For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, **pydoc** tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function `help()` invokes the online help system in the interactive interpreter, which uses **pydoc** to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running **pydoc** as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the **sys** module, in a style similar to the manual pages shown by the Unix **man** command. The argument to **pydoc** can be the name of a function, module, or
package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to **pydoc** looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

| Note: | In order to find objects and their documentation, **pydoc** imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an `if __name__ == '__main__':` guard to only execute code when a file is invoked as a script and not just imported. |

When printing output to the console, **pydoc** attempts to paginate the output for easier reading. If the **PAGER** environment variable is set, **pydoc** will use its value as a pagination program.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix **man** command. The synopsis line of a module is the first line of its documentation string.

You can also use **pydoc** to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. **pydoc -p 1234** will start a HTTP server on port 1234, allowing you to browse the documentation at [http://localhost:1234/](http://localhost:1234/) in your preferred Web browser. **pydoc -g** will start the server and additionally bring up a small **Tkinter**-based graphical interface to help you search for documentation pages.

When **pydoc** generates documentation, it uses the current
environment and path to locate modules. Thus, invoking `pydoc spam` documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `https://docs.python.org/library/`. This can be overridden by setting the `PYTHONDOCS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.
25.2. doctest — Test interactive Python examples

The doctest module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
""
This is the "example" module.

The example module supplies one function, factorial(). For example,

```python
>>> factorial(5)
120
""

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.
    If the result is small enough to fit in an int, return an int.
    Else return a long.
    """
    [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> [factorial(long(n)) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
```
>>> factorial(30)
265252859812191058636308480000000L
>>> factorial(30L)
265252859812191058636308480000000L
>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must be an exact integer:
>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer
>>> factorial(30.0)
265252859812191058636308480000000L

It must also not be ridiculously large:
>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result

if __name__ == "__main__":
    import doctest
doctest.testmod()

If you run example.py directly from the command line, doctest works its magic:
There’s no output! That’s normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it’s trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
Trying:
    [factorial(long(n)) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
        ...
    OverflowError: n too large
ok
2 items passed all tests:
    1 tests in __main__
    8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
```

That’s all you need to know to start making productive use of
doctest! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file `Lib/test/test_doctest.py`.
25.2.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module \texttt{M} with:

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

\texttt{doctest} then examines docstrings in module \texttt{M}.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is 
***Test Failed*** \texttt{N failures.}, where \texttt{N} is the number of examples that failed.

Run it with the \texttt{-v} switch instead:

```
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing \texttt{verbose=True} to \texttt{testmod()}, or prohibit it by passing \texttt{verbose=False}. In either of those cases, \texttt{sys.argv} is not examined by \texttt{testmod()} (so passing \texttt{-v} or not has no effect).
Since Python 2.6, there is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section Basic API.
25.2.2. Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
======================

Using ``factorial``
-----------------

This is an example text file in reStructuredText format. First ```factorial``` from the ```example``` module:

```python
>>> from example import factorial
```

Now use it:

```python
>>> factorial(6)
120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
```
As with `testmod()`, `testfile()` won’t display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module’s directory. See section Basic API for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

Since Python 2.6, there is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section Basic API.
25.2.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

25.2.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if `M.__test__` exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from `M.__test__` are searched, and strings are treated as if they were docstrings. In output, a key \( K \) in `M.__test__` appears with name

```
<name of M>.__test__.K
```

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

*Changed in version 2.4:* A “private name” concept is deprecated and no longer documented.

25.2.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn’t trying to do an exact emulation of any
specific Python shell.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print "yes"
... else:
...     print "no"
...     print "NO"
...     print "NO!!"
... no
NO NO!!!
```

Any expected output must immediately follow the final `>>>` or `...` line containing the code, and the expected output (if any) extends to the next `>>>` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

  New in version 2.4: `<BLANKLINE>` was added; there was no way to use expected output containing empty lines in previous versions.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output are expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the `NORMALIZE_WHITESPACE`
option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom DocTestParser class.

*Changed in version 2.4:* Expanding tabs to spaces is new; previous versions tried to preserve hard tabs, with confusing results.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```python
>>> def f(x):
...   r'''Backslashes in a raw docstring: m\n'''
>>> print f.__doc__
```

Backslashes in a raw docstring: m

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```python
>>> def f(x):
...   '''Backslashes in a raw docstring: m\n'''
>>> print f.__doc__
```

Backslashes in a raw docstring: m

- The starting column doesn’t matter:
and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

25.2.3.3. What's the Execution Context?

By default, each time doctest finds a docstring to test, it uses a shallow copy of M's globals, so that running tests doesn't change the module’s real globals, and so that one test in M can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing globs=your_dict to testmod() or testfile() instead.

25.2.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:
That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi
   line
detail')
Traceback (most recent call last):
   File "<stdin>", line 1, in ?
ValueError: multi
   line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception’s type and detail, and the rest are ignored.

*Changed in version 2.4:* Previous versions were unable to handle multi-line exception details.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:
```python
>>> raise ValueError('multi
line\ndetail')
Traceback (most recent call last):
...
ValueError: multi
  line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest’s **ELLIPSIS** option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won’t need to remember:

- Doctest can’t guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn’t create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.

- When the **IGNORE_EXCEPTION_DETAIL** doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.

- The interactive shell omits the traceback header line for some **SyntaxError**s. But doctest uses the traceback header line to
distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.

- For some `SyntaxError`s, Python displays the character position of the syntax error, using a `^` marker:

```python
>>> 1 1
   File "<stdin>", line 1
   1 1
   ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```python
>>> 1 1
   File "<stdin>", line 1
   1 1
   ^
SyntaxError: invalid syntax
```

### 25.2.3.5. Option Flags

A number of option flags control various aspects of doctest’s behavior. Symbolic names for the flags are supplied as module constants, which can be or’ed together and passed to various functions. The names can also be used in doctest directives.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example’s expected output:

- `doctest.DONT_ACCEPT_TRUE_FOR_1`
By default, if an expected output block contains just 1, an actual output block containing just 1 or just True is considered to be a match, and similarly for 0 versus False. When DONT_ACCEPT_TRUE_FOR_1 is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest. DONT_ACCEPT_BLANKLINE**

By default, if an expected output block contains a line containing only the string <BLANKLINE>, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When DONT_ACCEPT_BLANKLINE is specified, this substitution is not allowed.

**doctest. NORMALIZE_WHITESPACE**

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. NORMALIZE_WHITESPACE is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

**doctest. ELLIPSIS**

When specified, an ellipsis marker (…) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that .* is prone to in regular expressions.
doctest. **IGNORE_EXCEPTION_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```python
>>> raise CustomError('message')
Traceback (most recent call last):
  CustomError: message
```

```python
>>> raise CustomError('message')
Traceback (most recent call last):
  my_module.CustomError: message
```

Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using **IGNORE_EXCEPTION_DETAIL** and the details from Python 2.3 is also the only clear way to write a doctest that doesn't care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support doctest directives and ignore them as irrelevant comments). For example:

```python
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say
“does not” instead of “doesn’t”.

Changed in version 2.7: `IGNORE_EXCEPTION_DETAIL` now also ignores any information relating to the module containing the exception under test.

doctest.SKIP
When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out” examples.

New in version 2.5.

doctest.COMPARISON_FLAGS
A bitmask or’ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.REPORT_UDIFF
When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.REPORT_CDIFF
When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.REPORT_NDIFF
When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as
across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

**doctest.** REPORT_ONLY_FIRST_FAILURE

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When **REPORT_ONLY_FIRST_FAILURE** is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

**doctest.** REPORTING_FLAGS

A bitmask or’ing together all the reporting flags above.

*New in version 2.4:* The constants **DONT_ACCEPT_BLANKLINE**, **NORMALIZE_WHITESPACE**, **ELLIPSIS**, **IGNORE_EXCEPTION_DETAIL**, **REPORT_UDIFF**, **REPORT_CDIFF**, **REPORT_NDIFF**, **REPORT_ONLY_FIRST_FAILURE**, **COMPARISON_FLAGS** and **REPORTING_FLAGS** were added.

There’s also a way to register new option flag names, although this isn’t useful unless you intend to extend doctest internals via subclassing:

**doctest.** register_optionflag(name)

Create a new option flag with a given name, and return the new flag’s integer value. **register_optionflag()** can be used when subclassing **OutputChecker** or **DocTestRunner** to create new options that are supported by your subclasses. **register_optionflag()** should always be called using the following idiom:
MY_FLAG = register_optionflag('MY_FLAG')

New in version 2.4.

25.2.3.6. Directives

Doctest directives may be used to modify the option flags for an individual example. Doctest directives are special Python comments following an example's source code:

```
directive  ::=  "#"  "doctest:"  directive_options
directive_options  ::=  directive_option  ("",""  directive_option (",""  directive_option)
directive_option  ::=  on_or_off  directive_option_name
on_or_off  ::=  "+"  |  "-"
directive_option_name  ::=  "DONT_ACCEPT_BLANKLINE"  |  "NORMALIZE_WHITESPACE"  |  ...
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

For example, this test passes:

```python
>>> print range(20) # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```python
>>> print range(20) # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```
Multiple directives can be used on a single physical line, separated by commas:

```python
>>> print range(20)  # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

If multiple directive comments are used for a single example, then they are combined:

```python
>>> print range(20)  # doctest: +ELLIPSIS
...  # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```python
>>> print range(5) + range(10, 20) + range(30, 40) + range(50, 60)
...  # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39, 50, ..., 59]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

*New in version 2.4:* Support for doctest directives was added.

### 25.2.3.7. Warnings

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will
probably surprise you a few times, as you learn exactly what Python
does and doesn't guarantee about output. For example, when
printing a dict, Python doesn't guarantee that the key-value pairs will
be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = foo().items()
>>> d.sort()
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()      # the default repr() for instances embeds an address
<__main__.C instance at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:

```python
>>> C()  # doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations
across platforms, because Python defers to the platform C library for
float formatting, and C libraries vary widely in quality here.
Numbers of the form \( \frac{1}{2.**J} \) are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

Simple fractions are also easier for people to understand, and that makes for better documentation.
25.2.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

```
doctest.testfile(filename[, module_relative][, name][, package][, globs][, verbose][, report][, optionflags][, extraglobs][, raise_on_error] [, parser][, encoding])
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `name` gives the name of the test; by default, or if `None`, `os.path.basename(filename)` is used.
Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is *False*.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if *None*, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like *dict.update()*: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if *None*, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if *None*, it’s true if and only if *'-v'* is in *sys.argv*.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument *optionflags* or's together option flags. See section *Option Flags*. 
Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

*New in version 2.4.*

*Changed in version 2.5:* The parameter *encoding* was added.

```python
doctest.testmod([m][, name][, globs][, verbose][, report][, optionflags][, extraglobs][, raise_on_error][, exclude_empty])
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is *None*), starting with *m.__doc__*.

Also test examples reachable from dict *m.__test__*, if it exists and is not *None*. *m.__test__* maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (*failure_count*, *test_count*).
Optional argument *name* gives the name of the module; by default, or if `None, m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The *exclude_empty* argument to the newer `DocTestFinder` constructor defaults to true.

Optional arguments *extraglobs, verbose, report, optionflags, raise_on_error, and globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

*Changed in version 2.3:* The parameter *optionflags* was added.

*Changed in version 2.4:* The parameters *extraglobs, raise_on_error* and *exclude_empty* were added.

*Changed in version 2.5:* The optional argument *isprivate*, deprecated in 2.4, was removed.

```python
doctest.run_docstring_examples(f, globs[, verbose][, name][, compileflags][, optionflags])
```

Test examples associated with object *f*, for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case
of an example failure.

Optional argument `compileflags` gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in `globs`.

Optional argument `optionflags` works as for function `testfile()` above.
25.2.5. Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. Prior to Python 2.4, `doctest` had a barely documented `Tester` class that supplied a rudimentary way to combine doctests from multiple modules. `Tester` was feeble, and in practice most serious Python testing frameworks build on the `unittest` module, which supplies many flexible ways to combine tests from multiple sources. So, in Python 2.4, `doctest`'s `Tester` class is deprecated, and `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

`doctest.DocFileSuite(*paths, [module_relative][, package][, setUp] [, tearDown][, globs][, optionflags][, parser][, encoding])`

Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a
failureException exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument module_relative specifies how the filenames in paths should be interpreted:

- If module_relative is True (the default), then each filename in paths specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the package argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use / characters to separate path segments, and may not be an absolute path (i.e., it may not begin with /).
- If module_relative is False, then each filename in paths specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument package is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in paths. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify package if module_relative is False.

Optional argument setUp specifies a set-up function for the test suite. This is called before running the tests in each file. The setUp function will be passed a DocTest object. The setUp function can access the test globals as the globs attribute of the test passed.
Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `optionflags` specifies the default doctest options for the tests, created by or-ing together individual option flags. See section Option Flags. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode.

*New in version 2.4.*

*Changed in version 2.5:* The global `__file__` was added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

*Changed in version 2.5:* The parameter `encoding` was added.

**Note:** Unlike `testmod()` and `DocTestFinder`, this function raises a `ValueError` if `module` contains no docstrings. You can prevent this error by passing a `DocTestFinder` instance as the `test_finder` argument with its `exclude_empty` keyword argument
**set to False:**

```python
>>> finder = doctest.DocTestFinder(exclude_empty=False)
>>> suite = doctest.DocTestSuite(test_finder=finder)
```

doctest.**DocTestSuite**([module][, globs][, extraglobs][, test_finder][, setUp][, tearDown][, checker])

Convert doctest tests for a module to a **unittest.TestSuite**.

The returned **unittest.TestSuite** is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a **failureException** exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument **module** provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument **globs** is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, **globs** is a new empty dictionary.

Optional argument **extraglobs** specifies an extra set of global variables, which is merged into **globs**. By default, no extra globals are used.

Optional argument **test_finder** is the **DocTestFinder** object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments **setUp**, **tearDown**, and **optionflags** are the same as for function **DocFileSuite()** above.
New in version 2.3.

Changed in version 2.4: The parameters `globs`, `extraglobs`, `test_finder`, `setUp`, `tearDown`, and `optionflags` were added; this function now uses the same search technique as `testmod()`.

Under the covers, `DocTestSuite()` creates a `unittest.TestSuite` out of `doctest.DocTestCase` instances, and `DocTestCase` is a subclass of `unittest.TestCase`. `DocTestCase` isn’t documented here (it’s an internal detail), but studying its code can answer questions about the exact details of `unittest` integration.

Similarly, `DocFileSuite()` creates a `unittest.TestSuite` out of `doctest.DocFileCase` instances, and `DocFileCase` is a subclass of `DocTestCase`.

So both ways of creating a `unittest.TestSuite` run instances of `DocTestCase`. This is important for a subtle reason: when you run `doctest` functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you’re writing a `unittest` framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there’s no way to pass options through `unittest` to `doctest` test runners.

For this reason, `doctest` also supports a notion of `doctest` reporting flags specific to `unittest` support, via this function:

```python
doctest.set_unittest_reportflags(flags)
```

Set the `doctest` reporting flags to use.

Argument `flags` or's together option flags. See section Option Flags. Only "reporting flags" can be used.
This is a module-global setting, and affects all future doctests run by module `unittest`: the `runTest()` method of `DocTestCase` looks at the option flags specified for the test case when the `DocTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`'s `unittest` reporting flags are or’ed into the option flags, and the option flags so augmented are passed to the `DocTestRunner` instance created to run the doctest. If any reporting flags were specified when the `DocTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the function was called is returned by the function.

*New in version 2.4.*
25.2.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python `statement`, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a `DocTestParser` to create a `DocTest` from every docstring that contains interactive examples.
- **DocTestParser**: Creates a `DocTest` object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a `DocTest`, and uses an `OutputChecker` to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
25.2.6.1. DocTest Objects

```python
class doctest.DocTest(examples, globs, name, filename, lineno, docstring)
```

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

*New in version 2.4.*

**DocTest** defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**examples**

A list of **Example** objects encoding the individual interactive Python examples that should be run by this test.

**globs**

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in **globs** after the test is run.

**name**

A string name identifying the **DocTest**. Typically, this is the name of the object or file that the test was extracted from.
**filename**

The name of the file that this DocTest was extracted from; or `None` if the filename is unknown, or if the DocTest was not extracted from a file.

**lineno**

The line number within `filename` where this DocTest begins, or `None` if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**

The string that the test was extracted from, or `None` if the string is unavailable, or if the test was not extracted from a string.

---

### 25.2.6.2. Example Objects

```python
class doctest.Example(source, want[, exc_msg][, lineno][, indent][, options])
```

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

*New in version 2.4.*

**Example** defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**

A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

**want**
The expected output from running the example’s source code (either from stdout, or a traceback in case of exception). `want` ends with a newline unless no output is expected, in which case it’s an empty string. The constructor adds a newline when necessary.

**exc_msg**
The exception message generated by the example, if the example is expected to generate an exception; or `None` if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. `exc_msg` ends with a newline unless it's `None`. The constructor adds a newline if needed.

**lineno**
The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**
The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**
A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the `DocTestRunner`'s `optionflags`). By default, no options are set.

### 25.2.6.3. DocTestFinder objects

```python
class doctest.DocTestFinder([verbose][, parser][, recurse][,]
```
A processing class used to extract the DocTest s that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTest s can currently be extracted from the following object types: modules, functions, classes, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

New in version 2.4.

DocTestFinder defines the following method:

\textbf{find}(obj[, name][, module][, globs][, extraglobs])

Return a list of the DocTest s that are defined by obj’s docstring, or by any of its contained objects’ docstrings.

The optional argument name specifies the object’s name; this name will be used to construct names for the returned DocTest s. If name is not specified, then obj.__name__ is used.

The optional parameter module is the module that contains
the given object. If the module is not specified or is None, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if globs is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than module are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If module is False, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if module is False, or is None but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each DocTest is formed by combining globs and extraglobs (bindings in extraglobs override bindings in globs). A new shallow copy of the globals dictionary is created for each DocTest. If globs is not specified, then it defaults to the module’s __dict__, if specified, or {} otherwise. If extraglobs is not specified, then it defaults to {}.

### 25.2.6.4. DocTestParser objects

**class doctest.DocTestParser**

A processing class used to extract interactive examples from a string, and use them to create a DocTest object.

New in version 2.4.

DocTestParser defines the following methods:
**get_doctest** *(string, globs, name, filename, lineno)*

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

* globs, name, filename, and lineno are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples** *(string[, name])*  
Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument name is a name identifying this string, and is only used for error messages.

**parse** *(string[, name])*  
Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument name is a name identifying this string, and is only used for error messages.

### 25.2.6.5. DocTestRunner objects

**class** doctest. **DocTestRunner** ([checker[, verbose[, optionflags]]])

A processing class used to execute and verify the interactive examples in a **DocTest**.

The comparison between expected outputs and actual outputs is done by an **OutputChecker**. This comparison may be customized with a number of option flags; see section **Option Flags** for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of
OutputChecker to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to TestRunner.run(); this function will be called with strings that should be displayed. It defaults to sys.stdout.write. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods report_start(), report_success(), report_unexpected_exception(), and report_failure().

The optional keyword argument checker specifies the OutputChecker object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument verbose controls the DocTestRunner’s verbosity. If verbose is True, then information is printed about each example, as it is run. If verbose is False, then only failures are printed. If verbose is unspecified, or None, then verbose output is used iff the command-line switch -v is used.

The optional keyword argument optionflags can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section Option Flags.

New in version 2.4.

DocTestParser defines the following methods:

report_start(out, test, example)  
Report that the test runner is about to process the given example. This method is provided to allow subclasses of
**DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_success**(*out, test, example, got*)

Report that the given example ran successfully. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_failure**(*out, test, example, got*)

Report that the given example failed. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_unexpected_exception**(*out, test, example, exc_info*)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *exc_info* is a tuple containing information about the unexpected exception
(as returned by `sys.exc_info()`). `test` is the test containing example. `out` is the output function that was passed to `DocTestRunner.run()`.

`run(test[, compileflags][, out][, clear_globs])`

Run the examples in `test` (a `DocTest` object), and display the results using the writer function `out`.

The examples are run in the namespace `test.globs`. If `clear_globs` is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use `clear_globs=False`.

`compileflags` gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to `globs`.

The output of each example is checked using the `DocTestRunner`'s output checker, and the results are formatted by the `DocTestRunner.report_*()` methods.

`summarize([verbose])`

Print a summary of all the test cases that have been run by this `DocTestRunner`, and return a named tuple `TestResults(failed, attempted)`.

The optional `verbose` argument controls how detailed the summary is. If the verbosity is not specified, then the `DocTestRunner`'s verbosity is used.

*Changed in version 2.6*: Use a named tuple.
25.2.6.6. OutputChecker objects

class doctest.OutputChecker

A class used to check whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: check_output(), which compares a given pair of outputs, and returns true if they match; and output_difference(), which returns a string describing the differences between two outputs.

New in version 2.4.

OutputChecker defines the following methods:

check_output(want, got, optionflags)

Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags for more information about option flags.

output_difference(example, got, optionflags)

Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
25.2.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```python
""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print x+3
...     import pdb; pdb.set_trace()
>>> f(3)
g
""
```

Then an interactive Python session may look like this:

```python
>>> import a, doctest
>>> doctest.testmod(a)--Return--
> <doctest a[1]>(3)g()--None
```
import doctest

Changed in version 2.4: The ability to use `pdb.set_trace()` usefully inside doctests was added.

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

```
doctest.script_from_examples(s)
```

Convert text with examples to a script.

Argument `s` is a string containing doctest examples. The string is converted to a Python script, where doctest examples in `s` are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```python
import doctest
```
print doctest.script_from_examples(r""
    Set \textit{x} and \textit{y} to 1 and 2.
    >>> x, y = 1, 2

    \texttt{Print their sum:}
    >>> print x+y
    3
"")

displays:

```
# Set \textit{x} and \textit{y} to 1 and 2.
x, y = 1, 2
#
# \texttt{Print their sum:}
print x+y
# \texttt{Expected:}
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

\textit{New in version 2.4.}

doctest.\texttt{testsource}\texttt{(module, name)}

Convert the doctest for an object to a script.

Argument \textit{module} is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument \textit{name} is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for \texttt{script_from_examples()} above. For example, if module \texttt{a.py} contains a top-level function \texttt{f()}, then

```python
import a, doctest
print doctest.testsource(a, "a.f")
```
prints a script version of function \( f() \)'s docstring, with doctests converted to code, and the rest placed in comments.

*New in version 2.3.*

```
>>> func = lambda x: x
>>> doctest.debug(f, 'print(f(2))')
```

**doctest.debug** *(module, name[, pm]*)

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function `testsource()` above. The synthesized Python script for the named object’s docstring is written to a temporary file, and then that file is run under the control of the Python debugger, `pdb`.

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem debugging is used. If *pm* has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via `pdb.post_mortem()`, passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate `execfile()` call to `pdb.run()`.

*New in version 2.3.*

*Changed in version 2.4:* The *pm* argument was added.

```
>>> doctest.debug_src('print(x)', pm)
```

**doctest.debug_src** *(src[, pm][, globs]*)

Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the *src* argument.
Optional argument \textit{pm} has the same meaning as in function \texttt{debug()} above.

Optional argument \textit{ globs} gives a dictionary to use as both local and global execution context. If not specified, or \texttt{None}, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

\textit{New in version 2.4.}

The \texttt{DebugRunner} class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially \texttt{DebugRunner}'s docstring (which is a doctest!) for more details:

\begin{verbatim}
class doctest. DebugRunner([checker], [verbose], [optionflags])
  A subclass of DocTestRunner that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an UnexpectedException exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a DocTestFailure exception is raised, containing the test, the example, and the actual output.

  For information about the constructor parameters and methods, see the documentation for DocTestRunner in section Advanced API.

There are two exceptions that may be raised by DebugRunner instances:

exception doctest. DocTestFailure(test, example, got)
  An exception raised by DocTestRunner to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.
\end{verbatim}
**DocTestFailure** defines the following attributes:

DocTestFailure.*test*

The **DocTest** object that was being run when the example failed.

DocTestFailure.*example*

The **Example** that failed.

DocTestFailure.*got*

The example's actual output.

*exception* doctest.**UnexpectedException**(test, example, exc_info)

An exception raised by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

**UnexpectedException** defines the following attributes:

UnexpectedException.*test*

The **DocTest** object that was being run when the example failed.

UnexpectedException.*example*

The **Example** that failed.

UnexpectedException.*exc_info*

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.
As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what’s actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It’s true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points
of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It’s a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```python
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.REPORT_ONLY_FIRST_FAILURE
    if len(sys.argv) > 1:
        name = sys.argv[1]
    if name in globals():
        obj = globals()[name]
    else:
        obj = __test__[name]
    doctest.run_docstring_examples(obj, globals(), name=name)
```
```python
else:
    fail, total = doctest.testmod(optionflags=flags)
    print("{} failures out of {} tests".format(fail, total))
```

**Footnotes**

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.
25.3. unittest — Unit testing framework

New in version 2.1.

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The Python unit testing framework, sometimes referred to as “PyUnit,” is a Python language version of JUnit, by Kent Beck and Erich Gamma. JUnit is, in turn, a Java version of Kent’s Smalltalk testing framework. Each is the de facto standard unit testing framework for its respective language.

unittest supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework. The unittest module provides classes that make it easy to support these qualities for a set of tests.

To achieve this, unittest supports some important concepts:

test fixture

A test fixture represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

test case

A test case is the smallest unit of testing. It checks for a specific response to a particular set of inputs. unittest provides a base class, TestCase, which may be used to create new test cases.

test suite
A test suite is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

test runner

A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

The test case and test fixture concepts are supported through the TestCase and FunctionTestCase classes; the former should be used when creating new tests, and the latter can be used when integrating existing test code with a unittest-driven framework. When building test fixtures using TestCase, the setUp() and tearDown() methods can be overridden to provide initialization and cleanup for the fixture. With FunctionTestCase, existing functions can be passed to the constructor for these purposes. When the test is run, the fixture initialization is run first; if it succeeds, the cleanup method is run after the test has been executed, regardless of the outcome of the test. Each instance of the TestCase will only be used to run a single test method, so a new fixture is created for each test.

Test suites are implemented by the TestSuite class. This class allows individual tests and test suites to be aggregated; when the suite is executed, all tests added directly to the suite and in “child” test suites are run.

A test runner is an object that provides a single method, run(), which accepts a TestCase or TestSuite object as a parameter, and returns a result object. The class TestResult is provided for use as the result object. unittest provides the TextTestRunner as an example test runner which reports test results on the standard error stream by default. Alternate runners can be implemented for other environments (such as graphical environments) without any need to
derive from a specific class.

25.3.1. Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```python
import unittest

class TestStringMethods(unittest.TestCase):
    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised.
These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section Organizing test code.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```python
...  
Ran 3 tests in 0.000s  
OK  
```

Instead of `unittest.main()`, there are other ways to run the tests with a finer level of control, less terse output, and no requirement to be run from the command line. For example, the last two lines may be replaced with:

```python
suite = unittest.TestLoader().loadTestsFromTestCase(TestStringMethods)  
suite = unittest.TextTestRunner(verbosity=2).run(suite)  
```

Running the revised script from the interpreter or another script produces the following output:

```python
test_isupper (__main__.TestStringMethods) ... ok  
test_split (__main__.TestStringMethods) ... ok  
test_upper (__main__.TestStringMethods) ... ok  

Ran 3 tests in 0.001s  
OK  
```
The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
25.3.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag:

```
python -m unittest -v test_module
```

For a list of all the command-line options:

```
python -m unittest -h
```

*Changed in version 2.7:* In earlier versions it was only possible to run individual test methods and not modules or classes.

25.3.2.1. Command-line options

`unittest` supports these command-line options:

**-b, --buffer**

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

**-c, --catch**
Control-C during the test run waits for the current test to end and then reports all the results so far. A second Control-C raises the normal KeyboardInterrupt exception.

See Signal Handling for the functions that provide this functionality.

-f, --failfast
Stop the test run on the first error or failure.

New in version 2.7: The command-line options -b, -c and -f were added.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
25.3.3. Test Discovery

New in version 2.7.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in `TestLoader.discover()`, but can also be used from the command line. The basic command-line usage is:

```
import os
os.chdir('project_directory')
python -m unittest discover
```

The `discover` sub-command has the following options:

- **-v, --verbose**
  Verbose output

- **-s, --start-directory directory**
  Directory to start discovery (. default)

- **-p, --pattern pattern**
  Pattern to match test files (test*.py default)

- **-t, --top-level-directory directory**
  Top level directory of project (defaults to start directory)

The `-s`, `-p`, and `-t` options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p "*_test.py"
python -m unittest discover project_directory "*_test.py"
```
As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the `load_tests` protocol.
25.3.4. Organizing test code

The basic building blocks of unit testing are *test cases* — single scenarios that must be set up and checked for correctness. In *unittest*, test cases are represented by instances of *unittest*'s *TestCase* class. To make your own test cases you must write subclasses of *TestCase*, or use *FunctionTestCase*.

An instance of a *TestCase*-derived class is an object that can completely run a single test method, together with optional set-up and tidy-up code.

The testing code of a *TestCase* instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest *TestCase* subclass will simply override the *runTest()* method in order to perform specific testing code:

```python
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
    def runTest(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50), 'incorrect default size')
```

Note that in order to test something, we use one of the *assert*() methods provided by the *TestCase* base class. If the test fails, an exception will be raised, and *unittest* will identify the test case as a *failure*. Any other exceptions will be treated as *errors*. This helps you identify where the problem is: *failures* are caused by incorrect results - a 5 where you expected a 6. *Errors* are caused by incorrect code - e.g., a *TypeError* caused by an incorrect function call.
The way to run a test case will be described later. For now, note that to construct an instance of such a test case, we call its constructor without arguments:

```python
testCase = DefaultWidgetSizeTestCase()
```

Now, such test cases can be numerous, and their set-up can be repetitive. In the above case, constructing a `Widget` in each of 100 `Widget` test case subclasses would mean unsightly duplication.

Luckily, we can factor out such set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for us when we run the test:

```python
import unittest
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

class DefaultWidgetSizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

class WidgetResizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')
```

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the `runTest()` method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the `runTest()` method has been run:

```python
import unittest
```
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')
    def tearDown(self):
        self.widget.dispose()
        self.widget = None

If `setUp()` succeeded, the `tearDown()` method will be run whether `runTest()` succeeded or not.

Such a working environment for the testing code is called a fixture.

Often, many small test cases will use the same fixture. In this case, we would end up subclassing `SimpleWidgetTestCase` into many small one-method classes such as `DefaultWidgetSizeTestCase`. This is time-consuming and discouraging, so in the same vein as JUnit, `unittest` provides a simpler mechanism:

```python
import unittest
class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')
    def tearDown(self):
        self.widget.dispose()
        self.widget = None
    def test_default_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')
    def test_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')
```

Here we have not provided a `runTest()` method, but have instead provided two different test methods. Class instances will now each
run one of the test_*() methods, with `self.widget` created and destroyed separately for each instance. When creating an instance we must specify the test method it is to run. We do this by passing the method name in the constructor:

```python
defaultSizeTestCase = WidgetTestCase('test_default_size')
resizeTestCase = WidgetTestCase('test_resize')
```

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the test suite, represented by `unittest`'s `TestSuite` class:

```python
widgetTestSuite = unittest.TestSuite()
widgetTestSuite.addTest(WidgetTestCase('test_default_size'))
widgetTestSuite.addTest(WidgetTestCase('test_resize'))
```

For the ease of running tests, as we will see later, it is a good idea to provide in each test module a callable object that returns a pre-built test suite:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

or even:

```python
def suite():
    tests = ['test_default_size', 'test_resize']

    return unittest.TestSuite(map(WidgetTestCase, tests))
```

Since it is a common pattern to create a `TestCase` subclass with many similarly named test functions, `unittest` provides a `TestLoader` class that can be used to automate the process of creating a test suite and populating it with individual tests. For example,
suite = unittest.TestLoader().loadTestsFromTestCase(WidgetTestCase)

will create a test suite that will run
WidgetTestCase.test_default_size() and
WidgetTestCase.test_resize. TestLoader uses the 'test' method
name prefix to identify test methods automatically.

Note that the order in which the various test cases will be run is
determined by sorting the test function names with respect to the
built-in ordering for strings.

Often it is desirable to group suites of test cases together, so as to
run tests for the whole system at once. This is easy, since TestSuite
instances can be added to a TestSuite just as TestCase instances
can be added to a TestSuite:

```python
suite1 = module1.TheTestSuite()
suite2 = module2.TheTestSuite()
alltests = unittest.TestSuite([suite1, suite2])
```

You can place the definitions of test cases and test suites in the
same modules as the code they are to test (such as widget.py), but
there are several advantages to placing the test code in a separate
module, such as test_widget.py:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it
tests without a good reason.
- Test code should be modified much less frequently than the
code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules
anyway, so why not be consistent?
If the testing strategy changes, there is no need to change the source code.
25.3.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from unittest, without converting every old test function to a TestCase subclass.

For this reason, unittest provides a FunctionTestCase class. This subclass of TestCase can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows:

```python
testcase = unittest.FunctionTestCase(testSomething)
```

If there are additional set-up and tear-down methods that should be called as part of the test case’s operation, they can also be provided like so:

```python
testcase = unittest.FunctionTestCase(testSomething,
        setUp=makeSomethingDB,
        tearDown=deleteSomethingDB)
```

To make migrating existing test suites easier, unittest supports tests raising AssertionError to indicate test failure. However, it is recommended that you use the explicit TestCase.fail*() and TestCase.assert*() methods instead, as future versions of unittest may treat AssertionError differently.
Note: Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the `doctest` module. If so, `doctest` provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.
25.3.6. Skipping tests and expected failures

New in version 2.7.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a TestResult.

Skipping a test is simply a matter of using the skip() decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of the lib
        pass

    @unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:

test_format (__main__.MyTestCase) ... skipped 'not supported in
test_nothing (__main__.MyTestCase) ... skipped 'demonstrating s
test_windows_support (__main__.MyTestCase) ... skipped 'require

Ran 3 tests in 0.005s
Classes can be skipped just like methods:

```python
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{} doesn't have {!r}".format(obj, a
```

The following decorators implement test skipping and expected failures:

```python
unittest.skip(reason)
```

Unconditionally skip the decorated test. `reason` should describe why the test is being skipped.
unittest. skipIf(condition, reason)
    Skip the decorated test if condition is true.

unittest. skipUnless(condition, reason)
    Skip the decorated test unless condition is true.

unittest. expectedFailure()
    Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

exception unittest.SkipTest(reason)
    This exception is raised to skip a test.

    Usually you can use testCase.skipTest() or one of the skipping decorators instead of raising this directly.

Skipped tests will not have setUp() or tearDown() run around them. Skipped classes will not have setUpClass() or tearDownClass() run.
25.3.7. Classes and functions

This section describes in depth the API of `unittest`.

25.3.7.1. Test cases

```python
class unittest.TestCase(methodName='runTest')
```

Instances of the `TestCase` class represent the smallest testable units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the test, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single test method: the method named `methodName`. If you remember, we had an earlier example that went something like this:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

Here, we create two instances of `WidgetTestCase`, each of which runs a single test.

`methodName` defaults to `runTest()`.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.
Methods in the first group (running the test) are:

**setUp()**
Method called to prepare the test fixture. This is called immediately before calling the test method; other than `AssertionError` or `SkipTest`, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**
Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than `AssertionError` or `SkipTest`, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the `setUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**
A class method called before tests in an individual class run. `setUpClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def setUpClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 2.7.*

**tearDownClass()**
A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def tearDownClass(cls):
    ...
```

See Class and Module Fixtures for more details.

*New in version 2.7.*

**run(result=None)**

Run the test, collecting the result into the test result object passed as `result`. If `result` is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is not returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

**skipTest(reason)**

Calling this during a test method or `setUp()` skips the current test. See Skipping tests and expected failures for more information.

*New in version 2.7.*

**debug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The `TestCase` class provides several assert methods to check for
and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td>assertEqual(a, b)</td>
<td>a == b</td>
<td></td>
</tr>
<tr>
<td>assertNotEqual(a, b)</td>
<td>a != b</td>
<td></td>
</tr>
<tr>
<td>assertTrue(x)</td>
<td>bool(x) is True</td>
<td></td>
</tr>
<tr>
<td>assertFalse(x)</td>
<td>bool(x) is False</td>
<td></td>
</tr>
<tr>
<td>assertIs(a, b)</td>
<td>a is b</td>
<td>2.7</td>
</tr>
<tr>
<td>assertIsNot(a, b)</td>
<td>a is not b</td>
<td>2.7</td>
</tr>
<tr>
<td>assertIsNone(x)</td>
<td>x is None</td>
<td>2.7</td>
</tr>
<tr>
<td>assertIsNotNone(x)</td>
<td>x is not None</td>
<td>2.7</td>
</tr>
<tr>
<td>assertIn(a, b)</td>
<td>a in b</td>
<td>2.7</td>
</tr>
<tr>
<td>assertNotIn(a, b)</td>
<td>a not in b</td>
<td>2.7</td>
</tr>
<tr>
<td>assertIsInstance(a, b)</td>
<td>isinstance(a, b)</td>
<td>2.7</td>
</tr>
<tr>
<td>assertNotIsInstance(a, b)</td>
<td>not isinstance(a, b)</td>
<td>2.7</td>
</tr>
</tbody>
</table>

All the assert methods (except `assertRaises()`, `assertRaisesRegexp()`) accept a `msg` argument that, if specified, is used as the error message on failure (see also `longMessage`).

**assertEqual(first, second, msg=None)**

Test that `first` and `second` are equal. If the values do not compare equal, the test will fail.

In addition, if `first` and `second` are the exact same type and one of list, tuple, dict, set, frozenset or unicode or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

*Changed in version 2.7:* Added the automatic calling of type-specific equality function.
assertNotEqual(first, second, msg=None)
    Test that first and second are not equal. If the values do compare equal, the test will fail.

assertTrue(expr, msg=None)
assertFalse(expr, msg=None)
    Test that expr is true (or false).

    Note that this is equivalent to bool(expr) is True and not to expr is True (use assertIs(expr, True) for the latter). This method should also be avoided when more specific methods are available (e.g. assertEqual(a, b) instead of assertTrue(a == b)), because they provide a better error message in case of failure.

assertIs(first, second, msg=None)
assertIsNot(first, second, msg=None)
    Test that first and second evaluate (or don’t evaluate) to the same object.

    New in version 2.7.

assertIsNone(expr, msg=None)
assertIsNotNone(expr, msg=None)
    Test that expr is (or is not) None.

    New in version 2.7.

assertIn(first, second, msg=None)
assertNotIn(first, second, msg=None)
    Test that first is (or is not) in second.

    New in version 2.7.

assertIsInstance(obj, cls, msg=None)
**assertNotIsInstance**(obj, cls, msg=None)

Test that obj is (or is not) an instance of cls (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls).

*New in version 2.7.*

It is also possible to check that exceptions and warnings are raised using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertRaises(exc, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds)</code> raises <code>exc</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRaisesRegexp(exc, r, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds)</code> raises <code>exc</code> and the message matches regex <code>r</code></td>
<td>2.7</td>
</tr>
</tbody>
</table>

**assertRaises(exception, callable, *args, **kwds)**

Test that an exception is raised when callable is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if exception is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as exception.

