it is not hashable.
New in version 2.6.

int PyObject_IsTrue(PyObject *o)
    Returns 1 if the object o is considered to be true, and 0 otherwise. This is equivalent to the Python expression not not o. On failure, return -1.

int PyObject_Not(PyObject *o)
    Returns 0 if the object o is considered to be true, and 1 otherwise. This is equivalent to the Python expression not o. On failure, return -1.

PyObject* PyObject_Type(PyObject *o)
When o is non-NULL, returns a type object corresponding to the object type of object o. On failure, raises SystemError and returns NULL. This is equivalent to the Python expression type(o). This function increments the reference count of the return value. There’s really no reason to use this function instead of the common expression o->ob_type, which returns a pointer of type PyTypeObject*, except when the incremented reference count is needed.

int PyObject_TypeCheck(PyObject *o, PyTypeObject *type)
Return true if the object o is of type type or a subtype of type. Both parameters must be non-NULL.

New in version 2.2.

Py_ssize_t PyObject_Length(PyObject *o)
Py_ssize_t PyObject_Size(PyObject *o)
Return the length of object o. If the object o provides either the sequence and mapping protocols, the sequence length is
returned. On error, -1 is returned. This is the equivalent to the Python expression \texttt{\texttt{len(o)}}.

\texttt{PyObject* PyObject\_GetItem(PyObject *o, PyObject *key)}

\textit{Return value: New reference.}
Return element of \texttt{o} corresponding to the object \texttt{key} or \texttt{NULL} on failure. This is the equivalent of the Python expression \texttt{o[key]}.

\texttt{int PyObject\_SetItem(PyObject *o, PyObject *key, PyObject *v)}
Map the object \texttt{key} to the value \texttt{v}. Returns -1 on failure. This is the equivalent of the Python statement \texttt{o[key] = v}.

\texttt{int PyObject\_DelItem(PyObject *o, PyObject *key)}
Delete the mapping for \texttt{key} from \texttt{o}. Returns -1 on failure. This is the equivalent of the Python statement \texttt{del o[key]}.

\texttt{int PyObject\_AsFileDescriptor(PyObject *o)}
Derives a file descriptor from a Python object. If the object is an integer or long integer, its value is returned. If not, the object's \texttt{fileno()} method is called if it exists; the method must return an integer or long integer, which is returned as the file descriptor value. Returns -1 on failure.

\texttt{PyObject* PyObject\_Dir(PyObject *o)}
\textit{Return value: New reference.}
This is equivalent to the Python expression \texttt{\texttt{dir(o)}}, returning a (possibly empty) list of strings appropriate for the object argument, or \texttt{NULL} if there was an error. If the argument is \texttt{NULL}, this is like the Python \texttt{dir()}, returning the names of the current locals; in this case, if no execution frame is active then \texttt{NULL} is returned but \texttt{PyErr\_Occurred} will return false.

\texttt{PyObject* PyObject\_GetIter(PyObject *o)}
This is equivalent to the Python expression \texttt{iter(o)}. It returns a new iterator for the object argument, or the object itself if the object is already an iterator. Raises \texttt{TypeError} and returns \texttt{NULL} if the object cannot be iterated.
Number Protocol

int **PyNumber_Check**(PyObject **o**)

    Returns **1** if the object **o** provides numeric protocols, and false otherwise. This function always succeeds.

**PyObject**\* **PyNumber_Add**(PyObject **o1**, PyObject **o2**)

    *Return value: New reference.*

    Returns the result of adding \( o1 \) and \( o2 \), or **NULL** on failure. This is the equivalent of the Python expression \( o1 + o2 \).

**PyObject**\* **PyNumber_Subtract**(PyObject **o1**, PyObject **o2**)

    *Return value: New reference.*

    Returns the result of subtracting \( o2 \) from \( o1 \), or **NULL** on failure. This is the equivalent of the Python expression \( o1 - o2 \).

**PyObject**\* **PyNumber_Multiply**(PyObject **o1**, PyObject **o2**)

    *Return value: New reference.*

    Returns the result of multiplying \( o1 \) and \( o2 \), or **NULL** on failure. This is the equivalent of the Python expression \( o1 \times o2 \).