If only the exception argument is given, returns a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```
The context manager will store the caught exception object in its `exception` attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()
the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 2.7:* Added the ability to use `assertRaises()` as a context manager.

```python
assertRaisesRegexp(exception, regexp, callable, *args, **kwds)
assertRaisesRegexp(exception, regexp)
```

Like `assertRaises()` but also tests that `regexp` matches on the string representation of the raised exception. `regexp` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```python
self.assertRaisesRegexp(ValueError, "invalid literal for.*XYZ'\)
```

or:

```python
with self.assertRaisesRegexp(ValueError, 'literal):
    int('XYZ')
```

*New in version 2.7.*

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
<td>Version</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertLess(a, b)</code></td>
<td><code>a &lt; b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertLessEqual(a, b)</code></td>
<td><code>a &lt;= b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertRegexpMatches(s, r)</code></td>
<td><code>r.search(s)</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertNotRegexpMatches(s, r)</code></td>
<td><code>not r.search(s)</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertItemsEqual(a, b)</code></td>
<td><code>sorted(a) == sorted(b)</code> and works with unhashable objs</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertDictContainsSubset(a, b)</code></td>
<td>all the key/value pairs in <code>a</code> exist in <code>b</code></td>
<td>2.7</td>
</tr>
</tbody>
</table>

`assertAlmostEqual(first, second, places=7, msg=None, delta=None)`

`assertNotAlmostEqual(first, second, places=7, msg=None, delta=None)`

Test that `first` and `second` are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal `places` (default 7), and comparing to zero. Note that these methods round the values to the given number of decimal places (i.e. like the `round()` function) and not significant digits.

If `delta` is supplied instead of `places` then the difference between `first` and `second` must be less or equal to (or greater than) `delta`.

Supplying both `delta` and `places` raises a `TypeError`.

*Changed in version 2.7:* `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the `delta` keyword argument.
assertGreater\( (first, second, msg=None) \)
assertGreaterEqual\( (first, second, msg=None) \)
assertLess\( (first, second, msg=None) \)
assertLessEqual\( (first, second, msg=None) \)

Test that \( first \) is respectively \( >, \geq, < \) or \( \leq \) than \( second \) depending on the method name. If not, the test will fail:

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

*New in version 2.7.*

assertRegexpMatches\( (text, regexp, msg=None) \)

Test that a \( regexp \) search matches \( text \). In case of failure, the error message will include the pattern and the \( text \) (or the pattern and the part of \( text \) that unexpectedly matched). \( regexp \) may be a regular expression object or a string containing a regular expression suitable for use by \( re.search() \).

*New in version 2.7.*

assertNotRegexpMatches\( (text, regexp, msg=None) \)

Verifies that a \( regexp \) search does not match \( text \). Fails with an error message including the pattern and the part of \( text \) that matches. \( regexp \) may be a regular expression object or a string containing a regular expression suitable for use by \( re.search() \).

*New in version 2.7.*

assertItemsEqual\( (actual, expected, msg=None) \)

Test that sequence \( expected \) contains the same elements as \( actual \), regardless of their order. When they don’t, an error message listing the differences between the sequences will
be generated.

Duplicate elements are *not* ignored when comparing *actual* and *expected*. It verifies if each element has the same count in both sequences. It is the equivalent of `assertEqual(sorted(expected), sorted(actual))` but it works with sequences of unhashable objects as well.

In Python 3, this method is named `assertCountEqual`.

*New in version 2.7.*

`assertDictContainsSubset(expected, actual, msg=None)`
Tests whether the key/value pairs in dictionary *actual* are a superset of those in *expected*. If not, an error message listing the missing keys and mismatched values is generated.

*New in version 2.7.*

*Deprecated since version 3.2.*

The `assertEqual()` method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it’s also possible to register new methods using `addTypeEqualityFunc()`:

`addTypeEqualityFunc(typeobj, function)`
Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected – possibly providing useful
information and explaining the inequalities in details in the error message.

*New in version 2.7.*

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertMultiLineEqual(a, b)</code></td>
<td>strings</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertSequenceEqual(a, b)</code></td>
<td>sequences</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertListEqual(a, b)</code></td>
<td>lists</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertTupleEqual(a, b)</code></td>
<td>tuples</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertSetEqual(a, b)</code></td>
<td>sets or frozensets</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertDictEqual(a, b)</code></td>
<td>dicts</td>
<td>2.7</td>
</tr>
</tbody>
</table>

`assertMultiLineEqual(first, second, msg=None)`

Test that the multiline string `first` is equal to the string `second`. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

*New in version 2.7.*

`assertSequenceEqual(seq1, seq2, msg=None, seq_type=None)`

Tests that two sequences are equal. If a `seq_type` is supplied, both `seq1` and `seq2` must be instances of `seq_type` or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and
assertTupleEqual().

*New in version 2.7.*

**assertListEqual(list1, list2, msg=None)**

**assertTupleEqual(tuple1, tuple2, msg=None)**

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 2.7.*

**assertSetEqual(set1, set2, msg=None)**

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of `set1` or `set2` does not have a `set.difference()` method.

*New in version 2.7.*

**assertDictEqual(expected, actual, msg=None)**

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

*New in version 2.7.*

Finally the **TestCase** provides the following methods and attributes:
fail(msg=None)

Signals a test failure unconditionally, with msg or None for the error message.

failureException

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is AssertionError.

longMessage

If set to True then any explicit failure message you pass in to the assert methods will be appended to the end of the normal failure message. The normal messages contain useful information about the objects involved, for example the message from assertEqual shows you the repr of the two unequal objects. Setting this attribute to True allows you to have a custom error message in addition to the normal one.

This attribute defaults to False, meaning that a custom message passed to an assert method will silence the normal message.

The class setting can be overridden in individual tests by assigning an instance attribute to True or False before calling the assert methods.

New in version 2.7.

maxDiff

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are assertSequenceEqual() (including all the sequence
comparison methods that delegate to it), \texttt{assertDictEqual()} and \texttt{assertMultiLineEqual()}.

Setting \texttt{maxDiff} to \texttt{None} means that there is no maximum length of diffs.

\textit{New in version 2.7.}

Testing frameworks can use the following methods to collect information on the test:

\textbf{countTestCases()}

Return the number of tests represented by this test object. For \texttt{TestCase} instances, this will always be 1.

\textbf{defaultTestResult()}

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the \texttt{run()} method).

For \texttt{TestCase} instances, this will always be an instance of \texttt{TestResult}; subclasses of \texttt{TestCase} should override this as necessary.

\textbf{id()}

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

\textbf{shortDescription()}

Returns a description of the test, or \texttt{None} if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or \texttt{None}. 
addCleanup(function, *args, **kwargs)
Add a function to be called after tearDown() to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into addCleanup() when they are added.

If setUp() fails, meaning that tearDown() is not called, then any cleanup functions added will still be called.

*New in version 2.7.*

doCleanups()
This method is called unconditionally after tearDown(), or after setUp() if setUp() raises an exception.

It is responsible for calling all the cleanup functions added by addCleanup(). If you need cleanup functions to be called prior to tearDown() then you can call doCleanups() yourself.

doCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 2.7.*

class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)
This class implements the portion of the TestCase interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a unittest-based test framework.

25.3.7.1.1. Deprecated aliases
For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias(es)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual()</code></td>
<td><code>failUnlessEqual, assertEquals</code></td>
</tr>
<tr>
<td><code>assertNotEqual()</code></td>
<td><code>failIfEqual</code></td>
</tr>
<tr>
<td><code>assertTrue()</code></td>
<td><code>failUnless, assert_</code></td>
</tr>
<tr>
<td><code>assertFalse()</code></td>
<td><code>failIf</code></td>
</tr>
<tr>
<td><code>assertRaises()</code></td>
<td><code>failUnlessRaises</code></td>
</tr>
<tr>
<td><code>assertAlmostEqual()</code></td>
<td><code>failUnlessAlmostEqual</code></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual()</code></td>
<td><code>failIfAlmostEqual</code></td>
</tr>
</tbody>
</table>

*Deprecated since version 2.7:* the aliases listed in the second column

### 25.3.7.2. Grouping tests

```python
class unittest.TestSuite(tests=())
```

This class represents an aggregation of individual tests cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite, running each test individually.

If `tests` is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

`TestSuite` objects behave much like `TestCase` objects, except they do not actually implement a test. Instead, they are used to
aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to TestSuite instances:

**addTest(test)**

Add a **TestCase** or **TestSuite** to the suite.

**addTests(tests)**

Add all the tests from an iterable of **TestCase** and **TestSuite** instances to this test suite.

This is equivalent to iterating over *tests*, calling **addTest()** for each element.

**TestSuite** shares the following methods with **TestCase**:

**run(result)**

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike **TestCase.run()**, **TestSuite.run()** requires the result object to be passed in.

**debug()**

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases()**

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**__iter__()**

Tests grouped by a **TestSuite** are always accessed by
iteration. Subclasses can lazily provide tests by overriding `__iter__()`. Note that this method maybe called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned must be the same for repeated iterations.

*Changed in version 2.7:* In earlier versions the `TestSuite` accessed tests directly rather than through iteration, so overriding `__iter__()` wasn’t sufficient for providing tests.

In the typical usage of a `TestSuite` object, the `run()` method is invoked by a `TestRunner` rather than by the end-user test harness.

### 25.3.7.3. Loading and running tests

*class* `unittest.TestLoader`

The `TestLoader` class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the `unittest` module provides an instance that can be shared as `unittest.defaultTestLoader`. Using a subclass or instance, however, allows customization of some configurable properties.

`TestLoader` objects have the following methods:

- `loadTestsFromTestCase(testCaseClass)`
  Return a suite of all tests cases contained in the `TestCase`-derived `testCaseClass`.

- `loadTestsFromModule(module)`
  Return a suite of all tests cases contained in the given module. This method searches `module` for classes derived from `TestCase` and creates an instance of the class for each
test method defined for the class.

**Note:** While using a hierarchy of `TestCase`-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the `load_tests` protocol.

*Changed in version 2.7:* Support for `load_tests` added.

`loadTestsFromName(name, module=None)`

Return a suite of all tests cases given a string specifier.

The specifier `name` is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules
and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves name relative to the given module.

`loadTestsFromNames(names, module=None)`

Similar to `loadTestsFromName()`, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

`getTestCaseNames(testCaseClass)`

Return a sorted sequence of method names found within `testCaseClass`; this should be a subclass of `TestCase`.

`discover(start_dir, pattern='test*.py', top_level_dir=None)`

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match `pattern` will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue.

If a test package name (directory with `__init__.py`) matches the pattern then the package will be checked for a `load_tests` function. If this exists then it will be called with `loader, tests, pattern`. 
If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. `top_level_dir` is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

`start_dir` can be a dotted module name as well as a directory.

*New in version 2.7.*

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods. The default value is the built-in `cmp()` function; the attribute can also be set to `None` to disable the sort.

**suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.
class unittest.TestResult

This class is used to compile information about which tests have succeeded and which have failed.

A TestResult object stores the results of a set of tests. The TestCase and TestSuite classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of unittest may want access to the TestResult object generated by running a set of tests for reporting purposes; a TestResult instance is returned by the TestRunner.run() method for this purpose.

TestResult instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

errors

A list containing 2-tuples of TestCase instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

Changed in version 2.2: Contains formatted tracebacks instead of sys.exc_info() results.

failures

A list containing 2-tuples of TestCase instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the TestCase.assert*() methods.

Changed in version 2.2: Contains formatted tracebacks instead of sys.exc_info() results.

skipped
A list containing 2-tuples of `TestCase` instances and strings holding the reason for skipping the test.

*New in version 2.7.*

**expectedFailures**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**
A list containing `TestCase` instances that were marked as expected failures, but succeeded.

**shouldStop**
Set to `True` when the execution of tests should stop by `stop()`.

**testsRun**
The total number of tests run so far.

**buffer**
If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 2.7.*

**failfast**
If set to true `stop()` will be called on the first failure or error, halting the test run.

*New in version 2.7.*
**wasSuccessful()**

Return `True` if all tests run so far have passed, otherwise returns `False`.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to `True`. **TestRunner** objects should respect this flag and return without running any additional tests.

For example, this feature is used by the **TextTestRunner** class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide **TestRunner** implementations can use this in a similar manner.

The following methods of the **TestResult** class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest(**`test`**)**

Called when the test case `test` is about to be run.

**stopTest(**`test`**)**

Called after the test case `test` has been executed, regardless of the outcome.

**startTestRun()**

Called once before any tests are executed.

*New in version 2.7.*

**stopTestRun()**
Called once after all tests are executed.

*New in version 2.7.*

**addError** *(test, err)*

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by `sys.exc_info()`: *(type, value, traceback)*.

The default implementation appends a tuple *(test, formatted_err)* to the instance’s *errors* attribute, where *formatted_err* is a formatted traceback derived from *err*.

**addFailure** *(test, err)*

Called when the test case *test* signals a failure. *err* is a tuple of the form returned by `sys.exc_info()`: *(type, value, traceback)*.

The default implementation appends a tuple *(test, formatted_err)* to the instance’s *failures* attribute, where *formatted_err* is a formatted traceback derived from *err*.

**addSuccess** *(test)*

Called when the test case *test* succeeds.

The default implementation does nothing.

**addSkip** *(test, reason)*

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple *(test, reason)* to the instance’s *skipped* attribute.

**addExpectedFailure** *(test, err)*
Called when the test case `test` fails, but was marked with the `expectedFailure()` decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's `expectedFailures` attribute, where `formatted_err` is a formatted traceback derived from `err`.

`addUnexpectedSuccess(test)`
Called when the test case `test` was marked with the `expectedFailure()` decorator, but succeeded.

The default implementation appends the test to the instance's `unexpectedSuccesses` attribute.

```python
class unittest.TextTestResult(stream, descriptions, verbosity)
A concrete implementation of TestResult used by the TextTestRunner.

New in version 2.7: This class was previously named _TextTestResult. The old name still exists as an alias but is deprecated.
```

```python
unittest.defaultTestLoader
Instance of the TestLoader class intended to be shared. If no customization of the TestLoader is needed, this instance can be used instead of repeatedly creating new instances.
```

```python
class unittest.TextTestRunner(stream=sys.stderr, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None)
A basic test runner implementation which prints results on standard error. It has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations.
```
_makeResult()

This method returns the instance of TestResult used by run(). It is not intended to be called directly, but can be overridden in subclasses to provide a custom TestResult.

_makeResult() instantiates the class or callable passed in the TextTestRunner constructor as the resultclass argument. It defaults to TextTestResult if no resultclass is provided. The result class is instantiated with the following arguments:

stream, descriptions, verbosity

unittest.main([module[, defaultTest[, argv[, testRunner[, testLoader[, exit[, verbosity[, failfast[, catchbreak[, buffer]]]]]]]]]]])

A command-line program that loads a set of tests from module and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

if __name__ == '__main__':
    unittest.main()

You can run tests with more detailed information by passing in the verbosity argument:

if __name__ == '__main__':
    unittest.main(verbosity=2)

The defaultTest argument is the name of the test to run if no test names are specified via argv. If not specified or None and no test names are provided via argv, all tests found in module are run.

The argv argument can be a list of options passed to the program, with the first element being the program name. If not specified or None, the values of sys.argv are used.
The *testRunner* argument can either be a test runner class or an already created instance of it. By default *main* calls *sys.exit()* with an exit code indicating success or failure of the tests run.

The *testLoader* argument has to be a *TestLoader* instance, and defaults to *defaultTestLoader*.

*main* supports being used from the interactive interpreter by passing in the argument *exit=False*. This displays the result on standard output without calling *sys.exit()*:

```python
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The *failfast*, *catchbreak* and *buffer* parameters have the same effect as the same-name command-line options.

Calling *main* actually returns an instance of the *TestProgram* class. This stores the result of the tests run as the *result* attribute.

*Changed in version 2.7*: The *exit*, *verbosity*, *failfast*, *catchbreak* and *buffer* parameters were added.

### 25.3.7.3.1. load_tests Protocol

*New in version 2.7.*

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called *load_tests*.

If a test module defines *load_tests* it will be called by *TestLoader.loadTestsFromModule()* with the following arguments:
load_tests(loader, standard_tests, None)

It should return a TestSuite.

loader is the instance of TestLoader doing the loading. standard_tests are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical load_tests function that loads tests from a specific set of TestCase classes may look like:

test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite

If discovery is started, either from the command line or by calling TestLoader.discover(), with a pattern that matches a package name then the package __init__.py will be checked for load_tests.

**Note:** The default pattern is 'test*.py'. This matches all Python files that start with 'test' but won't match any test directories.

A pattern like 'test*' will match test packages as well as modules.

If the package __init__.py defines load_tests then it will be called and discovery not continued into the package. load_tests is called with the following arguments:

load_tests(loader, standard_tests, pattern)
This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:

```python
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir, pattern)
    standard_tests.addTests(package_tests)
    return standard_tests
```
25.3.8. Class and Module Fixtures

Class and module level fixtures are implemented in TestSuite. When the test suite encounters a test from a new class then tearDownClass() from the previous class (if there is one) is called, followed by setUpClass() from the new class.

Similarly if a test is from a different module from the previous test then tearDownModule from the previous module is run, followed by setUpModule from the new module.

After all the tests have run the final tearDownClass and tearDownModule are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to setUpClass / setUpModule (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A BaseTestSuite still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an _ErrorHolder object (that has the
same interface as a `TestCase`) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

### 25.3.8.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject()

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in `TestCase` are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a `SkipTest` exception then the class will be reported as having been skipped instead of as an error.

### 25.3.8.2. setUpModule and tearDownModule

These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
```
If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
25.3.9. Signal Handling

The `-c/--catch` command-line option to `unittest`, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but isn’t the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

*New in version 2.7.*

`unittest.registerResult(result)`

Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn’t prevent the result from being garbage collected.
Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

*New in version 2.7.*

`unittest.removeResult(result)`

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

*New in version 2.7.*

`unittest.removeHandler(function=None)`

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```python
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

*New in version 2.7.*
25.4. 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library lib2to3 is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. lib2to3 could also be adapted to custom applications in which Python code needs to be edited automatically.
25.4.1. Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3’s basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```python
def greet(name):
    print "Hello, {0}".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```python
def greet(name):
    print("Hello, {0}".format(name))
print("What's your name?")
name = input()
greet(name)
```
Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of predefined fixers. The -1 flag lists all available fixers. An explicit set of fixers to run can be given with -f. Likewise the -x explicitly disables a fixer. The following example runs only the imports and has_key fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the apply fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are explicit, meaning they aren’t run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing all enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the -d flag. Note that only doctests will be refactored. This also doesn’t require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The -v option enables output of more information on the translation process.
Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the \texttt{from \_\_future\_ import print\_function} compiler directive, it modifies its internal grammar to interpret \texttt{print()} as a function. This change can also be enabled manually with the \texttt{-p} flag. Use \texttt{-p} to run fixers on code that already has had its print statements converted.

The \texttt{-o} or \texttt{--output-dir} option allows specification of an alternate directory for processed output files to be written to. The \texttt{-n} flag is required when using this as backup files do not make sense when not overwriting the input files.

\textit{New in version 2.7.3:} The \texttt{-o} option was added.

The \texttt{-W} or \texttt{--write-unchanged-files} flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with \texttt{-o} so that an entire Python source tree is copied with translation from one directory to another. This option implies the \texttt{-w} flag as it would not make sense otherwise.

\textit{New in version 2.7.3:} The \texttt{-w} flag was added.

The \texttt{--add-suffix} option specifies a string to append to all output filenames. The \texttt{-n} flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

\begin{verbatim}
$ 2to3 -n -W --add-suffix=3 example.py
\end{verbatim}

Will cause a converted file named \texttt{example.py3} to be written.

\textit{New in version 2.7.3:} The \texttt{--add-suffix} option was added.

To translate an entire project from one directory tree to another use:
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
25.4.2. Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

**apply**

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

**asserts**

Replaces deprecated `unittest` method names with the correct ones.

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>failUnlessEqual(a, b)</td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td>assertEquals(a, b)</td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td>failIfEqual(a, b)</td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td>assertNotEquals(a, b)</td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td>failUnless(a)</td>
<td><code>assertTrue(a)</code></td>
</tr>
<tr>
<td>assert_(a)</td>
<td><code>assertTrue(a)</code></td>

<tr>
<td>failIf(a)</td>
<td><code>assertFalse(a)</code></td>
</tr>
<tr>
<td>failUnlessRaises(exc, cal)</td>
<td><code>assertRaises(exc, cal)</code></td>
</tr>
<tr>
<td>failUnlessAlmostEqual(a, b)</td>
<td><code>assertAlmostEqual(a, b)</code></td>
</tr>
<tr>
<td>assertAlmostEquals(a, b)</td>
<td><code>assertAlmostEqual(a, b)</code></td>
</tr>
<tr>
<td>failIfAlmostEqual(a, b)</td>
<td><code>assertNotAlmostEqual(a, b)</code></td>
</tr>
<tr>
<td>assertNotAlmostEquals(a, b)</td>
<td><code>assertNotAlmostEqual(a, b)</code></td>
</tr>
</tbody>
</table>

**basestring**

Converts `basestring` to `str`.

**buffer**
Converts buffer to memoryview. This fixer is optional because the memoryview API is similar but not exactly the same as that of buffer.

callable
Converting callable(x) to isinstance(x, collections.Callable), adding an import to collections if needed. Note callable(x) has returned in Python 3.2, so if you do not intend to support Python 3.1, you can disable this fixer.

dict
Fixes dictionary iteration methods. dict.iteritems() is converted to dict.items(), dict.iterkeys() to dict.keys(), and dict.itervalues() to dict.values(). Similarly, dict.viewitems(), dict.viewkeys() and dict.viewvalues() are converted respectively to dict.items(), dict.keys() and dict.values(). It also wraps existing usages of dict.items(), dict.keys(), and dict.values() in a call to list.

except
Converting except X, T to except X as T.

exec
Converting the exec statement to the exec() function.

execfile
Removes usage of execfile(). The argument to execfile() is wrapped in calls to open(), compile(), and exec().

exitfunc
Changes assignment of sys.exitfunc to use of the atexit module.

filter
Wraps \texttt{filter()} usage in a \texttt{list} call.

\textbf{funcattrs}

Fixes function attributes that have been renamed. For example, \texttt{my\_function.func\_closure} is converted to \texttt{my\_function.\_closure\_}.

\textbf{future}

Removes \texttt{from \_\_future\_ import new\_feature} statements.

\textbf{getcwdu}

Renames \texttt{os.getcwdu()} to \texttt{os.getcwd()}.

\textbf{has\_key}

Changes \texttt{dict.has\_key(key)} to \texttt{key in dict}.

\textbf{idioms}

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like \texttt{type(x) is SomeClass} and \texttt{type(x) == SomeClass} are converted to \texttt{isinstance(x, SomeClass)}. \texttt{while 1} becomes \texttt{while True}. This fixer also tries to make use of \texttt{sorted()} in appropriate places. For example, this block

\begin{verbatim}
L = list(some_iterable)
L.sort()
\end{verbatim}

is changed to

\begin{verbatim}
L = sorted(some_iterable)
\end{verbatim}

\textbf{import}

Detects sibling imports and converts them to relative imports.

\textbf{imports}

Handles module renames in the standard library.
imports2
Handles other modules renames in the standard library. It is separate from the imports fixer only because of technical limitations.

input
Converts input(prompt) to eval(input(prompt)).

intern
Converts intern() to sys.intern().

isinstance
Fixes duplicate types in the second argument of isinstance(). For example, isinstance(x, (int, int)) is converted to isinstance(x, (int)).

itertools_imports
Removes imports of itertools.ifilter(), itertools.izip(), and itertools.imap(). Imports of itertools.ifilterfalse() are also changed to itertools.filterfalse().

itertools
Changes usage of itertools.ifilter(), itertools.izip(), and itertools.imap() to their built-in equivalents. itertools.ifilterfalse() is changed to itertools.filterfalse().

long
Renames long to int.

map
Wraps map() in a list call. It also changes map(None, x) to list(x). Using from future_builtins import map disables this fixer.
**metaclass**

Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new `(class X(metaclass=Meta))`.

**methodattrs**

Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

**ne**

Converts the old not-equal syntax, `<>`, to `!=`.

**next**

Converts the use of iterator's `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

**nonzero**

Renames `__nonzero__()` to `__bool__()`.

**numliterals**

Converts octal literals into the new syntax.

**paren**

Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

**print**

Converts the `print` statement to the `print()` function.

**raise**

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in Python 3.

**raw_input**
Converts \texttt{raw\_input()} to \texttt{input()}.

\textbf{reduce}

Handles the move of \texttt{reduce()} to \texttt{functools.reduce()}.

\textbf{renames}

Changes \texttt{sys.maxint} to \texttt{sys.maxsize}.

\textbf{repr}

Replaces backtick \texttt{repr} with the \texttt{repr()} function.

\textbf{set\_literal}

Replaces use of the \texttt{set} constructor with set literals. This fixer is optional.

\textbf{standarderror}

Renames \texttt{StandardError} to \texttt{Exception}.

\textbf{sys\_exc}

Changes the deprecated \texttt{sys.exc\_value, sys.exc\_type, sys.exc\_traceback} to use \texttt{sys.exc\_info()}.

\textbf{throw}

Fixes the API change in generator's \texttt{throw()} method.

\textbf{tuple\_params}

Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

\textbf{types}

Fixes code broken from the removal of some members in the \texttt{types} module.

\textbf{unicode}

Renames \texttt{unicode} to \texttt{str}.
urllib
Handles the rename of urllib and urllib2 to the urllib package.

ws_comma
Removes excess whitespace from comma separated items. This fixer is optional.

xrange
Renames xrange() to range() and wraps existing range() calls with list.

xreadlines
Changes for x in file.xreadlines() to for x in file.

zip
Wraps zip() usage in a list call. This is disabled when from future_builtins import zip appears.
25.4.3. *lib2to3* - 2to3's library

**Note:** The *lib2to3* API should be considered unstable and may change drastically in the future.
25.5. **test** — Regression tests package for Python

**Note:** The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The `test` package contains all regression tests for Python as well as the modules `test.test_support` and `test.regrtest`. `test.test_support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a “traditional” testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**See also:**

- **Module unittest**
  - Writing PyUnit regression tests.
- **Module doctest**
  - Tests embedded in documentation strings.
25.5.1. Writing Unit Tests for the test package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import test_support

class MyTestCase1(unittest.TestCase):
    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...
```
This boilerplate code allows the testing suite to be run by `test.regrtest` as well as on its own as a script.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.

- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.

- Make sure to clean up after your tests (such as close and remove all temporary files).

- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequences(unittest.TestCase):
    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequences):
    arg = [1, 2, 3]

class AcceptStrings(TestFuncAcceptsSequences):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequences):
    arg = (1, 2, 3)
```

See also:
Test Driven Development
A book by Kent Beck on writing tests before code.
25.5.2. Running tests using the command-line interface

The test.regrtest module can be run as a script to drive Python's regression test suite, thanks to the -m option: python -m test.regrtest. Running the script by itself automatically starts running all regression tests in the test package. It does this by finding all modules in the package whose name starts with test_, importing them, and executing the function test_main() if present. The names of tests to execute may also be passed to the script. Specifying a single regression test (python -m test.regrtest test_spam) will minimize output and only print whether the test passed or failed and thus minimize output.

Running test.regrtest directly allows what resources are available for tests to use to be set. You do this by using the -u command-line option. Specifying all as the value for the -u option enables all possible resources: python -m test.regrtest -u all. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after all. The command python -m test.regrtest -u all,-audio,-largefile will run test.regrtest with all resources except the audio and largefile resources. For a list of all resources and more command-line options, run python -m test.regrtest -h.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run make test at the top-level directory where Python was built. On Windows, executing rt.bat from your PBuild directory will run all regression tests.
25.6. `test.test_support` — Utility functions for tests

**Note:** The `test.test_support` module has been renamed to `test.support` in Python 3.x.

The `test.test_support` module provides support for Python's regression tests.

This module defines the following exceptions:

```python
exception test.test_support.TestFailed
    Exception to be raised when a test fails. This is deprecated in favor of unittest-based tests and unittest.TestCase's assertion methods.
```

```python
exception test.test_support.ResourceDenied
    Subclass of unittest.SkipTest. Raised when a resource (such as a network connection) is not available. Raised by the requires() function.
```

The `test.test_support` module defines the following constants:

```python
test.test_support.verbose
    True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by test.regrtest.
```

```python
test.test_support.have_unicode
    True when Unicode support is available.
```

```python
test.test_support.is_jython
    True if the running interpreter is Jython.
```
test.test_support.TESTFN

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The test.test_support module defines the following functions:

test.test_support.forget(module_name)

Remove the module named module_name from sys.modules and delete any byte-compiled files of the module.

test.test_support.is_resource_enabled(resource)

Return True if resource is enabled and available. The list of available resources is only set when test.regrtest is executing the tests.

test.test_support.requires(resource[, msg])

Raise ResourceDenied if resource is not available. msg is the argument to ResourceDenied if it is raised. Always returns True if called by a function whose __name__ is '__main__'. Used when tests are executed by test.regrtest.

test.test_support.findfile(filename)

Return the path to the file named filename. If no match is found filename is returned. This does not equal a failure since it could be the path to the file.

test.test_support.run_unittest(*classes)

Execute unittest.TestCase subclasses passed to the function. The function scans the classes for methods starting with the prefix test__ and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in sys.modules. Each associated module will be scanned by
unittest.TestLoader.loadTestsFromModule(). This is usually seen in the following `test_main()` function:

```python
def test_main():
    test_support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.test_support.check_warnings(*filters, quiet=True)

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling

```python
warnings.catch_warnings(record=True)
```

with `warningssimplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form ("message\sregexp", `WarningCategory`) as positional arguments. If one or more `filters` are provided, or if the optional keyword argument `quiet` is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set `quiet` to `True`.

If no arguments are specified, it defaults to:

```python
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a `WarningRecorder` instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object’s `warnings` attribute. As a convenience, the attributes of the object representing the most
recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return None.

The recorder object also has a reset() method, which clears the warnings list.

The context manager is designed to be used like this:

```python
with check_warnings("assertion is always true", SyntaxWarning("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, check_warnings() would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```python
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*New in version 2.6.*

*Changed in version 2.7:* New optional arguments filters and quiet.
test.test_support.**check_py3k_warnings(***filters*, *quiet=False*)

Similar to **check_warnings()**, but for Python 3 compatibility warnings. If `sys.py3kwarning == 1`, it checks if the warning is effectively raised. If `sys.py3kwarning == 0`, it checks that no warning is raised. It accepts 2-tuples of the form ("message regexp", `WarningCategory`) as positional arguments. When the optional keyword argument `quiet` is `True`, it does not fail if a filter catches nothing. Without arguments, it defaults to:

```
check_py3k_warnings(("", `DeprecationWarning`), quiet=False)
```

*New in version 2.7.*

**test.test_support.captured_stdout**

This is a context manager that runs the `with` statement body using a `StringIO.StringIO` object as `sys.stdout`. That object can be retrieved using the `as` clause of the `with` statement.

Example use:

```
with captured_stdout() as s:
    print "hello"
assert s.getvalue() == "hello\n"
```

*New in version 2.6.*

**test.test_support.import_module**(name, deprecated=False)

This function imports and returns the named module. Unlike a normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if `deprecated` is `True`.

*New in version 2.7.*
test.test_support.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

*fresh* is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

*blocked* is an iterable of module names that are replaced with `0` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`.

This function will raise `unittest.SkipTest` if the named module cannot be imported.

Example use:

```python
# Get copies of the warnings module for testing without
# affecting the version being used by the rest of the test suite.
# One copy uses the C implementation, the other is forced to
# the pure Python fallback implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

*New in version 2.7.*

The `test.test_support` module defines the following classes:
class test.test_support.TransientResource(exc[, **kwargs])

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.

New in version 2.6.

class test.test_support.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying os.environ. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

New in version 2.6.

Changed in version 2.7: Added dictionary interface.

EnvironmentVarGuard.set(envvar, value)

Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)

Temporarily unset the environment variable envvar.

class test.test_support.WarningsRecorder

Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.

New in version 2.6.
These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```
exception bdb.BdbQuit
```

Exception raised by the `Bdb` class for quitting the debugger.

The `bdb` module also defines two classes:

```
class bdb.Breakpoint(self, file, line, temporary=0, cond=None, funcname=None)
```

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by `(file, line)` pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a `funcname` is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

`Breakpoint` instances have the following methods:

```
deleteMe()
```

Delete the breakpoint from the list associated to a file/line. If it
is the last breakpoint in that position, it also deletes the entry for the file/line.

**enable()**

Mark the breakpoint as enabled.

**disable()**

Mark the breakpoint as disabled.

**pprint([out])**

Print all the information about the breakpoint:

- The breakpoint number.
- If it is temporary or not.
- Its file, line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

```python
class bdb.Bdb(skip=None)
```

The `Bdb` class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (`pdb.Pdb`) is an example.

The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

*New in version 2.7:* The `skip` argument.

The following methods of `Bdb` normally don’t need to be
canonic(filename)

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

reset()

Set the botframe, stopframe, returnframe and quitting attributes with values ready to start debugging.

trace_dispatch(frame, event, arg)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. event can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The arg parameter depends on the previous event.
See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to The standard type hierarchy.

**dispatch_line**(frame)
If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_call**(frame, arg)
If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return**(frame, arg)
If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_exception**(frame, arg)
If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a
reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don’t override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**stop_here(frame)**
This method checks if the `frame` is somewhere below `botframe` in the call stack. `botframe` is the frame in which debugging started.

**break_here(frame)**
This method checks if there is a breakpoint in the filename and line belonging to `frame` or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**break_anywhere(frame)**
This method checks if there is a breakpoint in the filename of the current frame.

Derived classes should override these methods to gain control over debugger operation.

**user_call(frame, argument_list)**
This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line(frame)**
This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields `True`.

**user_return(frame, return_value)**
This method is called from `dispatch_return()` when
stop_here() yields True.

user_exception(frame, exc_info)
    This method is called from dispatch_exception() when stop_here() yields True.

do_clear(arg)
    Handle how a breakpoint must be removed when it is a temporary one.

    This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

set_step()
    Stop after one line of code.

set_next(frame)
    Stop on the next line in or below the given frame.

set_return(frame)
    Stop when returning from the given frame.

set_until(frame)
    Stop when the line with the line no greater than the current one is reached or when returning from current frame.

set_trace([frame])
    Start debugging from frame. If frame is not specified, debugging starts from caller’s frame.

set_continue()
    Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.
set_quit()
    Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*( ) methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

set_break(filename, lineno, temporary=0, cond=None, funcname=None)
    Set a new breakpoint. If the lineno line doesn’t exist for the filename passed as argument, return an error message. The filename should be in canonical form, as described in the canonic() method.

clear_break(filename, lineno)
    Delete the breakpoints in filename and lineno. If none were set, an error message is returned.

clear_bpbynumber(arg)
    Delete the breakpoint which has the index arg in the Breakpoint.bpbynumber. If arg is not numeric or out of range, return an error message.

clear_all_file_breaks(filename)
    Delete all breakpoints in filename. If none were set, an error message is returned.

clear_all_breaks()
    Delete all existing breakpoints.

get_break(filename, lineno)
    Check if there is a breakpoint for lineno of filename.
get_breaks(filename, lineno)
Return all breakpoints for lineno in filename, or an empty list if none are set.

get_file_breaks(filename)
Return all breakpoints in filename, or an empty list if none are set.

get_all_breaks()
Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

get_stack(f, t)
Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

format_stack_entry(frame_lineno[], lprefix=': ')
Return a string with information about a stack entry, identified by a (frame, lineno) tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a statement, given as a string.

run(cmd[, globals[, locals]])
Debug a statement executed via the exec statement. globals
defaults to \_\_main\_.\_\_dict\_, \_\_locals\_ defaults to \_\_globals\_.

\texttt{runeval}([\texttt{expr}[, \_\_globals\_[[, \_\_locals\_]]]])

Debug an expression executed via the \texttt{eval()} function. \_\_globals\_ and \_\_locals\_ have the same meaning as in \texttt{run()}.

\texttt{runcntx}([\texttt{cmd}, \_\_globals\_, \_\_locals\_])

For backwards compatibility. Calls the \texttt{run()} method.

\texttt{runcall}([\texttt{func}, \_\_args\_, \_\_kwds\_])

Debug a single function call, and return its result.

Finally, the module defines the following functions:

\texttt{bdb.\_\_checkfuncname\_\_}([\texttt{b}, \texttt{frame}])

Check whether we should break here, depending on the way the breakpoint \texttt{b} was set.

If it was set via line number, it checks if \texttt{b.line} is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

\texttt{bdb.\_\_effective\_\_}([\texttt{file}, \texttt{line}, \texttt{frame}])

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return (\texttt{None, None}) if there is no matching breakpoint.

\texttt{bdb.\_\_set\_\_trace\_\_}()

Start debugging with a \texttt{Bdb} instance from caller’s frame.
26.2. **pdb — The Python Debugger**

**Source code**: Lib/pdb.py

The module **pdb** defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible — it is actually defined as the class **Pdb**. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules **bdb** and **cmd**.

The debugger’s prompt is (**Pdb**). Typical usage to run a program under control of the debugger is:

```python
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

**pdb.py** can also be invoked as a script to debug other scripts. For example:

```bash
python -m pdb myscript.py
```

When invoked as a script, pdb will automatically enter post-mortem
debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), pdb will restart the program. Automatic restarting preserves pdb’s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

*New in version 2.4:* Restarting post-mortem behavior added.

The typical usage to break into the debugger from a running program is to insert

```python
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the `c` command.

The typical usage to inspect a crashed program is:

```python
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "./mymodule.py", line 4, in test
    test2()
  File "./mymodule.py", line 3, in test
    print spam
NameError: name 'spam'
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print spam
(Pdb)
```

The module defines the following functions; each enters the debugger in a slightly different way:

```python
pdb.run(statement[, globals[, locals]])
```

Execute the `statement` (given as a string) under debugger
The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can step through the statement using `step` or `next` (all these commands are explained below). The optional `globals` and `locals` arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the `exec` statement or the `eval()` built-in function.)

```
pdb. runeval(expression[, globals[, locals]])
```
Evaluate the `expression` (given as a string) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`.

```
pdb. runcall(function[, argument, ...])
```
Call the `function` (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

```
pdb. set_trace()
```
Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails).

```
pdb. post_mortem([traceback])
```
Enter post-mortem debugging of the given `traceback` object. If no `traceback` is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

```
pdb. pm()
```
Enter post-mortem debugging of the traceback found in `sys.last_traceback`.

The `run*` functions and `set_trace()` are aliases for instantiating the `Pdb` class and calling the method of the same name. If you want to access further features, you have to do this yourself:

```python
class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None):
    Pdb is the debugger class.
```

The `completekey`, `stdin` and `stdout` arguments are passed to the underlying `cmd.Cmd` class; see the description there.

The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. [1]

Example call to enable tracing with `skip`:

```python
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

*New in version 2.7:* The `skip` argument.

```python
run(statement[, globals[, locals]])
runeval(expression[, globals[, locals]])
runcall(function[, argument, ...])
set_trace()
```

See the documentation for the functions explained above.
The debugger recognizes the following commands. Most commands can be abbreviated to one or two letters; e.g. h(e1p) means that either h or help can be used to enter the help command (but not he or hel, nor H or Help or HELP). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ]) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a list command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

Multiple commands may be entered on a single line, separated by ;;. (A single ; is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first ;; pair, even if it is in the middle of a quoted string.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

If a file .pdbrc exists in the user’s home directory or in the current
directory, it is read in and executed as if it had been typed at the
debugger prompt. This is particularly useful for aliases. If both files
exist, the one in the home directory is read first and aliases defined
there can be overridden by the local file.

h(elp) [command]
Without argument, print the list of available commands. With a
command as argument, print help about that command. help pdb
displays the full documentation file; if the environment variable
PAGER is defined, the file is piped through that command instead.
Since the command argument must be an identifier, help exec
must be entered to get help on the ! command.

w(here)
Print a stack trace, with the most recent frame at the bottom. An
arrow indicates the current frame, which determines the context
of most commands.

d(own)
Move the current frame one level down in the stack trace (to a
newer frame).

u(p)
Move the current frame one level up in the stack trace (to an
older frame).

b(reak) [[filename:]lineno | function[, condition]]
With a lineno argument, set a break there in the current file. With
a function argument, set a break at the first executable statement
within that function. The line number may be prefixed with a
filename and a colon, to specify a breakpoint in another file
(probably one that hasn’t been loaded yet). The file is searched
on sys.path. Note that each breakpoint is assigned a number to
which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must
evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[filename:]lineno | function[, condition]]
    Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as break.

cl(ear) [[filename:lineno | bpnumber [bpnumber ...]]
    With a filename:lineno argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber [bpnumber ...]]
    Disables the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber [bpnumber ...]]
    Enables the breakpoints specified.

ignore bpnumber [count]
    Sets the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

condition bpnumber [condition]
    Condition is an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.
commands [bpnumber]

Specify a list of commands for breakpoint number bpnumber. The commands themselves appear on the following lines. Type a line containing just ‘end’ to terminate the commands. An example:

```
(Pdb) commands 1
(com) print some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with end; that is, give no commands.

With no bpnumber argument, commands refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the continue command, or step, or any other command that resumes execution.

Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

*New in version 2.5.*

s(tep)
Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

n(ext)
Continue execution until the next line in the current function is reached or it returns. (The difference between next and step is that step stops inside a called function, while next executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

unt(il)
Continue execution until the line with the line number greater than the current one is reached or when returning from current frame.

*New in version 2.6.*

r(eturn)
Continue execution until the current function returns.

c(ont(inue))
Continue execution, only stop when a breakpoint is encountered.

j(ump) *lineno*
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed — for instance it is not possible to jump into the middle of a *for* loop or out of a *finally* clause.

l(ist) [*first*, *last*]
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With one argument, list 11 lines around at that line. With two
arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

a(rgs)
Print the argument list of the current function.

p expression
Evaluate the expression in the current context and print its value.

**Note:** `print` can also be used, but is not a debugger command — this executes the Python `print` statement.

pp expression
Like the `p` command, except the value of the expression is pretty-printed using the `pprint` module.

alias [name [command]]
Creates an alias called `name` that executes `command`. The command must not be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%*` is replaced by all the parameters. If no command is given, the current alias for `name` is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands can be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```python
#Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print "%1.%s","=%",%1.%s
#Print instance variables in self
```
alias ps pi self

unalias name

Deletes the specified alias.

[!]statement

Execute the (one-line) statement in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a global command on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

run [args ...]

Restart the debugged Python program. If an argument is supplied, it is split with “shlex” and the result is used as the new sys.argv. History, breakpoints, actions and debugger options are preserved. “restart” is an alias for “run”.

New in version 2.6.

q(uит)

Quit from the debugger. The program being executed is aborted.

Footnotes

[1] Whether a frame is considered to originate in a certain module is determined by the __name__ in the frame globals.
26.4. The Python Profilers

**Source code:** `Lib/profile.py` and `Lib/pstats.py`
26.4.1. Introduction to the profilers

cProfile and profile provide deterministic profiling of Python programs. A profile is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the pstats module.

The Python standard library provides three different implementations of the same profiling interface:

1. cProfile is recommended for most users; it’s a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on lsprof, contributed by Brett Rosen and Ted Czotter.

   New in version 2.5.

2. profile, a pure Python module whose interface is imitated by cProfile, but which adds significant overhead to profiled programs. If you’re trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

   Changed in version 2.4: Now also reports the time spent in calls to built-in functions and methods.

3. hotshot was an experimental C module that focused on minimizing the overhead of profiling, at the expense of longer data post-processing times. It is no longer maintained and may be dropped in a future version of Python.

   Changed in version 2.5: The results should be more meaningful than in the past: the timing core contained a critical bug.
The `profile` and `cProfile` modules export the same interface, so they are mostly interchangeable; `cProfile` has a much lower overhead but is newer and might not be available on all systems. `cProfile` is really a compatibility layer on top of the internal `_lsprof` module. The `hotshot` module is reserved for specialized usage.

**Note:** The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is `timeit` for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.
This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```python
import cProfile
import re

cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
197 function calls (192 primitive calls) in 0.002 seconds
Ordered by: standard name
ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
1    0.000    0.000    0.001    0.001  <string>:1(<module>)
1    0.000    0.000    0.001    0.001  re.py:212(compile)
1    0.000    0.000    0.001    0.001  re.py:268(_compile)
1    0.000    0.000    0.000    0.000  sre_compile.py:172(_
1    0.000    0.000    0.000    0.000  sre_compile.py:201(_
4    0.000    0.000    0.000    0.000  sre_compile.py:25(_i
3/1  0.000    0.000    0.000    0.000  sre_compile.py:33(_c
```

The first line indicates that 197 calls were monitored. Of those calls, 192 were `primitive`, meaning that the call was not induced via recursion. The next line: `Ordered by: standard name`, indicates that the text string in the far right column was used to sort the output. The column headings include:
ncalls
    for the number of calls,

tottime
    for the total time spent in the given function (and excluding time made in calls to sub-functions)

percall
    is the quotient of tottime divided by ncalls

cumtime
    is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.

percall
    is the quotient of cumtime divided by primitive calls

filename:lineno(function)
    provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the run() function:

```python
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The `pstats.Stats` class reads profile results from a file and formats them in various ways.
The file `cProfile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] myscript.py
```

- `-o` writes the profile results to a file instead of to stdout.
- `-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

The `pstats` module’s `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```python
import pstats
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```python
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```python
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.
If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```python
p.sort_stats('time').print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```python
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```python
p.sort_stats('time', 'cum').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (p is still sorted according to the last criteria) do:

```python
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you’re going to have to read the manual, or guess what the following functions do:

```python
p.print_callees()
p.add('restats')
```
Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.
Both the `profile` and `cProfile` modules provide the following functions:

**profile.run**(command, filename=None, sort=-1)

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```python
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified it is passed to this `Stats` instance to control how the results are sorted.

**profile.runctx**(command, globals, locals, filename=None)

This function is similar to `run()`, with added arguments to supply the globals and locals dictionaries for the `command` string. This routine executes:

```python
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

**class profile.Profile**(timer=None, timeunit=0.0, subcalls=True, builtins=True)

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.
A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `0.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```python
import cProfile, pstats, StringIO
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = StringIO.StringIO()
sortby = 'cumulative'
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print s.getvalue()
```

- **enable()**
  
  Start collecting profiling data.

- **disable()**
  
  Stop collecting profiling data.

- **create_stats()**
  
  Stop collecting profiling data and record the results internally as the current profile.

- **print_stats(sort=-1)**
  
  Create a `Stats` object based on the current profile and print the results to stdout.

- **dump_stats(filename)**
Write the results of the current profile to *filename*.

**run**(cmd)
Profile the cmd via `exec()`.

**runc**tx(cmd, **globals, locals**)
Profile the cmd via `exec()` with the specified global and local environment.

**runcall**(func, *args, **kwargs)
Profile `func(*args, **kwargs)`
26.4.4. The stats Class

Analysis of the profiler data is done using the Stats class.

```python
class pstats.Stats(*filenames or profile, stream=sys.stdout)
```

This class constructor creates an instance of a “statistics object” from a filename (or list of filenames) or from a Profile instance. Output will be printed to the stream specified by stream.

The file selected by the above constructor must have been created by the corresponding version of profile or cProfile. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing Stats object, the add() method can be used.

Instead of reading the profile data from a file, a cProfile.Profile or profile.Profile object can be used as the profile data source.

Stats objects have the following methods:

```python
strip_dirs()
```

This method for the Stats class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a “random” order, as it was just after object initialization and loading. If strip_dirs() causes two function names to be indistinguishable (they are
on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

**add(** *filenames*)

This method of the **Stats** class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of **profile.run()** or **cProfile.run()**. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

**dump_stats**(filename)

Save the data loaded into the **Stats** object to a file named **filename**. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the **profile.Profile** and **cProfile.Profile** classes.

*New in version 2.3.*

**sort_stats**(**keys**)

This method modifies the **Stats** object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example: 'time' or 'name').

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, **sort_stats('name', 'file')** will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the
abbreviation is unambiguous. The following are the keys currently defined:

<table>
<thead>
<tr>
<th>Valid Arg</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'calls'</td>
<td>call count</td>
</tr>
<tr>
<td>'cumulative'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'cumtime'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'file'</td>
<td>file name</td>
</tr>
<tr>
<td>'filename'</td>
<td>file name</td>
</tr>
<tr>
<td>'module'</td>
<td>file name</td>
</tr>
<tr>
<td>'ncalls'</td>
<td>call count</td>
</tr>
<tr>
<td>'pcalls'</td>
<td>primitive call count</td>
</tr>
<tr>
<td>'line'</td>
<td>line number</td>
</tr>
<tr>
<td>'name'</td>
<td>function name</td>
</tr>
<tr>
<td>'nfl'</td>
<td>name/file/line</td>
</tr>
<tr>
<td>'stdname'</td>
<td>standard name</td>
</tr>
<tr>
<td>'time'</td>
<td>internal time</td>
</tr>
<tr>
<td>'tottime'</td>
<td>internal time</td>
</tr>
</tbody>
</table>

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, `sort_stats('nfl')` is the same as `sort_stats('name', 'file', 'line')`.

For backward-compatibility reasons, the numeric arguments `-1, 0, 1,` and `2` are permitted. They are interpreted as...
'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

**reverse_order()**

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

**print_stats(*restrictions)**

This method for the `Stats` class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a regular expression (to pattern match the standard name that is printed. If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.*foo:`. In contrast, the command:

```
print_stats('foo:', .1)
```
would limit the list to all functions having file names `.*foo:`, and then proceed to only print the first 10% of them.

**print_callers(*restrictions)**

This method for the Stats class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

**print_callees(*restrictions)**

This method for the Stats class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the `print_callers()` method.
26.4.5. What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
26.4.6. Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it can accumulate and become very significant.

The problem is more important with profile than with the lower-overhead cProfile. For this reason, profile provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-) ). Do not be alarmed by negative numbers in the profile. They should only appear if you have calibrated your profiler, and the results are actually better than without calibration.
26.4.7. Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see Limitations).

```python
import profile
pr = profile.Profile()
for i in range(5):
    print pr.calibrate(10000)
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running Mac OS X, and using Python’s `time.clock()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is very fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it: [1]

```python
import profile

# 1. Apply computed bias to all Profile instances created here
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias
```
# 3. Specify computed bias in instance constructor.

```python
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.
26.4.8. Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the Profile class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`'s return value will be interpreted differently:

**profile.Profile**

`your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see Calibration). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is pretty bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

**cProfile.Profile**

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For
example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

**Footnotes**

[1] Prior to Python 2.2, it was necessary to edit the profiler source code to embed the bias as a literal number. You still can, but that method is no longer described, because no longer needed.
26.5. hotshot — High performance logging profiler

New in version 2.2.

This module provides a nicer interface to the _hotshot C module. Hotshot is a replacement for the existing profile module. As it’s written mostly in C, it should result in a much smaller performance impact than the existing profile module.

Note: The hotshot module focuses on minimizing the overhead while profiling, at the expense of long data post-processing times. For common usage it is recommended to use cProfile instead. hotshot is not maintained and might be removed from the standard library in the future.

Changed in version 2.5: The results should be more meaningful than in the past: the timing core contained a critical bug.

Note: The hotshot profiler does not yet work well with threads. It is useful to use an unthreaded script to run the profiler over the code you’re interested in measuring if at all possible.

class hotshot. Profile(logfile[, lineevents[, linetimings]])

The profiler object. The argument logfile is the name of a log file to use for logged profile data. The argument lineevents specifies whether to generate events for every source line, or just on function call/return. It defaults to 0 (only log function call/return). The argument linetimings specifies whether to record timing information. It defaults to 1 (store timing information).
26.5.1. Profile Objects

Profile objects have the following methods:

Profile. `addinfo(key, value)`
Add an arbitrary labelled value to the profile output.

Profile. `close()`
Close the logfile and terminate the profiler.

Profile. `fileno()`
Return the file descriptor of the profiler’s log file.

Profile. `run(cmd)`
Profile an `exec`-compatible string in the script environment. The globals from the `__main__` module are used as both the globals and locals for the script.

Profile. `runcall(func, *args, **keywords)`
Profile a single call of a callable. Additional positional and keyword arguments may be passed along; the result of the call is returned, and exceptions are allowed to propagate cleanly, while ensuring that profiling is disabled on the way out.

Profile. `runctx(cmd, globals, locals)`
Evaluate an `exec`-compatible string in a specific environment. The string is compiled before profiling begins.

Profile. `start()`
Start the profiler.

Profile. `stop()`
Stop the profiler.
26.5.2. Using hotshot data

New in version 2.2.

This module loads hotshot profiling data into the standard pstats Stats objects.

hotshot.stats.load(filename)

Load hotshot data from filename. Returns an instance of the pstats.Stats class.

See also:

Module profile
The profile module's stats class
Note that this example runs the Python “benchmark” pystones. It can take some time to run, and will produce large output files.

```python
>>> import hotshot, hotshot.stats, test.pystone
>>> prof = hotshot.Profile("stones.prof")
>>> benchtime, stones = prof.runcall(test.pystone.pystones)
>>> prof.close()
>>> stats = hotshot.stats.load("stones.prof")
>>> stats.strip_dirs()
>>> stats.sort_stats('time', 'calls')
>>> stats.print_stats(20)
850004 function calls in 10.090 CPU seconds

Ordered by: internal time, call count

26.6. timeit — Measure execution time of small code snippets

New in version 2.3.

**Source code:** Lib/timeit.py

This module provides a simple way to time small bits of Python code. It has both a Command-Line Interface as well as a callable one. It avoids a number of common traps for measuring execution times. See also Tim Peters' introduction to the “Algorithms” chapter in the *Python Cookbook*, published by O'Reilly.
26.6.1. Basic Examples

The following example shows how the Command-Line Interface can be used to compare three different expressions:

```
$ python -m timeit '"-.join(str(n) for n in range(100))'
10000 loops, best of 3: 40.3 usec per loop
$ python -m timeit '"-.join([str(n) for n in range(100)])'
10000 loops, best of 3: 33.4 usec per loop
$ python -m timeit '"-.join(map(str, range(100)))'
10000 loops, best of 3: 25.2 usec per loop
```

This can be achieved from the Python Interface with:

```
>>> import timeit
>>> timeit.timeit(""-.join(str(n) for n in range(100))", number=10000)
0.8187260627746582
>>> timeit.timeit(""-.join([str(n) for n in range(100)])", number=10000)
0.7288308143615723
>>> timeit.timeit(""-.join(map(str, range(100)))", number=10000)
0.5858950614929199
```

Note however that `timeit` will automatically determine the number of repetitions only when the command-line interface is used. In the Examples section you can find more advanced examples.
26.6.2. Python Interface

The module defines three convenience functions and a public class:

```python
timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000)
```

Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `timeit()` method with `number` executions.

*New in version 2.6.*

```python
timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=3, number=1000000)
```

Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `repeat()` method with the given `repeat` count and `number` executions.

*New in version 2.6.*

```python
timeit.default_timer()
```

Define a default timer, in a platform-specific manner. On Windows, `time.clock()` has microsecond granularity, but `time.time()`'s granularity is 1/60th of a second. On Unix, `time.clock()` has 1/100th of a second granularity, and `time.time()` is much more precise. On either platform, `default_timer()` measures wall clock time, not the CPU time. This means that other processes running on the same computer may interfere with the timing.

```python
class timeit.Timer(stmt='pass', setup='pass', timer=<timer function>)
```

Class for timing execution speed of small code snippets.
The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to 'pass'; the timer function is platform-dependent (see the module doc string). stmt and setup may also contain multiple statements separated by ; or newlines, as long as they don’t contain multi-line string literals.

To measure the execution time of the first statement, use the timeit() method. The repeat() method is a convenience to call timeit() multiple times and return a list of results.

Changed in version 2.6: The stmt and setup parameters can now also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by timeit(). Note that the timing overhead is a little larger in this case because of the extra function calls.

```
-timeit(number=1000000)
```

Time number executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

Note: By default, timeit() temporarily turns off garbage collection during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the setup string. For example:
repea**t**(repeat=3, number=1000000)
Call timeit() a few times.

This is a convenience function that calls the timeit() repeatedly, returning a list of results. The first argument specifies how many times to call timeit(). The second argument specifies the number argument for timeit().

**Note:** It’s tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python’s speed, but by other processes interfering with your timing accuracy. So the min() of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

print_exc(file=None)
Helper to print a traceback from the timed code.

Typical use:

```python
t = Timer(...)  # outside the try/except
try:
    t.timeit(...)  # or t.repeat(...)
except:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional
file argument directs where the traceback is sent; it defaults to 
sys.stderr.
26.6.3. Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-s S] [-t] [-c] [-h] [statement]
```

Where the following options are understood:

- **-n N, --number=N**
  how many times to execute ‘statement’

- **-r N, --repeat=N**
  how many times to repeat the timer (default 3)

- **-s S, --setup=S**
  statement to be executed once initially (default pass)

- **-t, --time**
  use `time.time()` (default on all platforms but Windows)

- **-c, --clock**
  use `time.clock()` (default on Windows)

- **-v, --verbose**
  print raw timing results; repeat for more digits precision

- **-h, --help**
  print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.
If \(-n\) is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.

`default_timer()` measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 3 repetitions is probably enough in most cases. On Unix, you can use `time.clock()` to measure CPU time.

**Note:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn’t try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions. Also, to fairly compare older Python versions to Python 2.3, you may want to use Python’s `-O` option (see Optimizations) for the older versions to avoid timing SET_LINENO instructions.
26.6.4. Examples

It is possible to provide a setup statement that is executed only once at the beginning:

```python
import timeit

import timeit
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"'
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"'
1.7246671520006203

The same can be done using the Timer class and its methods:

```python
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample string"
0.395516149999312
>>> t.repeat()
[0.40193588800002544, 0.3960157959998014, 0.39594301399984033]

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes:

```python
$ python -m timeit 'try: ' str.__nonzero__' except AttributeError
100000 loops, best of 3: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__nonzero__"): pass'
100000 loops, best of 3: 4.26 usec per loop

$ python -m timeit 'try: ' int.__nonzero__' except AttributeError
100000 loops, best of 3: 1.43 usec per loop
$ python -m timeit 'if hasattr(int, "__nonzero__"): pass'
```
To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement:

```python
def test():
    """Stupid test function""
    L = []
    for i in range(100):
        L.append(i)

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import t"
26.7. `trace` — Trace or track Python statement execution

**Source code:** `Lib/trace.py`

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.
26.7.1. Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

**--help**
Display usage and exit.

**--version**
Display the version of the module and exit.

26.7.1.1. Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

**-c, --count**
Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

**-t, --trace**
Display lines as they are executed.

**-l, --listfuncs**
Display the functions executed by running the program.
-r, --report
  Produce an annotated list from an earlier program run that used the --count and --file option. This does not execute any code.

-T, --trackcalls
  Display the calling relationships exposed by running the program.

26.7.1.2. Modifiers

-f, --file=<file>
  Name of a file to accumulate counts over several tracing runs. Should be used with the --count option.

-C, --coverdir=<dir>
  Directory where the report files go. The coverage report for package.module is written to file dir/package/module.cover.

-m, --missing
  When generating annotated listings, mark lines which were not executed with >>>>>>.

-s, --summary
  When using --count or --report, write a brief summary to stdout for each file processed.

-R, --no-report
  Do not generate annotated listings. This is useful if you intend to make several runs with --count, and then produce a single set of annotated listings at the end.

-g, --timing
  Prefix each line with the time since the program started. Only used while tracing.

26.7.1.3. Filters
These options may be repeated multiple times.

**--ignore-module**\=<mod>

Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

**--ignore-dir**\=<dir>

Ignore all modules and packages in the named directory and subtdirectories. The argument can be a list of directories separated by *os.pathsep*. 
class trace. Trace([count=1[, trace=1[, countfuncs=0[, countcallers=0[, ignoremods=()[, ignoredirs=()[, infile=None[, outfile=None[, timing=False]]]]]]]]])

Create an object to trace execution of a single statement or expression. All parameters are optional. count enables counting of line numbers. trace enables line execution tracing. countfuncs enables listing of the functions called during the run. countcallers enables call relationship tracking. ignoremods is a list of modules or packages to ignore. ignoredirs is a list of directories whose modules or packages should be ignored. infile is the name of the file from which to read stored count information. outfile is the name of the file in which to write updated count information. timing enables a timestamp relative to when tracing information was started to be displayed.

run(cmd)

Execute the command and gather statistics from the execution with the current tracing parameters. cmd must be a string or code object, suitable for passing into exec().

runctx(cmd, globals=None, locals=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, globals and locals default to empty dictionaries.

runfunc(func, *args, **kwds)

Call func with the given arguments under control of the Trace object with the current tracing parameters.
results()

Return a CoverageResults object that contains the cumulative results of all previous calls to run, runctx and runfunc for the given Trace instance. Does not reset the accumulated trace results.

class trace.CoverageResults

A container for coverage results, created by Trace.results(). Should not be created directly by the user.

update(other)

Merge in data from another CoverageResults object.

write_results([show_missing=True, summary=False, coverdir=None])

Write coverage results. Set show_missing to show lines that had no hits. Set summary to include in the output the coverage summary per module. coverdir specifies the directory into which the coverage result files will be output. If None, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, and whether
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')
```
# make a report, placing output in the current directory
r = tracer.results()
```
r.write_results(show_missing=True, coverdir=".")
```
27. Software Packaging and Distribution

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the Python Package Index, they can also be used with a local index server, or without any index server at all.

- **27.1. distutils** — Building and installing Python modules
- **27.2. ensurepip** — Bootstrapping the pip installer
  - 27.2.1. Command line interface
  - 27.2.2. Module API
27.1. distutils — Building and installing Python modules

The distutils package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

Most Python users will not want to use this module directly, but instead use the cross-version tools maintained by the Python Packaging Authority. In particular, setuptools is an enhanced alternative to distutils that provides:

- support for declaring project dependencies
- additional mechanisms for configuring which files to include in source releases (including plugins for integration with version control systems)
- the ability to declare project “entry points”, which can be used as the basis for application plugin systems
- the ability to automatically generate Windows command line executables at installation time rather than needing to prebuild them
- consistent behaviour across all supported Python versions

The recommended pip installer runs all setup.py scripts with setuptools, even if the script itself only imports distutils. Refer to the Python Packaging User Guide for more information.

For the benefits of packaging tool authors and users seeking a deeper understanding of the details of the current packaging and distribution system, the legacy distutils based user documentation and API reference remain available:
• Installing Python Modules (Legacy version)
• Distributing Python Modules (Legacy version)
27.2. ensurepip — Bootstrapping the pip installer

New in version 2.7.9.

The ensurepip package provides support for bootstrapping the pip installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that pip is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn't need to invoke this module directly (as pip should be bootstrapped by default), but it may be needed if installing pip was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling pip.

**Note:** This module does not access the internet. All of the components needed to bootstrap pip are included as internal parts of the package.

**See also:**

**Installing Python Modules**

The end user guide for installing Python packages

**PEP 453: Explicit bootstrapping of pip in Python installations**

The original rationale and specification for this module.

**PEP 477: Backport ensurepip (PEP 453) to Python 2.7**

The rationale and specification for backporting PEP 453 to Python 2.7.
27.2.1. Command line interface

The command line interface is invoked using the interpreter’s `--m` switch.

The simplest possible invocation is:

```
python -m ensurepip
```

This invocation will install `pip` if it is not already installed, but otherwise does nothing. To ensure the installed version of `pip` is at least as recent as the one bundled with `ensurepip`, pass the `--upgrade` option:

```
python -m ensurepip --upgrade
```

By default, `pip` is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options:

- `--root <dir>`: Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- `--user`: Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts `pip`, `pipX`, and `pipX.Y` will be installed (where `X.Y` stands for the version of Python used to invoke `ensurepip`). The scripts installed can be controlled through two additional command line options:
- `--altinstall`: if an alternate installation is requested, the `pip` and `pipx` script will *not* be installed.
- `--no-default-pip`: if a non-default installation is request, the `pip` script will *not* be installed.
27.2.2. Module API

`ensurepip` exposes two functions for programmatic use:

```python
ensurepip.version()
```

Returns a string specifying the bundled version of pip that will be installed when bootstrapping an environment.

```python
ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=True, verbosity=0)
```

Bootstraps pip into the current or designated environment.

- `root` specifies an alternative root directory to install relative to. If `root` is `None`, then installation uses the default install location for the current environment.

- `upgrade` indicates whether or not to upgrade an existing installation of an earlier version of pip to the bundled version.

- `user` indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pip`, `pipX`, and `pipX.Y` will be installed (where X.Y stands for the current version of Python).

If `altinstall` is set, then `pip` and `pipX` will not be installed.

If `default_pip` is set to `False`, then `pip` will not be installed.

Setting both `altinstall` and `default_pip` will trigger `ValueError`.

`verbosity` controls the level of output to `sys.stdout` from the bootstrapping operation.
**Note:** The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

**Note:** The bootstrapping process may install additional modules required by `pip`, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of `pip`).
28. Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

- **28.1. `sys`** — System-specific parameters and functions
- **28.2. `sysconfig`** — Provide access to Python's configuration information
  - 28.2.1. Configuration variables
  - 28.2.2. Installation paths
  - 28.2.3. Other functions
- **28.3. `__builtin__`** — Built-in objects
- **28.4. `future_builtins`** — Python 3 builtins
- **28.5. `__main__`** — Top-level script environment
- **28.6. `warnings`** — Warning control
  - 28.6.1. Warning Categories
  - 28.6.2. The Warnings Filter
    - 28.6.2.1. Default Warning Filters
  - 28.6.3. Temporarily Suppressing Warnings
  - 28.6.4. Testing Warnings
  - 28.6.5. Updating Code For New Versions of Python
  - 28.6.6. Available Functions
  - 28.6.7. Available Context Managers
- **28.7. `contextlib`** — Utilities for with-statement contexts
- **28.8. `abc`** — Abstract Base Classes
- **28.9. `atexit`** — Exit handlers
  - 28.9.1. `atexit` Example
- **28.10. `traceback`** — Print or retrieve a stack traceback
  - 28.10.1. Traceback Examples
- **28.11. `__future__`** — Future statement definitions
- **28.12. `gc`** — Garbage Collector interface
• 28.13. inspect — Inspect live objects
  o 28.13.1. Types and members
  o 28.13.2. Retrieving source code
  o 28.13.3. Classes and functions
  o 28.13.4. The interpreter stack
• 28.14. site — Site-specific configuration hook
• 28.15. user — User-specific configuration hook
• 28.16. fpectl — Floating point exception control
  o 28.16.1. Example
  o 28.16.2. Limitations and other considerations
This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

**sys.argv**

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `-c`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the `fileinput` module.

**sys.byteorder**

An indicator of the native byte order. This will have the value 'big' on big-endian (most-significant byte first) platforms, and 'little' on little-endian (least-significant byte first) platforms.

*New in version 2.0.*

**sys.builtin_module_names**

A tuple of strings giving the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way — `modules.keys()` only lists the imported modules.)

**sys.call_tracing(func, args)**

Call `func(*args)`, while tracing is enabled. The tracing state is
saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug some other code.

sys.\texttt{copyright}
A string containing the copyright pertaining to the Python interpreter.

sys.\texttt{\_clear\_type\_cache()}
Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function \texttt{only} to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

\textit{New in version 2.6.}

sys.\texttt{\_current\_frames()}
Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the \texttt{traceback} module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

\textit{New in version 2.5.}
**sys.dllhandle**

Integer specifying the handle of the Python DLL. Availability: Windows.

**sys.displayhook(value)**

If `value` is not `None`, this function prints it to `sys.stdout`, and saves it in `__builtin__.__displayhook__`.

`sys.displayhook` is called on the result of evaluating an expression entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

**sys.dont_write_bytecode**

If this is true, Python won’t try to write `.pyc` or `.pyo` files on the import of source modules. This value is initially set to `True` or `False` depending on the `-B` command line option and the `PYTHONDONTRCWRITEBYTECODE` environment variable, but you can set it yourself to control bytecode file generation.

*New in version 2.6.*

**sys.excepthook(type, value, traceback)**

This function prints out a given traceback and exception to `sys.stderr`.

When an exception is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

**sys.__displayhook__**
**sys.__excepthook__**

These objects contain the original values of `displayhook` and `excepthook` at the start of the program. They are saved so that `displayhook` and `excepthook` can be restored in case they happen to get replaced with broken objects.

**sys.exc_info()**

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, “handling an exception” is defined as “executing or having executed an except clause.” For any stack frame, only information about the most recently handled exception is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three `None` values is returned. Otherwise, the values returned are `(type, value, traceback)`. Their meaning is: *type* gets the exception type of the exception being handled (a class object); *value* gets the exception parameter (its associated value or the second argument to `raise`, which is always a class instance if the exception type is a class object); *traceback* gets a traceback object (see the Reference Manual) which encapsulates the call stack at the point where the exception originally occurred.

If `exc_clear()` is called, this function will return three `None` values until either another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

**Warning:** Assigning the *traceback* return value to a local
variable in a function that is handling an exception will cause a circular reference. This will prevent anything referenced by a local variable in the same function or by the traceback from being garbage collected. Since most functions don't need access to the traceback, the best solution is to use something like `exctype, value = sys.exc_info()[:2]` to extract only the exception type and value. If you do need the traceback, make sure to delete it after use (best done with a `try ... finally` statement) or to call `exc_info()` in a function that does not itself handle an exception.

**Note:** Beginning with Python 2.2, such cycles are automatically reclaimed when garbage collection is enabled and they become unreachable, but it remains more efficient to avoid creating cycles.

```python
sys.exc_clear()
```

This function clears all information relating to the current or last exception that occurred in the current thread. After calling this function, `exc_info()` will return three `None` values until another exception is raised in the current thread or the execution stack returns to a frame where another exception is being handled.

This function is only needed in only a few obscure situations. These include logging and error handling systems that report information on the last or current exception. This function can also be used to try to free resources and trigger object finalization, though no guarantee is made as to what objects will be freed, if any.

*New in version 2.3.*

```python
sys.exc_type
sys.exc_value
sys.exc_traceback
```
Deprecated since version 1.5: Use `exc_info()` instead.

Since they are global variables, they are not specific to the current thread, so their use is not safe in a multi-threaded program. When no exception is being handled, `exc_type` is set to `None` and the other two are undefined.

**sys.exec_prefix**

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the `configure` script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example 2.7.

**sys.executable**

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, `sys.executable` will be an empty string or `None`.

**sys.exit([arg])**

Exit from Python. This is implemented by raising the `SystemExit` exception, so cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

The optional argument `arg` can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and
the like. Most systems require it to be in the range 0–127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, None is equivalent to passing zero, and any other object is printed to stderr and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately “only" raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted.

**sys.exitfunc**

This value is not actually defined by the module, but can be set by the user (or by a program) to specify a clean-up action at program exit. When set, it should be a parameterless function. This function will be called when the interpreter exits. Only one function may be installed in this way; to allow multiple functions which will be called at termination, use the `atexit` module.

**Note:** The exit function is not called when the program is killed by a signal, when a Python fatal internal error is detected, or when `os._exit()` is called.

*Deprecated since version 2.4:* Use `atexit` instead.

**sys.flags**

The struct sequence `flags` exposes the status of command line flags. The attributes are read only.

<table>
<thead>
<tr>
<th>attribute</th>
<th>flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>-d</td>
</tr>
</tbody>
</table>
New in version 2.6.

New in version 2.7.3: The hash_randomization attribute.

sys. `float_info`
A structseq holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the ‘C’ programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], ‘Characteristics of floating types’, for details.

</tr>
</tbody>
</table>

The attribute `sys.float_info.dig` needs further explanation. If \( s \) is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting \( s \) to a float
and back again will recover a string representing the same decimal value:

```python
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'  # decimal string with 15 significant digits
>>> format(float(s), '.15g')  # convert to float and back ->
'3.14159265358979'
```

But for strings with more than `sys.float_info.dig` significant digits, this isn’t always true:

```python
>>> s = '9876543211234567'  # 16 significant digits is too many!
>>> format(float(s), '.16g')  # conversion changes value
'9876543211234568'
```

*New in version 2.6.*

**sys.float_repr_style**

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 2.7 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 2.7.

*New in version 2.7.*

**sys.getcheckinterval()**

Return the interpreter’s “check interval”; see `setcheckinterval()`.

*New in version 2.3.*

**sys.getdefaultencoding()**

Return the name of the current default string encoding used by
the Unicode implementation.

*New in version 2.0.*

c**sys. getdlopenflags()**
Return the current value of the flags that are used for `dlopen()` calls. The flag constants are defined in the `dl` and `DLFCN` modules. Availability: Unix.

*New in version 2.2.*

c**sys. getfilesystemencoding()**
Return the name of the encoding used to convert Unicode filenames into system file names, or `None` if the system default encoding is used. The result value depends on the operating system:

- On Mac OS X, the encoding is `'utf-8'`.
- On Unix, the encoding is the user’s preference according to the result of `nl_langinfo(CODESET)`, or `None` if the `nl_langinfo(CODESET)` failed.
- On Windows NT+, file names are Unicode natively, so no conversion is performed. `getfilesystemencoding()` still returns `'mbcs'`, as this is the encoding that applications should use when they explicitly want to convert Unicode strings to byte strings that are equivalent when used as file names.
- On Windows 9x, the encoding is `'mbcs'`.

*New in version 2.3.*

c**sys. getrefcount(object)**
Return the reference count of the object. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to `getrefcount()`.
sys.\texttt{getrecursionlimit()}  
Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by \texttt{setrecursionlimit()}.  

sys.\texttt{getsizeof}(\texttt{object[, default]})  
Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.  

If given, \texttt{default} will be returned if the object does not provide means to retrieve the size. Otherwise a \texttt{TypeError} will be raised.  

\texttt{getsizeof()} calls the object's \texttt{\_\_sizeof\_} method and adds an additional garbage collector overhead if the object is managed by the garbage collector.  

\textit{New in version 2.6.}  

sys.\texttt{\_\_getframe\_(\texttt{depth})}  
Return a frame object from the call stack. If optional integer \texttt{depth} is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, \texttt{ValueError} is raised. The default for \texttt{depth} is zero, returning the frame at the top of the call stack.  

\textbf{CPython implementation detail:} This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.  

sys.\texttt{getprofile()}
Get the profiler function as set by `setprofile()`.

*New in version 2.6.*

**sys.gettrace()**

Get the trace function as set by `settrace()`.

**CPython implementation detail:** The `gettrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

*New in version 2.6.*

**sys.getwindowsversion()**

Return a named tuple describing the Windows version currently running. The named elements are `major`, `minor`, `build`, `platform`, `service_pack`, `service_pack_minor`, `service_pack_major`, `suite_mask`, and `product_type`. `service_pack` contains a string while all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

`platform` may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (VER_PLATFORM_WIN32s)</td>
<td>Win32s on Windows 3.1</td>
</tr>
<tr>
<td>1 (VER_PLATFORM_WIN32_WINDOWS)</td>
<td>Windows 95/98/ME</td>
</tr>
<tr>
<td>2 (VER_PLATFORM_WIN32_NT)</td>
<td>Windows NT/2000/XP/x64</td>
</tr>
<tr>
<td>3 (VER_PLATFORM_WIN32_CE)</td>
<td>Windows CE</td>
</tr>
</tbody>
</table>
*product_type* may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (VER_NT_WORKSTATION)</td>
<td>The system is a workstation.</td>
</tr>
<tr>
<td>2 (VER_NT_DOMAIN_CONTROLLER)</td>
<td>The system is a domain controller.</td>
</tr>
<tr>
<td>3 (VER_NT_SERVER)</td>
<td>The system is a server, but not a domain controller.</td>
</tr>
</tbody>
</table>

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

Availability: Windows.

*New in version 2.3.*

*Changed in version 2.7:* Changed to a named tuple and added `service_pack_minor`, `service_pack_major`, `suite_mask`, and `product_type`.

**sys.hexversion**

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```python
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The `version_info` value may be used for a more
human-friendly encoding of the same information.

The `hexversion` is a 32-bit number with the following layout:

<table>
<thead>
<tr>
<th>Bits (big endian order)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-8</td>
<td><code>PY_MAJOR_VERSION</code> (the 2 in 2.1.0a3)</td>
</tr>
<tr>
<td>9-16</td>
<td><code>PY_MINOR_VERSION</code> (the 1 in 2.1.0a3)</td>
</tr>
<tr>
<td>17-24</td>
<td><code>PY_MICRO_VERSION</code> (the 0 in 2.1.0a3)</td>
</tr>
<tr>
<td>25-28</td>
<td><code>PY_RELEASE_LEVEL</code> (0xA for alpha, 0xB for beta, 0xC for release candidate and 0xF for final)</td>
</tr>
<tr>
<td>29-32</td>
<td><code>PY_RELEASE_SERIAL</code> (the 3 in 2.1.0a3, zero for final releases)</td>
</tr>
</tbody>
</table>

Thus 2.1.0a3 is hexversion 0x020100a3.

**New in version 1.5.2.**

`sys.long_info`

A struct sequence that holds information about Python's internal representation of integers. The attributes are read only.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bits_per_digit</code></td>
<td>number of bits held in each digit. Python integers are stored internally in base $2^{\text{long_info.bits_per_digit}}$</td>
</tr>
<tr>
<td><code>sizeof_digit</code></td>
<td>size in bytes of the C type used to represent a digit</td>
</tr>
</tbody>
</table>

**New in version 2.7.**

`sys.last_type`
`sys.last_value`
`sys.last_traceback`

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error
message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is import pdb; pdb.pm() to enter the post-mortem debugger; see chapter pdb — The Python Debugger for more information.)

The meaning of the variables is the same as that of the return values from exc_info() above. (Since there is only one interactive thread, thread-safety is not a concern for these variables, unlike for exc_type etc.)

**sys.maxint**

The largest positive integer supported by Python’s regular integer type. This is at least 2**31-1. The largest negative integer is -\text{maxint-1} — the asymmetry results from the use of 2's complement binary arithmetic.

**sys.maxsize**

The largest positive integer supported by the platform’s Py_ssize_t type, and thus the maximum size lists, strings, dicts, and many other containers can have.

**sys.maxunicode**

An integer giving the largest supported code point for a Unicode character. The value of this depends on the configuration option that specifies whether Unicode characters are stored as UCS-2 or UCS-4.

**sys.meta_path**

A list of finder objects that have their find_module() methods called to see if one of the objects can find the module to be imported. The find_module() method is called at least with the absolute name of the module being imported. If the module to be imported is contained in package then the parent package's
__path__ attribute is passed in as a second argument. The method returns None if the module cannot be found, else returns a loader.

sys.meta_path is searched before any implicit default finders or sys.path.

See PEP 302 for the original specification.

sys.modules
This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. Note that removing a module from this dictionary is not the same as calling reload() on the corresponding module object.

sys.path
A list of strings that specifies the search path for modules. Initialized from the environment variable PYTHONPATH, plus an installation-dependent default.

As initialized upon program startup, the first item of this list, path[0], is the directory containing the script that was used to invoke the Python interpreter. If the script directory is not available (e.g. if the interpreter is invoked interactively or if the script is read from standard input), path[0] is the empty string, which directs Python to search modules in the current directory first. Notice that the script directory is inserted before the entries inserted as a result of PYTHONPATH.

A program is free to modify this list for its own purposes.

Changed in version 2.3: Unicode strings are no longer ignored.

See also: Module site This describes how to use .pth files to
extend sys.path.

sys. **path_hooks**
A list of callables that take a path argument to try to create a finder for the path. If a finder can be created, it is to be returned by the callable, else raise ImportError.

Originally specified in **PEP 302**.

sys. **path_importer_cache**
A dictionary acting as a cache for finder objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no explicit finder is found on `sys.path_hooks` then `None` is stored to represent the implicit default finder should be used. If the path is not an existing path then `imp.NullImporter` is set.

Originally specified in **PEP 302**.

sys. **platform**
This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For most Unix systems, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```python
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
```

*Changed in version 2.7.3*: Since lots of code check for `sys.platform == 'linux2'`, and there is no essential change
between Linux 2.x and 3.x, `sys.platform` is always set to 'linux2', even on Linux 3.x. In Python 3.3 and later, the value will always be set to 'linux', so it is recommended to always use the `startswith` idiom presented above.

For other systems, the values are:

<table>
<thead>
<tr>
<th>System</th>
<th>Platform value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux (2.x and 3.x)</td>
<td>'linux2'</td>
</tr>
<tr>
<td>Windows</td>
<td>'win32'</td>
</tr>
<tr>
<td>Windows/Cygwin</td>
<td>'cygwin'</td>
</tr>
<tr>
<td>Mac OS X</td>
<td>'darwin'</td>
</tr>
<tr>
<td>OS/2</td>
<td>'os2'</td>
</tr>
<tr>
<td>OS/2 EMX</td>
<td>'os2emx'</td>
</tr>
<tr>
<td>RiscOS</td>
<td>'riscos'</td>
</tr>
<tr>
<td>AtheOS</td>
<td>'atheos'</td>
</tr>
</tbody>
</table>

See also: `os.name` has a coarser granularity. `os.uname()` gives system-dependent version information. The `platform` module provides detailed checks for the system's identity.

**sys.prefix**

A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string '/usr/local'. This can be set at build time with the `--prefix` argument to the `configure` script. The main collection of Python library modules is installed in the directory `prefix/lib/pythonX.Y` while the platform independent header files (all except `pyconfig.h`) are stored in `prefix/include/pythonX.Y`, where `X.Y` is the version number of Python, for example 2.7.

**sys.ps1**
**sys.ps2**

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are '>>> ' and '. . . '. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

**sys.py3kwarning**

Bool containing the status of the Python 3 warning flag. It’s `True` when Python is started with the `-3` option. (This should be considered read-only; setting it to a different value doesn't have an effect on Python 3 warnings.)

*New in version 2.6.*

**sys.setcheckinterval(interval)**

Set the interpreter’s “check interval”. This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is `100`, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value `<= 0` checks every virtual instruction, maximizing responsiveness as well as overhead.

**sys.setdefaultencoding(name)**

Set the current default string encoding used by the Unicode implementation. If `name` does not match any available encoding, `LookupError` is raised. This function is only intended to be used by the `site` module implementation and, where needed, by `sitecustomize`. Once used by the `site` module, it is removed from the `sys` module’s namespace.
New in version 2.0.

sys.setdlopenflags(n)
Set the flags used by the interpreter for dlopen() calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as sys.setdlopenflags(0). To share symbols across extension modules, call as sys.setdlopenflags(dl.RTLD_NOW | dl.RTLD_GLOBAL). Symbolic names for the flag modules can be either found in the dl module, or in the DLFCN module. If DLFCN is not available, it can be generated from /usr/include/dlfcn.h using the h2py script. Availability: Unix.

New in version 2.2.

sys.setprofile(profilefunc)
Set the system’s profile function, which allows you to implement a Python source code profiler in Python. See chapter The Python Profilers for more information on the Python profiler. The system’s profile function is called similarly to the system’s trace function (see settrace()), but it isn’t called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return None.

sys.setrecursionlimit(limit)
Set the maximum depth of the Python interpreter stack to limit. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.
The highest possible limit is platform-dependent. A user may need to set the limit higher when she has a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

```
import sys
sys.settrace(tracefunc)
```

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must be registered using `sys.settrace()` for each thread being debugged.

Trace functions should have three arguments: `frame`, `event`, and `arg`. `frame` is the current stack frame. `event` is a string: 'call', 'line', 'return', 'exception', 'c_call', 'c_return', or 'c_exception'. `arg` depends on the event type.

The trace function is invoked (with `event` set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used that scope, or `None` if the scope shouldn’t be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or `None` to turn off tracing in that scope.

The events have the following meaning:

`'call'`

A function is called (or some other code block entered). The global trace function is called; `arg` is `None`; the return value specifies the local trace function.

`'line'`

The interpreter is about to execute a new line of code or re-
execute the condition of a loop. The local trace function is called; *arg* is *None*; the return value specifies the new local trace function. See [Objects/lnotab_notes.txt](#) for a detailed explanation of how this works.

```
'return'
```

A function (or other code block) is about to return. The local trace function is called; *arg* is the value that will be returned, or *None* if the event is caused by an exception being raised. The trace function's return value is ignored.

```
'exception'
```

An exception has occurred. The local trace function is called; *arg* is a tuple (exception, value, traceback); the return value specifies the new local trace function.

```
'c_call'
```

A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

```
'c_return'
```

A C function has returned. *arg* is the C function object.

```
'c_exception'
```

A C function has raised an exception. *arg* is the C function object.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more information on code and frame objects, refer to [The standard type hierarchy](#).

**CPython implementation detail:** The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus
sys.setscdump(on_flag)

Activate dumping of VM measurements using the Pentium timestamp counter, if `on_flag` is true. Deactivate these dumps if `on_flag` is off. The function is available only if Python was compiled with `--with-tsc`. To understand the output of this dump, read `Python/ceval.c` in the Python sources.

*New in version 2.4.*

**CPython implementation detail:** This function is intimately bound to CPython implementation details and thus not likely to be implemented elsewhere.

sys.stdin
sys.stdout
sys.stderr

File objects corresponding to the interpreter’s standard input, output and error streams. `stdin` is used for all interpreter input except for scripts but including calls to `input()` and `raw_input()`. `stdout` is used for the output of `print` and `expression` statements and for the prompts of `input()` and `raw_input()`. The interpreter’s own prompts and (almost all of) its error messages go to `stderr`. `stdout` and `stderr` needn’t be built-in file objects: any object is acceptable as long as it has a `write()` method that takes a string argument. (Changing these objects doesn’t affect the standard I/O streams of processes executed by `os.popen()`, `os.system()` or the `exec*()` family of functions in the `os` module.)

sys.__stdin__
sys.__stdout__
sys.__stderr__
These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

`sys.subversion`

A triple (repo, branch, version) representing the Subversion information of the Python interpreter. `repo` is the name of the repository, `CPython`. `branch` is a string of one of the forms 'trunk', 'branches/name' or 'tags/name'. `version` is the output of `svnversion`, if the interpreter was built from a Subversion checkout; it contains the revision number (range) and possibly a trailing ‘M’ if there were local modifications. If the tree was exported (or `svnversion` was not available), it is the revision of `Include/patchlevel.h` if the branch is a tag. Otherwise, it is `None`.

New in version 2.5.

**Note:** Python is now developed using Mercurial. In recent Python 2.7 bugfix releases, `subversion` therefore contains placeholder information. It is removed in Python 3.3.

`sys.tracebacklimit`

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is `1000`. When set to `0` or less, all traceback information is suppressed and only the exception type and value are printed.
sys. **version**

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use **version_info** and the functions provided by the **platform** module.

sys. **api_version**

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

*New in version 2.3.*

sys. **version_info**

A tuple containing the five components of the version number: **major**, **minor**, **micro**, **releaselevel**, and **serial**. All values except **releaselevel** are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The **version_info** value corresponding to the Python version 2.0 is (2, 0, 0, 'final', 0). The components can also be accessed by name, so **sys.version_info[0]** is equivalent to **sys.version_info.major** and so on.

*New in version 2.0.*

*Changed in version 2.7*: Added named component attributes

sys. **warnoptions**

This is an implementation detail of the warnings framework; do not modify this value. Refer to the **warnings** module for more information on the warnings framework.

sys. **winver**

The version number used to form registry keys on Windows
platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of `version`. It is provided in the `sys` module for informational purposes; modifying this value has no effect on the registry keys used by Python. Availability: Windows.

**Citations**

28.2. sysconfig — Provide access to Python’s configuration information

*New in version 2.7.*

**Source code:** Lib/sysconfig.py

The `sysconfig` module provides access to Python’s configuration information like the list of installation paths and the configuration variables relevant for the current platform.
28.2.1. Configuration variables

A Python distribution contains a Makefile and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `distutils`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it’s a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable `name`. Equivalent to `get_config_vars().get(name)`.

If `name` is not found, return `None`.

Example of usage:

```python
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```
28.2.2. Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`.

Every new component that is installed using `distutils` or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports seven schemes:

- `posix_prefix`: scheme for Posix platforms like Linux or Mac OS X. This is the default scheme used when Python or a component is installed.
- `posix_home`: scheme for Posix platforms used when a `home` option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- `posix_user`: scheme for Posix platforms used when a component is installed through Distutils and the `user` option is used. This scheme defines paths located under the user home directory.
- `nt`: scheme for NT platforms like Windows.
- `nt_user`: scheme for NT platforms, when the `user` option is used.
- `os2`: scheme for OS/2 platforms.
- `os2_home`: scheme for OS/2 platforms, when the `user` option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- `stdlib`: directory containing the standard Python library files that
are not platform-specific.
- `platstdlib`: directory containing the standard Python library files that are platform-specific.
- `platlib`: directory for site-specific, platform-specific files.
- `purelib`: directory for site-specific, non-platform-specific files.
- `include`: directory for non-platform-specific header files.
- `platininclude`: directory for platform-specific header files.
- `scripts`: directory for script files.
- `data`: directory for data files.

`sysconfig` provides some functions to determine these paths.

`sysconfig.get_scheme_names()`
Return a tuple containing all schemes currently supported in `sysconfig`.

`sysconfig.get_path_names()`
Return a tuple containing all path names currently supported in `sysconfig`.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`  
Return an installation path corresponding to the path `name`, from the install scheme named `scheme`.

`name` has to be a value from the list returned by `get_path_names()`.

`sysconfig` stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the `stdlib` path for the `nt` scheme is: `{base}/Lib`.

`get_path()` will use the variables returned by `get_config_vars()` to expand the path. All variables have default values for each platform so one may call this function and get the default value.
If `scheme` is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary return by `get_config_vars()`.

If `expand` is set to `False`, the path will not be expanded using the variables.

If `name` is not found, return `None`.

```python
sysconfig.get_paths([scheme[, vars[, expand]]])
```

Return a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If `scheme` is not provided, will use the default scheme for the current platform.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If `expand` is set to false, the paths will not be expanded.

If `scheme` is not an existing scheme, `get_paths()` will raise a `KeyError`.
28.2.3. Other functions

sysconfig.\texttt{get\_python\_version()}

Return the \texttt{MAJOR.MINOR} Python version number as a string. Similar to \texttt{sys.version[:3]}.

sysconfig.\texttt{get\_platform()}

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by \texttt{os.uname()}), although the exact information included depends on the OS; e.g. for IRIX the architecture isn’t particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn’t particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u
- irix-5.3
- irix64-6.2

Windows will return one of:

- win-amd64 (64bit Windows on AMD64 (aka x86_64, Intel64, EM64T, etc)
- win-ia64 (64bit Windows on Itanium)
- win32 (all others - specifically, \texttt{sys.platform} is returned)

Mac OS X can return:

- macosx-10.6-ppc
macosx-10.4-ppc64
macosx-10.3-i386
macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`  
Return `True` if the current Python installation was built from source.

`sysconfig.parse_config_h(fp[, vars])`  
Parse a `config.h`-style file.

`fp` is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`  
Return the path of `pyconfig.h`.

`sysconfig.get_makefile_filename()`  
Return the path of `Makefile`. 
28.3. __builtin__ — Built-in objects

This module provides direct access to all ‘built-in’ identifiers of Python; for example, __builtin__.open is the full name for the built-in function open(). See Built-in Functions and Built-in Constants for documentation.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an open() function that wraps the built-in open(), this module can be used directly:

```python
import __builtin__

def open(path):
    f = __builtin__.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

# ...
```

**CPython implementation detail:** Most modules have the name __builtins__ (note the 's') made available as part of their globals. The value of __builtins__ is normally either this module or the value of this module's __dict__ attribute. Since this is an implementation detail, it may not be used by alternate
implementations of Python.
28.4. future_builtins — Python 3 builtins

New in version 2.6.

This module provides functions that exist in 2.x, but have different behavior in Python 3, so they cannot be put into the 2.x builtins namespace.

Instead, if you want to write code compatible with Python 3 builtins, import them from this module, like this:

```python
from future_builtins import map, filter
... code using Python 3-style map and filter ...
```

The 2to3 tool that ports Python 2 code to Python 3 will recognize this usage and leave the new builtins alone.

**Note:** The Python 3 `print()` function is already in the builtins, but cannot be accessed from Python 2 code unless you use the appropriate future statement:

```python
from __future__ import print_function
```

Available builtins are:

```python
future_builtins.ascii(object)
```

Returns the same as `repr()`. In Python 3, `repr()` will return printable Unicode characters unescaped, while `ascii()` will always backslash-escape them. Using `future_builtins.ascii()` instead of `repr()` in 2.6 code makes it clear that you need a pure ASCII return value.
**future_builtins.** **filter**(*function*, *iterable*)

Works like `itertools.ifilter()`.

**future_builtins.** **hex**(*object*)

Works like the built-in `hex()`, but instead of `__hex__()` it will use the `__index__()` method on its argument to get an integer that is then converted to hexadecimal.

**future_builtins.** **map**(*function*, *iterable*, ...)  

Works like `itertools.imap()`.

**Note:** In Python 3, `map()` does not accept `None` for the function argument.

**future_builtins.** **oct**(*object*)

Works like the built-in `oct()`, but instead of `__oct__()` it will use the `__index__()` method on its argument to get an integer that is then converted to octal.

**future_builtins.** **zip**(*iterables*)

Works like `itertools.izip()`.
28.5. __main__ — Top-level script environment

This module represents the (otherwise anonymous) scope in which the interpreter's main program executes — commands read either from standard input, from a script file, or from an interactive prompt. It is this environment in which the idiomatic “conditional script” stanza causes a script to run:

```python
if __name__ == "__main__":
    main()
```
Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn’t warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see Exception Handling for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category (see below), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.
The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

**See also:** `logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.
28.6.1. Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings. The following warnings category classes are currently defined:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>This is the base class of all warning category classes. It is a subclass of Exception.</td>
</tr>
<tr>
<td>UserWarning</td>
<td>The default category for <code>warn()</code>.</td>
</tr>
<tr>
<td>DeprecationWarning</td>
<td>Base category for warnings about deprecated features (ignored by default).</td>
</tr>
<tr>
<td>SyntaxWarning</td>
<td>Base category for warnings about dubious syntactic features.</td>
</tr>
<tr>
<td>RuntimeWarning</td>
<td>Base category for warnings about dubious runtime features.</td>
</tr>
<tr>
<td>FutureWarning</td>
<td>Base category for warnings about constructs that will change semantically in the future.</td>
</tr>
<tr>
<td>PendingDeprecationWarning</td>
<td>Base category for warnings about features that will be deprecated in the future (ignored by default).</td>
</tr>
<tr>
<td>ImportWarning</td>
<td>Base category for warnings triggered during the process of importing a module (ignored by default).</td>
</tr>
<tr>
<td>UnicodeWarning</td>
<td>Base category for warnings related to Unicode.</td>
</tr>
</tbody>
</table>

While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.
User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.

*Changed in version 2.7:* `DeprecationWarning` is ignored by default.
28.6.2. The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the match determines the disposition of the match. Each entry is a tuple of the form \((\text{action}, \text{message}, \text{category}, \text{module}, \text{lineno})\), where:

- \textit{action} is one of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Disposition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;error&quot;</td>
<td>turn matching warnings into exceptions</td>
</tr>
<tr>
<td>&quot;ignore&quot;</td>
<td>never print matching warnings</td>
</tr>
<tr>
<td>&quot;always&quot;</td>
<td>always print matching warnings</td>
</tr>
<tr>
<td>&quot;default&quot;</td>
<td>print the first occurrence of matching warnings for each location where the warning is issued</td>
</tr>
<tr>
<td>&quot;module&quot;</td>
<td>print the first occurrence of matching warnings for each module where the warning is issued</td>
</tr>
<tr>
<td>&quot;once&quot;</td>
<td>print only the first occurrence of matching warnings, regardless of location</td>
</tr>
</tbody>
</table>

- \textit{message} is a string containing a regular expression that the start of the warning message must match. The expression is compiled to always be case-insensitive.

- \textit{category} is a class (a subclass of \texttt{Warning}) of which the warning category must be a subclass in order to match.

- \textit{module} is a string containing a regular expression that the module name must match. The expression is compiled to be case-sensitive.
• \textit{lineno} is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the \texttt{Warning} class is derived from the built-in \texttt{Exception} class, to turn a warning into an error we simply raise \texttt{category(message)}.

The warnings filter is initialized by \texttt{-w} options passed to the Python interpreter command line. The interpreter saves the arguments for all \texttt{-w} options without interpretation in \texttt{sys.warnoptions}; the \texttt{warnings} module parses these when it is first imported (invalid options are ignored, after printing a message to \texttt{sys.stderr}).

\textbf{28.6.2.1. Default Warning Filters}

By default, Python installs several warning filters, which can be overridden by the command-line options passed to \texttt{-w} and calls to \texttt{filterwarnings()}.

• \texttt{DeprecationWarning} and \texttt{PendingDeprecationWarning}, and \texttt{ImportWarning} are ignored.
• \texttt{BytesWarning} is ignored unless the \texttt{-b} option is given once or twice; in this case this warning is either printed (\texttt{-b}) or turned into an exception (\texttt{-bb}).
28.6.3. Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning, then it is possible to suppress the warning using the \texttt{catch\_warnings} context manager:

\begin{verbatim}
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
\end{verbatim}

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the \texttt{catch\_warnings} context manager at the same time, the behavior is undefined.
28.6.4. Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```python
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert issubclass(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.
When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).
28.6.5. Updating Code For New Versions of Python

Warnings that are only of interest to the developer are ignored by default. As such you should make sure to test your code with typically ignored warnings made visible. You can do this from the command-line by passing `-wd` to the interpreter (this is shorthand for `-W default`). This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you simply change what argument is passed to `-W`, e.g. `-W error`. See the `-W` flag for more details on what is possible.

To programmatically do the same as `-wd`, use:

```python
warnings.simplefilter('default')
```

Make sure to execute this code as soon as possible. This prevents the registering of what warnings have been raised from unexpectedly influencing how future warnings are treated.

Having certain warnings ignored by default is done to prevent a user from seeing warnings that are only of interest to the developer. As you do not necessarily have control over what interpreter a user uses to run their code, it is possible that a new version of Python will be released between your release cycles. The new interpreter release could trigger new warnings in your code that were not there in an older interpreter, e.g. `DeprecationWarning` for a module that you are using. While you as a developer want to be notified that your code is using a deprecated module, to a user this information is essentially noise and provides no benefit to them.
28.6.6. Available Functions

```
warnings.warn(message[, category[, stacklevel]])
```

Issue a warning, or maybe ignore it or raise an exception. The `category` argument, if given, must be a warning category class (see above); it defaults to `UserWarning`. Alternatively `message` can be a `Warning` instance, in which case `category` will be ignored and `message.__class__` will be used. In this case the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the warnings filter see above. The `stacklevel` argument can be used by wrapper functions written in Python, like this:

```
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecation()`'s caller, rather than to the source of `deprecation()` itself (since the latter would defeat the purpose of the warning message).

```
warnings.warnExplicit(message, category, filename, lineno[, module[, registry[, module_globals]]]])
```

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. `message` must be a string and `category` a subclass of `Warning` or `message` may be a `Warning` instance, in which case `category` will be ignored.
module_globals, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

*Changed in version 2.5:* Added the module_globals parameter.

```
warnings.warnpy3k(message[, category[, stacklevel]])
```

Issue a warning related to Python 3.x deprecation. Warnings are only shown when Python is started with the -3 option. Like `warn()` `message` must be a string and `category` a subclass of `Warning`. `warnpy3k()` is using `DeprecationWarning` as default warning class.