**PyObject**\* **PyNumber_Divide**(PyObject **o1**, PyObject **o2**)

    *Return value: New reference.*

    Returns the result of dividing \( o1 \) by \( o2 \), or **NULL** on failure. This is the equivalent of the Python expression \( o1 / o2 \).

**PyObject**\* **PyNumber_FloorDivide**(PyObject **o1**, PyObject **o2**)

    *Return value: New reference.*

    Return the floor of \( o1 \) divided by \( o2 \), or **NULL** on failure. This is equivalent to the “classic” division of integers.

    *New in version 2.2.*
PyObject* **PyNumber_TrueDivide**(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Return a reasonable approximation for the mathematical value of o1 divided by o2, or *NULL* on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers.

*New in version 2.2.*

PyObject* **PyNumber_Remainder**(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the remainder of dividing o1 by o2, or *NULL* on failure. This is the equivalent of the Python expression o1 % o2.

PyObject* **PyNumber_Divmod**(PyObject *o1, PyObject *o2)

*Return value: New reference.*

See the built-in function *divmod()*.

Returns *NULL* on failure. This is the equivalent of the Python expression *divmod(o1, o2).*

PyObject* **PyNumber_Power**(PyObject *o1, PyObject *o2, PyObject *o3)

*Return value: New reference.*

See the built-in function *pow()*.

Returns *NULL* on failure. This is the equivalent of the Python expression *pow(o1, o2, o3)*, where o3 is optional. If o3 is to be ignored, pass *Py_None* in its place (passing *NULL* for o3 would cause an illegal memory access).

PyObject* **PyNumber_Negative**(PyObject *o)

*Return value: New reference.*

Returns the negation of o on success, or *NULL* on failure. This is the equivalent of the Python expression *-o.*
PyObject* PyNumber_Positive(PyObject *o)

*Return value: New reference.*
Returns o on success, or NULL on failure. This is the equivalent of the Python expression +o.

PyObject* PyNumber_Absolute(PyObject *o)

*Return value: New reference.*
Returns the absolute value of o, or NULL on failure. This is the equivalent of the Python expression abs(o).

PyObject* PyNumber_Invert(PyObject *o)

*Return value: New reference.*
Returns the bitwise negation of o on success, or NULL on failure. This is the equivalent of the Python expression ~o.

PyObject* PyNumber_Lshift(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the result of left shifting o1 by o2 on success, or NULL on failure. This is the equivalent of the Python expression o1 << o2.

PyObject* PyNumber_Rshift(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the result of right shifting o1 by o2 on success, or NULL on failure. This is the equivalent of the Python expression o1 >>= o2.

PyObject* PyNumber_And(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the “bitwise and” of o1 and o2 on success and NULL on failure. This is the equivalent of the Python expression o1 & o2.

PyObject* PyNumber_Xor(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the “bitwise exclusive or” of o1 by o2 on success, or NULL on failure. This is the equivalent of the Python expression `o1 ^ o2`.

PyObject* `PyNumber_Or` (PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the “bitwise or” of o1 and o2 on success, or NULL on failure. This is the equivalent of the Python expression `o1 | o2`.

PyObject* `PyNumber_InPlaceAdd` (PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of adding o1 and o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement `o1 += o2`.

PyObject* `PyNumber_InPlaceSubtract` (PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of subtracting o2 from o1, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement `o1 -= o2`.

PyObject* `PyNumber_InPlaceMultiply` (PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of multiplying o1 and o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement `o1 *= o2`.

PyObject* `PyNumber_InPlaceDivide` (PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement `o1 /= o2`.
PyObject* PyNumber_InPlaceFloorDivide(PyObject *o1, PyObject *o2)

Returns the mathematical floor of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 //= o2.

New in version 2.2.

PyObject* PyNumber_InPlaceTrueDivide(PyObject *o1, PyObject *o2)

Return a reasonable approximation for the mathematical value of o1 divided by o2, or NULL on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers. The operation is done in-place when o1 supports it.

New in version 2.2.

PyObject* PyNumber_InPlaceRemainder(PyObject *o1, PyObject *o2)

Returns the remainder of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 %= o2.