*New in version 2.6.*

```
warnings.showwarning(message, category, filename, lineno[, file[, line]])
```

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to `file`, which defaults to `sys.stderr`. You may replace this function with an alternative implementation by assigning to `warnings.showwarning`. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `showwarning()` will try to read the line specified by `filename` and `lineno`.

*Changed in version 2.7:* The `line` argument is required to be supported.

```
warnings.formatwarning(message, category, filename, lineno[, line])
```

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. `line` is a
line of source code to be included in the warning message; if line is not supplied, `formatwarning()` will try to read the line specified by `filename` and `lineno`.

*Changed in version 2.6:* Added the `line` argument.

```python
warnings.filterwarnings(action[, message[, category[, module[, lineno[, append]]]]])
```

Insert an entry into the list of `warnings` filter specifications. The entry is inserted at the front by default; if `append` is true, it is inserted at the end. This checks the types of the arguments, compiles the `message` and `module` regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

```python
warnings.simplefilter(action[, category[, lineno[, append]]])
```

Insert a simple entry into the list of `warnings` filter specifications. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

```python
warnings.resetwarnings()
```

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.
28.6.7. Available Context Managers

```python
class warnings.catch_warnings([*, record=False, module=None])
```

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the `record` argument is `False` (the default) the context manager returns `None` on entry. If `record` is `True`, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The `module` argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

**Note:** The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

**Note:** In Python 3, the arguments to the constructor for `catch_warnings` are keyword-only arguments.

*New in version 2.6.*
28.7. contextlib — Utilities for with-statement contexts

*New in version 2.5.*

**Source code:** Lib/contextlib.py

This module provides utilities for common tasks involving the `with` statement. For more information see also Context Manager Types and With Statement Context Managers.

**Functions provided:**

```python
contextlib.contextmanager(func)
```

This function is a decorator that can be used to define a factory function for `with` statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

A simple example (this is not recommended as a real way of generating HTML!):

```
from contextlib import contextmanager

@contextmanager
def tag(name):
    print "<%s>" % name
    yield
    print "</%s>" % name

>>> with tag("h1"):
...    print "foo"
...
<h1>foo</h1>
```
The function being decorated must return a generator-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the with statement's as clause, if any.

At the point where the generator yields, the block nested in the with statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a try...except...finally statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the with statement that the exception has been handled, and execution will resume with the statement immediately following the with statement.

```
contextlib.nested(mgr1[, mgr2[, ...]])
```

Combine multiple context managers into a single nested context manager.

This function has been deprecated in favour of the multiple manager form of the with statement.

The one advantage of this function over the multiple manager form of the with statement is that argument unpacking allows it to be used with a variable number of context managers as follows:

```
from contextlib import nested

with nested(*managers):
    do_something()
```

Note that if the __exit__() method of one of the nested context managers indicates an exception should be suppressed, no
exception information will be passed to any remaining outer context managers. Similarly, if the \_exit\_() method of one of the nested managers raises an exception, any previous exception state will be lost; the new exception will be passed to the \_exit\_() methods of any remaining outer context managers. In general, \_exit\_() methods should avoid raising exceptions, and in particular they should not re-raise a passed-in exception.

This function has two major quirks that have led to it being deprecated. Firstly, as the context managers are all constructed before the function is invoked, the \_new\_() and \_init\_() methods of the inner context managers are not actually covered by the scope of the outer context managers. That means, for example, that using nested() to open two files is a programming error as the first file will not be closed promptly if an exception is thrown when opening the second file.

Secondly, if the \_enter\_() method of one of the inner context managers raises an exception that is caught and suppressed by the \_exit\_() method of one of the outer context managers, this construct will raise RuntimeError rather than skipping the body of the with statement.

Developers that need to support nesting of a variable number of context managers can either use the warnings module to suppress the DeprecationWarning raised by this function or else use this function as a model for an application specific implementation.

**Deprecated since version 2.7:** The with-statement now supports this functionality directly (without the confusing error prone quirks).
contextlib.closing(thing)

Return a context manager that closes thing upon completion of the block. This is basically equivalent to:

```python
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()
```

And lets you write code like this:

```python
from contextlib import closing
import urllib

with closing(urllib.urlopen('http://www.python.org')) as page:
    for line in page:
        print line
```

without needing to explicitly close page. Even if an error occurs, page.close() will be called when the with block is exited.

PEP 343 - The “with” statement

The specification, background, and examples for the Python with statement.
New in version 2.6.

Source code: Lib/abc.py

This module provides the infrastructure for defining abstract base classes (ABCs) in Python, as outlined in PEP 3119; see the PEP for why this was added to Python. (See also PEP 3141 and the numbers module regarding a type hierarchy for numbers based on ABCs.)

The collections module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition the collections module has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, is it hashable or a mapping.

This module provides the following class:

class abc. ABCMeta

Metaclass for defining Abstract Base Classes (ABCs).

Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as “virtual subclasses” – these and their descendants will be considered subclasses of the registering ABC by the built-in issubclass() function, but the registering ABC won’t show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via super()). [1]

Classes created with a metaclass of ABCMeta have the following
method:

**register(subclass)**

Register *subclass* as a “virtual subclass” of this ABC. For example:

```python
from abc import ABCMeta
class MyABC:
    __metaclass__ = ABCMeta
MyABC.register(tuple)
assertissubclass(tuple, MyABC)
assertissubclass((), MyABC)
```

You can also override this method in an abstract base class:

**__subclasshook__(subclass)**

(Must be defined as a class method.)

Check whether *subclass* is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the **__subclasscheck__()** method of the ABC.)

This method should return **True, False** or **NotImplemented**. If it returns **True**, the *subclass* is considered a subclass of this ABC. If it returns **False**, the *subclass* is not considered a subclass of this ABC, even if it would normally be one. If it returns **NotImplemented**, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:
The ABC `MyIterable` defines the standard iterable method, `__iter__()`, as an abstract method. The implementation given here can still be called from subclasses. The `get_iterator()` method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`,
even though it does not define an \_\texttt{iter\_}(()) method (it uses the old-style iterable protocol, defined in terms of \_\texttt{len\_}(()) and \_\texttt{getitem\_}(())). Note that this will not make \texttt{get\_iterator} available as a method of \texttt{Foo}, so it is provided separately.

It also provides the following decorators:

\begin{description}
\item [abc.\texttt{abstractmethod}(\textit{function})] A decorator indicating abstract methods.
\end{description}

Using this decorator requires that the class’s metaclass is \texttt{ABCMeta} or is derived from it. A class that has a metaclass derived from \texttt{ABCMeta} cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal ‘super’ call mechanisms.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are not supported. The \texttt{abstractmethod()} only affects subclasses derived using regular inheritance; “virtual subclasses” registered with the ABC’s \texttt{register()} method are not affected.

Usage:

\begin{python}
class \texttt{C}:
    \_\texttt{metaclass\_} = ABCMeta
@abstractmethod
    def \texttt{my\_abstract\_method}(\texttt{self}, \ldots):
        ...
\end{python}

\textbf{Note:} Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the \texttt{super()} mechanism from the class that overrides it. This could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.
abc.abstractproperty([fget[, fset[, fdel[, doc]]]])

A subclass of the built-in property(), indicating an abstract property.

Using this function requires that the class’s metaclass is ABCMeta or is derived from it. A class that has a metaclass derived from ABCMeta cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract properties can be called using any of the normal ‘super’ call mechanisms.

Usage:

class C:
    __metaclass__ = ABCMeta
    @abstractproperty
def my_abstract_property(self):
        ...

This defines a read-only property; you can also define a read-write abstract property using the ‘long’ form of property declaration:

class C:
    __metaclass__ = ABCMeta
def getx(self): ...
def setx(self, value): ...
x = abstractproperty(getx, setx)

Footnotes

[1] C++ programmers should note that Python’s virtual base class concept is not the same as C++’s.
28.9. `atexit` — Exit handlers

New in version 2.0.

**Source code:** Lib/atexit.py

The `atexit` module defines a single function to register cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the reverse order in which they were registered; if you register `A`, `B`, and `C`, at interpreter termination time they will be run in the order `C`, `B`, `A`.

**Note:** The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

This is an alternate interface to the functionality provided by the `sys.exitfunc()` variable.

**Note:** This module is unlikely to work correctly when used with other code that sets `sys.exitfunc`. In particular, other core Python modules are free to use `atexit` without the programmer's knowledge. Authors who use `sys.exitfunc` should convert their code to use `atexit` instead. The simplest way to convert code that sets `sys.exitfunc` is to import `atexit` and register the function that had been bound to `sys.exitfunc`.

```python
atexit.register(func[, *args[, **kargs]])
```

Register `func` as a function to be executed at termination. Any optional arguments that are to be passed to `func` must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.
At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run the last exception to be raised is re-raised.

*Changed in version 2.6:* This function now returns `func`, which makes it possible to use it as a decorator.

---

**See also:**

**Module** `readline`

Useful example of `atexit` to read and write `readline` history files.
28.9.1. atexit Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter's updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```python
try:
    _count = int(open("counter").read())
except IOError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    open("counter", "w").write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```python
def goodbye(name, adjective):
    print 'Goodbye, %s, it was %s to meet you.' % (name, adjective)

import atexit
atexit.register(goodbye, 'Donny', 'nice')

# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Usage as a `decorator`: 
import atexit

@atexit.register
def goodbye():
    print "You are now leaving the Python sector."

This only works with functions that can be called without arguments.
This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects — this is the object type that is stored in the variables `sys.exc_traceback` (deprecated) and `sys.last_traceback` and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

`traceback.print_tb(tb[, limit[, file]])`
Print up to `limit` stack trace entries from the traceback object `tb`. If `limit` is omitted or `None`, all entries are printed. If `file` is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

`traceback.print_exception(etype, value, tb[, limit[, file]])`
Print exception information and up to `limit` stack trace entries from the traceback `tb` to `file`. This differs from `print_tb()` in the following ways: (1) if `tb` is not `None`, it prints a header `Traceback (most recent call last)`:; (2) it prints the exception `etype` and `value` after the stack trace; (3) if `etype` is `SyntaxError` and `value` has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.
traceback.\texttt{print}._\texttt{exc}([\texttt{limit}[, \texttt{file}]]]

This is a shorthand for \texttt{print}._\texttt{exception(sys.exc_type, sys.exc_value, sys.exc_traceback, limit, file)}. (In fact, it uses \texttt{sys.exc_info()} to retrieve the same information in a thread-safe way instead of using the deprecated variables.)

traceback.\texttt{format}._\texttt{exc}([\texttt{limit}])

This is like \texttt{print}._\texttt{exc(limit)} but returns a string instead of printing to a file.

\textit{New in version 2.4.}

traceback.\texttt{print}._\texttt{last}([\texttt{limit}[, \texttt{file}]]]

This is a shorthand for \texttt{print}._\texttt{exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file)}. In general it will work only after an exception has reached an interactive prompt (see \texttt{sys.last_type}).

traceback.\texttt{print}._\texttt{stack}([\texttt{f}[, \texttt{limit}[, \texttt{file}]]]

This function prints a stack trace from its invocation point. The optional \texttt{f} argument can be used to specify an alternate stack frame to start. The optional \texttt{limit} and \texttt{file} arguments have the same meaning as for \texttt{print}._\texttt{exception}.

traceback.\texttt{extract}._\texttt{tb}(\texttt{tb}[, \texttt{limit}])

Return a list of up to \texttt{limit} “pre-processed” stack trace entries extracted from the traceback object \texttt{tb}. It is useful for alternate formatting of stack traces. If \texttt{limit} is omitted or \texttt{None}, all entries are extracted. A “pre-processed” stack trace entry is a 4-tuple (\texttt{filename}, \texttt{line number}, function name*, \texttt{text}) representing the information that is usually printed for a stack trace. The \texttt{text} is a string with leading and trailing whitespace stripped; if the source
is not available it is None.

```
traceback.extract_stack([f, limit])
```

Extract the raw traceback from the current stack frame. The return value has the same format as for `extract_tb()`. The optional `f` and `limit` arguments have the same meaning as for `print_stack()`.

```
traceback.format_list(extracted_list)
```

Given a list of tuples as returned by `extract_tb()` or `extract_stack()`, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not None.

```
traceback.format_exception_only(etype, value)
```

Format the exception part of a traceback. The arguments are the exception type, `etype` and `value` such as given by `sys.last_type` and `sys.last_value`. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for `SyntaxError` exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

```
traceback.format_exception(etype, value, tb[[], limit])
```

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.
traceback.format_tb(tb[, limit])

A shorthand for \texttt{format_list(extract_tb(tb, limit))}.

traceback.format_stack([f[, limit]])

A shorthand for \texttt{format_list(extract_stack(f, limit))}.

traceback.tb_lineno(tb)

This function returns the current line number set in the traceback object. This function was necessary because in versions of Python prior to 2.3 when the \texttt{-o} flag was passed to Python the \texttt{tb.tb_lineno} was not updated correctly. This function has no use in versions past 2.3.
28.10.1. Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the code module.

```python
import sys, traceback

def run_user_code(envdir):
    source = raw_input(">>> ")
    try:
        exec source in envdir
    except:
        print "Exception in user code:"
        print '-'*60
        traceback.print_exc(file=sys.stdout)
        print '-'*60

envdir = {}
while 1:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```python
import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
    print "*** print_tb:"
    traceback.print_tb(exc_traceback, limit=1, file=sys.stdout)
    print "*** print_exception:"
The output for the example would look similar to this:

```python
print "*** print_tb:
    File "<doctest...>", line 10, in <module>
        lumberjack()
*** print_exception:
Traceback (most recent call last):
File "<doctest...>", line 10, in <module>
    lumberjack()
File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):
File "<doctest...>", line 10, in <module>
    lumberjack()
File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
*** format_exc, first and last line:
[Traceback (most recent call last):
    File "<doctest...>", line 10, in <module>
    lumberjack()
    File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
    File "<doctest...>", line 7, in bright_side_of_death
    return tuple()[0]
IndexError: tuple index out of range]
```
The following example shows the different ways to print and format the stack:

```python
>>> import traceback
>>> def another_function():
...    lumberstack()
...
>>> def lumberstack():
...    traceback.print_stack()
...    print repr(traceback.extract_stack())
...    print repr(traceback.format_stack())
...
>>> another_function()
  File "<doctest>", line 10, in another_function
  File "<doctest>", line 3, in another_function
      lumberstack()
  File "<doctest>", line 6, in lumberstack
      traceback.print_stack()

[('doctest...', 10, 'lumberjack()'),
 ('doctest...', 4, 'lumberjack', 'bright_side_of_death()'),
 ('doctest...', 7, 'bright_side_of_death', 'return tuple()[0]

This last example demonstrates the final few formatting functions:

```
```python
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range
']
```
28.11. __future__ — Future statement definitions

Source code: Lib/__future__.py

__future__ is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they’re importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of __future__ will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing __future__ and examining its contents.

Each statement in __future__.py is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease, CompilerFlag)
```

where, normally, OptionalRelease is less than MandatoryRelease, and both are 5-tuples of the same form as sys.version_info:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; a string
 PY_RELEASE_SERIAL # the 3; an int
)
```
OptionalRelease records the first release in which the feature was accepted.

In the case of a MandatoryRelease that has not yet occurred, MandatoryRelease predicts the release in which the feature will become part of the language.

Else MandatoryRelease records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

MandatoryRelease may also be None, meaning that a planned feature got dropped.

Instances of class _Feature have two corresponding methods, getOptionalRelease() and getMandatoryRelease().

CompilerFlag is the (bitfield) flag that should be passed in the fourth argument to the built-in function compile() to enable the feature in dynamically compiled code. This flag is stored in the compiler_flag attribute on _Feature instances.

No feature description will ever be deleted from __future__. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

<table>
<thead>
<tr>
<th>feature</th>
<th>optional in</th>
<th>mandatory in</th>
<th>effect</th>
</tr>

**Future statements**

How the compiler treats future imports.
28.12. gc — Garbage Collector Interface

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

`gc.enable()`  
Enable automatic garbage collection.

`gc.disable()`  
Disable automatic garbage collection.

`gc.isenabled()`  
Returns true if automatic collection is enabled.

`gc.collect([generation])`  
With no arguments, run a full collection. The optional argument `generation` may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is invalid. The number of unreachable objects found is returned.
*Changed in version 2.5:* The optional *generation* argument was added.

*Changed in version 2.6:* The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular *int* and *float*.

```
> gc.set_debug(flags)
Set the garbage collection debugging flags. Debugging information will be written to *sys.stderr*. See below for a list of debugging flags which can be combined using bit operations to control debugging.

> gc.get_debug()
Return the debugging flags currently set.

> gc.get_objects()
Returns a list of all objects tracked by the collector, excluding the list returned.

*New in version 2.2.*

> gc.set_threshold(threshold0[, threshold1[, threshold2]])
Set the garbage collection thresholds (the collection frequency). Setting *threshold0* to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object
allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds \(threshold0\), collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than \(threshold1\) times since generation 1 has been examined, then generation 1 is examined as well. Similarly, \(threshold2\) controls the number of collections of generation 1 before collecting generation 2.

\[
\text{gc.} \, \text{get\_count()}
\]

Return the current collection counts as a tuple of \((\text{count0}, \text{count1}, \text{count2})\).

*New in version 2.5.*

\[
\text{gc.} \, \text{get\_threshold()}
\]

Return the current collection thresholds as a tuple of \((\text{threshold0}, \text{threshold1}, \text{threshold2})\).

\[
\text{gc.} \, \text{get\_referrers(*objs)}
\]

Return the list of objects that directly refer to any of objs. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call \text{collect()} before calling \text{get\_referrers()}.

Care must be taken when using objects returned by \text{get\_referrers()} because some of them could still be under construction and hence in a temporarily invalid state. Avoid using
get_referrers() for any purpose other than debugging.

New in version 2.2.

gc.get_referents(*objs)
Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level tp_traverse methods (if any), and may not be all objects actually directly reachable. tp_traverse methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

New in version 2.3.

gc.is_tracked(obj)
Returns True if the object is currently tracked by the garbage collector, False otherwise. As a general rule, instances of atomic types aren't tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):

```python
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```
The following variable is provided for read-only access (you can mutate its value but should not rebind it):

\texttt{gc.garbage}

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). By default, this list contains only objects with \texttt{__del__() methods}. [1] Objects that have \texttt{__del__() methods} and are part of a reference cycle cause the entire reference cycle to be uncollectable, including objects not necessarily in the cycle but reachable only from it. Python doesn’t collect such cycles automatically because, in general, it isn’t possible for Python to guess a safe order in which to run the \texttt{__del__() methods}. If you know a safe order, you can force the issue by examining the \texttt{garbage list}, and explicitly breaking cycles due to your objects within the list. Note that these objects are kept alive even so by virtue of being in the \texttt{garbage list}, so they should be removed from \texttt{garbage} too. For example, after breaking cycles, do \texttt{del gc.garbage[:]} to empty the list. It’s generally better to avoid the issue by not creating cycles containing objects with \texttt{__del__() methods}, and \texttt{garbage} can be examined in that case to verify that no such cycles are being created.

If \texttt{DEBUG_SAVEALL} is set, then all unreachable objects will be added to this list rather than freed.

The following constants are provided for use with \texttt{set_debug()}:

\texttt{gc.DEBUG_STATS}

Print statistics during collection. This information can be useful when tuning the collection frequency.
gc. **DEBUG_COLLECTABLE**
Print information on collectable objects found.

gc. **DEBUG_UNCOLLECTABLE**
Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the garbage list.

gc. **DEBUG_INSTANCES**
When **DEBUG_COLLECTABLE** or **DEBUG_UNCOLLECTABLE** is set, print information about instance objects found.

gc. **DEBUG_OBJECTS**
When **DEBUG_COLLECTABLE** or **DEBUG_UNCOLLECTABLE** is set, print information about objects other than instance objects found.

gc. **DEBUG_SAVEALL**
When set, all unreachable objects found will be appended to garbage rather than being freed. This can be useful for debugging a leaking program.

gc. **DEBUG_LEAK**
The debugging flags necessary for the collector to print information about a leaking program (equal to **DEBUG_COLLECTABLE** | **DEBUG_UNCOLLECTABLE** | **DEBUG_INSTANCES** | **DEBUG_OBJECTS** | **DEBUG_SAVEALL**).

Footnotes

[1] Prior to Python 2.2, the list contained all instance objects in unreachable cycles, not only those with `__del__()` methods.
28.13. inspect — Inspect live objects

New in version 2.1.

Source code: Lib/inspect.py

The inspect module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.
28.13.1. Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The sixteen functions whose names begin with “is” are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes:

<table>
<thead>
<tr>
<th>Type</th>
<th>Attribute</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>

</tbody>
</table>

Note:

1. Changed in version 2.2: `im_class` used to refer to the class that defined the method.

**inspect.getmembers**(object[, predicate])

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional predicate argument is supplied, only members for which the predicate returns a true value are included.

**Note:**  `getmembers()` does not return metaclass attributes when the argument is a class (this behavior is inherited from the `dir()` function).

**inspect.getmoduleinfo**(path)

Return a tuple of values that describe how Python will interpret the file identified by path if it is a module, or None if it would not be identified as a module. The return tuple is (name, suffix, mode, module_type), where name is the name of the module without the name of any enclosing package, suffix is the trailing part of the
file name (which may not be a dot-delimited extension), mode is the open() mode that would be used ('r' or 'rb'), and module_type is an integer giving the type of the module. module_type will have a value which can be compared to the constants defined in the imp module; see the documentation for that module for more information on module types.

*Changed in version 2.6:* Returns a named tuple ModuleInfo(name, suffix, mode, module_type).

inspect.getmodulename(path)
Return the name of the module named by the file path, without including the names of enclosing packages. This uses the same algorithm as the interpreter uses when searching for modules. If the name cannot be matched according to the interpreter’s rules, None is returned.

inspect.ismodule(object)
Return true if the object is a module.

inspect.isclass(object)
Return true if the object is a class, whether built-in or created in Python code.

inspect.ismethod(object)
Return true if the object is a bound or unbound method written in Python.

inspect.isfunction(object)
Return true if the object is a Python function, which includes functions created by a lambda expression.

inspect.isgeneratorfunction(object)
Return true if the object is a Python generator function.
New in version 2.6.

inspect.**isgenerator**(object)
    Return true if the object is a generator.

New in version 2.6.

inspect.**istraceback**(object)
    Return true if the object is a traceback.

inspect.**isframe**(object)
    Return true if the object is a frame.

inspect.**iscode**(object)
    Return true if the object is a code.

inspect.**isbuiltin**(object)
    Return true if the object is a built-in function or a bound built-in method.

inspect.**isroutine**(object)
    Return true if the object is a user-defined or built-in function or method.

inspect.**isabstract**(object)
    Return true if the object is an abstract base class.

New in version 2.6.

inspect.**ismethoddescriptor**(object)
    Return true if the object is a method descriptor, but not if
    `ismethod()`, `isclass()`, `isfunction()` or `isbuiltin()` are true.

This is new as of Python 2.2, and, for example, is true of
`int.__add__`. An object passing this test has a `__get__()` method
but not a `__set__()` method, but beyond that the set of attributes
A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return false from the `ismethoddescriptor()` test, simply because the other tests promise more – you can, e.g., count on having the `im_func` attribute (etc) when an object passes `ismethod()`.

`inspect.isdatadescriptor(object)`
Return true if the object is a data descriptor.

Data descriptors have both a `__get__` and a `__set__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

_New in version 2.3._

`inspect.isgetsetdescriptor(object)`
Return true if the object is a getset descriptor.

_CPython implementation detail:_ getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return `False`.

_New in version 2.5._

`inspect.ismemberdescriptor(object)`
Return true if the object is a member descriptor.

**CPython implementation detail:** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return `False`.

*New in version 2.5.*
28.13.2. Retrieving source code

**inspect.getdoc**(object)
Get the documentation string for an object, cleaned up with cleandoc().

**inspect.getcomments**(object)
Return in a single string any lines of comments immediately preceding the object’s source code (for a class, function, or method), or at the top of the Python source file (if the object is a module).

**inspect.getfile**(object)
Return the name of the (text or binary) file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

**inspect.getmodule**(object)
Try to guess which module an object was defined in.

**inspect.getsourcefile**(object)
Return the name of the Python source file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

**inspect.getsourcelines**(object)
Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An IOError is raised if the source code cannot be retrieved.
**inspect.** `getsourc`e(*object*)

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An `IOError` is raised if the source code cannot be retrieved.

**inspect.** `cleandoc`(*doc*)

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

*New in version 2.6.*
28.13.3. Classes and functions

inspect.getclasstree(classes[, unique])

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the unique argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

inspect.getargspec(func)

Get the names and default values of a Python function's arguments. A tuple of four things is returned: (args, varargs, keywords, defaults). args is a list of the argument names (it may contain nested lists). varargs and keywords are the names of the * and ** arguments or None. defaults is a tuple of default argument values or None if there are no default arguments; if this tuple has n elements, they correspond to the last n elements listed in args.

Changed in version 2.6: Returns a named tuple ArgSpec(args, varargs, keywords, defaults).

inspect.getargvalues(frame)

Get information about arguments passed into a particular frame. A tuple of four things is returned: (args, varargs, keywords, locals). args is a list of the argument names (it may contain nested lists). varargs and keywords are the names of the * and ** arguments or None. locals is the locals dictionary of the given frame.
Changed in version 2.6: Returns a named tuple `ArgInfo(args, varargs, keywords, locals).

`inspect.formatargspec(args[, varargs, varkw, defaults, formatarg, formatvarargs, formatvarkw, formatvalue, join])`

Format a pretty argument spec from the four values returned by `getargspec()`. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

`inspect.formatargvalues(args[, varargs, varkw, locals, formatarg, formatvarargs, formatvarkw, formatvalue, join])`

Format a pretty argument spec from the four values returned by `getargvalues()`. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

`inspect.getmro(cls)`

Return a tuple of class cls’s base classes, including cls, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on cls’s type. Unless a very peculiar user-defined metatype is in use, cls will be the first element of the tuple.

`inspect.getcallargs(func[, *args][, **kwds])`

Bind the `args` and `kwds` to the argument names of the Python function or method `func`, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the * and ** arguments, if any) to their values from `args` and `kwds`. In case of invoking `func` incorrectly, i.e. whenever `func(*args, **kwds)` would raise an exception because of incompatible signature, an exception of the
same type and the same or similar message is raised. For example:

```python
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
>>> getcallargs(f, 1, 2, 3)
{'a': 1, 'named': {}, 'b': 2, 'pos': (3,)}
>>> getcallargs(f, a=2, x=4)
{'a': 2, 'named': {'x': 4}, 'b': 1, 'pos': ()}
>>> getcallargs(f)
Traceback (most recent call last):
...  
TypeError: f() takes at least 1 argument (0 given)
```

*New in version 2.7.*
28.13.4. The interpreter stack

When the following functions return “frame records,” each record is a tuple of six items: the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

**Note:** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python’s optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```python
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

The optional `context` argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.
inspect.getframeinfo(frame[, context])
Get information about a frame or traceback object. A 5-tuple is returned, the last five elements of the frame's frame record.

*Changed in version 2.6:* Returns a named tuple Traceback(filename, lineno, function, code_context, index).

inspect.getouterframes(frame[, context])
Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of frame. The first entry in the returned list represents frame; the last entry represents the outermost call on frame's stack.

inspect.getinnerframes(traceback[, context])
Get a list of frame records for a traceback's frame and all inner frames. These frames represent calls made as a consequence of frame. The first entry in the list represents traceback; the last entry represents where the exception was raised.

inspect.currentframe()
Return the frame object for the caller’s stack frame.

**CPython implementation detail:** This function relies on Python stack frame support in the interpreter, which isn’t guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns None.

inspect.stack([context])
Return a list of frame records for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.
inspect.trace([context])

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.
28.14. site — Site-specific configuration hook

Source code: Lib/site.py

This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter's -s option.

Importing this module will append site-specific paths to the module search path and add a few builtins.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses sys.prefix and sys.exec_prefix; empty heads are skipped. For the tail part, it uses the empty string and then lib/site-packages (on Windows) or lib/pythonX.Y/site-packages and then lib/site-python (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to sys.path and also inspects the newly added path for configuration files.

A path configuration file is a file whose name has the form name.pth and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to sys.path. Non-existing items are never added to sys.path, and no check is made that the item refers to a directory rather than a file. No item is added to sys.path more than once. Blank lines and lines beginning with # are skipped. Lines starting with import (followed by space or tab) are executed.

Changed in version 2.6: A space or tab is now required after the
import keyword.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```python
# foo package configuration
foo
bar
bletch
```

and `bar.pth` contains:

```python
# bar package configuration
bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```python
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn’t exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the site-packages directory. If this import fails with an
**ImportError** exception, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any exception other than **ImportError** causes a silent and perhaps mysterious failure of the process.

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user site-packages directory (see below), which is part of `sys.path` unless disabled by `-s`. An **ImportError** will be silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

```
site.PREFIXES
  A list of prefixes for site-packages directories.

  New in version 2.6.
```

```
site.ENABLE_USER_SITE
  Flag showing the status of the user site-packages directory. True means that it is enabled and was added to `sys.path`. False means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). None means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

  New in version 2.6.
```

```
site.USER_SITE
Path to the user site-packages for the running Python. Can be None if `getusersitepackages()` hasn’t been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework Mac OS X builds, `~/Library/Python/X.Y/lib/python/site-packages` for Mac framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

*New in version 2.6.*

**site.USER_BASE**

Path to the base directory for the user site-packages. Can be None if `getuserbase()` hasn’t been called yet. Default value is `~/.local` for UNIX and Mac OS X non-framework builds, `~/Library/Python/X.Y` for Mac framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils to compute the installation directories for scripts, data files, Python modules, etc. for the user installation scheme. See also `PYTHONUSERBASE`.

*New in version 2.6.*

**site.addsitedir(sitedir, known_paths=None)**

Add a directory to sys.path and process its `.pth` files. Typically used in `sitecustomize` or `usercustomize` (see above).

**site.getsitepackages()**

Return a list containing all global site-packages directories (and possibly site-python).

*New in version 2.7.*

**site.getuserbase()**
Return the path of the user base directory, \texttt{USER\_BASE}. If it is not initialized yet, this function will also set it, respecting \texttt{PYTHONUSERBASE}.

\textit{New in version 2.7.}

\texttt{site.getusersitepackages()}

Return the path of the user-specific site-packages directory, \texttt{USER\_SITE}. If it is not initialized yet, this function will also set it, respecting \texttt{PYTHONNOUSERSITE} and \texttt{USER\_BASE}.

\textit{New in version 2.7.}

The \texttt{site} module also provides a way to get the user directories from the command line:

\begin{verbatim}
$ python -m site --user-site
/home/user/.local/lib/python2.7/site-packages
\end{verbatim}

If it is called without arguments, it will print the contents of \texttt{sys.path} on the standard output, followed by the value of \texttt{USER\_BASE} and whether the directory exists, then the same thing for \texttt{USER\_SITE}, and finally the value of \texttt{ENABLE\_USER\_SITE}.

\texttt{--user-base}

Print the path to the user base directory.

\texttt{--user-site}

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by \texttt{os.pathsep}.

If any option is given, the script will exit with one of these values: \texttt{0} if the user site-packages directory is enabled, \texttt{1} if it was disabled by
the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

See also: PEP 370 – Per user site-packages directory
28.15. user — User-specific configuration hook

*Deprecated since version 2.6:* The `user` module has been removed in Python 3.

As a policy, Python doesn't run user-specified code on startup of Python programs. (Only interactive sessions execute the script specified in the `PYTHONSTARTUP` environment variable if it exists).

However, some programs or sites may find it convenient to allow users to have a standard customization file, which gets run when a program requests it. This module implements such a mechanism. A program that wishes to use the mechanism must execute the statement

```
import user
```

The `user` module looks for a file `.pythonrc.py` in the user's home directory and if it can be opened, executes it (using `execfile()`) in its own (the module `user`'s) global namespace. Errors during this phase are not caught; that's up to the program that imports the `user` module, if it wishes. The home directory is assumed to be named by the `HOME` environment variable; if this is not set, the current directory is used.

The user's `.pythonrc.py` could conceivably test for `sys.version` if it wishes to do different things depending on the Python version.

A warning to users: be very conservative in what you place in your `.pythonrc.py` file. Since you don't know which programs will use it, changing the behavior of standard modules or functions is generally
not a good idea.

A suggestion for programmers who wish to use this mechanism: a simple way to let users specify options for your package is to have them define variables in their `.pythonrc.py` file that you test in your module. For example, a module `spam` that has a verbosity level can look for a variable `user.spam_verbose`, as follows:

```python
import user
verbose = bool(getattr(user, "spam_verbose", 0))
```

(The three-argument form of `getattr()` is used in case the user has not defined `spam_verbose` in their `.pythonrc.py` file.)

Programs with extensive customization needs are better off reading a program-specific customization file.

Programs with security or privacy concerns should not import this module; a user can easily break into a program by placing arbitrary code in the `.pythonrc.py` file.

Modules for general use should not import this module; it may interfere with the operation of the importing program.

**See also:**

**Module site**

Site-wide customization mechanism.
Most computers carry out floating point operations in conformance with the so-called IEEE-754 standard. On any real computer, some floating point operations produce results that cannot be expressed as a normal floating point value. For example, try

```python
>>> import math
>>> math.exp(1000)
inf
>>> math.exp(1000) / math.exp(1000)
nan
```

(The example above will work on many platforms. DEC Alpha may be one exception.) “Inf” is a special, non-numeric value in IEEE-754 that stands for “infinity”, and “nan” means “not a number.” Note that, other than the non-numeric results, nothing special happened when you asked Python to carry out those calculations. That is in fact the default behaviour prescribed in the IEEE-754 standard, and if it works for you, stop reading now.

In some circumstances, it would be better to raise an exception and stop processing at the point where the faulty operation was attempted. The `fpectl` module is for use in that situation. It provides control over floating point units from several hardware manufacturers, allowing the user to turn on the generation of `SIGFPE` whenever any of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid Operation occurs. In tandem with a pair of
wrapper macros that are inserted into the C code comprising your python system, SIGFPE is trapped and converted into the Python FloatingPointError exception.

The fpectl module defines the following functions and may raise the given exception:

fpectl.turnon_sigfpe()
   Turn on the generation of SIGFPE, and set up an appropriate signal handler.

fpectl.turnoff_sigfpe()
   Reset default handling of floating point exceptions.

exception fpectl.FloatingPointError
   After turnon_sigfpe() has been executed, a floating point operation that raises one of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid operation will in turn raise this standard Python exception.
28.16.1. Example

The following example demonstrates how to start up and test operation of the `fpectl` module.

```python
>>> import fpectl
>>> import fpetest
>>> fpectl.turnon_sigfpe()
>>> fpetest.test()
overflow    PASS
FloatingPointError: Overflow

div by 0    PASS
FloatingPointError: Division by zero

[ more output from test elided ]
```
28.16.2. Limitations and other considerations

Setting up a given processor to trap IEEE-754 floating point errors currently requires custom code on a per-architecture basis. You may have to modify `fpectl` to control your particular hardware.

Conversion of an IEEE-754 exception to a Python exception requires that the wrapper macros `PyFPE_START_PROTECT` and `PyFPE_END_PROTECT` be inserted into your code in an appropriate fashion. Python itself has been modified to support the `fpectl` module, but many other codes of interest to numerical analysts have not.

The `fpectl` module is not thread-safe.

**See also:** Some files in the source distribution may be interesting in learning more about how this module operates. The include file `Include/pyfpe.h` discusses the implementation of this module at some length. `Modules/fpetestmodule.c` gives several examples of use. Many additional examples can be found in `Objects/floatobject.c`. 
29. Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python's interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the code module. (The codeop module is lower-level, used to support compiling a possibly-incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- 29.1. code — Interpreter base classes
  - 29.1.1. Interactive Interpreter Objects
  - 29.1.2. Interactive Console Objects
- 29.2. codeop — Compile Python code
29.1. code — Interpreter base classes

The code module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

```python
class code.InteractiveInterpreter([locals])
```

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional `locals` argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key '__name__' set to '__console__' and key '__doc__' set to None.

```python
class code.InteractiveConsole([locals[, filename]])
```

Closely emulate the behavior of the interactive Python interpreter. This class builds on InteractiveInterpreter and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.

```python
code.interact([banner[, readfunc[, local]]])
```

Convenience function to run a read-eval-print loop. This creates a new instance of InteractiveConsole and sets `readfunc` to be used as the InteractiveConsole.raw_input() method, if provided. If `local` is provided, it is passed to the InteractiveConsole constructor for use as the default namespace for the interpreter loop. The interact() method of the instance is then run with `banner` passed as the banner to use, if provided. The console object is discarded after use.
code.compile_command(source[, filename[, symbol]])

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

*source* is the source string; *filename* is the optional filename from which source was read, defaulting to 'input'; and *symbol* is the optional grammar start symbol, which should be either 'single' (the default) or 'eval'.

Returns a code object (the same as compile(source, filename, symbol)) if the command is complete and valid; None if the command is incomplete; raises **SyntaxError** if the command is complete and contains a syntax error, or raises **OverflowError** or **ValueError** if the command contains an invalid literal.
29.1.1. Interactive Interpreter Objects

InteractiveInterpreter.runsource(source[, filename[, symbol]])

Compile and run some source in the interpreter. Arguments are the same as for compile_command(); the default for filename is '<input>', and for symbol is 'single'. One several things can happen:

- The input is incorrect; compile_command() raised an exception (SyntaxError or OverflowError). A syntax traceback will be printed by calling the showsyntaxerror() method. runsource() returns False.
- The input is incomplete, and more input is required; compile_command() returned None. runsource() returns True.
- The input is complete; compile_command() returned a code object. The code is executed by calling the runcode() (which also handles run-time exceptions, except for SystemExit). runsource() returns False.

The return value can be used to decide whether to use sys.ps1 or sys.ps2 to prompt the next line.

InteractiveInterpreter.runcode(code)

Execute a code object. When an exception occurs, showtraceback() is called to display a traceback. All exceptions are caught except SystemExit, which is allowed to propagate.

A note about KeyboardInterrupt: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

InteractiveInterpreter.showsyntaxerror([filename])
Display the syntax error that just occurred. This does not display a stack trace because there isn’t one for syntax errors. If `filename` is given, it is stuffed into the exception instead of the default filename provided by Python’s parser, because it always uses ‘<string>’ when reading from a string. The output is written by the `write()` method.

`InteractiveInterpreter.showtraceback()`
Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

`InteractiveInterpreter.write(data)`
Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.
29.1.2. Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact([banner])`

Closely emulate the interactive Python console. The optional banner argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it's so close!).

`InteractiveConsole.push(line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer()`

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input([prompt])`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation uses the
built-in function `raw_input()`; a subclass may replace this with a different implementation.
29.2. codeop — Compile Python code

The codeop module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the code module. As a result, you probably don’t want to use the module directly; if you want to include such a loop in your program you probably want to use the code module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print ‘>>>’ or ‘...’ next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The codeop module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

```
codeop.compile_command(source[, filename[, symbol]])
```

Tries to compile source, which should be a string of Python code and return a code object if source is valid Python code. In that case, the filename attribute of the code object will be filename, which defaults to '<input>'. Returns None if source is not valid Python code, but is a prefix of valid Python code.

If there is a problem with source, an exception will be raised. SyntaxError is raised if there is invalid Python syntax, and OverflowError or ValueError if there is an invalid literal.

The symbol argument determines whether source is compiled as
a statement ("single", the default) or as an expression ("eval"). Any other value will cause ValueError to be raised.

**Note:** It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

```python
class codeop.Compile
Instances of this class have __call__() methods identical in signature to the built-in function compile(), but with the difference that if the instance compiles program text containing a __future__ statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

class codeop.CommandCompiler
Instances of this class have __call__() methods identical in signature to compile_command(); the difference is that if the instance compiles program text containing a __future__ statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

A note on version compatibility: the Compile and CommandCompiler are new in Python 2.2. If you want to enable the future-tracking features of 2.2 but also retain compatibility with 2.1 and earlier versions of Python you can either write

```python
try:
    from codeop import CommandCompiler
    compile_command = CommandCompiler()
    del CommandCompiler
except ImportError:
    from codeop import compile_command
```
which is a low-impact change, but introduces possibly unwanted global state into your program, or you can write:

```python
try:
    from codeop import CommandCompiler
except ImportError:
    def CommandCompiler():
        from codeop import compile_command
        return compile_command
```

and then call `CommandCompiler` every time you need a fresh compiler object.
30. Restricted Execution

**Warning:** In Python 2.3 these modules have been disabled due to various known and not readily fixable security holes. The modules are still documented here to help in reading old code that uses the rexec and Bastion modules.

*Restricted execution* is the basic framework in Python that allows for the segregation of trusted and untrusted code. The framework is based on the notion that trusted Python code (a *supervisor*) can create a “padded cell’ (or environment) with limited permissions, and run the untrusted code within this cell. The untrusted code cannot break out of its cell, and can only interact with sensitive system resources through interfaces defined and managed by the trusted code. The term “restricted execution” is favored over “safe-Python” since true safety is hard to define, and is determined by the way the restricted environment is created. Note that the restricted environments can be nested, with inner cells creating subcells of lesser, but never greater, privilege.

An interesting aspect of Python’s restricted execution model is that the interfaces presented to untrusted code usually have the same names as those presented to trusted code. Therefore no special interfaces need to be learned to write code designed to run in a restricted environment. And because the exact nature of the padded cell is determined by the supervisor, different restrictions can be imposed, depending on the application. For example, it might be deemed “safe” for untrusted code to read any file within a specified directory, but never to write a file. In this case, the supervisor may redefine the built-in `open()` function so that it raises an exception whenever the *mode* parameter is `'w'`. It might also perform a `chroot()`-like operation on the *filename* parameter, such that root is always relative to some safe “sandbox” area of the filesystem. In this...
case, the untrusted code would still see a built-in `open()` function in its environment, with the same calling interface. The semantics would be identical too, with `IOError` being raised when the supervisor determined that an unallowable parameter is being used.

The Python run-time determines whether a particular code block is executing in restricted execution mode based on the identity of the `__builtins__` object in its global variables: if this is (the dictionary of) the standard `__builtin__` module, the code is deemed to be unrestricted, else it is deemed to be restricted.

Python code executing in restricted mode faces a number of limitations that are designed to prevent it from escaping from the padded cell. For instance, the function object attribute `func_globals` and the class and instance object attribute `__dict__` are unavailable.

Two modules provide the framework for setting up restricted execution environments:

- **30.1. rexec — Restricted execution framework**
  - **30.1.1. RExec Objects**
  - **30.1.2. Defining restricted environments**
  - **30.1.3. An example**
- **30.2. Bastion — Restricting access to objects**

**See also:**

**Grail Home Page**
Grail, an Internet browser written in Python, uses these modules to support Python applets. More information on the use of Python’s restricted execution mode in Grail is available on the Web site.
30.1. `rexec` — Restricted execution framework

Deprecation warning: The `rexec` module has been removed in Python 3.

Changed in version 2.3: Disabled module.

Warning: The documentation has been left in place to help in reading old code that uses the module.

This module contains the `RExec` class, which supports `r_eval()`, `r_execfile()`, `r_exec()`, and `r_import()` methods, which are restricted versions of the standard Python functions `eval()`, `execfile()` and the `exec` and `import` statements. Code executed in this restricted environment will only have access to modules and functions that are deemed safe; you can subclass `RExec` to add or remove capabilities as desired.

Warning: While the `rexec` module is designed to perform as described below, it does have a few known vulnerabilities which could be exploited by carefully written code. Thus it should not be relied upon in situations requiring "production ready" security. In such situations, execution via sub-processes or very careful "cleansing" of both code and data to be processed may be necessary. Alternatively, help in patching known `rexec` vulnerabilities would be welcomed.

Note: The `RExec` class can prevent code from performing unsafe operations like reading or writing disk files, or using TCP/IP.
sockets. However, it does not protect against code using extremely large amounts of memory or processor time.

```python
class rexec.RExec([hooks[, verbose]])
```

Returns an instance of the `RExec` class.

`hooks` is an instance of the `RHooks` class or a subclass of it. If it is omitted or `None`, the default `RHooks` class is instantiated. Whenever the `rexec` module searches for a module (even a built-in one) or reads a module's code, it doesn't actually go out to the file system itself. Rather, it calls methods of an `RHooks` instance that was passed to or created by its constructor. (Actually, the `RExec` object doesn’t make these calls — they are made by a module loader object that's part of the `RExec` object. This allows another level of flexibility, which can be useful when changing the mechanics of `import` within the restricted environment.)

By providing an alternate `RHooks` object, we can control the file system accesses made to import a module, without changing the actual algorithm that controls the order in which those accesses are made. For instance, we could substitute an `RHooks` object that passes all filesystem requests to a file server elsewhere, via some RPC mechanism such as ILU. Grail's applet loader uses this to support importing applets from a URL for a directory.

If `verbose` is true, additional debugging output may be sent to standard output.

It is important to be aware that code running in a restricted environment can still call the `sys.exit()` function. To disallow restricted code from exiting the interpreter, always protect calls that cause restricted code to run with a `try/except` statement that catches the `SystemExit` exception. Removing the `sys.exit()`
function from the restricted environment is not sufficient — the restricted code could still use `raise SystemExit`. Removing `SystemExit` is not a reasonable option; some library code makes use of this and would break were it not available.

**See also:**

**Grail Home Page**

Grail is a Web browser written entirely in Python. It uses the `reexec` module as a foundation for supporting Python applets, and can be used as an example usage of this module.
30.1.1. RExec Objects

RExec instances support the following methods:

**RExec. r_eval(code)**

*code* must either be a string containing a Python expression, or a compiled code object, which will be evaluated in the restricted environment's `__main__` module. The value of the expression or code object will be returned.

**RExec. r_exec(code)**

*code* must either be a string containing one or more lines of Python code, or a compiled code object, which will be executed in the restricted environment's `__main__` module.

**RExec. r_execfile(filename)**

Execute the Python code contained in the file *filename* in the restricted environment's `__main__` module.

Methods whose names begin with `s_` are similar to the functions beginning with `r_`, but the code will be granted access to restricted versions of the standard I/O streams `sys.stdin`, `sys.stderr`, and `sys.stdout`.

**RExec. s_eval(code)**

*code* must be a string containing a Python expression, which will be evaluated in the restricted environment.

**RExec. s_exec(code)**

*code* must be a string containing one or more lines of Python code, which will be executed in the restricted environment.

**RExec. s_execfile(code)**
Execute the Python code contained in the file `filename` in the restricted environment.

_RExec_ objects must also support various methods which will be implicitly called by code executing in the restricted environment. Overriding these methods in a subclass is used to change the policies enforced by a restricted environment.

```
RExec.r_import(modulename[, globals[, locals[, fromlist]]]])
```

Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.

```
RExec.r_open(filename[, mode[, bufsize]])
```

Method called when `open()` is called in the restricted environment. The arguments are identical to those of `open()`, and a file object (or a class instance compatible with file objects) should be returned. _RExec_'s default behaviour is allow opening any file for reading, but forbidding any attempt to write a file. See the example below for an implementation of a less restrictive `r_open()`.

```
RExec.r_reload(module)
```

Reload the module object `module`, re-parsing and re-initializing it.

```
RExec.r_unload(module)
```

Unload the module object `module` (remove it from the restricted environment's `sys.modules` dictionary).

And their equivalents with access to restricted standard I/O streams:

```
RExec.s_import(modulename[, globals[, locals[, fromlist]]]])
```

Import the module `modulename`, raising an `ImportError` exception if the module is considered unsafe.
RExec.s_reload(module)
Reload the module object \textit{module}, re-parsing and re-initializing it.

RExec.s_unload(module)
Unload the module object \textit{module}. 
30.1.2. Defining restricted environments

The `RExec` class has the following class attributes, which are used by the `__init__()` method. Changing them on an existing instance won’t have any effect; instead, create a subclass of `RExec` and assign them new values in the class definition. Instances of the new class will then use those new values. All these attributes are tuples of strings.

`RExec.nok_builtin_names`

Contains the names of built-in functions which will not be available to programs running in the restricted environment. The value for `RExec` is `('open', 'reload', '__import__')`. (This gives the exceptions, because by far the majority of built-in functions are harmless. A subclass that wants to override this variable should probably start with the value from the base class and concatenate additional forbidden functions — when new dangerous built-in functions are added to Python, they will also be added to this module.)

`RExec.ok_builtin_modules`

Contains the names of built-in modules which can be safely imported. The value for `RExec` is `('audioop', 'array', 'binascii', 'cmath', 'errno', 'imageop', 'marshal', 'math', 'md5', 'operator', 'parser', 'regex', 'select', 'sha', '_sre', 'strop', 'struct', 'time')`. A similar remark about overriding this variable applies — use the value from the base class as a starting point.

`RExec.ok_path`

Contains the directories which will be searched when an `import` is performed in the restricted environment. The value for `RExec` is the same as `sys.path` (at the time the module is loaded) for
unrestricted code.

**RExec. ok_posix_names**

Contains the names of the functions in the *os* module which will be available to programs running in the restricted environment. The value for *RExec* is ('error', 'fstat', 'listdir', 'lstat', 'readlink', 'stat', 'times', 'uname', 'getpid', 'getppid', 'getcwd', 'getuid', 'getgid', 'geteuid', 'getegid').

**RExec. ok_sys_names**

Contains the names of the functions and variables in the *sys* module which will be available to programs running in the restricted environment. The value for *RExec* is ('ps1', 'ps2', 'copyright', 'version', 'platform', 'exit', 'maxint').

**RExec. ok_file_types**

Contains the file types from which modules are allowed to be loaded. Each file type is an integer constant defined in the *imp* module. The meaningful values are *PY_SOURCE*, *PY_COMPILED*, and *C_EXTENSION*. The value for *RExec* is (*C_EXTENSION*, *PY_SOURCE*). Adding *PY_COMPILED* in subclasses is not recommended; an attacker could exit the restricted execution mode by putting a forged byte-compiled file (*.pyc*) anywhere in your file system, for example by writing it to */tmp* or uploading it to the */incoming* directory of your public FTP server.
30.1.3. An example

Let us say that we want a slightly more relaxed policy than the standard \texttt{RExec} class. For example, if we're willing to allow files in \texttt{/tmp} to be written, we can subclass the \texttt{RExec} class:

```python
class TmpWriterRExec(rexec.RExec):
    def r_open(self, file, mode='r', buf=-1):
        if mode in ('r', 'rb'):
            pass
        elif mode in ('w', 'wb', 'a', 'ab'):
            # check filename: must begin with /tmp/
            if file[5:]!='/tmp/':
                raise IOError("can't write outside /tmp")
            elif string.find(file, '/../') >= 0 or
            file[3:] == '/../' or file[-3:] == '/../':
                raise IOError("'..' in filename forbidden")
        else:
            raise IOError("Illegal open() mode")
        return open(file, mode, buf)
```

Notice that the above code will occasionally forbid a perfectly valid filename; for example, code in the restricted environment won't be able to open a file called \texttt{/tmp/foo/../bar}. To fix this, the \texttt{r_open()} method would have to simplify the filename to \texttt{/tmp/bar}, which would require splitting apart the filename and performing various operations on it. In cases where security is at stake, it may be preferable to write simple code which is sometimes overly restrictive, instead of more general code that is also more complex and may harbor a subtle security hole.
30.2. Bastion — Restricting access to objects

*Deprecated since version 2.6:* The `Bastion` module has been removed in Python 3.

*Changed in version 2.3:* Disabled module.

**Note:** The documentation has been left in place to help in reading old code that uses the module.

According to the dictionary, a bastion is “a fortified area or position”, or “something that is considered a stronghold.” It’s a suitable name for this module, which provides a way to forbid access to certain attributes of an object. It must always be used with the `reexec` module, in order to allow restricted-mode programs access to certain safe attributes of an object, while denying access to other, unsafe attributes.

```
Bastion.Bastion(object[, filter[, name[, class]]])
```

Protect the object `object`, returning a bastion for the object. Any attempt to access one of the object’s attributes will have to be approved by the `filter` function; if the access is denied an `AttributeError` exception will be raised.

If present, `filter` must be a function that accepts a string containing an attribute name, and returns true if access to that attribute will be permitted; if `filter` returns false, the access is denied. The default filter denies access to any function beginning with an underscore (`'_'`). The bastion’s string representation will be `<Bastion for name>` if a value for `name` is provided; otherwise,
repr(object) will be used.

class, if present, should be a subclass of BastionClass; see the code in bastion.py for the details. Overriding the default BastionClass will rarely be required.

class Bastion. BastionClass(getfunc, name)
Class which actually implements bastion objects. This is the default class used by Bastion(). The getfunc parameter is a function which returns the value of an attribute which should be exposed to the restricted execution environment when called with the name of the attribute as the only parameter. name is used to construct the repr() of the BastionClass instance.
31. Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- 31.1. imp — Access the import internals
  - 31.1.1. Examples
- 31.2. importlib — Convenience wrappers for __import__()  
- 31.3. imputil — Import utilities  
  - 31.3.1. Examples
- 31.4. zipimport — Import modules from Zip archives  
  - 31.4.1. zipimporter Objects  
  - 31.4.2. Examples
- 31.5. pkgutil — Package extension utility
- 31.6. modulefinder — Find modules used by a script 
  - 31.6.1. Example usage of ModuleFinder
- 31.7. runpy — Locating and executing Python modules
31.1. imp — Access the import internals

This module provides an interface to the mechanisms used to implement the import statement. It defines the following constants and functions:

imp.get_magic()
Return the magic string value used to recognize byte-compiled code files (.pyc files). (This value may be different for each Python version.)

imp.get_suffixes()
Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form (suffix, mode, type), where suffix is a string to be appended to the module name to form the filename to search for, mode is the mode string to pass to the built-in open() function to open the file (this can be 'r' for text files or 'rb' for binary files), and type is the file type, which has one of the values PY_SOURCE, PY_COMPILED, or C_EXTENSION, described below.

imp.find_module(name[, path])
Try to find the module name. If path is omitted or None, the list of directory names given by sys.path is searched, but first a few special places are searched: the function tries to find a built-in module with the given name (C_BUILTIN), then a frozen module (PY_FROZEN), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).

Otherwise, path must be a list of directory names; each directory
is searched for files with any of the suffixes returned by
get_suffixes() above. Invalid names in the list are silently
ignored (but all list items must be strings).

If search is successful, the return value is a 3-element tuple
(file, pathname, description):

file is an open file object positioned at the beginning, pathname is
the pathname of the file found, and description is a 3-element
tuple as contained in the list returned by get_suffixes()
describing the kind of module found.

If the module does not live in a file, the returned file is None,
pathname is the empty string, and the description tuple contains
empty strings for its suffix and mode; the module type is indicated
as given in parentheses above. If the search is unsuccessful,
ImportError is raised. Other exceptions indicate problems with
the arguments or environment.

If the module is a package, file is None, pathname is the package
path and the last item in the description tuple is PKG_DIRECTORY.

This function does not handle hierarchical module names (names
containing dots). In order to find P.M, that is, submodule M of
package P, use find_module() and load_module() to find and
load package P, and then use find_module() with the path
argument set to P.__path__. When P itself has a dotted name,
apply this recipe recursively.

```python
import load_module

load_module(name, file, pathname, description)
```

Load a module that was previously found by find_module() (or by
an otherwise conducted search yielding compatible results). This
function does more than importing the module: if the module was
already imported, it is equivalent to a reload()! The name
argument indicates the full module name (including the package name, if this is a submodule of a package). The file argument is an open file, and pathname is the corresponding file name; these can be None and '', respectively, when the module is a package or not being loaded from a file. The description argument is a tuple, as would be returned by get_suffixes(), describing what kind of module must be loaded.

If the load is successful, the return value is the module object; otherwise, an exception (usually ImportError) is raised.

**Important:** the caller is responsible for closing the file argument, if it was not None, even when an exception is raised. This is best done using a try ... finally statement.

```python
imp.new_module(name)
```

Return a new empty module object called name. This object is not inserted in sys.modules.

```python
imp.lock_held()
```

Return True if the import lock is currently held, else False. On platforms without threads, always return False.

On platforms with threads, a thread executing an import holds an internal lock until the import is complete. This lock blocks other threads from doing an import until the original import completes, which in turn prevents other threads from seeing incomplete module objects constructed by the original thread while in the process of completing its import (and the imports, if any, triggered by that).

```python
imp.acquire_lock()
```

Acquire the interpreter’s import lock for the current thread. This lock should be used by import hooks to ensure thread-safety
when importing modules.

Once a thread has acquired the import lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

*New in version 2.3.*

**imp.** `release_lock()`

Release the interpreter’s import lock. On platforms without threads, this function does nothing.

*New in version 2.3.*

The following constants with integer values, defined in this module, are used to indicate the search result of `find_module()`.

**imp.** `PY_SOURCE`

The module was found as a source file.

**imp.** `PY_COMPILED`

The module was found as a compiled code object file.

**imp.** `C_EXTENSION`

The module was found as a dynamically loadable shared library.

**imp.** `PKG_DIRECTORY`

The module was found as a package directory.

**imp.** `C_BUILTIN`

The module was found as a built-in module.

**imp.** `PY_FROZEN`

The module was found as a frozen module (see `init_frozen()`).
The following constant and functions are obsolete; their functionality is available through \texttt{find\_module()} or \texttt{load\_module()}. They are kept around for backward compatibility:

\texttt{imp.\nm SEARCH\_ERROR}

Unused.

\texttt{imp.\nin\_builtin(name)\n}

Initialize the built-in module called \textit{name} and return its module object along with storing it in \texttt{sys.modules}. If the module was already initialized, it will be initialized again. Re-initialization involves the copying of the built-in module's \texttt{\_dict\_} from the cached module over the module's entry in \texttt{sys.modules}. If there is no built-in module called \textit{name}, \texttt{None} is returned.

\texttt{imp.\nin\_frozen(name)\n}

Initialize the frozen module called \textit{name} and return its module object. If the module was already initialized, it will be initialized again. If there is no frozen module called \textit{name}, \texttt{None} is returned. (Frozen modules are modules written in Python whose compiled byte-code object is incorporated into a custom-built Python interpreter by Python's \texttt{freeze} utility. See \texttt{Tools/freeze/} for now.)

\texttt{imp.\nis\_builtin(name)\n}

Return 1 if there is a built-in module called \textit{name} which can be initialized again. Return -1 if there is a built-in module called \textit{name} which cannot be initialized again (see \texttt{init\_builtin()}). Return 0 if there is no built-in module called \textit{name}.

\texttt{imp.\nis\_frozen(name)\n}

Return \texttt{True} if there is a frozen module (see \texttt{init\_frozen()}) called \textit{name}, or \texttt{False} if there is no such module.

\texttt{imp.\nload\_compiled(name, pathname\[, file])\n}
Load and initialize a module implemented as a byte-compiled code file and return its module object. If the module was already initialized, it will be initialized again. The name argument is used to create or access a module object. The pathname argument points to the byte-compiled code file. The file argument is the byte-compiled code file, open for reading in binary mode, from the beginning. It must currently be a real file object, not a user-defined class emulating a file.

```python
imp.load_dynamic(name, pathname[, file])
```

Load and initialize a module implemented as a dynamically loadable shared library and return its module object. If the module was already initialized, it will be initialized again. Re-initialization involves copying the `__dict__` attribute of the cached instance of the module over the value used in the module cached in `sys.modules`. The pathname argument must point to the shared library. The name argument is used to construct the name of the initialization function: an external C function called `initname()` in the shared library is called. The optional file argument is ignored. (Note: using shared libraries is highly system dependent, and not all systems support it.)

**CPython implementation detail:** The import internals identify extension modules by filename, so doing `foo = load_dynamic("foo", "mod.so")` and `bar = load_dynamic("bar", "mod.so")` will result in both foo and bar referring to the same module, regardless of whether or not `mod.so` exports an `initbar` function. On systems which support them, symlinks can be used to import multiple modules from the same shared library, as each reference to the module will use a different file name.
imp. **load_source**(name, pathname[, file])

Load and initialize a module implemented as a Python source file and return its module object. If the module was already initialized, it will be initialized again. The *name* argument is used to create or access a module object. The *pathname* argument points to the source file. The *file* argument is the source file, open for reading as text, from the beginning. It must currently be a real file object, not a user-defined class emulating a file. Note that if a properly matching byte-compiled file (with suffix .pyc or .pyo) exists, it will be used instead of parsing the given source file.

**class imp. NullImporter(path_string)**

The **NullImporter** type is a PEP 302 import hook that handles non-directory path strings by failing to find any modules. Calling this type with an existing directory or empty string raises **ImportError**. Otherwise, a **NullImporter** instance is returned.

Python adds instances of this type to **sys.path_importer_cache** for any path entries that are not directories and are not handled by any other path hooks on **sys.path_hooks**. Instances have only one method:

**find_module**(fullname[, path])

This method always returns **None**, indicating that the requested module could not be found.

*New in version 2.5.*
31.1.1. Examples

The following function emulates what was the standard import statement up to Python 1.4 (no hierarchical module names). (This implementation wouldn't work in that version, since `find_module()` has been extended and `load_module()` has been added in 1.4.)

```python
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist=None):
    # Fast path: see if the module has already been imported.
    try:
        return sys.modules[name]
    except KeyError:
        pass

    # If any of the following calls raises an exception,
    # there's a problem we can't handle -- let the caller handle it.
    fp, pathname, description = imp.find_module(name)

    try:
        return imp.load_module(name, fp, pathname, description)
    finally:
        # Since we may exit via an exception, close fp explicitly.
        if fp:
            fp.close()
```

A more complete example that implements hierarchical module names and includes a `reload()` function can be found in the module `knee`. The `knee` module can be found in Demo/imputil/ in the Python source distribution.
31.2. importlib — Convenience wrappers for __import__()  

_New in version 2.7._

This module is a minor subset of what is available in the more full-featured package of the same name from Python 3.1 that provides a complete implementation of `import`. What is here has been provided to help ease in transitioning from 2.7 to 3.1.

```python
import import_module(name, package=None)
```

Import a module. The `name` argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `.mod`). If the name is specified in relative terms, then the `package` argument must be specified to the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`). The specified module will be inserted into `sys.modules` and returned.
31. Importing Modules

In this section, we will cover the basics of importing modules in Python. Modules are files that contain Python code that can be used by other programs or scripts. Modules are used to organize code into logical units, making it easier to manage and reuse code.

To import a module, you can use the `import` statement. For example:

```python
import math
```

This will import the `math` module, which contains a variety of mathematical functions.

You can also import specific functions or variables from a module using the `from` statement. For example:

```python
from math import pi
```

This will import the `pi` constant from the `math` module.

For more information on importing modules, see the documentation for the `import` statement in the Python Standard Library.
This module provides a very handy and useful mechanism for custom import hooks. Compared to the older `ihooks` module, `imputil` takes a dramatically simpler and more straight-forward approach to custom import functions.

```python
class imputil.ImportManager(fs_imp):
    Manage the import process.

    install([namespace])
    Install this ImportManager into the specified namespace.

    uninstall()
    Restore the previous import mechanism.

    add_suffix(suffix, importFunc)
    Undocumented.
```

```python
class imputil.Importer
    Base class for replacing standard import functions.

    import_top(name)
    Import a top-level module.

    get_code(parent, modname, fqname)
    Find and retrieve the code for the given module.

    parent specifies a parent module to define a context for
```
importing. It may be None, indicating no particular context for the search.

`modname` specifies a single module (not dotted) within the parent.

`fqname` specifies the fully-qualified module name. This is a (potentially) dotted name from the “root” of the module namespace down to the modname.

If there is no parent, then modname==fqname.

This method should return None, or a 3-tuple.

- If the module was not found, then None should be returned.
- The first item of the 2- or 3-tuple should be the integer 0 or 1, specifying whether the module that was found is a package or not.
- The second item is the code object for the module (it will be executed within the new module's namespace). This item can also be a fully-loaded module object (e.g. loaded from a shared lib).
- The third item is a dictionary of name/value pairs that will be inserted into new module before the code object is executed. This is provided in case the module's code expects certain values (such as where the module was found). When the second item is a module object, then these names/values will be inserted after the module has been loaded/initialized.

class imputil.BuiltinImporter

Emulate the import mechanism for built-in and frozen modules. This is a sub-class of the Importer class.
get_code(parent, modname, fqname)
  Undocumented.

imputil.py_suffix_importer(filename, finfo, fqname)
  Undocumented.

class imputil.DynLoadSuffixImporter([desc])
  Undocumented.

import_file(filename, finfo, fqname)
  Undocumented.
31.3.1. Examples

This is a re-implementation of hierarchical module import.

This code is intended to be read, not executed. However, it does work – all you need to do to enable it is “import knee”.

(The name is a pun on the clunkier predecessor of this module, “ni”.)

```python
import sys, imp, __builtin__

# Replacement for __import__()

def import_hook(name, globals=None, locals=None, fromlist=None):
    parent = determine_parent(globals)
    q, tail = find_head_package(parent, name)
    m = load_tail(q, tail)
    if not fromlist:
        return q
    if hasattr(m, "__path__"):
        ensure_fromlist(m, fromlist)
    return m

def determine_parent(globals):
    if not globals or not globals.has_key("__name__"):
        return None
    pname = globals['__name__']
    if globals.has_key("__path__"):
        parent = sys.modules[pname]
        assert globals is parent.__dict__
        return parent
    if '.' in pname:
        i = pname.rfind('.')
        pname = pname[:i]
        parent = sys.modules[pname]
        assert parent.__name__ == pname
        return parent
    return None

def find_head_package(parent, name):
    if '.' in name:
        i = name.find('.
        head = name[:i]
```

tail = name[i+1:]
else:
    head = name
    tail = ""
if parent:
    qname = "%s.%s" % (parent.__name__, head)
else:
    qname = head
q = import_module(head, qname, parent)
if q: return q, tail
if parent:
    qname = head
    parent = None
    q = import_module(head, qname, parent)
    if q: return q, tail
raise ImportError("No module named " + qname)

def load_tail(q, tail):
    m = q
    while tail:
        i = tail.find('.
if i < 0: i = len(tail)
head, tail = tail[:i], tail[i+1:]
mname = "%s.%s" % (m.__name__, head)
m = import_module(head, mname, m)
if not m:
    raise ImportError("No module named " + mname)
return m

def ensure_fromlist(m, fromlist, recursive=0):
    for sub in fromlist:
        if sub == "*":
            if not recursive:
                try:
                    all = m.__all__
                except AttributeError:
                    pass
                else:
            ensure_fromlist(m, all, 1)
        continue
        if sub != "*" and not hasattr(m, sub):
            subname = "%s.%s" % (m.__name__, sub)
            submod = import_module(sub, subname, m)
            if not submod:
                raise ImportError("No module named " + subname)

def import_module(partname, fqname, parent):
```python
try:
    return sys.modules[fqname]
except KeyError:
    pass
try:
    fp, pathname, stuff = imp.find_module(partname, parent and parent)
except ImportError:
    return None
try:
    m = imp.load_module(fqname, fp, pathname, stuff)
finally:
    if fp: fp.close()
    if parent:
        setattr(parent, partname, m)
return m
```

# Replacement for reload()

def reload_hook(module):
    name = module.__name__
    if '.' not in name:
        return import_module(name, name, None)
    i = name.rfind('.
    pname = name[:i]
    parent = sys.modules[pname]
    return import_module(name[i+1:], name, parent)

# Save the original hooks
original_import = __builtins__.import_
original_reload = __builtins__.reload

# Now install our hooks
__builtins__.import_ = import_hook
__builtins__.reload = reload_hook
```

Also see the importers module (which can be found in Demo/imputil/ in the Python source distribution) for additional examples.
31.4. `zipimport` — Import modules from Zip archives

*New in version 2.3.*

This module adds the ability to import Python modules (*.py, *.py[co]) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but only files `.py` and `.py[co]` are available for import. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` or `.pyo` file, meaning that if a ZIP archive doesn’t contain `.pyc` files, importing may be rather slow.

Using the built-in `reload()` function will fail if called on a module loaded from a ZIP archive; it is unlikely that `reload()` would be needed, since this would imply that the ZIP has been altered during runtime.

ZIP archives with an archive comment are currently not supported.
See also:

**PKZIP Application Note**
Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

**PEP 273 - Import Modules from Zip Archives**
Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302.

**PEP 302 - New Import Hooks**
The PEP to add the import hooks that help this module work.

This module defines an exception:

```python
exception zipimport.ZipImportError
    Exception raised by zipimporter objects. It's a subclass of ImportError, so it can be caught as ImportError, too.
```

### 31.4.1. zipimporter Objects

`zipimporter` is the class for importing ZIP files.

```python
class zipimport.zipimporter(archivepath)
```
Create a new zipimporter instance. `archivepath` must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an `archivepath` of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if `archivepath` doesn’t point to a valid ZIP archive.

```python
find_module(fullname[, path])
```
Search for a module specified by `fullname`. `fullname` must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or `None` if it wasn’t. The optional `path` argument is ignored—it’s there for compatibility with the importer protocol.

```python
get_code(fullname)
```
Return the code object for the specified module. Raise `ZipImportError` if the module couldn’t be found.

```python
get_data(pathname)
```
Return the data associated with `pathname`. Raise `IOError` if the file wasn’t found.

```python
get_filename(fullname)
```
Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn’t be found.
New in version 2.7.

get_source(fullname)
Return the source code for the specified module. Raise ZipImportError if the module couldn't be found, return None if the archive does contain the module, but has no source for it.

is_package(fullname)
Return True if the module specified by fullname is a package. Raise ZipImportError if the module couldn’t be found.

load_module(fullname)
Load the module specified by fullname. fullname must be the fully qualified (dotted) module name. It returns the imported module, or raises ZipImportError if it wasn’t found.

archive
The file name of the importer’s associated ZIP file, without a possible subpath.

prefix
The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

The archive and prefix attributes, when combined with a slash, equal the original archivepath argument given to the zipimporter constructor.
31.4.2. Examples

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```bash
$ unzip -l example.zip
Archive: example.zip
  Length     Date   Time     Name
   --------  ----      ----      ----
       8467 11-26-02 22:30  jwzthreading.py
   --------      -------
       8467
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file to front
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```
New in version 2.3.

Source code: Lib/pkgutil.py

This module provides utilities for the import system, in particular package support.

pkgutil.\texttt{extend\_path}(\textit{path}, \textit{name})

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's \texttt{\_init\_}.py:

\begin{verbatim}
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
\end{verbatim}

This will add to the package's \texttt{\_path\_} all subdirectories of directories on \texttt{sys.path} named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for \texttt{*\_pkg} files beginning where \* matches the \textit{name} argument. This feature is similar to \texttt{*\_pth} files (see the site module for more information), except that it doesn't special-case lines starting with \texttt{import}. A \texttt{*\_pkg} file is trusted at face value: apart from checking for duplicates, all entries found in a \texttt{*\_pkg} file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it
is returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not (Unicode or 8-bit) strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

```python
class pkgutil.ImpImporter(dirname=None)

PEP 302 Importer that wraps Python’s “classic” import algorithm.

If `dirname` is a string, a PEP 302 importer is created that searches that directory. If `dirname` is `None`, a PEP 302 importer is created that searches the current `sys.path`, plus any modules that are frozen or built-in.

Note that `ImpImporter` does not currently support being used by placement on `sys.meta_path`.
```

```python
class pkgutil.ImpLoader(fullname, file, filename, etc)

PEP 302 Loader that wraps Python’s “classic” import algorithm.
```

```python
pkgutil.find_loader(fullname)

Find a PEP 302 “loader” object for `fullname`.

If `fullname` contains dots, path must be the containing package’s `__path__`. Returns `None` if the module cannot be found or imported. This function uses `iter_importers()`, and is thus subject to the same limitations regarding platform-specific special import locations such as the Windows registry.
```

```python
pkgutil.get_importer(path_item)

Retrieve a PEP 302 importer for the given `path_item`.
```
The returned importer is cached in `sys.path_importer_cache` if it was newly created by a path hook.

If there is no importer, a wrapper around the basic import machinery is returned. This wrapper is never inserted into the importer cache (None is inserted instead).

The cache (or part of it) can be cleared manually if a rescan of `sys.path_hooks` is necessary.

`pkgutil.get_loader(module_or_name)`

Get a PEP 302 “loader” object for `module_or_name`.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns None if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package __path__.

This function uses `iter_importers()`, and is thus subject to the same limitations regarding platform-specific special import locations such as the Windows registry.

`pkgutil.iter_importers(fullname=``)`

Yield PEP 302 importers for the given module name.

If fullname contains a ‘.’, the importers will be for the package containing fullname, otherwise they will be importers for `sys.meta_path`, `sys.path`, and Python’s “classic” import machinery, in that order. If the named module is in a package, that package is imported as a side effect of invoking this function.

Non-PEP 302 mechanisms (e.g. the Windows registry) used by the standard import machinery to find files in alternative locations
are partially supported, but are searched after \texttt{sys.path}. Normally, these locations are searched before \texttt{sys.path}, preventing \texttt{sys.path} entries from shadowing them.

For this to cause a visible difference in behaviour, there must be a module or package name that is accessible via both \texttt{sys.path} and one of the non-\texttt{PEP 302} file system mechanisms. In this case, the emulation will find the former version, while the builtin import mechanism will find the latter.

Items of the following types can be affected by this discrepancy: \texttt{imp.C\_EXTENSION}, \texttt{imp.PY\_SOURCE}, \texttt{imp.PY\_COMPILED}, \texttt{imp.PKG\_DIRECTORY}.

\texttt{pkgutil.iter\_modules(path=None, prefix='')}

Yields \texttt{(module\_loader, name, ispkg)} for all submodules on \texttt{path}, or, if \texttt{path} is \texttt{None}, all top-level modules on \texttt{sys.path}.

\texttt{path} should be either \texttt{None} or a list of paths to look for modules in.

\texttt{prefix} is a string to output on the front of every module name on output.

\texttt{pkgutil.walk\_packages(path=None, prefix='', onerror=None)}

Yields \texttt{(module\_loader, name, ispkg)} for all modules recursively on \texttt{path}, or, if \texttt{path} is \texttt{None}, all accessible modules.

\texttt{path} should be either \texttt{None} or a list of paths to look for modules in.

\texttt{prefix} is a string to output on the front of every module name on output.

Note that this function must import all \texttt{packages} (\textit{not} all modules!)
on the given *path*, in order to access the *__path__* attribute to find submodules.

*onerror* is a function which gets called with one argument (the name of the package which was being imported) if any exception occurs while trying to import a package. If no *onerror* function is supplied, *ImportError* s are caught and ignored, while all other exceptions are propagated, terminating the search.

Examples:

```python
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')
```

**pkgutil.get_data(*package*, *resource*)**

Get a resource from a package.

This is a wrapper for the PEP 302 loader *get_data()* API. The *package* argument should be the name of a package, in standard module format (*foo.bar*). The *resource* argument should be in the form of a relative filename, using / as the path separator. The parent directory name .. is not allowed, and nor is a rooted name (starting with a /).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```python
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```
If the package cannot be located or loaded, or it uses a **PEP 302** loader which does not support `get_data()`, then `None` is returned.

*New in version 2.6.*
31.6. modulefinder — Find modules used by a script

New in version 2.3.

Source code: Lib/modulefinder.py

This module provides a ModuleFinder class that can be used to determine the set of modules imported by a script. modulefinder.py can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

modulefinder. AddPackagePath(pkg_name, path)
Record that the package named pkg_name can be found in the specified path.

modulefinder. ReplacePackage(oldname, newname)
Allows specifying that the module named oldname is in fact the package named newname. The most common usage would be to handle how the _xmlplus package replaces the xml package.

class modulefinder. ModuleFinder([path=None, debug=0,
excludes=[], replace_paths=[]])
This class provides run_script() and report() methods to determine the set of modules imported by a script. path can be a list of directories to search for modules; if not specified, sys.path is used. debug sets the debugging level; higher values make the class print debugging messages about what it’s doing. excludes is a list of module names to exclude from the analysis. replace_paths is a list of (oldpath, newpath) tuples that will be
replaced in module paths.

**report()**
Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

**run_script**(pathname)
Analyze the contents of the *pathname* file, which must contain Python code.

**modules**
A dictionary mapping module names to modules. See Example usage of ModuleFinder.
31.6.1. Example usage of ModuleFinder

The script that is going to get analyzed later on (bacon.py):

```python
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```python
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print 'Loaded modules:'
for name, mod in finder.modules.iteritems():
    print '%s: %s, %s, %s' % (name, mod.globalnames.keys()[:3])

print '-'*50
print 'Modules not imported:'
print '\n'.join(finder.badmodules.iterkeys())
```

Sample output (may vary depending on the architecture):

```
Loaded modules:
  _types:
  copy_reg: __inverted_registry, __slotnames, __all__
  sre_compile: isstring, _sre, _optimize_unicode
  _sre:
  sre_constants: REPEAT_ONE, makedict, AT_END_LINE
  sys:
```
re: __module__,finditer,_expand
itertools:
__main__: re,itertools,baconhameggs
sre_parse: __getslice__,__PATTERNENDERS,SRE_FLAG_UNICODE
array:
types: __module__,IntType,TypeType
---------------------------------------------------
Modules not imported:
guido.python.ham
baconhameggs
31.7. runpy — Locating and executing Python modules

New in version 2.5.

Source code: Lib/runpy.py

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

The `runpy` module provides two functions:

```python
runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)
```

Execute the code of the specified module and return the resulting module globals dictionary. The module's code is first located using the standard import mechanism (refer to PEP 302 for details) and then executed in a fresh module namespace.

If the supplied module name refers to a package rather than a normal module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_module()`.
The special global variables \_\_name\_\_, \_\_file\_\_, \_\_loader\_\_ and \_\_package\_\_ are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

\_\_name\_\_ is set to run\_name if this optional argument is not None, to mod\_name + \'.\_\_main\_\_' if the named module is a package and to the mod\_name argument otherwise.

\_\_file\_\_ is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to None.

\_\_loader\_\_ is set to the PEP 302 module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism).

\_\_package\_\_ is set to mod\_name if the named module is a package and to mod\_name.rpartition('\.')[0] otherwise.

If the argument alter\_sys is supplied and evaluates to True, then sys.argv[0] is updated with the value of \_\_file\_\_ and sys.modules[\_\_name\_\_] is updated with a temporary module object for the module being executed. Both sys.argv[0] and sys.modules[\_\_name\_\_] are restored to their original values before the function returns.

Note that this manipulation of sys is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the sys module be left alone when invoking this function from threaded code.
See also: The -m option offering equivalent functionality from the command line.

Changed in version 2.7: Added ability to execute packages by looking for a __main__ submodule.

runpy.run_path(file_path, init_globals=None, run_name=None)

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid sys.path entry containing a __main__ module (e.g. a zipfile containing a top-level __main__.py file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid sys.path entry (typically a zipfile or directory), the entry is first added to the beginning of sys.path. The function then looks for and executes a __main__ module using the updated path. Note that there is no special protection against invoking an existing __main__ entry located elsewhere on sys.path if there is no such module at the specified location.

The optional dictionary argument init_globals may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by run_path().

The special global variables __name__, __file__, __loader__ and __package__ are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).
__name__ is set to run_name if this optional argument is not None and to '<run_path>' otherwise.

__file__ is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to None. For a simple script, this will be set to file_path.

__loader__ is set to the PEP 302 module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism). For a simple script, this will be set to None.

__package__ is set to __name__.rpartition('.')[0].

A number of alterations are also made to the sys module. Firstly, sys.path may be altered as described above. sys.argv[0] is updated with the value of file_path and sys.modules[__name__] is updated with a temporary module object for the module being executed. All modifications to items in sys are reverted before the function returns.

Note that, unlike run_module(), the alterations made to sys are not optional in this function as these adjustments are essential to allowing the execution of sys.path entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

See also: Interface options for equivalent functionality on the command line (python path/to/script).

New in version 2.7.

Command line and environment - CPython command line details
32. Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **32.1. parser** — Access Python parse trees
  - 32.1.1. Creating ST Objects
  - 32.1.2. Converting ST Objects
  - 32.1.3. Queries on ST Objects
  - 32.1.4. Exceptions and Error Handling
  - 32.1.5. ST Objects
  - 32.1.6. Example: Emulation of `compile()`
- **32.2. ast** — Abstract Syntax Trees
  - 32.2.1. Node classes
  - 32.2.2. Abstract Grammar
  - 32.2.3. `ast` Helpers
- **32.3. symtable** — Access to the compiler’s symbol tables
  - 32.3.1. Generating Symbol Tables
  - 32.3.2. Examining Symbol Tables
- **32.4. symbol** — Constants used with Python parse trees
- **32.5. token** — Constants used with Python parse trees
- **32.6. keyword** — Testing for Python keywords
- **32.7. tokenize** — Tokenizer for Python source
- **32.8. tabnanny** — Detection of ambiguous indentation
- **32.9. pyc1br** — Python class browser support
  - 32.9.1. Class Objects
  - 32.9.2. Function Objects
- **32.10. py_compile** — Compile Python source files
- **32.11. compileall** — Byte-compile Python libraries
- 32.11.1. Command-line use
- 32.11.2. Public functions
- 32.12. dis — Disassembler for Python bytecode
  - 32.12.1. Python Bytecode Instructions
- 32.13. pickletools — Tools for pickle developers
32.1. parser — Access Python parse trees

The `parser` module provides an interface to Python’s internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

**Note:** From Python 2.5 onward, it’s much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the `ast` module.

The `parser` module exports the names documented here also with “st” replaced by “ast”; this is a legacy from the time when there was no other AST and has nothing to do with the AST found in Python 2.5. This is also the reason for the functions’ keyword arguments being called `ast`, not `st`. The “ast” functions have been removed in Python 3.

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the `parser` module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to *The Python Language Reference*. The parser itself is created from a grammar specification defined in the file `Grammar/Grammar` in the standard Python distribution. The parse
trees stored in the ST objects created by this module are the actual output from the internal parser when created by the `expr()` or `suite()` functions, described below. The ST objects created by `sequence2st()` faithfully simulate those structures. Be aware that the values of the sequences which are considered “correct” will vary from one version of Python to another as the formal grammar for the language is revised. However, transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, whereas source code has always been forward-compatible.

Each element of the sequences returned by `st2list()` or `st2tuple()` has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file `Include/graminit.h` and the Python module `symbol`. Each additional element of the sequence represents a component of the production as recognized in the input string: these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword `if` in an `if_stmt`, are included in the node tree without any special treatment. For example, the `if` keyword is represented by the tuple `(1, 'if')`, where `1` is the numeric value associated with all `NAME` tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as `(1, 'if', 12)`, where the `12` represents the line number at which the terminal symbol was found.
Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which was identified. The example of the `if` keyword above is representative. The various types of terminal symbols are defined in the C header file `Include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes: to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple “wrapper” class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

See also:

**Module symbol**
Useful constants representing internal nodes of the parse tree.

**Module token**
Useful constants representing leaf nodes of the parse tree and functions for testing node values.
32.1.1. Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the 'eval' and 'exec' forms.

parser.expr(source)

The expr() function parses the parameter source as if it were an input to compile(source, 'file.py', 'eval'). If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

parser.suite(source)

The suite() function parses the parameter source as if it were an input to compile(source, 'file.py', 'exec'). If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

parser.sequence2st(sequence)

This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the called. If there is a problem creating the internal representation, or if the tree cannot be validated, a ParserError exception is raised. An ST object created this way should not be assumed to compile correctly; normal exceptions raised by compilation may still be initiated when the ST object is passed to compilest(). This may indicate problems not related to syntax (such as a MemoryError exception), but may also be due to constructs such as the result of parsing del f(0), which escapes the Python
parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form \((1, \text{'name'})\) or as three-element lists of the form \((1, \text{'name'}, 56)\). If the third element is present, it is assumed to be a valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

\texttt{parser.\texttt{tuple2st}(sequence)}

This is the same function as \texttt{sequence2st()}. This entry point is maintained for backward compatibility.
32.1.2. Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple- trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

```python
parser.st2list(ast[, line_info])
```

This function accepts an ST object from the caller in `ast` and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, `st2tuple()` should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token ends. This information is omitted if the flag is false or omitted.

```python
parser.st2tuple(ast[, line_info])
```

This function accepts an ST object from the caller in `ast` and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to `st2list()`.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the
token. This information is omitted if the flag is false or omitted.

```
parser.compile(ast, filename='<syntax-tree>')</n```

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of an `exec` statement or a call to the built-in `eval()` function. This function provides the interface to the compiler, passing the internal parse tree from `ast` to the parser, using the source file name specified by the `filename` parameter. The default value supplied for `filename` indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a `SyntaxError` caused by the parse tree for `del f(θ)`: this statement is considered legal within the formal grammar for Python but is not a legal language construct. The `SyntaxError` raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the `parser` module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.
32.1.3. Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via `expr()` or `suite()` or from a parse tree via `sequence2st()`.

**parser**. `isexpr(ast)`

When `ast` represents an 'eval' form, this function returns true, otherwise it returns false. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

**parser**. `issuite(ast)`

This function mirrors `isexpr()` in that it reports whether an ST object represents an 'exec' form, commonly known as a “suite.” It is not safe to assume that this function is equivalent to `not isexpr(ast)`, as additional syntactic fragments may be supported in the future.
32.1.4. Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

\textit{exception} \texttt{parser.ParserError}

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built-in \texttt{SyntaxError} raised during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to \texttt{sequence2st()} and an explanatory string. Calls to \texttt{sequence2st()} need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions \texttt{compilest()}, \texttt{expr()}, and \texttt{suite()} may raise exceptions which are normally raised by the parsing and compilation process. These include the built in exceptions \texttt{MemoryError}, \texttt{OverflowError}, \texttt{SyntaxError}, and \texttt{SystemError}. In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.
32.1.5. ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the `pickle` module) is also supported.

**parser.STType**

The type of the objects returned by `expr()`, `suite()` and `sequence2st()`.

ST objects have the following methods:

**ST.compile([filename])**

Same as `compilest(st, filename)`.  

**ST.isexpr()**

Same as `isexpr(st)`.  

**ST.issuite()**

Same as `issuite(st)`.  

**ST.tolist([line_info])**

Same as `st2list(st, line_info)`.  

**ST.totuple([line_info])**

Same as `st2tuple(st, line_info)`.  

32.1.6. Example: Emulation of `compile()`

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the `parser` module to produce an intermediate data structure is equivalent to the code

```python
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the `parser` module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object:

```python
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions:

```python
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()

def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()
```
32.2. ast — Abstract Syntax Trees

New in version 2.5: The low-level _ast module containing only the node classes.

New in version 2.6: The high-level ast module containing all helpers.

**Source code:** Lib/ast.py

The ast module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programatically what the current grammar looks like.

An abstract syntax tree can be generated by passing ast.PyCF_ONLY_AST as a flag to the compile() built-in function, or using the parse() helper provided in this module. The result will be a tree of objects whose classes all inherit from ast.AST. An abstract syntax tree can be compiled into a Python code object using the built-in compile() function.
32.2.1. Node classes

```python
class ast.AST
    This is the base of all AST node classes. The actual node classes are derived from the Parser/Python.asdl file, which is reproduced below. They are defined in the _ast C module and re-exported in ast.
```

There is one class defined for each left-hand side symbol in the abstract grammar (for example, `ast.stmt` or `ast.expr`). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, `ast.BinOp` inherits from `ast.expr`. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

_`fields`

Each concrete class has an attribute `_fields` which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, `ast.BinOp` instances have an attribute `left` of type `ast.expr`.

If these attributes are marked as optional in the grammar (using a question mark), the value might be `None`. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with `compile()`.
Instances of `ast.expr` and `ast.stmt` subclasses have `lineno` and `col_offset` attributes. The `lineno` is the line number of source text (1-indexed so the first line is line 1) and the `col_offset` is the UTF-8 byte offset of the first token that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

The constructor of a class `ast.T` parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in `T._fields`; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an `ast.UnaryOp` node, you could use

```python
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Num()
nombre.operand.n = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

or the more compact

```python
node = ast.UnaryOp(ast.USub(), ast.Num(5, lineno=0, col_offset=0)
```

New in version 2.6: The constructor as explained above was added. In Python 2.5 nodes had to be created by calling the class constructor without arguments and setting the attributes
afterwards.
32.2.2. Abstract Grammar

The module defines a string constant \_version\_ which is the decimal Subversion revision number of the file shown below.