PyObject* PyNumber_InPlacePower(PyObject *o1, PyObject *o2, PyObject *o3)

See the built-in function pow(). Returns NULL on failure. The operation is done in-place when o1 supports it. This is the
equivalent of the Python statement \( o_1 **= o_2 \) when \( o_3 \) is `Py_None`, or an in-place variant of `pow(o_1, o_2, o_3)` otherwise. If \( o_3 \) is to be ignored, pass `Py_None` in its place (passing `NULL` for \( o_3 \) would cause an illegal memory access).

`PyObject* PyNumber_InPlaceLshift(PyObject *o1, PyObject *o2)`

*Return value: New reference.*
Returns the result of left shifting \( o_1 \) by \( o_2 \) on success, or `NULL` on failure. The operation is done *in-place* when \( o_1 \) supports it. This is the equivalent of the Python statement \( o_1 <<= o_2 \).

`PyObject* PyNumber_InPlaceRshift(PyObject *o1, PyObject *o2)`

*Return value: New reference.*
Returns the result of right shifting \( o_1 \) by \( o_2 \) on success, or `NULL` on failure. The operation is done *in-place* when \( o_1 \) supports it. This is the equivalent of the Python statement \( o_1 >>= o_2 \).

`PyObject* PyNumber_InPlaceAnd(PyObject *o1, PyObject *o2)`

*Return value: New reference.*
Returns the “bitwise and” of \( o_1 \) and \( o_2 \) on success and `NULL` on failure. The operation is done *in-place* when \( o_1 \) supports it. This is the equivalent of the Python statement \( o_1 &= o_2 \).

`PyObject* PyNumber_InPlaceXor(PyObject *o1, PyObject *o2)`

*Return value: New reference.*
Returns the “bitwise exclusive or” of \( o_1 \) by \( o_2 \) on success, or `NULL` on failure. The operation is done *in-place* when \( o_1 \) supports it. This is the equivalent of the Python statement \( o_1 ^= o_2 \).

`PyObject* PyNumber_InPlaceOr(PyObject *o1, PyObject *o2)`

*Return value: New reference.*
Returns the “bitwise or” of \( o_1 \) and \( o_2 \) on success, or `NULL` on failure. The operation is done *in-place* when \( o_1 \) supports it. This
is the equivalent of the Python statement \( o_1 = o_2 \).

```c
int PyNumber_Coerce(PyObject **p1, PyObject **p2)
```

This function takes the addresses of two variables of type `PyObject*`. If the objects pointed to by \( *p1 \) and \( *p2 \) have the same type, increment their reference count and return 0 (success). If the objects can be converted to a common numeric type, replace \( *p1 \) and \( *p2 \) by their converted value (with ‘new’ reference counts), and return 0. If no conversion is possible, or if some other error occurs, return -1 (failure) and don’t increment the reference counts. The call `PyNumber_Coerce(&o1, &o2)` is equivalent to the Python statement `o1, o2 = coerce(o1, o2).

```c
int PyNumber_CoerceEx(PyObject **p1, PyObject **p2)
```

This function is similar to `PyNumber_Coerce`, except that it returns 1 when the conversion is not possible and when no error is raised. Reference counts are still not increased in this case.

```c
PyObject* PyNumber_Int(PyObject *o)
```

*Return value: New reference.*

Returns the \( o \) converted to an integer object on success, or NULL on failure. If the argument is outside the integer range a long object will be returned instead. This is the equivalent of the Python expression `int(o)`.

```c
PyObject* PyNumber_Long(PyObject *o)
```

*Return value: New reference.*

Returns the \( o \) converted to a long integer object on success, or NULL on failure. This is the equivalent of the Python expression `long(o)`.

```c
PyObject* PyNumber_Float(PyObject *o)
```

*Return value: New reference.*
Returns the o converted to a float object on success, or NULL on failure. This is the equivalent of the Python expression float(o).

PyObject* PyNumber_Index(PyObject *o)
Returns the o converted to a Python int or long on success or NULL with a TypeError exception raised on failure.

New in version 2.5.

PyObject* PyNumber_ToBase(PyObject *n, int base)
Returns the the integer n converted to base as a string with a base marker of '0b', '0o', or '0x' if appended applicable. When base is not 2, 8, 10, or 16, the format is 'x#num' where x is the base. If n is not an int object, it is converted with PyNumber_Index first.