The abstract grammar is currently defined as follows:

```
module Python version "\$Revision\$
{
    mod = Module(stmt* body)
    | Interactive(stmt* body)
    | Expression(expr body)

    -- not really an actual node but useful in Jython's
    | Suite(stmt* body)

    stmt = FunctionDef(identifier name, arguments args,
        stmt* body, expr* decorator_list)
    | ClassDef(identifier name, expr* bases, stmt* body,
        expr* decorator_list)
    | Return(expr? value)
    | Delete(expr* targets)
    | Assign(expr* targets, expr value)
    | AugAssign(expr target, operator op, expr value)

    -- not sure if bool is allowed, can always use in
    | Print(expr? dest, expr* values, bool nl)

    -- use 'orelse' because else is a keyword in target
    | For(expr target, expr iter, stmt* body, stmt* orelse)
    | While(expr test, stmt* body, stmt* orelse)
    | If(expr test, stmt* body, stmt* orelse)
    | With(expr context_expr, expr? optional_vars, stmt*

    -- 'type' is a bad name
    | Raise(expr? type, expr? inst, expr? tback)
    | TryExcept(stmt* body, excepthandler* handlers,
        TryFinally(stmt* body, stmt* finalbody)
    | Assert(expr test, expr? msg)
    | Import(alias* names)
```
ImportFrom(identifier? module, alias* names, in
| Exec(expr body, expr? globals, expr? locals)
| Global(identifier* names)
| Expr(expr value)
| Pass | Break | Continue

-- XXX Jython will be different
-- col_offset is the byte offset in the utf8 string attributes (int lineno, int col_offset)

-- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
| BinOp(expr left, operator op, expr right)
| UnaryOp(unaryop op, expr operand)
| Lambda(arguments args, expr body)
| IfExp(expr test, expr body, expr orelse)
| Dict(expr* keys, expr* values)
| Set(expr* elts)
| ListComp(expr elt, comprehension* generators)
| SetComp(expr elt, comprehension* generators)
| DictComp(expr key, expr value, comprehension* generators)
| GeneratorExp(expr elt, comprehension* generators)
-- the grammar constrains where yield expressions
| Yield(expr? value)
-- need sequences for compare to distinguish between
-- x < 4 < 3 and (x < 4) < 3
| Compare(expr left, cmpop* ops, expr* comparators
| Call(expr func, expr* args, keyword* keywords,
  expr? starargs, expr? kwargs)
| Repr(expr value)
| Num(object n) -- a number as a PyObject.
| Str(string s) -- need to specify raw, unicode, e
-- other literals? bools?
-- the following expression can appear in assignment
| Attribute(expr value, identifier attr, expr_context
| Subscript(expr value, slice slice, expr_context
| Name(identifier id, expr_context ctx)
| List(expr* elts, expr_context ctx)
| Tuple(expr* elts, expr_context ctx)

-- col_offset is the byte offset in the utf8 stri
attributes (int lineno, int col_offset)
expr_context = Load | Store | Del | AugLoad | AugStore

slice = Ellipsis | Slice(expr? lower, expr? upper, expr?) | ExtSlice(slice* dims) | Index(expr value)

boolop = And | Or
operator = Add | Sub | Mult | Div | Mod | Pow | LShift | RShift | BitOr | BitXor | BitAnd | FloorDiv
unaryop = Invert | Not | UAdd | USub

cmpop = Eq | NotEq | Lt | LtE | Gt | GtE | Is | IsNot |
comprehension = (expr target, expr iter, expr* ifs)

-- not sure what to call the first argument for raise a
excepthandler = ExceptHandler(expr? type, expr? name, stmt* body)

arguments = (expr* args, identifier? vararg, identifier? kwarg, expr* defaults)

-- keyword arguments supplied to call
keyword = (identifier arg, expr value)

-- import name with optional 'as' alias.
alias = (identifier name, identifier? asname)
32.2.3. ast Helpers

*New in version 2.6.*

Apart from the node classes, ast module defines these utility functions and classes for traversing abstract syntax trees:

```python
ast.parse(source, filename='<unknown>', mode='exec')
```

Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

```python
ast.literal_eval(node_or_string)
```

Safely evaluate an expression node or a Unicode or *Latin-1* encoded string containing a Python literal or container display. The string or node provided may only consist of the following Python literal structures: strings, numbers, tuples, lists, dicts, booleans, and `None`.

This can be used for safely evaluating strings containing Python values from untrusted sources without the need to parse the values oneself. It is not capable of evaluating arbitrarily complex expressions, for example involving operators or indexing.

```python
ast.get_docstring(node, clean=True)
```

Return the docstring of the given `node` (which must be a `FunctionDef`, `ClassDef` or `Module` node), or `None` if it has no docstring. If `clean` is true, clean up the docstring’s indentation with `inspect.cleandoc()`.

```python
ast.fix_missing_locations(node)
```

When you compile a node tree with `compile()`, the compiler expects `lineno` and `col_offset` attributes for every node that supports them. This is rather tedious to fill in for generated
nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at node.

```
ast.increment_lineno(node, n=1)
```
Increment the line number of each node in the tree starting at node by n. This is useful to “move code” to a different location in a file.

```
ast.copy_location(new_node, old_node)
```
Copy source location (lineno and col_offset) from old_node to new_node if possible, and return new_node.

```
ast.iter_fields(node)
```
Yield a tuple of (fieldname, value) for each field in node._fields that is present on node.

```
ast.iter_child_nodes(node)
```
Yield all direct child nodes of node, that is, all fields that are nodes and all items of fields that are lists of nodes.

```
ast.walk(node)
```
Recursively yield all descendant nodes in the tree starting at node (including node itself), in no specified order. This is useful if you only want to modify nodes in place and don’t care about the context.

```
class ast.NodeVisitor
```
A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the visit() method.

This class is meant to be subclassed, with the subclass adding visitor methods.
visit(node)

Visit a node. The default implementation calls the method called `self.visit_classname` where `classname` is the name of the node class, or `generic_visit()` if that method doesn’t exist.

generic_visit(node)

This visitor calls `visit()` on all children of the node.

Note that child nodes of nodes that have a custom visitor method won’t be visited unless the visitor calls `generic_visit()` or visits them itself.

Don’t use the `NodeVisitor` if you want to apply changes to nodes during traversal. For this a special visitor exists (`NodeTransformer`) that allows modifications.

class ast.NodeTransformer

A `NodeVisitor` subclass that walks the abstract syntax tree and allows modification of nodes.

The `NodeTransformer` will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is `None`, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (`foo`) to `data['foo']`:

```python
class RewriteName(NodeTransformer):
    def visit_Name(self, node):
        return copy_location(Subscript(  
```
Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the `generic_visit()` method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

Usually you use the transformer like this:

```python
node = YourTransformer().visit(node)
```

```
 ast.dump(node, annotate_fields=True, include_attributes=False)
```

Return a formatted dump of the tree in `node`. This is mainly useful for debugging purposes. The returned string will show the names and the values for fields. This makes the code impossible to evaluate, so if evaluation is wanted `annotate_fields` must be set to `False`. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, `include_attributes` can be set to `True`. 
32.3. symtable — Access to the compiler’s symbol tables

**Source code:** Lib/symtable.py

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. *symtable* provides an interface to examine these tables.
32.3.1. Generating Symbol Tables

`symtable.symtable(code, filename, compile_type)`

Return the toplevel `SymbolTable` for the Python source `code`. `filename` is the name of the file containing the code. `compile_type` is like the `mode` argument to `compile()`.
32.3.2. Examining Symbol Tables

class symtable.SymbolTable
A namespace table for a block. The constructor is not public.

get_type()
Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

get_id()
Return the table’s identifier.

get_name()
Return the table’s name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (get_type() returns 'module').

get_lineno()
Return the number of the first line in the block this table represents.

is_optimized()
Return True if the locals in this table can be optimized.

is_nested()
Return True if the block is a nested class or function.

has_children()
Return True if the block has nested namespaces within it. These can be obtained with get_children().

has_exec()
Return `True` if the block uses `exec`.

`has_import_star()`
Return `True` if the block uses a starred from-import.

`get_identifiers()`
Return a list of names of symbols in this table.

`lookup(name)`
Lookup `name` in the table and return a `Symbol` instance.

`get_symbols()`
Return a list of `Symbol` instances for names in the table.

`get_children()`
Return a list of the nested symbol tables.

class `symtable.Function`
A namespace for a function or method. This class inherits `SymbolTable`.

`get_parameters()`
Return a tuple containing names of parameters to this function.

`get_locals()`
Return a tuple containing names of locals in this function.

`getGlobals()`
Return a tuple containing names of globals in this function.

`get_frees()`
Return a tuple containing names of free variables in this function.
class symtable.

**Class**

A namespace of a class. This class inherits `SymbolTable`.

**get_methods()**

Return a tuple containing the names of methods declared in the class.

**class symtable. Symbol**

An entry in a `SymbolTable` corresponding to an identifier in the source. The constructor is not public.

**get_name()**

Return the symbol’s name.

**is_referenced()**

Return `True` if the symbol is used in its block.

**is_imported()**

Return `True` if the symbol is created from an import statement.

**is_parameter()**

Return `True` if the symbol is a parameter.

**is_global()**

Return `True` if the symbol is global.

**isDeclaredGlobal()**

Return `True` if the symbol is declared global with a global statement.

**is_local()**

Return `True` if the symbol is local to its block.

**is_free()**
Return `True` if the symbol is referenced in its block, but not assigned to.

### is_assigned()

Return `True` if the symbol is assigned to in its block.

### is_namespace()

Return `True` if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

For example:

```python
gt>> table = symtable.symtable("def some_func(): pass", "string"
<...>
gt>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

### get_namespaces()

Return a list of namespaces bound to this name.

### get_namespace()

Return the namespace bound to this name. If more than one namespace is bound, a `ValueError` is raised.
This module provides constants which represent the numeric values of internal nodes of the parse tree. Unlike most Python constants, these use lower-case names. Refer to the file Grammar/Grammar in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one additional data object:

```
symbol. sym_name
```

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.
32.5. token — Constants used with Python parse trees

**Source code:** Lib/token.py

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file `Grammar/Grammar` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

**token. tok_name**

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

**token. ISTERMINAL(x)**

Return true for terminal token values.

**token. ISNONTERMINAL(x)**

Return true for non-terminal token values.

**token. ISEOF(x)**

Return true if x is the marker indicating the end of input.

The token constants are:

**token. ENDMARKER**

**token. NAME**
See also:

**Module** `parser`

The second example for the `parser` module shows how to use the `symbol` module.
This module allows a Python program to determine if a string is a keyword.

```python
keyword.iskeyword(s)
```

Return true if s is a Python keyword.

```python
keyword.kwlist
```

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.
32.7. `tokenize` — Tokenizer for Python source

**Source code:** `Lib/tokenize.py`

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers,” including colorizers for on-screen displays.

To simplify token stream handling, all Operators and Delimiters tokens are returned using the generic `token.OP` token type. The exact type can be determined by checking the second field (containing the actual token string matched) of the tuple returned from `tokenize.generate_tokens()` for the character sequence that identifies a specific operator token.

The primary entry point is a generator:

```python
tokenizer.generate_tokens(readline)
```

The `generate_tokens()` generator requires one argument, `readline`, which must be a callable object which provides the same interface as the `readline()` method of built-in file objects (see section File Objects). Each call to the function should return one line of input as a string. Alternately, `readline` may be a callable object that signals completion by raising `StopIteration`.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple `(srow, scol)` of ints specifying the row and column where the token begins in the source; a 2-tuple `(erow, ecol)` of ints specifying the row and column where the token ends in the source; and the line on which the token was
found. The line passed (the last tuple item) is the *logical* line; continuation lines are included.

*New in version 2.2.*

An older entry point is retained for backward compatibility:

```python
tokenize(tokenize(readline[, tokeneater])
```

The `tokenize()` function accepts two parameters: one representing the input stream, and one providing an output mechanism for `tokenize()`.

The first parameter, `readline`, must be a callable object which provides the same interface as the `readline()` method of built-in file objects (see section *File Objects*). Each call to the function should return one line of input as a string. Alternately, `readline` may be a callable object that signals completion by raising `StopIteration`.

*Changed in version 2.5:* Added `StopIteration` support.

The second parameter, `tokeneater`, must also be a callable object. It is called once for each token, with five arguments, corresponding to the tuples generated by `generate_tokens()`.

All constants from the `token` module are also exported from `tokenize`, as are two additional token type values that might be passed to the `tokeneater` function by `tokenize()`:

```python
tokenize.COMMENT
    Token value used to indicate a comment.
    
tokenize.NL
    Token value used to indicate a non-terminating newline. The NEWLINE token indicates the end of a logical line of Python
code; NL tokens are generated when a logical line of code is
continued over multiple physical lines.
Another function is provided to reverse the tokenization process.
This is useful for creating tools that tokenize a script, modify the
token stream, and write back the modified script.
tokenize. untokenize (iterable)

Converts tokens back into Python source code. The iterable must
return sequences with at least two elements, the token type and
the token string. Any additional sequence elements are ignored.
The reconstructed script is returned as a single string. The result
is guaranteed to tokenize back to match the input so that the
conversion is lossless and round-trips are assured. The
guarantee applies only to the token type and token string as the
spacing between tokens (column positions) may change.
New in version 2.5.
exception tokenize. TokenError
Raised when either a docstring or expression that may be split
over several lines is not completed anywhere in the file, for
example:
"""Beginning of
docstring

or:
[1,
2,
3

Note that unclosed single-quoted strings do not cause an error to be
raised. They are tokenized as ERRORTOKEN , followed by the
tokenization of their contents.


Example of a script re-writer that transforms float literals into Decimal objects:

```python
def decistmt(s):
    """Substitute Decimals for floats in a string of statements."""

    >> from decimal import Decimal
    >> s = 'print +21.3e-5*-1234/81.7'
    >> decistmt(s)
    "print +Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7')"'

    >>> exec(s)
    -3.21716034272e-007
    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7

    ""
    result = []
    g = generate_tokens(StringIO(s).readline)  # tokenize the
    for toknum, tokval, _, _, _ in g:
        if toknum == NUMBER and '.' in tokval:  # replace NUMBER
            result.extend([
                (NAME, 'Decimal'),
                (OP, '('),
                (STRING, repr(tokval)),
                (OP, ')')
            ])
        else:
            result.append((toknum, tokval))
    return untokenize(result)
```

32.8. **tabnanny — Detection of ambiguous indentation**

**Source code:** Lib/tabnanny.py

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

**Note:** The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

```python
def check(file_or_dir):
    if file_or_dir is a directory and not a symbolic link, then recursively descend the directory tree named by file_or_dir, checking all .py files along the way. If file_or_dir is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the print statement.
```

**tabnanny.** `verbose`

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

**tabnanny.** `filename_only`

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.

**exception** `tabnanny.NannyNag`

Raised by `tokeneater()` if detecting an ambiguous indent. Captured and handled in `check()`.
tabnanny. **tokeneater**(type, token, start, end, line)

This function is used by `check()` as a callback parameter to the function `tokenize.tokenize()`.

**See also:**

**Module** `tokenize`

Lexical scanner for Python source code.
The `pyclbr` module can be used to determine some limited information about the classes, methods and top-level functions defined in a module. The information provided is sufficient to implement a traditional three-pane class browser. The information is extracted from the source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyclbr.readmodule(module, path=None)`

Read a module and return a dictionary mapping class names to class descriptor objects. The parameter `module` should be the name of a module as a string; it may be the name of a module within a package. The `path` parameter should be a sequence, and is used to augment the value of `sys.path`, which is used to locate module source code.

`pyclbr.readmodule_ex(module, path=None)`

Like `readmodule()`, but the returned dictionary, in addition to mapping class names to class descriptor objects, also maps top-level function names to function descriptor objects. Moreover, if the module being read is a package, the key `__path__` in the returned dictionary has as its value a list which contains the package search path.
32.9.1. Class Objects

The class objects used as values in the dictionary returned by readmodule() and readmodule_ex() provide the following data attributes:

**Class.module**

The name of the module defining the class described by the class descriptor.

**Class.name**

The name of the class.

**Class.super**

A list of class objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by readmodule() are listed as a string with the class name instead of as class objects.

**Class.methods**

A dictionary mapping method names to line numbers.

**Class.file**

Name of the file containing the class statement defining the class.

**Class.lineno**

The line number of the class statement within the file named by file.
32.9.2. Function Objects

The `Function` objects used as values in the dictionary returned by `readmodule_ex()` provide the following attributes:

Function. `module`

- The name of the module defining the function described by the function descriptor.

Function. `name`

- The name of the function.

Function. `file`

- Name of the file containing the `def` statement defining the function.

Function. `lineno`

- The line number of the `def` statement within the file named by `file`.
32.10. py_compile — Compile Python source files

Source code: Lib/py_compile.py

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

```
exception py_compile.PyCompileError
    Exception raised when an error occurs while attempting to compile the file.
```

```
py_compile.compile(file[, cfile[, dfile[, doraise]]])
    Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named `file`. The byte-code is written to `cfile`, which defaults to `file + 'c'` (`'o'` if optimization is enabled in the current interpreter). If `dfile` is specified, it is used as the name of the source file in error messages instead of `file`. If `doraise` is true, a PyCompileError is raised when an error is encountered while compiling `file`. If `doraise` is false (the default), an error string is written to `sys.stderr`, but no exception is raised.
```

```
py_compile.main([args])
    Compile several source files. The files named in `args` (or on the
```
command line, if *args* is not specified) are compiled and the resulting bytecode is cached in the normal manner. This function does not search a directory structure to locate source files; it only compiles files named explicitly. If `-` is the only parameter in *args*, the list of files is taken from standard input.

*Changed in version 2.7:* Added support for `-`.

When this module is run as a script, the `main()` is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

*Changed in version 2.6:* Added the nonzero exit status when module is run as a script.

**See also:**

**Module** *compileall*

Utilities to compile all Python source files in a directory tree.
This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached bytecode files at library installation time, which makes them available for use even by users who don’t have write permission to the library directories.
32.11.1. Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

```markdown
**directory ...**
**file ...**
```

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

- `-l`
  Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

- `-f`
  Force rebuild even if timestamps are up-to-date.

- `-q`
  Do not print the list of files compiled, print only error messages.

- `-d destdir`
  Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled into the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

- `-x regex`
  regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

- `-i list`
Read the file list and add each line that it contains to the list of files and directories to compile. If list is -, read lines from stdin.

*Changed in version 2.7:* Added the `-i` option.
compileall.compile_dir(dir[, maxlevels[, ddir[, force[, rx[, quiet]]]]])

Recursively descend the directory tree named by dir, compiling all .py files along the way.

The maxlevels parameter is used to limit the depth of the recursion; it defaults to 10.

If ddir is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If force is true, modules are re-compiled even if the timestamps are up to date.

If rx is given, its search method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped.

If quiet is true, nothing is printed to the standard output unless errors occur.

compileall.compile_file(fullname[, ddir[, force[, rx[, quiet]]]])

Compile the file with path fullname.

If ddir is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file
does not exist at the time the byte-code file is executed.

If \( rx \) is given, its search method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and \texttt{True} is returned.

If \texttt{quiet} is true, nothing is printed to the standard output unless errors occur.

\textit{New in version 2.7.}

\texttt{compileall.compile\_path([\texttt{skip\_curdir}, \texttt{maxlevels}, \texttt{force}])}

Byte-compile all the .py files found along \texttt{sys.path}. If \texttt{skip\_curdir} is true (the default), the current directory is not included in the search. All other parameters are passed to the \texttt{compile\_dir()} function. Note that unlike the other compile functions, \texttt{maxlevels} defaults to 0.

To force a recompile of all the .py files in the \texttt{Lib/} subdirectory and all its subdirectories:

```python
import compileall
compileall.compile_dir('Lib/', force=True)
```

# Perform same compilation, excluding files in .svn directories
```
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\][.]svn'), f
```

\textbf{See also:}

\textbf{Module} \textit{py\_compile}

Byte-compile a single source file.
32.12. dis — Disassembler for Python bytecode

Source code: Lib/dis.py

The dis module supports the analysis of CPython bytecode by disassembling it. The CPython bytecode which this module takes as an input is defined in the file Include/opcode.h and used by the compiler and the interpreter.

**CPython implementation detail:** Bytecode is an implementation detail of the CPython interpreter! No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Example: Given the function myfunc():

```python
def myfunc(alist):
    return len(alist)
```

the following command can be used to get the disassembly of myfunc():

```python
>>> dis.dis(myfunc)
  2           0 LOAD_GLOBAL              0 (len)
  3           3 LOAD_FAST                0 (alist)
  6           6 CALL_FUNCTION            1
  9           9 RETURN_VALUE
```

(The “2” is a line number).
The `dis` module defines the following functions and constants:

**dis.dis([`bytesource`])**
Disassemble the `bytesource` object. `bytesource` can denote either a module, a class, a method, a function, or a code object. For a module, it disassembles all functions. For a class, it disassembles all methods. For a single code sequence, it prints one line per bytecode instruction. If no object is provided, it disassembles the last traceback.

**dis.distb([`tb`])**
Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

**dis.disassemble(`code`, `lasti`)**
Disassembles a code object, indicating the last instruction if `lasti` was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.
The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

**dis.disco(`code`, `lasti`)**
A synonym for `disassemble()`. It is more convenient to type, and kept for compatibility with earlier Python releases.

**dis.findlinestarts(`code`)**
This generator function uses the `co_firstlineno` and `co_lnotab` attributes of the code object `code` to find the offsets which are starts of lines in the source code. They are generated as `(offset, lineno)` pairs.

```
dis.findlabels(code)
Detect all offsets in the code object `code` which are jump targets, and return a list of these offsets.
```

```
dis.opname
Sequence of operation names, indexable using the bytecode.
```

```
dis.opmap
Dictionary mapping operation names to bytecodes.
```

```
dis.cmp_op
Sequence of all compare operation names.
```

```
dis.hasconst
Sequence of bytecodes that have a constant parameter.
```

```
dis.hasfree
Sequence of bytecodes that access a free variable.
```

```
dis.hasname
Sequence of bytecodes that access an attribute by name.
```

```
dis.hasjrel
Sequence of bytecodes that have a relative jump target.
```

```
dis.hasjabs
Sequence of bytecodes that have an absolute jump target.
```

```
dis.haslocal
Sequence of bytecodes that access a local variable.
```

```
dis.hascompare
```
Sequence of bytecodes of Boolean operations.
32.12.1. Python Bytecode Instructions

The Python compiler currently generates the following bytecode instructions.

**STOP_CODE()**
Indicates end-of-code to the compiler, not used by the interpreter.

**NOP()**
Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP_TOP()**
Removes the top-of-stack (TOS) item.

**ROT_TWO()**
Swaps the two top-most stack items.

**ROT_THREE()**
Lifts second and third stack item one position up, moves top down to position three.

**ROT_FOUR()**
Lifts second, third and forth stack item one position up, moves top down to position four.

**DUP_TOP()**
Duplicates the reference on top of the stack.

Unary Operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY_POSITIVE()**
Implements $TOS = +TOS$. 
UNARY_NEGATIVE()
    Implements \( TOS = -TOS \).

UNARY_NOT()
    Implements \( TOS = \text{not } TOS \).

UNARY_CONVERT()
    Implements \( TOS = \text{`TOS`} \).

UNARY_INVERT()
    Implements \( TOS = \text{~TOS} \).

GET_ITER()
    Implements \( TOS = \text{iter(TOS)} \).

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

BINARY_POWER()
    Implements \( TOS = TOS1 ** TOS \).

BINARY_MULTIPLY()
    Implements \( TOS = TOS1 * TOS \).

BINARY_DIVIDE()
    Implements \( TOS = TOS1 / TOS \) when from __future__ import division is not in effect.

BINARY_FLOOR_DIVIDE()
    Implements \( TOS = TOS1 // TOS \).

BINARY_TRUE_DIVIDE()
    Implements \( TOS = TOS1 / TOS \) when from __future__ import division is in effect.
**BINARY_MODULO()**
Implements $TOS = TOS1 \% TOS$.

**BINARY_ADD()**
Implements $TOS = TOS1 + TOS$.

**BINARY_SUBTRACT()**
Implements $TOS = TOS1 - TOS$.

**BINARY_SUBSCR()**
Implements $TOS = TOS1[TOS]$.

**BINARY_LSHIFT()**
Implements $TOS = TOS1 << TOS$.

**BINARY_RSHIFT()**
Implements $TOS = TOS1 >> TOS$.

**BINARY_AND()**
Implements $TOS = TOS1 \& TOS$.

**BINARY_XOR()**
Implements $TOS = TOS1 ^ TOS$.

**BINARY_OR()**
Implements $TOS = TOS1 | TOS$.

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

**INPLACE_POWER()**
Implements in-place $TOS = TOS1 ** TOS$. 
**INPLACE_MULTIPLY()**
Implements in-place $\text{TOS} = \text{TOS1} \times \text{TOS}$.

**INPLACE_DIVIDE()**
Implements in-place $\text{TOS} = \text{TOS1} / \text{TOS}$ when `from __future__ import division` is not in effect.

**INPLACE_FLOOR_DIVIDE()**
Implements in-place $\text{TOS} = \text{TOS1} \div \text{TOS}$.

**INPLACE_TRUE_DIVIDE()**
Implements in-place $\text{TOS} = \text{TOS1} / \text{TOS}$ when `from __future__ import division` is in effect.

**INPLACE_MODULO()**
Implements in-place $\text{TOS} = \text{TOS1} \mod \text{TOS}$.

**INPLACE_ADD()**
Implements in-place $\text{TOS} = \text{TOS1} + \text{TOS}$.

**INPLACE_SUBTRACT()**
Implements in-place $\text{TOS} = \text{TOS1} - \text{TOS}$.

**INPLACE_LSHIFT()**
Implements in-place $\text{TOS} = \text{TOS1} \ll \text{TOS}$.

**INPLACE_RSHIFT()**
Implements in-place $\text{TOS} = \text{TOS1} \gg \text{TOS}$.

**INPLACE_AND()**
Implements in-place $\text{TOS} = \text{TOS1} \& \text{TOS}$.

**INPLACE_XOR()**
Implements in-place $\text{TOS} = \text{TOS1} \^ \text{TOS}$.
INPLACE_OR()
Implements in-place $\text{TOS} = \text{TOS1} \mid \text{TOS}$.

The slice opcodes take up to three parameters.

SLICE+0()
Implements $\text{TOS} = \text{TOS}[:]$.

SLICE+1()
Implements $\text{TOS} = \text{TOS1}[\text{TOS}:]$.

SLICE+2()
Implements $\text{TOS} = \text{TOS1}[:\text{TOS}]$.

SLICE+3()
Implements $\text{TOS} = \text{TOS2}[\text{TOS1}:\text{TOS}]$.

Slice assignment needs even an additional parameter. As any statement, they put nothing on the stack.

STORE_SLICE+0()
Implements $\text{TOS}[:] = \text{TOS1}$.

STORE_SLICE+1()
Implements $\text{TOS1}[\text{TOS}:] = \text{TOS2}$.

STORE_SLICE+2()
Implements $\text{TOS1}[:\text{TOS}] = \text{TOS2}$.

STORE_SLICE+3()
Implements $\text{TOS2}[\text{TOS1}:\text{TOS}] = \text{TOS3}$.

DELETE_SLICE+0()
Implements $\text{del} \ \text{TOS}[:]$. 
DELETE_SLICE+1()
  Implements del TOS1[TOS:].

DELETE_SLICE+2()
  Implements del TOS1[:TOS].

DELETE_SLICE+3()
  Implements del TOS2[TOS1:TOS].

STORE_SUBSCR()
  Implements TOS1[TOS] = TOS2.

DELETE_SUBSCR()
  Implements del TOS1[TOS].

Miscellaneous opcodes.

PRINT_EXPR()
  Implements the expression statement for the interactive mode. TOS is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with POP_TOP.

PRINT_ITEM()
  Prints TOS to the file-like object bound to sys.stdout. There is one such instruction for each item in the print statement.

PRINT_ITEM_TO()
  Like PRINT_ITEM, but prints the item second from TOS to the file-like object at TOS. This is used by the extended print statement.

PRINT_NEWLINE()
  Prints a new line on sys.stdout. This is generated as the last operation of a print statement, unless the statement ends with a comma.
PRINT_NEWLINE_TO()

Like PRINT_NEWLINE, but prints the new line on the file-like object on the TOS. This is used by the extended print statement.

BREAK_LOOP()

Terminates a loop due to a break statement.

CONTINUE_LOOP(target)

Continues a loop due to a continue statement. target is the address to jump to (which should be a FOR_ITER instruction).

LIST_APPEND(i)

Calls list.append(TOS[-i], TOS). Used to implement list comprehensions. While the appended value is popped off, the list object remains on the stack so that it is available for further iterations of the loop.

LOAD_LOCALS()

Pushes a reference to the locals of the current scope on the stack. This is used in the code for a class definition: After the class body is evaluated, the locals are passed to the class definition.

RETURN_VALUE()

Returns with TOS to the caller of the function.

YIELD_VALUE()

Pops tos and yields it from a generator.

IMPORT_STAR()

Loads all symbols not starting with '_' directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements from module import *.

EXEC_STMT()
Implements `exec TOS2,TOS1,TOS`. The compiler fills missing optional parameters with `None`.

**POP_BLOCK()**
Removes one block from the block stack. Per frame, there is a stack of blocks, denoting nested loops, try statements, and such.

**END_FINALLY()**
Terminates a `finally` clause. The interpreter recalls whether the exception has to be re-raised, or whether the function returns, and continues with the outer-next block.

**BUILD_CLASS()**
Creates a new class object. TOS is the methods dictionary, TOS1 the tuple of the names of the base classes, and TOS2 the class name.

**SETUP_WITH(delta)**
This opcode performs several operations before a with block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_CLEANUP`. Then, `__enter__()` is called, and a finally block pointing to `delta` is pushed. Finally, the result of calling the enter method is pushed onto the stack. The next opcode will either ignore it (POP_TOP), or store it in (a) variable(s) (STORE_FAST, STORE_NAME, or UNPACK_SEQUENCE).

**WITH_CLEANUP()**
Cleans up the stack when a `with` statement block exits. On top of the stack are 1–3 values indicating how/why the finally clause was entered:

- TOP = `None`
- (TOP, SECOND) = (`WHY_{RETURN, CONTINUE}`), retval
- TOP = WHY_*; no retval below it
- (TOP, SECOND, THIRD) = exc_info()

Under them is EXIT, the context manager’s __exit__() bound method.

In the last case, EXIT(TOP, SECOND, THIRD) is called, otherwise EXIT(None, None, None).

EXIT is removed from the stack, leaving the values above it in the same order. In addition, if the stack represents an exception, and the function call returns a ‘true’ value, this information is "zapped", to prevent END_FINALLY from re-raising the exception. (But non-local gotos should still be resumed.)

All of the following opcodes expect arguments. An argument is two bytes, with the more significant byte last.

STORE_NAME(namei)
Implements name = TOS. namei is the index of name in the attribute co_names of the code object. The compiler tries to use STORE_FAST or STORE_GLOBAL if possible.

DELETE_NAME(namei)
Implements del name, where namei is the index into co_names attribute of the code object.

UNPACK_SEQUENCE(count)
Unpacks TOS into count individual values, which are put onto the stack right-to-left.

DUP_TOPX(count)
Duplicate count items, keeping them in the same order. Due to implementation limits, count should be between 1 and 5 inclusive.
STORE_ATTR(namei)
    Implements TOS\_name = TOS1, where namei is the index of name
    in co\_names.

DELETE_ATTR(namei)
    Implements del TOS\_name, using namei as index into co\_names.

STORE_GLOBAL(namei)
    Works as STORE\_NAME, but stores the name as a global.

DELETE_GLOBAL(namei)
    Works as DELETE\_NAME, but deletes a global name.

LOAD_CONST(consti)
    Pushes co\_consts[consti] onto the stack.

LOAD_NAME(namei)
    Pushes the value associated with co\_names[namei] onto the stack.

BUILD_TUPLE(count)
    Creates a tuple consuming count items from the stack, and
    pushes the resulting tuple onto the stack.

BUILD_LIST(count)
    Works as BUILD\_TUPLE, but creates a list.

BUILD_SET(count)
    Works as BUILD\_TUPLE, but creates a set.

    *New in version 2.7.*

BUILD_MAP(count)
    Pushes a new dictionary object onto the stack. The dictionary is
    pre-sized to hold count entries.
LOAD_ATTR(namei)
Replaces TOS with `getattr(TOS, co_names[namei])`.

COMPARE_OP(opname)
Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

IMPORT_NAME(namei)
Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the `fromlist` and `level` arguments of `__import__()`.
The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent `STORE_FAST` instruction modifies the namespace.

IMPORT_FROM(namei)
Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a `STORE_FAST` instruction.

JUMP_FORWARD(delta)
Increments bytecode counter by `delta`.

POP_JUMP_IF_TRUE(target)
If TOS is true, sets the bytecode counter to `target`. TOS is popped.

POP_JUMP_IF_FALSE(target)
If TOS is false, sets the bytecode counter to `target`. TOS is popped.

JUMP_IF_TRUE_OR_POP(target)
If TOS is true, sets the bytecode counter to `target` and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

JUMP_IF_FALSE_OR_POP(target)
If TOS is false, sets the bytecode counter to `target` and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

**JUMP_ABSOLUTE**(*target*)

Set bytecode counter to `target`.

**FOR_ITER**(*delta*)

TOS is an *iterator*. Call its `next()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the bytecode counter is incremented by `delta`.

**LOAD_GLOBAL**(*name*)

Loads the global named `co_names[name]` onto the stack.

**SETUP_LOOP**(*delta*)

Pushes a block for a loop onto the block stack. The block spans from the current instruction with a size of `delta` bytes.

**SETUP_EXCEPT**(*delta*)

Pushes a try block from a try-except clause onto the block stack. `delta` points to the first except block.

**SETUP_FINALLY**(*delta*)

Pushes a try block from a try-except clause onto the block stack. `delta` points to the finally block.

**STORE_MAP**()

Store a key and value pair in a dictionary. Pops the key and value while leaving the dictionary on the stack.

**LOAD_FAST**(*var_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

**STORE_FAST**(*var_num*)
Stores TOS into the local `co_varnames[var_num]`.

**DELETE_FAST**(var_num)

Deletes local `co_varnames[var_num]`.

**LOAD_CLOSURE**(i)

Pushes a reference to the cell contained in slot `i` of the cell and free variable storage. The name of the variable is `co_cellvars[i]` if `i` is less than the length of `co_cellvars`. Otherwise it is `co_freevars[i - len(co_cellvars)]`.

**LOAD_DEREF**(i)

Loads the cell contained in slot `i` of the cell and free variable storage. Pushes a reference to the object the cell contains on the stack.

**STORE_DEREF**(i)

Stores TOS into the cell contained in slot `i` of the cell and free variable storage.

**SET_LINENO**(lineno)

This opcode is obsolete.

**RAISE_VARARGS**(argc)

Raises an exception. `argc` indicates the number of parameters to the raise statement, ranging from 0 to 3. The handler will find the traceback as TOS2, the parameter as TOS1, and the exception as TOS.

**CALL_FUNCTION**(argc)

Calls a function. The low byte of `argc` indicates the number of positional parameters, the high byte the number of keyword parameters. On the stack, the opcode finds the keyword parameters first. For each keyword argument, the value is on top of the key. Below the keyword parameters, the positional
parameters are on the stack, with the right-most parameter on top. Below the parameters, the function object to call is on the stack. Pops all function arguments, and the function itself off the stack, and pushes the return value.

**MAKE_FUNCTION**(argc)

Pushes a new function object on the stack. TOS is the code associated with the function. The function object is defined to have `argc` default parameters, which are found below TOS.

**MAKE_CLOSURE**(argc)

Creates a new function object, sets its `func_closure` slot, and pushes it on the stack. TOS is the code associated with the function, TOS1 the tuple containing cells for the closure's free variables. The function also has `argc` default parameters, which are found below the cells.

**BUILD_SLICE**(argc)

Pushes a slice object on the stack. `argc` must be 2 or 3. If it is 2, `slice(TOS1, TOS)` is pushed; if it is 3, `slice(TOS2, TOS1, TOS)` is pushed. See the `slice()` built-in function for more information.

**EXTENDED_ARG**(ext)

Prefixes any opcode which has an argument too big to fit into the default two bytes. `ext` holds two additional bytes which, taken together with the subsequent opcode’s argument, comprise a four-byte argument, `ext` being the two most-significant bytes.

**CALL_FUNCTION_VAR**(argc)

Calls a function. `argc` is interpreted as in `CALL_FUNCTION`. The top element on the stack contains the variable argument list, followed by keyword and positional arguments.

**CALL_FUNCTION_KW**(argc)

Calls a function. `argc` is interpreted as in `CALL_FUNCTION`. The top
element on the stack contains the keyword arguments dictionary, followed by explicit keyword and positional arguments.

**CALL_FUNCTION_VAR_Kw(argc)**

Calls a function. *argc* is interpreted as in `CALL_FUNCTION`. The top element on the stack contains the keyword arguments dictionary, followed by the variable-arguments tuple, followed by explicit keyword and positional arguments.

**HAVE_ARGUMENT()**

This is not really an opcode. It identifies the dividing line between opcodes which don't take arguments `< HAVE_ARGUMENT` and those which do `>= HAVE_ARGUMENT`.
32.13. pickletools — Tools for pickle developers

New in version 2.3.

Source code: Lib.pickletools.py

This module contains various constants relating to the intimate details of the pickle module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the pickle and cPickle implementations; ordinary users of the pickle module probably won’t find the pickletools module relevant.

pickletools.dis(pickle, out=None, memo=None, indentlevel=4)
Outputs a symbolic disassembly of the pickle to the file-like object out, defaulting to sys.stdout. pickle can be a string or a file-like object. memo can be a Python dictionary that will be used as the pickle’s memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by MARK opcodes in the stream, are indented by indentlevel spaces.

pickletools.genops(pickle)
Provides an iterator over all of the opcodes in a pickle, returning a sequence of (opcode, arg, pos) triples. opcode is an instance of an OpcodeInfo class; arg is the decoded value, as a Python object, of the opcode’s argument; pos is the position at which this opcode is located. pickle can be a string or a file-like object.

pickletools.optimize(picklestring)
Returns a new equivalent pickle string after eliminating unused `PUT` opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.

*New in version 2.6.*
33. Python compiler package

**Deprecated since version 2.6:** The `compiler` package has been removed in Python 3.

The Python compiler package is a tool for analyzing Python source code and generating Python bytecode. The compiler contains libraries to generate an abstract syntax tree from Python source code and to generate Python bytecode from the tree.

The `compiler` package is a Python source to bytecode translator written in Python. It uses the built-in parser and standard `parser` module to generate a concrete syntax tree. This tree is used to generate an abstract syntax tree (AST) and then Python bytecode.

The full functionality of the package duplicates the built-in compiler provided with the Python interpreter. It is intended to match its behavior almost exactly. Why implement another compiler that does the same thing? The package is useful for a variety of purposes. It can be modified more easily than the built-in compiler. The AST it generates is useful for analyzing Python source code.

This chapter explains how the various components of the `compiler` package work. It blends reference material with a tutorial.
33.1. The basic interface

The top-level of the package defines four functions. If you import *compiler*, you will get these functions and a collection of modules contained in the package.

**compiler.parse(buf)**

Returns an abstract syntax tree for the Python source code in *buf*. The function raises *SyntaxError* if there is an error in the source code. The return value is a *compiler.ast.Module* instance that contains the tree.

**compiler.parseFile(path)**

Return an abstract syntax tree for the Python source code in the file specified by *path*. It is equivalent to `parse(open(path).read())`.

**compiler.walk(ast, visitor[, verbose])**

Do a pre-order walk over the abstract syntax tree *ast*. Call the appropriate method on the *visitor* instance for each node encountered.

**compiler.compile(source, filename, mode, flags=None, dont_inherit=None)**

Compile the string *source*, a Python module, statement or expression, into a code object that can be executed by the exec statement or *eval().* This function is a replacement for the built-in *compile()* function.

The *filename* will be used for run-time error messages.

The *mode* must be ‘exec’ to compile a module, ‘single’ to compile a single (interactive) statement, or ‘eval’ to compile an
expression.

The flags and dont_inherit arguments affect future-related statements, but are not supported yet.

```
compiler.compileFile(source)
```

Compiles the file source and generates a .pyc file.

The compiler package contains the following modules: ast, consts, future, misc, pyassem, pycodegen, symbols, transformer, and visitor.
33.2. Limitations

There are some problems with the error checking of the compiler package. The interpreter detects syntax errors in two distinct phases. One set of errors is detected by the interpreter’s parser, the other set by the compiler. The compiler package relies on the interpreter’s parser, so it gets the first phases of error checking for free. It implements the second phase itself, and that implementation is incomplete. For example, the compiler package does not raise an error if a name appears more than once in an argument list: `def f(x, x): ...`

A future version of the compiler should fix these problems.
33.3. Python Abstract Syntax

The \texttt{compiler.ast} module defines an abstract syntax for Python. In the abstract syntax tree, each node represents a syntactic construct. The root of the tree is \texttt{Module} object.

The abstract syntax offers a higher level interface to parsed Python source code. The \texttt{parser} module and the compiler written in C for the Python interpreter use a concrete syntax tree. The concrete syntax is tied closely to the grammar description used for the Python parser. Instead of a single node for a construct, there are often several levels of nested nodes that are introduced by Python’s precedence rules.

The abstract syntax tree is created by the \texttt{compiler.transformer} module. The transformer relies on the built-in Python parser to generate a concrete syntax tree. It generates an abstract syntax tree from the concrete tree.

The \texttt{transformer} module was created by Greg Stein and Bill Tutt for an experimental Python-to-C compiler. The current version contains a number of modifications and improvements, but the basic form of the abstract syntax and of the transformer are due to Stein and Tutt.

33.3.1. AST Nodes

The \texttt{compiler.ast} module is generated from a text file that describes each node type and its elements. Each node type is represented as a class that inherits from the abstract base class \texttt{compiler.ast.Node} and defines a set of named attributes for child nodes.

\texttt{class compiler.ast.Node}

The \texttt{Node} instances are created automatically by the parser
generator. The recommended interface for specific Node instances is to use the public attributes to access child nodes. A public attribute may be bound to a single node or to a sequence of nodes, depending on the Node type. For example, the bases attribute of the class node, is bound to a list of base class nodes, and the doc attribute is bound to a single node.

Each Node instance has a lineno attribute which may be None. XXX Not sure what the rules are for which nodes will have a useful lineno.

All Node objects offer the following methods:

getChildren()

Returns a flattened list of the child nodes and objects in the order they occur. Specifically, the order of the nodes is the order in which they appear in the Python grammar. Not all of the children are Node instances. The names of functions and classes, for example, are plain strings.

getChildNodes()

Returns a flattened list of the child nodes in the order they occur. This method is like getChildren(), except that it only returns those children that are Node instances.

Two examples illustrate the general structure of Node classes. The while statement is defined by the following grammar production:

```
while_stmt:    "while" expression ":" suite
              ["else" ":" suite]
```

The While node has three attributes: test, body, and else_. (If the natural name for an attribute is also a Python reserved word, it can't be used as an attribute name. An underscore is appended to the
word to make it a legal identifier, hence `else_` instead of `else`.)

The `if` statement is more complicated because it can include several tests.

```
if_stmt: 'if' test ':' suite ('elif' test ':' suite)* ['else' ':' suite]
```

The `If` node only defines two attributes: `tests` and `else_`. The `tests` attribute is a sequence of test expression, consequent body pairs. There is one pair for each `if/elif` clause. The first element of the pair is the test expression. The second elements is a `stmt` node that contains the code to execute if the test is true.

The `getChildren()` method of `If` returns a flat list of child nodes. If there are three `if/elif` clauses and no `else` clause, then `getChildren()` will return a list of six elements: the first test expression, the first `stmt`, the second test expression, etc.

The following table lists each of the `Node` subclasses defined in `compiler.ast` and each of the public attributes available on their instances. The values of most of the attributes are themselves `Node` instances or sequences of instances. When the value is something other than an instance, the type is noted in the comment. The attributes are listed in the order in which they are returned by `getChildren()` and `getChildNodes()`.

33.3.2. Assignment nodes

There is a collection of nodes used to represent assignments. Each assignment statement in the source code becomes a single `Assign` node in the AST. The `nodes` attribute is a list that contains a node for each assignment target. This is necessary because assignment can be chained, e.g. `a = b = 2`. Each `Node` in the list will be one of the following classes: `AssAttr`, `AssList`, `AssName`, or `AssTuple`.

Each target assignment node will describe the kind of object being assigned to: `AssName` for a simple name, e.g. `a = 1`. `AssAttr` for an attribute assigned, e.g. `a.x = 1`. `AssList` and `AssTuple` for list and tuple expansion respectively, e.g. `a, b, c = a_tuple`.

The target assignment nodes also have a `flags` attribute that indicates whether the node is being used for assignment or in a
delete statement. The AssName is also used to represent a delete statement, e.g. del x.

When an expression contains several attribute references, an assignment or delete statement will contain only one AssAttr node – for the final attribute reference. The other attribute references will be represented as Getattr nodes in the expr attribute of the AssAttr instance.

### 33.3.3. Examples

This section shows several simple examples of ASTs for Python source code. The examples demonstrate how to use the parse() function, what the repr of an AST looks like, and how to access attributes of an AST node.

The first module defines a single function. Assume it is stored in doublelib.py.

```python
"""This is an example module.

This is the docstring.
"""

def double(x):
    "Return twice the argument"
    return x * 2
```

In the interactive interpreter session below, I have reformatted the long AST reprs for readability. The AST reprs use unqualified class names. If you want to create an instance from a repr, you must import the class names from the compiler.ast module.

```python
>>> import compiler
>>> mod = compiler.parseFile("doublelib.py")
>>> mod
Module('This is an example module.

This is the docstring.
',

def double(x):
    "Return twice the argument"
    return x * 2
```
>>> from compiler.ast import *
>>> Module('This is an example module.

This is the docstring.

Function(None, 'double', ['x'], [], 0, 'Return twice the argument',
Stmt([Return(Mul((Name('x'), Const(2))))]))

>>> mod.doc
'This is an example module.

This is the docstring.
'
>>> for node in mod.node.nodes:
    print node

Function(None, 'double', ['x'], [], 0, 'Return twice the argument',
Stmt([Return(Mul((Name('x'), Const(2))))]))

>>> func = mod.node.nodes[0]
>>> func.code
Stmt([Return(Mul((Name('x'), Const(2))))])
33.4. Using Visitors to Walk ASTs

The visitor pattern is ... The compiler package uses a variant on the visitor pattern that takes advantage of Python’s introspection features to eliminate the need for much of the visitor’s infrastructure.

The classes being visited do not need to be programmed to accept visitors. The visitor need only define visit methods for classes it is specifically interested in; a default visit method can handle the rest.

XXX The magic visit() method for visitors.

```
compiler.visitor.walk(tree, visitor[, verbose])
```

```
class compiler.visitor.ASTVisitor
```

The ASTVisitor is responsible for walking over the tree in the correct order. A walk begins with a call to preorder(). For each node, it checks the visitor argument to preorder() for a method named ‘visitNodeType,’ where NodeType is the name of the node’s class, e.g. for a While node a visitWhile() would be called. If the method exists, it is called with the node as its first argument.

The visitor method for a particular node type can control how child nodes are visited during the walk. The ASTVisitor modifies the visitor argument by adding a visit method to the visitor; this method can be used to visit a particular child node. If no visitor is found for a particular node type, the default() method is called.

ASTVisitor objects have the following methods:

XXX describe extra arguments
default(node[,...])

dispatch(node[,...])

preorder(tree, visitor)
33.5. Bytecode Generation

The code generator is a visitor that emits bytecodes. Each visit method can call the `emit()` method to emit a new bytecode. The basic code generator is specialized for modules, classes, and functions. An assembler converts that emitted instructions to the low-level bytecode format. It handles things like generation of constant lists of code objects and calculation of jump offsets.
34. Miscellaneous Services

The modules described in this chapter provide miscellaneous services that are available in all Python versions. Here's an overview:

- **34.1. formatter — Generic output formatting**
  - 34.1.1. The Formatter Interface
  - 34.1.2. Formatter Implementations
  - 34.1.3. The Writer Interface
  - 34.1.4. Writer Implementations
34.1. **formatter — Generic output formatting**

This module supports two interface definitions, each with multiple implementations. The *formatter* interface is used by the `HTMLParser` class of the `htmllib` module, and the *writer* interface is required by the formatter interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored; writers need not be able to handle relative changes nor any sort of “change back” operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.
34.1.1. The Formatter Interface

Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level:

`formatter.AS_IS`

Value which can be used in the font specification passed to the `push_font()` method described below, or as the new value to any other `push_property()` method. Pushing the `AS_IS` value allows the corresponding `pop_property()` method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects:

`formatter.writer`

The writer instance with which the formatter interacts.

`formatter.end_paragraph(blanklines)`

Close any open paragraphs and insert at least `blanklines` before the next paragraph.

`formatter.add_line_break()`

Add a hard line break if one does not already exist. This does not break the logical paragraph.

`formatter.add_hor_rule(*args, **kw)`

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the writer’s `send_line_break()` method.
formatter.\texttt{add\_flowing\_data}(\textit{data})

Provide data which should be formatted with collapsed whitespace. Whitespace from preceding and successive calls to \texttt{add\_flowing\_data()} is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

formatter.\texttt{add\_literal\_data}(\textit{data})

Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of \textit{data}.

formatter.\texttt{add\_label\_data}(\textit{format}, \textit{counter})

Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the \textit{format} value is a string, it is interpreted as a format specification for \textit{counter}, which should be an integer. The result of this formatting becomes the value of the label; if \textit{format} is not a string it is used as the label value directly. The label value is passed as the only argument to the writer's \texttt{send\_label\_data()} method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character '1' represents the counter value formatter as an Arabic number, the characters 'A' and 'a' represent alphabetic representations of the counter value in upper and lower case, respectively, and 'I' and 'i' represent the counter value in Roman numerals, in upper and lower case.
Note that the alphabetic and roman transforms require that the counter value be greater than zero.

`formatter.flush_softspace()`
Send any pending whitespace buffered from a previous call to `add_flowing_data()` to the associated writer object. This should be called before any direct manipulation of the writer object.

`formatter.push_alignment(align)`
Push a new alignment setting onto the alignment stack. This may be `AS_IS` if no change is desired. If the alignment value is changed from the previous setting, the writer’s `new_alignment()` method is called with the `align` value.

`formatter.pop_alignment()`
Restore the previous alignment.

`formatter.push_font((size, italic, bold, teletype))`
Change some or all font properties of the writer object. Properties which are not set to `AS_IS` are set to the values passed in while others are maintained at their current settings. The writer’s `new_font()` method is called with the fully resolved font specification.

`formatter.pop_font()`
Restore the previous font.

`formatter.push_margin(margin)`
Increase the number of left margin indentations by one, associating the logical tag `margin` with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than `AS_IS` are not sufficient to change the margin.

`formatter.pop_margin()`
Restore the previous margin.

**formatter.push_style(*styles)**

Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including `AS_IS` values, is passed to the writer’s `new_styles()` method.

**formatter.pop_style([n=1])**

Pop the last n style specifications passed to `push_style()`. A tuple representing the revised stack, including `AS_IS` values, is passed to the writer’s `new_styles()` method.

**formatter.set_spacing(spacing)**

Set the spacing style for the writer.

**formatter.assert_line_data([flag=1])**

Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional `flag` argument can be set to false if the writer manipulations produced a hard line break at the end of the output.
34.1.2. Formatter Implementations

Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

```python
class formatter.NullFormatter([writer])
    A formatter which does nothing. If writer is omitted, a NullWriter instance is created. No methods of the writer are called by NullFormatter instances. Implementations should inherit from this class if implementing a writer interface but don’t need to inherit any implementation.
```

```python
class formatter.AbstractFormatter(writer)
    The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.
```
34.1.3. The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the AbstractFormatter class as a formatter, the writer must typically be provided by the application.

writer.**flush**()
Flush any buffered output or device control events.

writer.**new_alignment**(align)
Set the alignment style. The align value can be any object, but by convention is a string or None, where None indicates that the writer’s “preferred” alignment should be used. Conventional align values are 'left', 'center', 'right', and 'justify'.

writer.**new_font**(font)
Set the font style. The value of font will be None, indicating that the device’s default font should be used, or a tuple of the form (size, italic, bold, teletype). Size will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The italic, bold, and teletype values are Boolean values specifying which of those font attributes should be used.

writer.**new_margin**(margin, level)
Set the margin level to the integer level and the logical tag to margin. Interpretation of the logical tag is at the writer’s discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of level.

writer.**new_spacing**(spacing)
Set the spacing style to *spacing*.

**writer.** `new_styles(styles)`

Set additional styles. The *styles* value is a tuple of arbitrary values; the value `AS_IS` should be ignored. The *styles* tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

**writer.** `send_line_break()`

Break the current line.

**writer.** `send_paragraph(blankline)`

Produce a paragraph separation of at least *blankline* blank lines, or the equivalent. The *blankline* value will be an integer. Note that the implementation will receive a call to `send_line_break()` before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

**writer.** `send_hor_rule(*args, **kw)`

Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via `send_line_break()`.

**writer.** `send_flowing_data(data)`

Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.

**writer.** `send_literal_data(data)`

Output character data which has already been formatted for display. Generally, this should be interpreted to mean that line.
breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the `send_formatted_data()` interface.

`writer.send_label_data(data)`

Set `data` to the left of the current left margin, if possible. The value of `data` is not restricted; treatment of non-string values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.
34.1.4. Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the NullWriter class.

```python
class formatter.NullWriter
    A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.

class formatter.AbstractWriter
    A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.

class formatter.DumbWriter(file=None, maxcol=72)
    Simple writer class which writes output on the file object passed in as file or, if file is None, on standard output. The output is simply word-wrapped to the number of columns specified by maxcol. This class is suitable for reflowing a sequence of paragraphs.
```
This chapter describes modules that are only available on MS Windows platforms.

- **35.1. msilib** — Read and write Microsoft Installer files
  - 35.1.1. Database Objects
  - 35.1.2. View Objects
  - 35.1.3. Summary Information Objects
  - 35.1.4. Record Objects
  - 35.1.5. Errors
  - 35.1.6. CAB Objects
  - 35.1.7. Directory Objects
  - 35.1.8. Features
  - 35.1.9. GUI classes
  - 35.1.10. Precomputed tables

  - 35.2.1. File Operations
  - 35.2.2. Console I/O
  - 35.2.3. Other Functions
- **35.3. _winreg** – Windows registry access
  - 35.3.1. Constants
    - 35.3.1.1. HKEY_* Constants
    - 35.3.1.2. Access Rights
      - 35.3.1.2.1. 64-bit Specific
    - 35.3.1.3. Value Types
  - 35.3.2. Registry Handle Objects
- **35.4. winsound** — Sound-playing interface for Windows
35.1. msilib — Read and write Microsoft Installer files

*New in version 2.5.*

The `msilib` supports the creation of Microsoft Installer (.msi) files. Because these files often contain an embedded “cabinet” file (.cab), it also exposes an API to create CAB files. Support for reading .cab files is currently not implemented; read support for the .msi database is possible.

This package aims to provide complete access to all tables in an .msi file, therefore, it is a fairly low-level API. Two primary applications of this package are the `distutils` command `bdist_msi`, and the creation of Python installer package itself (although that currently uses a different version of `msilib`).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

```python
msilib.FCICreate(cabname, files)
```

Create a new CAB file named `cabname`. `files` must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.
msilib. **UuidCreate()**

Return the string representation of a new unique identifier. This wraps the Windows API functions `UuidCreate()` and `UuidToString()`.

msilib. **OpenDatabase(path, persist)**

Return a new database object by calling MsiOpenDatabase. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

msilib. **CreateRecord(count)**

Return a new record object by calling `MSICreateRecord()`. *count* is the number of fields of the record.

msilib. **init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)**

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

*schema* must be a module object containing tables and _Validation_records attributes; typically, `msilib.schema` should be used.

The database will contain just the schema and the validation records when this function returns.

msilib. **add_data(database, table, records)**

Add all *records* to the table named *table* in *database*.

The *table* argument must be one of the predefined tables in the
MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

*records* should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, *None* can be passed.

Field values can be int or long numbers, strings, or instances of the Binary class.

```python
class msilib.Binary(filename)
    Represents entries in the Binary table; inserting such an object using add_data() reads the file named *filename* into the table.
```

```python
msilib.add_tables(database, module)
    Add all table content from *module* to *database*. *module* must contain an attribute *tables* listing all tables for which content should be added, and one attribute per table that has the actual content.

    This is typically used to install the sequence tables.
```

```python
msilib.add_stream(database, name, path)
    Add the file *path* into the _Stream table of *database*, with the stream name *name*.
```

```python
msilib.gen_uuid()
    Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).
```

**See also:** FCICreateFile UuidCreate UuidToString
35.1.1. Database Objects

Database. **OpenView(sql)**
Return a view object, by calling **MSIDatabaseOpenView()**. *sql* is the SQL statement to execute.

Database. **Commit()**
Commit the changes pending in the current transaction, by calling **MSIDatabaseCommit()**.

Database. **GetSummaryInformation(count)**
Return a new summary information object, by calling **MsiGetSummaryInformation()**. *count* is the maximum number of updated values.

**See also:**  **MSIDatabaseOpenView**  **MSIDatabaseCommit**  **MsiGetSummaryInformation**
35.1.2. View Objects

View.**Execute**(params)

Execute the SQL query of the view, through MSIViewExecute(). If *params* is not None, it is a record describing actual values of the parameter tokens in the query.

View.**GetColumnInfo**(kind)

Return a record describing the columns of the view, through calling MsiViewGetColumnInfo(). *kind* can be either MSICOLINFO_NAMES or MSICOLINFO_TYPES.

View.**Fetch**()

Return a result record of the query, through calling MsiViewFetch().

View.**Modify**(kind, data)

Modify the view, by calling MsiViewModify(). *kind* can be one of MSIMODIFY_SEEK, MSIMODIFY_REFRESH, MSIMODIFY_INSERT, MSIMODIFY_UPDATE, MSIMODIFY_ASSIGN, MSIMODIFY_REPLACE, MSIMODIFY_MERGE, MSIMODIFY_INSERT_TEMPORARY, MSIMODIFY_VALIDATE, MSIMODIFY_VALIDATE_NEW, MSIMODIFY_VALIDATE_FIELD, or MSIMODIFY_VALIDATE_DELETE.

*data* must be a record describing the new data.

View.**Close**()

Close the view, through MsiViewClose().

See also: MSIViewExecute MsiViewGetColumnInfo MsiViewFetch MsiViewModify MsiViewClose
35.1.3. Summary Information Objects

**SummaryInformation.GetProperty(field)**

Return a property of the summary, through `MsiSummaryInfoGetProperty()`. *field* is the name of the property, and can be one of the constants `PID_CODEPAGE`, `PID_TITLE`, `PID_SUBJECT`, `PID_AUTHOR`, `PID_KEYWORDS`, `PID_COMMENTS`, `PID_TEMPLATE`, `PID_LASTAUTHOR`, `PID_REVNUMBER`, `PID_LASTPRINTED`, `PID_CREATE_DTM`, `PID_LASTSAVE_DTM`, `PID_PAGECOUNT`, `PID_WORDCOUNT`, `PID_CHARCOUNT`, `PID_APPNAME`, or `PID_SECURITY`.

**SummaryInformation.GetPropertyCount()**

Return the number of summary properties, through `MsiSummaryInfoGetPropertyCount()`.

**SummaryInformation.SetProperty(field, value)**

Set a property through `MsiSummaryInfoSetProperty()`. *field* can have the same values as in `GetProperty()`, *value* is the new value of the property. Possible value types are integer and string.

**SummaryInformation.Persist()**

Write the modified properties to the summary information stream, using `MsiSummaryInfoPersist()`.

See also: MsiSummaryInfoGetProperty
MsiSummaryInfoGetPropertyCount MsiSummaryInfoSetProperty
MsiSummaryInfoPersist
35.1.4. Record Objects

**Record. `GetFieldCount()`**
Return the number of fields of the record, through `MsiRecordGetFieldCount()`.

**Record. `GetInteger(field)`**
Return the value of `field` as an integer where possible. `field` must be an integer.

**Record. `GetString(field)`**
Return the value of `field` as a string where possible. `field` must be an integer.

**Record. `SetString(field, value)`**
Set `field` to `value` through `MsiRecordSetString()`. `field` must be an integer; `value` a string.

**Record. `SetStream(field, value)`**
Set `field` to the contents of the file named `value`, through `MsiRecordSetStream()`. `field` must be an integer; `value` a string.

**Record. `SetInteger(field, value)`**
Set `field` to `value` through `MsiRecordSetInteger()`. Both `field` and `value` must be an integer.

**Record. `ClearData()`**
Set all fields of the record to 0, through `MsiRecordClearData()`.

**See also:** `MsiRecordGetFieldCount` `MsiRecordSetString` `MsiRecordSetStream` `MsiRecordSetInteger` `MsiRecordClear`
35.1.5. Errors

All wrappers around MSI functions raise `MsiError`; the string inside the exception will contain more detail.
35.1.6. CAB Objects

*class msilib.CAB(name)*

The class CAB represents a CAB file. During MSI construction, files will be added simultaneously to the Files table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

`name` is the name of the CAB file in the MSI file.

*append(full, file, logical)*

Add the file with the pathname `full` to the CAB file, under the name `logical`. If there is already a file named `logical`, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

*commit(database)*

Generate a CAB file, add it as a stream to the MSI file, put it into the Media table, and remove the generated file from the disk.
35.1.7. Directory Objects

class msilib.Directory(database, cab, basedir, physical, logical, default[, componentflags])

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through start_component(), or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be None), the path to the physical directory, and a logical directory name. default specifies the DefaultDir slot in the directory table. componentflags specifies the default flags that new components get.

start_component([component[, feature[, flags[, keyfile[, uuid]]]]])

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no feature is given, the current feature is used. If no flags are given, the directory's default flags are used. If no keyfile is given, the KeyPath is left null in the Component table.

add_file(file[, src[, version[, language]]])

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the src file is specified, it is interpreted relative to the current directory. Optionally, a version and a language can be specified for the entry in the File table.

glob(pattern[, exclude])
Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the *exclude* list.

```python
remove_pyc()
```

Remove `.pyc`/.`pyo` files on uninstall.

**See also:** Directory Table File Table Component Table FeatureComponents Table
35.1.8. Features

```python
class msilib.Feature(database, id, title, desc, display[, level=1[, parent[, directory[, attributes=0]]]])
```

Add a new record to the Feature table, using the values `id`, `parent.id`, `title`, `desc`, `display`, `level`, `directory`, and `attributes`. The resulting feature object can be passed to the `start_component()` method of `Directory`.

**set_current()**

Make this feature the current feature of `msilib`. New components are automatically added to the default feature, unless a feature is explicitly specified.

**See also:** Feature Table
35.1.9. GUI classes

`msilib` provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use `bdist_msi` to create MSI files with a user-interface for installing Python packages.

```python
class msilib.Control(dlg, name)
    Base class of the dialog controls. `dlg` is the dialog object the control belongs to, and `name` is the control’s name.

event(event, argument[, condition=1[, ordering]])
    Make an entry into the ControlEvent table for this control.

mapping(event, attribute)
    Make an entry into the EventMapping table for this control.

condition(action, condition)
    Make an entry into the ControlCondition table for this control.
```

```python
class msilib.RadioButtonGroup(dlg, name, property)
    Create a radio button control named `name`. `property` is the installer property that gets set when a radio button is selected.

    add(name, x, y, width, height, text[, value])
        Add a radio button named `name` to the group, at the coordinates `x`, `y`, `width`, `height`, and with the label `text`. If `value` is omitted, it defaults to `name`.
```

```python
class msilib.Dialog(db, name, x, y, w, h, attr, title, first, default, cancel)
    Return a new Dialog object. An entry in the Dialog table is made, with the specified coordinates, dialog attributes, title, name of the
first, default, and cancel controls.

**control**(name, type, x, y, width, height, attributes, property, text, control_next, help)

Return a new Control object. An entry in the Control table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

**text**(name, x, y, width, height, attributes, text)

Add and return a Text control.

**bitmap**(name, x, y, width, height, text)

Add and return a Bitmap control.

**line**(name, x, y, width, height)

Add and return a Line control.

**pushbutton**(name, x, y, width, height, attributes, text, next_control)

Add and return a PushButton control.

**radiogroup**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a RadioButtonGroup control.

**checkbox**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a CheckBox control.

See also: Dialog Table Control Table Control Types ControlCondition Table ControlEvent Table EventMapping Table RadioButton Table
35.1.10. Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

`msilib.schema`
This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `Validation_records` providing the data for MSI validation.

`msilib.sequence`
This module contains table contents for the standard sequence tables: `AdminExecuteSequence`, `AdminUISequence`, `AdvtExecuteSequence`, `InstallExecuteSequence`, and `InstallUISequence`.

`msilib.text`
This module contains definitions for the `UIText` and `ActionText` tables, for the standard installer actions.
35.2. msvcrt – Useful routines from the MS VC++ runtime

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the getpass module uses this in the implementation of the getpass() function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.
35.2.1. File Operations

`msvcrt.locking(fd, mode, nbytes)`
Lock part of a file based on file descriptor `fd` from the C runtime. Raises `IOError` on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

`msvcrt.LK_LOCK`
`msvcrt.LK_RLCK`
Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `IOError` is raised.

`msvcrt.LK_NBLCK`
`msvcrt.LK_NBRLCK`
Locks the specified bytes. If the bytes cannot be locked, `IOError` is raised.

`msvcrt.LK_UNLCK`
Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`
Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_osfhandle(handle, flags)`
Create a C runtime file descriptor from the file handle `handle`. The `flags` parameter should be a bitwise OR of `os.O_APPEND`,
os.O_RDONLY, and os.O_TEXT. The returned file descriptor may be used as a parameter to os.fdopen() to create a file object.

msvcrt.get_osfhandle(fd)
Return the file handle for the file descriptor fd. Raises IOError if fd is not recognized.
35.2.2. Console I/O

**msvcrt.**kbhit**()**
Return true if a keypress is waiting to be read.

**msvcrt.**getch**()**
Read a keypress and return the resulting character. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for Enter to be pressed. If the pressed key was a special function key, this will return '\\000' or '\xe0'; the next call will return the keycode. The Control-C keypress cannot be read with this function.

**msvcrt.**getwch**()**
Wide char variant of **getch()**, returning a Unicode value.

*New in version 2.6.*

**msvcrt.**getche**()**
Similar to **getch()**, but the keypress will be echoed if it represents a printable character.

**msvcrt.**getwche**()**
Wide char variant of **getche()**, returning a Unicode value.

*New in version 2.6.*

**msvcrt.**putch**(char)**
Print the character **char** to the console without buffering.

**msvcrt.**putwch**(unicode_char)**
Wide char variant of **putch()**, accepting a Unicode value.

*New in version 2.6.*
**msvcrt.** `ungetch(char)`

Cause the character `char` to be “pushed back” into the console buffer; it will be the next character read by `getch()` or `getche()`.

**msvcrt.** `ungetwch(unicode_char)`

Wide char variant of `ungetch()`, accepting a Unicode value.

*New in version 2.6.*
35.2.3. Other Functions

`msvcrt.heapmin()`

Force the `malloc()` heap to clean itself up and return unused blocks to the operating system. On failure, this raises `IOError`.
Note: The _winreg module has been renamed to winreg in Python 3. The 2to3 tool will automatically adapt imports when converting your sources to Python 3.

New in version 2.0.

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a handle object is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

This module offers the following functions:

_winreg.CloseKey(hkey)
Closes a previously opened registry key. The hkey argument specifies a previously opened key.

Note: If hkey is not closed using this method (or via hkey.Close()), it is closed when the hkey object is destroyed by Python.

_winreg.ConnectRegistry(computer_name, key)
Establishes a connection to a predefined registry handle on another computer, and returns a handle object.

computer_name is the name of the remote computer, of the form r"\computernamename". If None, the local computer is used.

key is the predefined handle to connect to.
The return value is the handle of the opened key. If the function fails, a `WindowsError` exception is raised.

```python
_winreg.CreateKey(key, sub_key)
```

Creates or opens the specified key, returning a handle object.

`key` is an already open key, or one of the predefined `HKEY_*` constants.

`sub_key` is a string that names the key this method opens or creates.

If `key` is one of the predefined keys, `sub_key` may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, a `WindowsError` exception is raised.

```python
_winreg.CreateKeyEx(key, sub_key[, res[, sam]])
```

Creates or opens the specified key, returning a handle object.

`key` is an already open key, or one of the predefined `HKEY_*` constants.

`sub_key` is a string that names the key this method opens or creates.

`res` is a reserved integer, and must be zero. The default is zero.

`sam` is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_ALL_ACCESS`. See Access Rights for other allowed values.
If `key` is one of the predefined keys, `sub_key` may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, a `WindowsError` exception is raised.

*New in version 2.7.*

```python
_winreg.DeleteKey(key, sub_key)
```

Deletes the specified key.

- `key` is an already open key, or any one of the predefined `HKEY_*` constants.

- `sub_key` is a string that must be a subkey of the key identified by the `key` parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, a `WindowsError` exception is raised.

```python
_winreg.DeleteKeyEx(key, sub_key[, sam[, res]])
```

Deletes the specified key.

**Note:** The `DeleteKeyEx()` function is implemented with the `RegDeleteKeyEx` Windows API function, which is specific to 64-bit versions of Windows. See the `RegDeleteKeyEx documentation`. 
key is an already open key, or any one of the predefined HKEY_*
constants.

sub_key is a string that must be a subkey of the key identified by
the key parameter. This value must not be None, and the key may
not have subkeys.

res is a reserved integer, and must be zero. The default is zero.

sam is an integer that specifies an access mask that describes
the desired security access for the key. Default is
KEY_WOW64_64KEY. See Access Rights for other allowed values.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its values,
is removed. If the method fails, a WindowsError exception is
raised.

On unsupported Windows versions, NotImplemented Exception is
raised.

New in version 2.7.

_winreg. DeleteValue(key, value)
Removes a named value from a registry key.

key is an already open key, or one of the predefined HKEY_*
constants.

value is a string that identifies the value to remove.

_winreg. EnumKey(key, index)
Enumerates subkeys of an open registry key, returning a string.

key is an already open key, or any one of the predefined HKEY_*
 CONSTANTS

_\textit{index}_ is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until a \texttt{WindowsError} exception is raised, indicating, no more values are available.

\texttt{_winreg.EnumValue(key, index)}

Enumerates values of an open registry key, returning a tuple.

\texttt{key} is an already open key, or any one of the predefined \texttt{HKEY_*} constants.

\texttt{index} is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until a \texttt{WindowsError} exception is raised, indicating no more values.

The result is a tuple of 3 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A string that identifies the value name</td>
</tr>
<tr>
<td>1</td>
<td>An object that holds the value data, and whose type depends on the underlying registry type</td>
</tr>
<tr>
<td>2</td>
<td>An integer that identifies the type of the value data (see table in docs for \texttt{SetValueEx()})</td>
</tr>
</tbody>
</table>

\texttt{_winreg.ExpandEnvironmentStrings(unicode)}

Expands environment variable placeholders \texttt{%NAME%} in unicode strings like \texttt{REG_EXPAND_SZ}:

```python
>>> ExpandEnvironmentStrings(u"%windir%")
u"C:\Windows"
```
New in version 2.6.

_winreg. **FlushKey**(key)

Writes all the attributes of a key to the registry.

*key* is an already open key, or one of the predefined **HKEY_* constants**.

It is not necessary to call **FlushKey()** to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike **CloseKey()**, the **FlushKey()** method returns only when all the data has been written to the registry. An application should only call **FlushKey()** if it requires absolute certainty that registry changes are on disk.

**Note:** If you don’t know whether a **FlushKey()** call is required, it probably isn’t.

_winreg. **LoadKey**(key, sub_key, file_name)

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

*key* is a handle returned by **ConnectRegistry()** or one of the constants **HKEY_USERS** or **HKEY_LOCAL_MACHINE**.

*sub_key* is a string that identifies the subkey to load.

*file_name* is the name of the file to load registry data from. This file must have been created with the **SaveKey()** function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to **LoadKey()** fails if the calling process does not have the
SE_RESTORE_PRIVILEGE privilege. Note that privileges are different from permissions – see the RegLoadKey documentation for more details.

If key is a handle returned by ConnectRegistry(), then the path specified in file_name is relative to the remote computer.

_winreg.OpenKey(key, sub_key[], res[], sam[])
Opens the specified key, returning a handle object.

key is an already open key, or any one of the predefined HKEY_* constants.

sub_key is a string that identifies the sub_key to open.

res is a reserved integer, and must be zero. The default is zero.

sam is an integer that specifies an access mask that describes the desired security access for the key. Default is KEY_READ. See Access Rights for other allowed values.

The result is a new handle to the specified key.

If the function fails, WindowsError is raised.

_winreg.OpenKeyEx()

The functionality of OpenKeyEx() is provided via OpenKey(), by the use of default arguments.

_winreg.QueryInfoKey(key)
Returns information about a key, as a tuple.

key is an already open key, or one of the predefined HKEY_* constants.

The result is a tuple of 3 items:
Index | Meaning
---|---
0 | An integer giving the number of sub keys this key has.
1 | An integer giving the number of values this key has.
2 | A long integer giving when the key was last modified (if available) as 100’s of nanoseconds since Jan 1, 1601.

_winreg.**QueryValue**(key, sub_key)
Retrieves the unnamed value for a key, as a string.

*key* is an already open key, or one of the predefined **HKEY_* constants**.

*sub_key* is a string that holds the name of the subkey with which the value is associated. If this parameter is **None** or empty, the function retrieves the value set by the **SetValue()** method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a NULL name. But the underlying API call doesn’t return the type, so always use **QueryValueEx()** if possible.

_winreg.**QueryValueEx**(key, value_name)
Retrieves the type and data for a specified value name associated with an open registry key.

*key* is an already open key, or one of the predefined **HKEY_* constants**.

*value_name* is a string indicating the value to query.

The result is a tuple of 2 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The value of the registry item.</td>
</tr>
</tbody>
</table>
_winreg. **SaveKey(key, file_name)**

Saves the specified key, and all its subkeys to the specified file.

*key* is an already open key, or one of the predefined HKEY_* constants.

*file_name* is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the `LoadKey()` method.

If *key* represents a key on a remote computer, the path described by *file_name* is relative to the remote computer. The caller of this method must possess the SeBackupPrivilege security privilege. Note that privileges are different than permissions – see the Conflicts Between User Rights and Permissions documentation for more details.

This function passes NULL for security_attributes to the API.

_\_winreg. **SetValue(key, sub_key, type, value)**

Associates a value with a specified key.

*key* is an already open key, or one of the predefined HKEY_* constants.

*sub_key* is a string that names the subkey with which the value is associated.

*type* is an integer that specifies the type of the data. Currently this must be REG_SZ, meaning only strings are supported. Use the `SetValueEx()` function for support for other data types.
value is a string that specifies the new value.

If the key specified by the sub_key parameter does not exist, the SetValue function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the key parameter must have been opened with KEY_SET_VALUE access.

_WINREG.SetValueEx(key, value_name, reserved, type, value)
Stores data in the value field of an open registry key.

key is an already open key, or one of the predefined HKEY_*
constants.

value_name is a string that names the subkey with which the value is associated.

type is an integer that specifies the type of the data. See Value Types for the available types.

reserved can be anything – zero is always passed to the API.

value is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with KEY_SET_VALUE access.

To open the key, use the CreateKey() or OpenKey() methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the
filenames stored in the configuration registry. This helps the registry perform efficiently.

_winreg. **DisableReflectionKey(key)**
Disables registry reflection for 32-bit processes running on a 64-bit operating system.

*key* is an already open key, or one of the predefined HKEY_* constants.

Will generally raise **NotImplemented** if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

_winreg. **EnableReflectionKey(key)**
Restores registry reflection for the specified disabled key.

*key* is an already open key, or one of the predefined HKEY_* constants.

Will generally raise **NotImplemented** if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

_winreg. **QueryReflectionKey(key)**
Determines the reflection state for the specified key.

*key* is an already open key, or one of the predefined HKEY_* constants.

Returns True if reflection is disabled.
Will generally raise `NotImplemented` if executed on a 32-bit operating system.
35.3.1. Constants

The following constants are defined for use in many _winreg
functions.

35.3.1.1. HKEY_* Constants

_winreg. HKEY_CLASSES_ROOT
Registry entries subordinate to this key define types (or classes) of
documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

_winreg. HKEY_CURRENT_USER
Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

_winreg. HKEY_LOCAL_MACHINE
Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

_winreg. HKEY_USERS
Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

_winreg. HKEY_PERFORMANCE_DATA
Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.
_winreg.HKEY_CURRENT_CONFIG
Contains information about the current hardware profile of the local computer system.

_winreg.HKEY_DYN_DATA
This key is not used in versions of Windows after 98.

35.3.1.2. Access Rights

For more information, see Registry Key Security and Access.

_winreg.KEY_ALL_ACCESS
Combines the STANDARD_RIGHTS_REQUIRED, KEY_QUERY_VALUE, KEY_SET_VALUE, KEY_CREATE_SUB_KEY,
KEY_ENUMERATE_SUB_KEYS, KEY_NOTIFY, and KEY_CREATE_LINK access rights.

_winreg.KEY_WRITE
Combines the STANDARD_RIGHTS_WRITE, KEY_SET_VALUE, and KEY_CREATE_SUB_KEY access rights.

_winreg.KEY_READ
Combines the STANDARD_RIGHTS_READ, KEY_QUERY_VALUE, KEY_ENUMERATE_SUB_KEYS, and KEY_NOTIFY values.

_winreg.KEY_EXECUTE
Equivalent to KEY_READ.

_winreg.KEY_QUERY_VALUE
Required to query the values of a registry key.

_winreg.KEY_SET_VALUE
Required to create, delete, or set a registry value.

_winreg.KEY_CREATE_SUB_KEY
Required to create a subkey of a registry key.
__winreg__\_.KEY\_ENUMERATE\_SUB\_KEYS
Required to enumerate the subkeys of a registry key.

__winreg__\_.KEY\_NOTIFY
Required to request change notifications for a registry key or for subkeys of a registry key.

__winreg__\_.KEY\_CREATE\_LINK
Reserved for system use.

### 35.3.1.2.1. 64-bit Specific

For more information, see Accessing an Alternate Registry View.

__winreg__\_.KEY\_WOW64\_64KEY
Indicates that an application on 64-bit Windows should operate on the 64-bit registry view.

__winreg__\_.KEY\_WOW64\_32KEY
Indicates that an application on 64-bit Windows should operate on the 32-bit registry view.

### 35.3.1.3. Value Types

For more information, see Registry Value Types.

__winreg__\_.REG\_BINARY
Binary data in any form.

__winreg__\_.REG\_DWORD
32-bit number.

__winreg__\_.REG\_DWORD\_LITTLE\_ENDIAN
A 32-bit number in little-endian format.

__winreg__\_.REG\_DWORD\_BIG\_ENDIAN
A 32-bit number in big-endian format.
_winreg.REG_EXPAND_SZ
   Null-terminated string containing references to environment variables (%PATH%).

_winreg.REG_LINK
   A Unicode symbolic link.

_winreg.REG_MULTI_SZ
   A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

_winreg.REG_NONE
   No defined value type.

_winreg.REG_RESOURCE_LIST
   A device-driver resource list.

_winreg.REG_FULL_RESOURCE_DESCRIPTOR
   A hardware setting.

_winreg.REG_RESOURCE_REQUIREMENTS_LIST
   A hardware resource list.

_winreg.REG_SZ
   A null-terminated string.
35.3.2. Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__nonzero__()` – thus:

```python
if handle:
    print "Yes"
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

```python
PyHKEY.Close()
```

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.
PyHKEY. **Detach()**

Detaches the Windows handle from the handle object.

The result is an integer (or long on 64 bit Windows) that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

PyHKEY. **__enter__()**

PyHKEY. **__exit__(*exc_info)**

The HKEY object implements **__enter__()** and **__exit__()** and thus supports the context protocol for the **with** statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ...
    # work with key
```

will automatically close `key` when control leaves the **with** block.

*New in version 2.6.*
35.4. winsound — Sound-playing interface for Windows

New in version 1.5.2.

The winsound module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

winsound.**Beep**(frequency, duration)

Beep the PC’s speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, *RuntimeError* is raised.

New in version 1.6.

winsound.**PlaySound**(sound, flags)

Call the underlying PlaySound() function from the Platform API. The *sound* parameter may be a filename, audio data as a string, or *None*. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is *None*, any currently playing waveform sound is stopped. If the system indicates an error, *RuntimeError* is raised.

winsound.**MessageBeep**(type=MB_OK)

Call the underlying MessageBeep() function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are -1, MB_ICONASTERISK, MB_ICONEXCLAMATION, MB_ICONHAND,
MB_ICONQUESTION, and MB_OK, all described below. The value -1 produces a “simple beep”; this is the final fallback if a sound cannot be played otherwise.

New in version 2.3.

winsound. SND_FILENAME
The sound parameter is the name of a WAV file. Do not use with SND_ALIAS.

winsound. SND_ALIAS
The sound parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless SND_NODEFAULT is also specified. If no default sound is registered, raise RuntimeError. Do not use with SND_FILENAME.

All Win32 systems support at least the following; most systems support many more:

<table>
<thead>
<tr>
<th>PlaySound() name</th>
<th>Corresponding Control Panel Sound name</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SystemAsterisk'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'SystemExclamation'</td>
<td>Exclamation</td>
</tr>
<tr>
<td>'SystemExit'</td>
<td>Exit Windows</td>
</tr>
<tr>
<td>'SystemHand'</td>
<td>Critical Stop</td>
</tr>
<tr>
<td>'SystemQuestion'</td>
<td>Question</td>
</tr>
</tbody>
</table>

For example:

```python
import winsound
#
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered
# "*" probably isn't the registered name of any sound).
winsound.PlaySound("*", winsound.SND_ALIAS)
```
**winsound. SND_LOOP**

Play the sound repeatedly. The SND_ASYNC flag must also be used to avoid blocking. Cannot be used with SND_MEMORY.

**winsound. SND_MEMORY**

The sound parameter to `PlaySound()` is a memory image of a WAV file, as a string.

**Note:** This module does not support playing from a memory image asynchronously, so a combination of this flag and SND_ASYNC will raise RuntimeError.

**winsound. SND_PURGE**

Stop playing all instances of the specified sound.

**Note:** This flag is not supported on modern Windows platforms.

**winsound. SND_ASYNC**

Return immediately, allowing sounds to play asynchronously.

**winsound. SND_NODEFAULT**

If the specified sound cannot be found, do not play the system default sound.

**winsound. SND_NOSTOP**

Do not interrupt sounds currently playing.

**winsound. SND_NOWAIT**

Return immediately if the sound driver is busy.

**Note:** This flag is not supported on modern Windows platforms.
winsound.**MB_ICONASTERISK**

Play the `SystemDefault` sound.

winsound.**MB_ICONEXCLAMATION**

Play the `SystemExclamation` sound.

winsound.**MB_ICONHAND**

Play the `SystemHand` sound.

winsound.**MB_ICONQUESTION**

Play the `SystemQuestion` sound.

winsound.**MB_OK**

Play the `SystemDefault` sound.
36. Unix Specific Services

The modules described in this chapter provide interfaces to features that are unique to the Unix operating system, or in some cases to some or many variants of it. Here's an overview:

- 36.1. posix — The most common POSIX system calls
  - 36.1.1. Large File Support
  - 36.1.2. Notable Module Contents
- 36.2. pwd — The password database
- 36.3. spwd — The shadow password database
- 36.4. grp — The group database
- 36.5. crypt — Function to check Unix passwords
- 36.6. dl — Call C functions in shared objects
  - 36.6.1. DL Objects
- 36.7. termios — POSIX style tty control
  - 36.7.1. Example
- 36.8. tty — Terminal control functions
- 36.9. pty — Pseudo-terminal utilities
- 36.10. fcntl — The fcntl and ioctl system calls
- 36.11. pipes — Interface to shell pipelines
  - 36.11.1. Template Objects
- 36.12. posixfile — File-like objects with locking support
- 36.13. resource — Resource usage information
  - 36.13.1. Resource Limits
  - 36.13.2. Resource Usage
- 36.14. nis — Interface to Sun’s NIS (Yellow Pages)
- 36.15. syslog — Unix syslog library routines
  - 36.15.1. Examples
    - 36.15.1.1. Simple example
- 36.16. commands — Utilities for running commands
This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

**Do not import this module directly.** Instead, import the module *os*, which provides a *portable* version of this interface. On Unix, the *os* module provides a superset of the *posix* interface. On non-Unix operating systems the *posix* module is not available, but a subset is always available through the *os* interface. Once *os* is imported, there is *no* performance penalty in using it instead of *posix*. In addition, *os* provides some additional functionality, such as automatically calling `putenv()` when an entry in *os.environ* is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise *OSError*. 

---

36.1. **posix** — The most common POSIX system calls
36.1.1. Large File Support

Several operating systems (including AIX, HP-UX, Irix and Solaris) provide support for files that are larger than 2 GB from a C programming model where `int` and `long` are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as *large files*.

Large file support is enabled in Python when the size of an `off_t` is larger than a `long` and the `long long` type is available and is at least as large as an `off_t`. Python longs are then used to represent file sizes, offsets and other values that can exceed the range of a Python `int`. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, it is enabled by default with recent versions of Irix, but with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \
./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='"-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64"' OPT="-g -O2 $CFLAGS" \
./configure
```
36.1.2. Notable Module Contents

In addition to many functions described in the `os` module documentation, `posix` defines the following data item:

```python
posix.environ
```

A dictionary representing the string environment at the time the interpreter was started. For example, `environ['HOME']` is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifying this dictionary does not affect the string environment passed on by `execv()`, `popen()` or `system()`; if you need to change the environment, pass `environ` to `execve()` or add variable assignments and export statements to the command string for `system()` or `popen()`.

**Note:** The `os` module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating `os.environ` will render this dictionary obsolete. Use of the `os` module version of this is recommended over direct access to the `posix` module.
36.2. `pwd` — The password database

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>pw_name</code></td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td><code>pw_passwd</code></td>
<td>Optional encrypted password</td>
</tr>
<tr>
<td>2</td>
<td><code>pw_uid</code></td>
<td>Numerical user ID</td>
</tr>
<tr>
<td>3</td>
<td><code>pw_gid</code></td>
<td>Numerical group ID</td>
</tr>
<tr>
<td>4</td>
<td><code>pw_gecos</code></td>
<td>User name or comment field</td>
</tr>
<tr>
<td>5</td>
<td><code>pw_dir</code></td>
<td>User home directory</td>
</tr>
<tr>
<td>6</td>
<td><code>pw_shell</code></td>
<td>User command interpreter</td>
</tr>
</tbody>
</table>

The uid and gid items are integers, all others are strings. `KeyError` is raised if the entry asked for cannot be found.

**Note:** In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module `crypt`). However most modern unices use a so-called shadow password system. On those unices the `pw_passwd` field only contains an asterisk (`'*'`) or the letter `x` where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent. If available, the `spwd` module should be used where access to the encrypted password is required.
It defines the following items:

```
pwd. getpwuid(uid)
    Return the password database entry for the given numeric user ID.
```

```
pwd. getpwnam(name)
    Return the password database entry for the given user name.
```

```
pwd. getpwall()
    Return a list of all available password database entries, in arbitrary order.
```

See also:

**Module** `grp`
   An interface to the group database, similar to this.

**Module** `spwd`
   An interface to the shadow password database, similar to this.
36.3. `spwd` — The shadow password database

*New in version 2.5.*

This module provides access to the Unix shadow password database. It is available on various Unix versions.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>sp_nam</code></td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td><code>sp_pwd</code></td>
<td>Encrypted password</td>
</tr>
<tr>
<td>2</td>
<td><code>sp_lstchg</code></td>
<td>Date of last change</td>
</tr>
<tr>
<td>3</td>
<td><code>sp_min</code></td>
<td>Minimal number of days between changes</td>
</tr>
<tr>
<td>4</td>
<td><code>sp_max</code></td>
<td>Maximum number of days between changes</td>
</tr>
<tr>
<td>5</td>
<td><code>sp_warn</code></td>
<td>Number of days before password expires to warn user about it</td>
</tr>
<tr>
<td>6</td>
<td><code>sp_inact</code></td>
<td>Number of days after password expires until account is blocked</td>
</tr>
<tr>
<td>7</td>
<td><code>sp_expire</code></td>
<td>Number of days since 1970-01-01 until account is disabled</td>
</tr>
<tr>
<td>8</td>
<td><code>sp_flag</code></td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The `sp_nam` and `sp_pwd` items are strings, all others are integers. `KeyError` is raised if the entry asked for cannot be found.
It defines the following items:

```
spwd.getspnam(name)
```
Return the shadow password database entry for the given user name.

```
spwd.getspall()
```
Return a list of all available shadow password database entries, in arbitrary order.

See also:

**Module grp**
An interface to the group database, similar to this.

**Module pwd**
An interface to the normal password database, similar to this.
This module provides access to the Unix group database. It is available on all Unix versions.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>gr_name</td>
<td>the name of the group</td>
</tr>
<tr>
<td>1</td>
<td>gr_passwd</td>
<td>the (encrypted) group password; often empty</td>
</tr>
<tr>
<td>2</td>
<td>gr_gid</td>
<td>the numerical group ID</td>
</tr>
<tr>
<td>3</td>
<td>gr_mem</td>
<td>all the group member’s user names</td>
</tr>
</tbody>
</table>

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a + or - is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid()`.)

It defines the following items:

- `grp.getgrgid(gid)`
  - Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

- `grp.getgrnam(name)`
  - Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.
grp. `getgrall()`

Return a list of all available group entries, in arbitrary order.

**See also:**

**Module `pwd`**

An interface to the user database, similar to this.