New in version 2.6.

Py_ssize_t PyNumber_AsSsize_t(PyObject *o, PyObject *exc)
Returns o converted to a Py_ssize_t value if o can be interpreted as an integer. If o can be converted to a Python int or long but the attempt to convert to a Py_ssize_t value would raise an OverflowError, then the exc argument is the type of exception that will be raised (usually IndexError or OverflowError). If exc is NULL, then the exception is cleared and the value is clipped to PY_SSIZE_T_MIN for a negative integer or PY_SSIZE_T_MAX for a positive integer.

New in version 2.5.

int PyIndex_Check(PyObject *o)
Returns True if o is an index integer (has the nb_index slot of the tp_as_number structure filled in).

New in version 2.5.
Sequence Protocol

int **PySequence_Check**(PyObject *o)
Return 1 if the object provides sequence protocol, and 0 otherwise. This function always succeeds.

Py_ssize_t **PySequence_Size**(PyObject *o)
Returns the number of objects in sequence o on success, and -1 on failure. For objects that do not provide sequence protocol, this is equivalent to the Python expression `len(o)`.

Py_ssize_t **PySequence_Length**(PyObject *o)
Alternate name for **PySequence_Size**.

PyObject* **PySequence_Concat**(PyObject *o1, PyObject *o2)
*Return value: New reference.*
Return the concatenation of o1 and o2 on success, and NULL on failure. This is the equivalent of the Python expression `o1 + o2`.

PyObject* **PySequence_Repeat**(PyObject *o, Py_ssize_t count)
*Return value: New reference.*
Return the result of repeating sequence object o count times, or NULL on failure. This is the equivalent of the Python expression `o * count`.

PyObject* **PySequence_InPlaceConcat**(PyObject *o1, PyObject *o2)
*Return value: New reference.*
Return the concatenation of o1 and o2 on success, and NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python expression `o1 += o2`.

PyObject* **PySequence_InPlaceRepeat**(PyObject *o, Py_ssize_t count)
count)

    Return the result of repeating sequence object o count times, or NULL on failure. The operation is done in-place when o supports it. This is the equivalent of the Python expression o *= count.

PyObject* PySequence_GetItem(PyObject *o, Py_ssize_t i)
    Return the i*th element of *o, or NULL on failure. This is the equivalent of the Python expression o[i].

PyObject* PySequence_GetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)
    Return the slice of sequence object o between i1 and i2, or NULL on failure. This is the equivalent of the Python expression o[i1:i2].

int PySequence_SetItem(PyObject *o, Py_ssize_t i, PyObject *v)
    Assign object v to the i*th element of *o. Returns -1 on failure. This is the equivalent of the Python statement o[i] = v. This function does not steal a reference to v.

int PySequence_DelItem(PyObject *o, Py_ssize_t i)
    Delete the i*th element of object *o. Returns -1 on failure. This is the equivalent of the Python statement del o[i].

int PySequence_SetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2, PyObject *v)
    Assign the sequence object v to the slice in sequence object o from i1 to i2. This is the equivalent of the Python statement o[i1:i2] = v.

int PySequence_DelSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)
Delete the slice in sequence object \( o \) from \( i1 \) to \( i2 \). Returns \(-1\) on failure. This is the equivalent of the Python statement `del o[i1:i2]`.

**Py_ssize_t PySequence_Count(PyObject *, PyObject *)**
Return the number of occurrences of \( \text{value} \) in \( o \), that is, return the number of keys for which \( o[\text{key}] == \text{value} \). On failure, return \(-1\). This is equivalent to the Python expression `o.count(value)`.

**int PySequence_Contains(PyObject *, PyObject *)**
Determine if \( o \) contains \( \text{value} \). If an item in \( o \) is equal to \( \text{value} \), return \( 1 \), otherwise return \( 0 \). On error, return \(-1\). This is equivalent to the Python expression `value in o`.

**Py_ssize_t PySequence_Index(PyObject *, PyObject *)**
Return the first index \( i \) for which \( o[i] == \text{value} \). On error, return \(-1\). This is equivalent to the Python expression `o.index(value)`.

**PyObject* PySequence_List(PyObject *)**

*Return value: New reference.*
Return a list object with the same contents as the arbitrary sequence \( o \). The returned list is guaranteed to be new.

**PyObject* PySequence_Tuple(PyObject *)**

*Return value: New reference.*
Return a tuple object with the same contents as the arbitrary sequence \( o \) or \( NULL \) on failure. If \( o \) is a tuple, a new reference will be returned, otherwise a tuple will be constructed with the appropriate contents. This is equivalent to the Python expression `tuple(o)`.

**PyObject* PySequence_Fast(PyObject *, const char *)**
Returns the sequence o as a tuple, unless it is already a tuple or list, in which case o is returned. Use PySequence_Fast_GET_ITEM to access the members of the result. Returns NULL on failure. If the object is not a sequence, raises TypeError with m as the message text.

PyObject* PySequence_Fast_GET_ITEM(PyObject *o, Py_ssize_t i)
  Return value: Borrowed reference.
  Return the i*th element of *o, assuming that o was returned by PySequence_Fast, o is not NULL, and that i is within bounds.

PyObject** PySequence_Fast_ITEMS(PyObject *o)
  Return the underlying array of PyObject pointers. Assumes that o was returned by PySequence_Fast and o is not NULL.
  
  Note, if a list gets resized, the reallocation may relocate the items array. So, only use the underlying array pointer in contexts where the sequence cannot change.
  
  New in version 2.4.

PyObject* PySequence_ITEM(PyObject *o, Py_ssize_t i)
  Return the i*th element of *o or NULL on failure. Macro form of PySequence_GetItem but without checking that PySequence_Check(o) is true and without adjustment for negative indices.
  
  New in version 2.3.

Py_ssize_t PySequence_Fast_GET_SIZE(PyObject *o)
  Returns the length of o, assuming that o was returned by PySequence_Fast and that o is not NULL. The size can also be
gotten by calling PySequence_Size on o, but PySequence_Fast_GET_SIZE is faster because it can assume o is a list or tuple.
Mapping Protocol

```c
int PyMapping_Check(PyObject *o)
   Return 1 if the object provides mapping protocol, and 0 otherwise. This function always succeeds.
```

```c
Py_ssize_t PyMapping_Length(PyObject *o)
   Returns the number of keys in object o on success, and -1 on failure. For objects that do not provide mapping protocol, this is equivalent to the Python expression len(o).
```

```c
int PyMapping_DelItemString(PyObject *o, char *key)
   Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement del o[key].
```

```c
int PyMapping_DelItem(PyObject *o, PyObject *key)
   Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement del o[key].
```

```c
int PyMapping_HasKeyString(PyObject *o, char *key)
   On success, return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to o[key], returning True on success and False on an exception. This function always succeeds.
```

```c
int PyMapping_HasKey(PyObject *o, PyObject *key)
   Return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to o[key], returning True on success and False on an exception. This function always succeeds.
```

```c
PyObject* PyMapping_Keys(PyObject *o)
   On success, return a list of the keys in object o. On failure, return
This is equivalent to the Python expression `o.keys()`.

**PyObject* PyMapping.Values(PyObject *o)**

*Return value: New reference.*

On success, return a list of the values in object `o`. On failure, return `NULL`. This is equivalent to the Python expression `o.values()`.

**PyObject* PyMapping_Items(PyObject *o)**

*Return value: New reference.*

On success, return a list of the items in object `o`, where each item is a tuple containing a key-value pair. On failure, return `NULL`. This is equivalent to the Python expression `o.items()`.

**PyObject* PyMapping.GetItemString(PyObject *o, char *key)**

*Return value: New reference.*

Return element of `o` corresponding to the object `key` or `NULL` on failure. This is the equivalent of the Python expression `o[key]`.

**int PyMapping_SetItemString(PyObject *o, char *key, PyObject *v)**

Map the object `key` to the value `v` in object `o`. Returns `-1` on failure. This is the equivalent of the Python statement `o[key] = v`. 
**Iterator Protocol**

*New in version 2.2.*

There are only a couple of functions specifically for working with iterators.

```c
int PyIter_Check(PyObject *o)

    Return true if the object o supports the iterator protocol.
```

```c
PyObject* PyIter_Next(PyObject *o)