**Module `spwd`**

An interface to the shadow password database, similar to this.
36.5. crypt — Function to check Unix passwords

This module implements an interface to the crypt(3) routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include allowing Python scripts to accept typed passwords from the user, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the crypt(3) routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

```python
crypt.crypt(word, salt)
```

word will usually be a user’s password as typed at a prompt or in a graphical interface. salt is usually a random two-character string which will be used to perturb the DES algorithm in one of 4096 ways. The characters in salt must be in the set `[./a-zA-Z0-9]`. Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt (the first two characters represent the salt itself).

Since a few crypt(3) extensions allow different values, with different sizes in the salt, it is recommended to use the full crypted password as salt when checking for a password.

A simple example illustrating typical use:

```python
import crypt, getpass, pwd

def login():
    username = raw_input('Python login:')
    cryptedpasswd = pwd.getpwnam(username)[1]
    if cryptedpasswd:
```
if cryptedpasswd == 'x' or cryptedpasswd == '*':
    raise NotImplementedError("Sorry, currently no support for shadow password")
    cleartext = getpass.getpass()
    return crypt.crypt(cleartext, cryptedpasswd) == cryptedpasswd
else:
    return 1
36.6. **d1** — Call C functions in shared objects

*Deprecated since version 2.6:* The **d1** module has been removed in Python 3. Use the **ctypes** module instead.

The **d1** module defines an interface to the **dlopen()** function, which is the most common interface on Unix platforms for handling dynamically linked libraries. It allows the program to call arbitrary functions in such a library.

**Warning:** The **d1** module bypasses the Python type system and error handling. If used incorrectly it may cause segmentation faults, crashes or other incorrect behaviour.

**Note:** This module will not work unless **sizeof(int) == sizeof(long) == sizeof(char *)**. If this is not the case, **SystemError** will be raised on import.

The **d1** module defines the following function:

```python
d1.open(name[, mode=RTLD_LAZY])
```

Open a shared object file, and return a handle. Mode signifies late binding (**RTLD_LAZY**) or immediate binding (**RTLD_NOW**). Default is **RTLD_LAZY**. Note that some systems do not support **RTLD_NOW**.

Return value is a **d1object**.

The **d1** module defines the following constants:

```python
d1.RTLD_LAZY
```
Useful as an argument to `open()`.

**dl. RTLD_NOW**

Useful as an argument to `open()`. Note that on systems which do not support immediate binding, this constant will not appear in the module. For maximum portability, use `hasattr()` to determine if the system supports immediate binding.

The **dl** module defines the following exception:

*exception dl.error*

Exception raised when an error has occurred inside the dynamic loading and linking routines.

Example:

```python
>>> import dl, time
>>> a=dl.open('/lib/libc.so.6')
>>> a.call('time'), time.time()
(929723914, 929723914.498)
```

This example was tried on a Debian GNU/Linux system, and is a good example of the fact that using this module is usually a bad alternative.
36.6.1. DI Objects

DI objects, as returned by `open()` above, have the following methods:

**dl.close()**
Free all resources, except the memory.

**dl.sym(name)**
Return the pointer for the function named `name`, as a number, if it exists in the referenced shared object, otherwise `None`. This is useful in code like:

```python
>>> if a.sym('time'):
...     a.call('time')
... else:
...     time.time()
```

(Note that this function will return a non-zero number, as zero is the `NULL` pointer)

**dl.call(name[, arg1[, arg2...]])**
Call the function named `name` in the referenced shared object. The arguments must be either Python integers, which will be passed as is, Python strings, to which a pointer will be passed, or `None`, which will be passed as `NULL`. Note that strings should only be passed to functions as `const char*`, as Python will not like its string mutated.

There must be at most 10 arguments, and arguments not given will be treated as `None`. The function’s return value must be a C `long`, which is a Python integer.
This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see termios(2) Unix manual page. It is only available for those Unix versions that support POSIX termios style tty I/O control configured during installation.

All functions in this module take a file descriptor \textit{fd} as their first argument. This can be an integer file descriptor, such as returned by \texttt{sys.stdin.fileno()}, or a file object, such as \texttt{sys.stdin} itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

\begin{description}
\item[termios.tcgetattr(fd)]
Return a list containing the tty attributes for file descriptor \textit{fd}, as follows: \texttt{[iflag, oflag, cflag, lflag, ispeed, ospeed, cc]} where \textit{cc} is a list of the tty special characters (each a string of length 1, except the items with indices \texttt{VMIN} and \texttt{VTIME}, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the \textit{cc} array must be done using the symbolic constants defined in the \texttt{termios} module.
\item[termios.tcsetattr(fd, when, attributes)]
Set the tty attributes for file descriptor \textit{fd} from the \textit{attributes}, which is a list like the one returned by \texttt{tcgetattr()}. The \textit{when}
argument determines when the attributes are changed: \texttt{TCSANOW} to change immediately, \texttt{TCSADRAIN} to change after transmitting all queued output, or \texttt{TCSAFLUSH} to change after transmitting all queued output and discarding all queued input.

\texttt{termios.tcsendbreak(fd, duration)}

Send a break on file descriptor \emph{fd}. A zero \emph{duration} sends a break for 0.25 –0.5 seconds; a nonzero \emph{duration} has a system dependent meaning.

\texttt{termios.tcdrain(fd)}

Wait until all output written to file descriptor \emph{fd} has been transmitted.

\texttt{termios.tcflush(fd, queue)}

Discard queued data on file descriptor \emph{fd}. The \emph{queue} selector specifies which queue: \texttt{TCIFLUSH} for the input queue, \texttt{TCOFLUSH} for the output queue, or \texttt{TCIOFLUSH} for both queues.

\texttt{termios.tcflow(fd, action)}

Suspend or resume input or output on file descriptor \emph{fd}. The \emph{action} argument can be \texttt{TCOOff} to suspend output, \texttt{TCOOn} to restart output, \texttt{TCIOFF} to suspend input, or \texttt{TCION} to restart input.

\texttt{See also:}

\texttt{Module tty}

Convenience functions for common terminal control operations.
36.7.1. Example

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try ... finally` statement to ensure that the old tty attributes are restored exactly no matter what happens:

```python
def getpass(prompt=\"Password: \"):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = raw_input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

Last updated on Dec 17, 2016.

Found a bug? Created using Sphinx 1.4.4.
The `tty` module defines functions for putting the tty into cbreak and raw modes.

Because it requires the `termios` module, it will work only on Unix.

The `tty` module defines the following functions:

- `tty.setraw(fd[, when])`
  Change the mode of the file descriptor `fd` to raw. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

- `tty.setcbreak(fd[, when])`
  Change the mode of file descriptor `fd` to cbreak. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

**See also:**

- **Module termios**
  Low-level terminal control interface.
The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programatically.

Because pseudo-terminal handling is highly platform dependent, there is code to do it only for Linux. (The Linux code is supposed to work on other platforms, but hasn’t been tested yet.)

The `pty` module defines the following functions:

**pty. fork()**
Fork. Connect the child’s controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets `pid 0`, and the `fd` is `invalid`. The parent’s return value is the `pid` of the child, and `fd` is a file descriptor connected to the child’s controlling terminal (and also to the child’s standard input and output).

**pty. openpty()**
Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

**pty. spawn(argv[, master_read[, stdin_read]])**
Spawn a process, and connect its controlling terminal with the current process’s standard io. This is often used to baffle programs which insist on reading from the controlling terminal.

The functions `master_read` and `stdin_read` should be functions which read from a file descriptor. The defaults try to read 1024
bytes each time they are called.
This module performs file control and I/O control on file descriptors. It is an interface to the `fcntl()` and `ioctl()` Unix routines. For a complete description of these calls, see `fcntl(2)` and `ioctl(2)` Unix manual pages.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a file object, such as `sys.stdin` itself, which provides a `fileno()` which returns a genuine file descriptor.

The module defines the following functions:

```python
fcntl. fcntl(fd, op[, arg])
```

Perform the operation *op* on file descriptor *fd* (file objects providing a `fileno()` method are accepted as well). The values used for *op* are operating system dependent, and are available as constants in the `fcntl` module, using the same names as used in the relevant C header files. The argument *arg* is optional, and defaults to the integer value 0. When present, it can either be an integer value, or a string. With the argument missing or an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is a string it represents a binary structure, e.g. created by `struct.pack()`. The binary data is copied to a buffer whose address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a string object. The length of the returned string will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is
larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` fails, an `IOError` is raised.

```
fcntl.ioctl(fd, op[, arg[, mutate_flag]])
```

This function is identical to the `fcntl()` function, except that the operations are typically defined in the library module `termios` and the argument handling is even more complicated.

The `op` parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the `op` argument can be found in the `termios` module, under the same names as used in the relevant C header files.

The parameter `arg` can be one of an integer, absent (treated identically to the integer 0), an object supporting the read-only buffer interface (most likely a plain Python string) or an object supporting the read-write buffer interface.

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the `mutate_flag` parameter.

If it is false, the buffer’s mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is as least as long as what the operating system wants to put there, things should work.

If `mutate_flag` is true, then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter’s return code is passed back to the calling Python, and the buffer’s new contents reflect the action of the `ioctl()`. This is a slight simplification, because if
the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to \texttt{ioctl()} and copied back into the supplied buffer.

If \textit{mutate\_flag} is not supplied, then from Python 2.5 it defaults to true, which is a change from versions 2.3 and 2.4. Supply the argument explicitly if version portability is a priority.

If the \texttt{ioctl()} fails, an \texttt{IOError} exception is raised.

An example:

\begin{verbatim}
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, "
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
\end{verbatim}

\texttt{fcntl.flock(fd, op)}

Perform the lock operation \textit{op} on file descriptor \textit{fd} (file objects providing a \texttt{fileno()} method are accepted as well). See the Unix manual \texttt{flock(2)} for details. (On some systems, this function is emulated using \texttt{fcntl()}.)

If the \texttt{flock()} fails, an \texttt{IOError} exception is raised.

\texttt{fcntl.lockf(fd, operation[, length[, start[, whence]]]])}

This is essentially a wrapper around the \texttt{fcntl()} locking calls. \textit{fd} is the file descriptor of the file to lock or unlock, and \textit{operation} is one of the following values:
- **LOCK_UN** – unlock
- **LOCK_SH** – acquire a shared lock
- **LOCK_EX** – acquire an exclusive lock

When *operation* is **LOCK_SH** or **LOCK_EX**, it can also be bitwise ORed with **LOCK_NB** to avoid blocking on lock acquisition. If **LOCK_NB** is used and the lock cannot be acquired, an **IOError** will be raised and the exception will have an *errno* attribute set to **EACCES** or **EAGAIN** (depending on the operating system; for portability, check for both values). On at least some systems, **LOCK_EX** can only be used if the file descriptor refers to a file opened for writing.

*length* is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with *io.IOBase.seek()* specifically:

- 0 – relative to the start of the file (**os.SEEK_SET**)
- 1 – relative to the current buffer position (**os.SEEK_CUR**)
- 2 – relative to the end of the file (**os.SEEK_END**)

The default for *start* is 0, which means to start at the beginning of the file. The default for *length* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

Examples (all on a SVR4 compliant system):

```python
import struct, fcntl, os

f = open(...)  # Open the file
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable *rv* will hold an integer value; in the second example it will hold a string value. The
structure lay-out for the lockdata variable is system dependent — therefore using the flock() call may be better.

See also:

Module os

If the locking flags O_SHLOCK and O_EXLOCK are present in the os module (on BSD only), the os.open() function provides an alternative to the lockf() and flock() functions.
36.11. pipes — Interface to shell pipelines

Source code: Lib/pipes.py

The pipes module defines a class to abstract the concept of a pipeline — a sequence of converters from one file to another.

Because the module uses /bin/sh command lines, a POSIX or compatible shell for os.system() and os.popen() is required.

class pipes.Template
    An abstraction of a pipeline.

Example:

```python
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '---')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```

pipes.quote(s)

Deprecated since version 2.7: Prior to Python 2.7, this function was not publicly documented. It is finally exposed publicly in Python 3.3 as the quote function in the shlex module.

Return a shell-escaped version of the string s. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe:
>>> filename = 'somefile; rm -rf ~'
>>> command = 'ls -l {}'.format(filename)
>>> print command  # executed by a shell: boom!
ls -l somefile; rm -rf ~

quote() lets you plug the security hole:

>>> command = 'ls -l {}'.format(quote(filename))
>>> print command
ls -l 'somefile; rm -rf ~'
>>> remote_command = 'ssh home {}'.format(quote(command))
>>> print remote_command
ssh home 'ls -l 'somefile; rm -rf ~''

The quoting is compatible with UNIX shells and with shlex.split():

>>> remote_command = shlex.split(remote_command)
>>> remote_command
['ssh', 'home', 'ls -l 'somefile; rm -rf ~''
>>> command = shlex.split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
36.11.1. Template Objects

Template objects following methods:

Template.reset()

Restore a pipeline template to its initial state.

Template.clone()

Return a new, equivalent, pipeline template.

Template.debug(flag)

If flag is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given `set -x` command to be more verbose.

Template.append(cmd, kind)

Append a new action at the end. The cmd variable must be a valid bourne shell command. The kind variable consists of two letters.

The first letter can be either of `-` (which means the command reads its standard input), `'f'` (which means the commands reads a given file on the command line) or `'.'` (which means the commands reads no input, and hence must be first.)

Similarly, the second letter can be either of `-` (which means the command writes to standard output), `'f'` (which means the command writes a file on the command line) or `'.'` (which means the command does not write anything, and hence must be last.)

Template.prepend(cmd, kind)

Add a new action at the beginning. See append() for explanations of the arguments.
Template. `open(file, mode)`

Return a file-like object, open to `file`, but read from or written to by the pipeline. Note that only one of `'r'`, `'w'` may be given.

Template. `copy(infile, outfile)`

Copy `infile` to `outfile` through the pipe.
36.12. **posixfile** — File-like objects with locking support

*Deprecated since version 1.5:* The locking operation that this module provides is done better and more portably by the `fcntl.lockf()` call.

This module implements some additional functionality over the built-in file objects. In particular, it implements file locking, control over the file flags, and an easy interface to duplicate the file object. The module defines a new file object, the posixfile object. It has all the standard file object methods and adds the methods described below. This module only works for certain flavors of Unix, since it uses `fcntl.fcntl()` for file locking.

To instantiate a posixfile object, use the `posixfile.open()` function. The resulting object looks and feels roughly the same as a standard file object.

The `posixfile` module defines the following constants:

```python
posixfile.SEEK_SET
  Offset is calculated from the start of the file.

posixfile.SEEK_CUR
  Offset is calculated from the current position in the file.

posixfile.SEEK_END
  Offset is calculated from the end of the file.
```

The `posixfile` module defines the following functions:

```python
posixfile.open(filename[, mode[, bufsize]])
```
Create a new posixfile object with the given filename and mode. The *filename*, *mode* and *bufsize* arguments are interpreted the same way as by the built-in *open()* function.

```python
posixfile.fileopen(fileobject)
```

Create a new posixfile object with the given standard file object. The resulting object has the same filename and mode as the original file object.

The posixfile object defines the following additional methods:

```python
posixfile.lock(fmt[, len[, start[, whence]]])
```

Lock the specified section of the file that the file object is referring to. The format is explained below in a table. The *len* argument specifies the length of the section that should be locked. The default is 0. *start* specifies the starting offset of the section, where the default is 0. The *whence* argument specifies where the offset is relative to. It accepts one of the constants `SEEK_SET`, `SEEK_CUR` or `SEEK_END`. The default is `SEEK_SET`. For more information about the arguments refer to the *fcntl(2)* manual page on your system.

```python
posixfile.flags([flags])
```

Set the specified flags for the file that the file object is referring to. The new flags are ORed with the old flags, unless specified otherwise. The format is explained below in a table. Without the *flags* argument a string indicating the current flags is returned (this is the same as the ? modifier). For more information about the flags refer to the *fcntl(2)* manual page on your system.

```python
posixfile.dup()
```

Duplicate the file object and the underlying file pointer and file descriptor. The resulting object behaves as if it were newly opened.
posixfile. **dup2(fd)**
Duplicate the file object and the underlying file pointer and file descriptor. The new object will have the given file descriptor. Otherwise the resulting object behaves as if it were newly opened.

posixfile. **file()**
Return the standard file object that the posixfile object is based on. This is sometimes necessary for functions that insist on a standard file object.

All methods raise **IOError** when the request fails.

Format characters for the **lock()** method have the following meaning:

<table>
<thead>
<tr>
<th>Format</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>u</td>
<td>unlock the specified region</td>
</tr>
<tr>
<td>r</td>
<td>request a read lock for the specified section</td>
</tr>
<tr>
<td>w</td>
<td>request a write lock for the specified section</td>
</tr>
</tbody>
</table>

In addition the following modifiers can be added to the format:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>l</td>
<td>wait until the lock has been granted</td>
<td></td>
</tr>
<tr>
<td>?</td>
<td>return the first lock conflicting with the requested lock, or None if there is no conflict.</td>
<td>(1)</td>
</tr>
</tbody>
</table>

Note:

1. The lock returned is in the format *(mode, len, start, whence, pid)* where *mode* is a character representing the type of lock (*'r'* or *'w'*). This modifier prevents a request from being granted; it is for query purposes only.
Format characters for the `flags()` method have the following meanings:

<table>
<thead>
<tr>
<th>Format</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>append only flag</td>
</tr>
<tr>
<td>c</td>
<td>close on exec flag</td>
</tr>
<tr>
<td>n</td>
<td>no delay flag (also called non-blocking flag)</td>
</tr>
<tr>
<td>s</td>
<td>synchronization flag</td>
</tr>
</tbody>
</table>

In addition the following modifiers can be added to the format:

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>turn the specified flags ‘off’, instead of the default ‘on’</td>
<td>(1)</td>
</tr>
<tr>
<td>=</td>
<td>replace the flags, instead of the default ‘OR’ operation</td>
<td>(1)</td>
</tr>
<tr>
<td>?</td>
<td>return a string in which the characters represent the flags</td>
<td>(2)</td>
</tr>
<tr>
<td></td>
<td>that are set.</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. The `!` and `=` modifiers are mutually exclusive.
2. This string represents the flags after they may have been altered by the same call.

Examples:

```python
import posixfile

def file = posixfile.open('testfile', 'w')
file.lock('w')
...
file.lock('u')
file.close()
```
36.13. resource — Resource usage information

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

A single exception is defined for errors:

\textit{exception resource.error}

The functions described below may raise this error if the underlying system call failures unexpectedly.
36.13.1. Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

resource. **RLIM_INFINITY**

Constant used to represent the limit for an unlimited resource.

resource. **getrlimit(resource)**

Returns a tuple `(soft, hard)` with the current soft and hard limits of `resource`. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

resource. **setrlimit(resource, limits)**

Sets new limits of consumption of `resource`. The `limits` argument must be a tuple `(soft, hard)` of two integers describing the new limits. A value of `RLIM_INFINITY` can be used to request a limit that is unlimited.

Raises `ValueError` if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its
hard limit. Specifying a limit of `RLIM_INFINITY` when the hard or system limit for that resource is not unlimited will result in a `ValueError`. A process with the effective UID of super-user can request any valid limit value, including unlimited, but `ValueError` will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise `error` if the underlying system call fails.

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences — symbols not defined for a platform will not be available from this module on that platform.

**resource.** `RLIMIT_CORE`  
The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

**resource.** `RLIMIT_CPU`  
The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a `SIGXCPU` signal is sent to the process. (See the `signal` module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

**resource.** `RLIMIT_FSIZE`  
The maximum size of a file which the process may create.
resource. **RLIMIT_DATA**  
The maximum size (in bytes) of the process's heap.

resource. **RLIMIT_STACK**  
The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

resource. **RLIMIT_RSS**  
The maximum resident set size that should be made available to the process.

resource. **RLIMIT_NPROC**  
The maximum number of processes the current process may create.

resource. **RLIMIT_NOFILE**  
The maximum number of open file descriptors for the current process.

resource. **RLIMIT_OFILE**  
The BSD name for `RLIMIT_NOFILE`.

resource. **RLIMIT_MEMLOCK**  
The maximum address space which may be locked in memory.

resource. **RLIMIT_VMEM**  
The largest area of mapped memory which the process may occupy.

resource. **RLIMIT_AS**  
The maximum area (in bytes) of address space which may be taken by the process.
These functions are used to retrieve resource usage information:

```c
resource.getrusage(who)
```

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the `who` parameter. The `who` parameter should be specified using one of the `RUSAGE_*` constants described below.

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running is user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick internal, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the `getrusage(2)` man page for detailed information about these values. A brief summary is presented here:

<table>
<thead>
<tr>
<th>Index</th>
<th>Field</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ru_utime</td>
<td>time in user mode (float)</td>
</tr>
<tr>
<td>1</td>
<td>ru_stime</td>
<td>time in system mode (float)</td>
</tr>
<tr>
<td>2</td>
<td>ru_maxrss</td>
<td>maximum resident set size</td>
</tr>
<tr>
<td>3</td>
<td>ru_ixrss</td>
<td>shared memory size</td>
</tr>
<tr>
<td>4</td>
<td>ru_idrss</td>
<td>unshared memory size</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>5</td>
<td><strong>ru_isrss</strong></td>
<td>unshared stack size</td>
</tr>
<tr>
<td>6</td>
<td><strong>ru_minflt</strong></td>
<td>page faults not requiring I/O</td>
</tr>
<tr>
<td>7</td>
<td><strong>ru_majflt</strong></td>
<td>page faults requiring I/O</td>
</tr>
<tr>
<td>8</td>
<td><strong>ru_nswap</strong></td>
<td>number of swap outs</td>
</tr>
<tr>
<td>9</td>
<td><strong>ru_inblock</strong></td>
<td>block input operations</td>
</tr>
<tr>
<td>10</td>
<td><strong>ru_oublock</strong></td>
<td>block output operations</td>
</tr>
<tr>
<td>11</td>
<td><strong>ru_msgsnd</strong></td>
<td>messages sent</td>
</tr>
<tr>
<td>12</td>
<td><strong>ru_msgrcv</strong></td>
<td>messages received</td>
</tr>
<tr>
<td>13</td>
<td><strong>ru_nsignals</strong></td>
<td>signals received</td>
</tr>
<tr>
<td>14</td>
<td><strong>ru_nvcsw</strong></td>
<td>voluntary context switches</td>
</tr>
<tr>
<td>15</td>
<td><strong>ru_nivcsw</strong></td>
<td>involuntary context switches</td>
</tr>
</tbody>
</table>

This function will raise a **ValueError** if an invalid **who** parameter is specified. It may also raise **error** exception in unusual circumstances.

*Changed in version 2.3:* Added access to values as attributes of the returned object.

**resource.**getpagesize()

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following **RUSAGE_*** symbols are passed to the **getrusage()** function to specify which processes information should be provided for.

**resource.**RUSAGE_SELF

**RUSAGE_SELF** should be used to request information pertaining only to the process itself.

**resource.**RUSAGE_CHILDREN

Pass to **getrusage()** to request resource information for child processes of the calling process.
resource. **RUSAGE_BOTH**

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.
The `nis` module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

The `nis` module defines the following functions:

```python
nis.match(key, mapname[, domain=default_domain])
```

Return the match for `key` in map `mapname`, or raise an error (`nis.error`) if there is none. Both should be strings, `key` is 8-bit clean. Return value is an arbitrary array of bytes (may contain `NULL` and other joys).

Note that `mapname` is first checked if it is an alias to another name.

*Changed in version 2.5:* The `domain` argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

```python
nis.cat(mapname[, domain=default_domain])
```

Return a dictionary mapping `key` to `value` such that `match(key, mapname)==value`. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that `mapname` is first checked if it is an alias to another name.

*Changed in version 2.5:* The `domain` argument allows overriding
the NIS domain used for the lookup. If unspecified, lookup is in
the default NIS domain.

```python
nis.maps([domain=default_domain])
```

Return a list of all valid maps.

*Changed in version 2.5:* The `domain` argument allows overriding
the NIS domain used for the lookup. If unspecified, lookup is in
the default NIS domain.

```python
nis.get_default_domain()
```

Return the system default NIS domain.

*New in version 2.5.*

The `nis` module defines the following exception:

```python
exception nis.error
```

An error raised when a NIS function returns an error code.
36.15. syslog — Unix syslog library routines

This module provides an interface to the Unix syslog library routines. Refer to the Unix manual pages for a detailed description of the syslog facility.

This module wraps the system syslog family of routines. A pure Python library that can speak to a syslog server is available in the logging.handlers module as SysLogHandler.

The module defines the following functions:

syslog. **syslog**(*message*)

syslog. **syslog**(*priority*, *message*)

Send the string message to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a facility and a level. The optional priority argument, which defaults to LOG_INFO, determines the message priority. If the facility is not encoded in priority using logical-or (LOG_INFO | LOG_USER), the value given in the openlog() call is used.

If openlog() has not been called prior to the call to syslog(), openlog() will be called with no arguments.

syslog. **openlog**([*ident*[ [, *logoption*[ [, *facility*]]]])

Logging options of subsequent syslog() calls can be set by calling openlog(). syslog() will call openlog() with no arguments if the log is not currently open.

The optional ident keyword argument is a string which is prepended to every message, and defaults to sys.argv[0] with
leading path components stripped. The optional logoption keyword argument (default is 0) is a bit field – see below for possible values to combine. The optional facility keyword argument (default is LOG_USER) sets the default facility for messages which do not have a facility explicitly encoded.

**syslog.closelog()**
Reset the syslog module values and call the system library closelog().

This causes the module to behave as it does when initially imported. For example, openlog() will be called on the first syslog() call (if openlog() hasn't already been called), and ident and other openlog() parameters are reset to defaults.

**syslog.setlogmask(maskpri)**
Set the priority mask to maskpri and return the previous mask value. Calls to syslog() with a priority level not set in maskpri are ignored. The default is to log all priorities. The function LOG_MASK(pri) calculates the mask for the individual priority pri. The function LOG_UPTO(pri) calculates the mask for all priorities up to and including pri.

The module defines the following constants:

Priority levels (high to low):

- LOG_EMERG
- LOG_ALERT
- LOG_CRIT
- LOG_ERR
- LOG_WARNING
- LOG_NOTICE
- LOG_INFO
- LOG_DEBUG

Facilities:

- LOG_KERN
- LOG_USER
- LOG_MAIL
- LOG_DAEMON
- LOG_AUTH
- LOG_LPR
- LOG_NEWS
- LOG_UUCP
- LOG_CRON
- LOG_SYSLOG
- LOG_LOCAL0 to LOG_LOCAL7

Log options:
LOG_PID, LOG_CONS, LOG_NDELAY, LOG_NOWAIT and LOG_PERROR if defined in <syslog.h>. 
36.15.1. Examples

36.15.1.1. Simple example

A simple set of examples:

```python
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```python
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```
36.16. commands — Utilities for running commands

*Deprecated since version 2.6:* The commands module has been removed in Python 3. Use the subprocess module instead.

The commands module contains wrapper functions for os.popen() which take a system command as a string and return any output generated by the command and, optionally, the exit status.

The subprocess module provides more powerful facilities for spawning new processes and retrieving their results. Using the subprocess module is preferable to using the commands module.

**Note:** In Python 3.x, getstatus() and two undocumented functions (mk2arg() and mkarg()) have been removed. Also, getstatusoutput() and getoutput() have been moved to the subprocess module.

The commands module defines the following functions:

```python
commands.getstatusoutput(cmd)
```

Execute the string cmd in a shell with os.popen() and return a 2-tuple (status, output). cmd is actually run as `{ cmd ; } 2>&1`, so that the returned output will contain output or error messages. A trailing newline is stripped from the output. The exit status for the command can be interpreted according to the rules for the C function wait().

```python
commands.getoutput(cmd)
```
Like `getstatusoutput()`, except the exit status is ignored and the return value is a string containing the command's output.

```python
commands.getstatus(file)
```

Return the output of `ls -ld file` as a string. This function uses the `getoutput()` function, and properly escapes backslashes and dollar signs in the argument.

*Deprecated since version 2.6:* This function is nonobvious and useless. The name is also misleading in the presence of `getstatusoutput()`.

Example:

```python
>>> import commands
>>> commands.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> commands.getstatusoutput('cat /bin/junk')
(256, 'cat: /bin/junk: No such file or directory')
>>> commands.getstatusoutput('/bin/junk')
(256, 'sh: /bin/junk: not found')
>>> commands.getoutput('ls /bin/ls')
'/bin/ls'
>>> commands.getstatus('/bin/ls')
'-rwxr-xr-x  1 root  13352 Oct 14 1994 /bin/ls'
```

**See also:**

Module `subprocess`

Module for spawning and managing subprocesses.
37. Mac OS X specific services

This chapter describes modules that are only available on the Mac OS X platform.

See the chapters MacPython OSA Modules and Undocumented Mac OS modules for more modules, and the HOWTO Using Python on a Macintosh for a general introduction to Mac-specific Python programming.

Note: Most of the OS X APIs that these modules use are deprecated or removed in recent versions of OS X. Many are not available when Python is executing in 64-bit mode. These modules have been removed in Python 3. You should avoid using them in Python 2.

- 37.1. ic — Access to the Mac OS X Internet Config
  - 37.1.1. IC Objects
- 37.2. MacOS — Access to Mac OS interpreter features
- 37.3. macostools — Convenience routines for file manipulation
- 37.4. findertools — The finder's Apple Events interface
- 37.5. EasyDialogs — Basic Macintosh dialogs
  - 37.5.1. ProgressBar Objects
- 37.6. FrameWork — Interactive application framework
  - 37.6.1. Application Objects
  - 37.6.2. Window Objects
  - 37.6.3. ControlsWindow Object
  - 37.6.4. ScrolledWindow Object
  - 37.6.5. DialogWindow Objects
- 37.7. autoGIL — Global Interpreter Lock handling in event loops
- 37.8. Mac OS Toolbox Modules
  - 37.8.1. Carbon.AE — Apple Events
37.8.2. Carbon.AH — Apple Help
37.8.3. Carbon.App — Appearance Manager
37.8.4. Carbon.Appearance — Appearance Manager constants
37.8.5. Carbon.CF — Core Foundation
37.8.6. Carbon.CG — Core Graphics
37.8.7. Carbon.CarbonEvt — Carbon Event Manager
37.8.9. Carbon.Cm — Component Manager
37.8.10. Carbon.Components — Component Manager constants
37.8.11. Carbon.ControlAccessor — Control Manager accessors
37.8.12. Carbon.Controls — Control Manager constants
37.8.13. Carbon.CoreFoundation — CoreFoundation constants
37.8.15. Carbon.Ctrl — Control Manager
37.8.16. Carbon.Dialogs — Dialog Manager constants
37.8.17. Carbon.Dlg — Dialog Manager
37.8.18. Carbon.Drag — Drag and Drop Manager
37.8.19. Carbon.Dragconst — Drag and Drop Manager constants
37.8.20. Carbon.Events — Event Manager constants
37.8.22. Carbon.File — File Manager
37.8.23. Carbon.Files — File Manager constants
37.8.24. Carbon.Fm — Font Manager
37.8.25. Carbon.Folder — Folder Manager
37.8.27. Carbon.Fonts — Font Manager constants
37.8.28. **Carbon.Help** — Help Manager
37.8.29. **Carbon.IBCarbon** — Carbon InterfaceBuilder
37.8.30. **Carbon.IBCarbonRuntime** — Carbon InterfaceBuilder constants
37.8.31. **Carbon.Icn** — Carbon Icon Manager
37.8.32. **Carbon.Icons** — Carbon Icon Manager constants
37.8.33. **Carbon.Launch** — Carbon Launch Services
37.8.34. **Carbon.LaunchServices** — Carbon Launch Services constants
37.8.35. **Carbon.List** — List Manager
37.8.36. **Carbon.Lists** — List Manager constants
37.8.37. **Carbon.MacHelp** — Help Manager constants
37.8.38. **Carbon.MediaDescr** — Parsers and generators for Quicktime Media descriptors
37.8.39. **Carbon.Menu** — Menu Manager
37.8.40. **Carbon.Menus** — Menu Manager constants
37.8.41. **Carbon.Mlte** — MultiLingual Text Editor
37.8.42. **Carbon.OSA** — Carbon OSA Interface

- 37.9. **ColorPicker** — Color selection dialog
37.1. **ic** — Access to the Mac OS X Internet Config

This module provides access to various internet-related preferences set through **System Preferences** or the **Finder**.

**Note:** This module has been removed in Python 3.x.

There is a low-level companion module **icglue** which provides the basic Internet Config access functionality. This low-level module is not documented, but the docstrings of the routines document the parameters and the routine names are the same as for the Pascal or C API to Internet Config, so the standard IC programmers’ documentation can be used if this module is needed.

The **ic** module defines the **error** exception and symbolic names for all error codes Internet Config can produce; see the source for details.

```python
exception ic.error
    Exception raised on errors in the ic module.
```

The **ic** module defines the following class and function:

```python
class ic.IC([signature[, ic]])
    Create an Internet Config object. The signature is a 4-character creator code of the current application (default 'Pyth') which may influence some of ICs settings. The optional ic argument is a low-level icglue.icinstance created beforehand, this may be useful if you want to get preferences from a different config file, etc.

ic.launchurl1(url[, hint])
```
ic.parseurl(data[, start[, end[, hint]]])
ic.mapfile(file)
ic.maptypecreator(type, creator[, filename])
ic.settypecreator(file)
    These functions are “shortcuts” to the methods of the same name, described below.
IC objects have a mapping interface, hence to obtain the mail address you simply get `ic['MailAddress']`. Assignment also works, and changes the option in the configuration file.

The module knows about various datatypes, and converts the internal IC representation to a “logical” Python data structure. Running the `ic` module standalone will run a test program that lists all keys and values in your IC database, this will have to serve as documentation.

If the module does not know how to represent the data it returns an instance of the `ICOpaqueData` type, with the raw data in its `data` attribute. Objects of this type are also acceptable values for assignment.

Besides the dictionary interface, IC objects have the following methods:

**IC.launchurl(url[, hint])**

Parse the given URL, launch the correct application and pass it the URL. The optional `hint` can be a scheme name such as `'mailto:'`, in which case incomplete URLs are completed with this scheme. If `hint` is not provided, incomplete URLs are invalid.

**IC.parseurl(data[, start[, end[, hint]]])**

Find a URL somewhere in `data` and return start position, end position and the URL. The optional `start` and `end` can be used to limit the search, so for instance if a user clicks in a long text field you can pass the whole text field and the click-position in `start` and this routine will return the whole URL in which the user clicked. As above, `hint` is an optional scheme used to complete
incomplete URLs.

**IC. mapfile(file)**

Return the mapping entry for the given file, which can be passed as either a filename or an \texttt{FSSpec()} result, and which need not exist.

The mapping entry is returned as a tuple \((version, \text{type}, \text{creator}, \text{postcreator}, \text{flags}, \text{extension}, \text{appname}, \text{postappname}, \text{mimetype}, \text{entryname})\), where \textit{version} is the entry version number, \textit{type} is the 4-character filetype, \textit{creator} is the 4-character creator type, \textit{postcreator} is the 4-character creator code of an optional application to post-process the file after downloading, \textit{flags} are various bits specifying whether to transfer in binary or ascii and such, \textit{extension} is the filename extension for this file type, \textit{appname} is the printable name of the application to which this file belongs, \textit{postappname} is the name of the postprocessing application, \textit{mimetype} is the MIME type of this file and \textit{entryname} is the name of this entry.

**IC. maptypecreator(type, creator[, filename])**

Return the mapping entry for files with given 4-character \textit{type} and \textit{creator} codes. The optional \textit{filename} may be specified to further help finding the correct entry (if the creator code is '????', for instance).

The mapping entry is returned in the same format as for \textit{mapfile}.

**IC. settypecreator(file)**

Given an existing \textit{file}, specified either as a filename or as an \texttt{FSSpec()} result, set its creator and type correctly based on its extension. The finder is told about the change, so the finder icon will be updated quickly.
This module provides access to MacOS specific functionality in the Python interpreter, such as how the interpreter eventloop functions and the like. Use with care.

**Note:** This module has been removed in Python 3.x.

Note the capitalization of the module name; this is a historical artifact.

**MacOS.runtimemodel**

Always 'macho', from Python 2.4 on. In earlier versions of Python the value could also be 'ppc' for the classic Mac OS 8 runtime model or 'carbon' for the Mac OS 9 runtime model.

**MacOS.linkmodel**

The way the interpreter has been linked. As extension modules may be incompatible between linking models, packages could use this information to give more decent error messages. The value is one of 'static' for a statically linked Python, 'framework' for Python in a Mac OS X framework, 'shared' for Python in a standard Unix shared library. Older Pythons could also have the value 'cfm' for Mac OS 9-compatible Python.

**exception MacOS.Error**

This exception is raised on MacOS generated errors, either from functions in this module or from other mac-specific modules like the toolbox interfaces. The arguments are the integer error code (the `OSErr` value) and a textual description of the error code. Symbolic names for all known error codes are defined in the
standard module `macerrors`.

**MacOS.** `GetErrorString(errno)`

Return the textual description of MacOS error code `errno`.

**MacOS.** `DebugStr(message[, object])`

On Mac OS X the string is simply printed to stderr (on older Mac OS systems more elaborate functionality was available), but it provides a convenient location to attach a breakpoint in a low-level debugger like `gdb`.

**Note:** Not available in 64-bit mode.

**MacOS.** `SysBeep()`

Ring the bell.

**Note:** Not available in 64-bit mode.

**MacOS.** `GetTicks()`

Get the number of clock ticks (1/60th of a second) since system boot.

**MacOS.** `GetCreatorAndType(file)`

Return the file creator and file type as two four-character strings. The `file` parameter can be a pathname or an `FSSpec` or `FSRef` object.

**Note:** It is not possible to use an `FSSpec` in 64-bit mode.

**MacOS.** `SetCreatorAndType(file, creator, type)`

Set the file creator and file type. The `file` parameter can be a pathname or an `FSSpec` or `FSRef` object. `creator` and `type` must be four character strings.
Note: It is not possible to use an FSSpec in 64-bit mode.

MacOS. `openrf(name[, mode])`

Open the resource fork of a file. Arguments are the same as for the built-in function `open()`. The object returned has file-like semantics, but it is not a Python file object, so there may be subtle differences.

MacOS. `WMAvailable()`

Checks whether the current process has access to the window manager. The method will return `False` if the window manager is not available, for instance when running on Mac OS X Server or when logged in via ssh, or when the current interpreter is not running from a fullblown application bundle. A script runs from an application bundle either when it has been started with `pythonw` instead of `python` or when running as an applet.

MacOS. `splash([resourceid])`

Opens a splash screen by resource id. Use `resourceid θ` to close the splash screen.

Note: Not available in 64-bit mode.
This module contains some convenience routines for file-manipulation on the Macintosh. All file parameters can be specified as pathnames, `FSRef` or `FSSpec` objects. This module expects a filesystem which supports forked files, so it should not be used on UFS partitions.

**Note:** This module has been removed in Python 3.

The `macostools` module defines the following functions:

### `macostools.copy(src, dst[, createpath[, copytimes]])`
Copy file `src` to `dst`. If `createpath` is non-zero the folders leading to `dst` are created if necessary. The method copies data and resource fork and some finder information (creator, type, flags) and optionally the creation, modification and backup times (default is to copy them). Custom icons, comments and icon position are not copied.

**Note:** This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

### `macostools.copytree(src, dst)`
Recursively copy a file tree from `src` to `dst`, creating folders as needed. `src` and `dst` should be specified as pathnames.

**Note:** This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

### `macostools.mkalias(src, dst)`
Create a finder alias \textit{dst} pointing to \textit{src}.

\textbf{Note:} This function does not work in 64-bit code because it uses APIs that are not available in 64-bit mode.

\texttt{macostools.touched(\textit{dst})}

Tell the finder that some bits of finder-information such as creator or type for file \textit{dst} has changed. The file can be specified by pathname or fsspec. This call should tell the finder to redraw the files icon.

\textcolor{red}{\textit{Deprecated since version 2.6:} The function is a no-op on OS X.}

\texttt{macostools.BUFSIZ}

The buffer size for \texttt{copy}, default 1 megabyte.

Note that the process of creating finder aliases is not specified in the Apple documentation. Hence, aliases created with \texttt{mkalias()} could conceivably have incompatible behaviour in some cases.
This module contains routines that give Python programs access to some functionality provided by the finder. They are implemented as wrappers around the AppleEvent interface to the finder.

All file and folder parameters can be specified either as full pathnames, or as FSRef or FSSpec objects.

The findertools module defines the following functions:

findertools.launch(file)
Tell the finder to launch file. What launching means depends on the file: applications are started, folders are opened and documents are opened in the correct application.

findertools.Print(file)
Tell the finder to print a file. The behaviour is identical to selecting the file and using the print command in the finder’s file menu.

findertools.copy(file, destdir)
Tell the finder to copy a file or folder file to folder destdir. The function returns an Alias object pointing to the new file.

findertools.move(file, destdir)
Tell the finder to move a file or folder file to folder destdir. The function returns an Alias object pointing to the new file.

findertools.sleep()
Tell the finder to put the Macintosh to sleep, if your machine supports it.

findertools.restart()
Tell the finder to perform an orderly restart of the machine.

```
findertools.shutdown()
```

Tell the finder to perform an orderly shutdown of the machine.
37.5. EasyDialogs — Basic Macintosh dialogs

The EasyDialogs module contains some simple dialogs for the Macintosh. The dialogs get launched in a separate application which appears in the dock and must be clicked on for the dialogs be displayed. All routines take an optional resource ID parameter id with which one can override the DLOG resource used for the dialog, provided that the dialog items correspond (both type and item number) to those in the default DLOG resource. See source code for details.

**Note:** This module has been removed in Python 3.x.

The EasyDialogs module defines the following functions:

**EasyDialogs.**`

- `Message(str[, id[, ok]])`
  Displays a modal dialog with the message text `str`, which should be at most 255 characters long. The button text defaults to “OK”, but is set to the string argument `ok` if the latter is supplied. Control is returned when the user clicks the “OK” button.

- `AskString(prompt[, default[, id[, ok[, cancel]]]])`
  Asks the user to input a string value via a modal dialog. `prompt` is the prompt message, and the optional `default` supplies the initial value for the string (otherwise an empty string is used). The text of the “OK” and “Cancel” buttons can be changed with the `ok` and `cancel` arguments. All strings can be at most 255 bytes long. `AskString()` returns the string entered or `None` in case the user cancelled.
EasyDialogs. **AskPassword**(prompt[, default[, id[, ok[, cancel]]]]))

Asks the user to input a string value via a modal dialog. Like **AskString()**, but with the text shown as bullets. The arguments have the same meaning as for **AskString()**.

EasyDialogs. **AskYesNoCancel**(question[, default[, yes[, no[, cancel[, id]]]]])

Presents a dialog with prompt question and three buttons labelled “Yes”, “No”, and “Cancel”. Returns 1 for “Yes”, 0 for “No” and -1 for “Cancel”. The value of default (or 0 if default is not supplied) is returned when the RETURN key is pressed. The text of the buttons can be changed with the yes, no, and cancel arguments; to prevent a button from appearing, supply ”” for the corresponding argument.

EasyDialogs. **ProgressBar**([title[, maxval[, label[, id]]]]))

Displays a modeless progress-bar dialog. This is the constructor for the **ProgressBar** class described below. title is the text string displayed (default “Working...”), maxval is the value at which progress is complete (default 0, indicating that an indeterminate amount of work remains to be done), and label is the text that is displayed above the progress bar itself.

EasyDialogs. **GetArgv**(optionlist[ commandlist[, addoldfile[, addnewfile[, addfolder[, id]]]]])

Displays a dialog which aids the user in constructing a command-line argument list. Returns the list in sys.argv format, suitable for passing as an argument to getopt.getopt(). addoldfile, addnewfile, and addfolder are boolean arguments. When nonzero, they enable the user to insert into the command line paths to an existing file, a (possibly) not-yet-existent file, and a folder, respectively. (Note: Option arguments must appear in the
command line before file and folder arguments in order to be recognized by `getopt.getopt()`.) Arguments containing spaces can be specified by enclosing them within single or double quotes. A `SystemExit` exception is raised if the user presses the “Cancel” button.

`optionlist` is a list that determines a popup menu from which the allowed options are selected. Its items can take one of two forms: `optstr` or `(optstr, descr)`. When present, `descr` is a short descriptive string that is displayed in the dialog while this option is selected in the popup menu. The correspondence between `optstrs` and command-line arguments is:

<table>
<thead>
<tr>
<th><code>optstr</code> format</th>
<th>Command-line format</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>-x (short option)</td>
</tr>
<tr>
<td>x: or x=</td>
<td>-x (short option with value)</td>
</tr>
<tr>
<td>xyz</td>
<td>--xyz (long option)</td>
</tr>
<tr>
<td>xyz: or xyz=</td>
<td>--xyz (long option with value)</td>
</tr>
</tbody>
</table>

`commandlist` is a list of items of the form `cmdstr` or `(cmdstr, descr)`, where `descr` is as above. The `cmdstrs` will appear in a popup menu. When chosen, the text of `cmdstr` will be appended to the command line as is, except that a trailing `':='` or `'= '` (if present) will be trimmed off.

*New in version 2.0.*

Post a dialog asking the user for a file to open, and return the file selected or `None` if the user cancelled. `message` is a text
message to display, typeList is a list of 4-char filetypes allowable, defaultLocation is the pathname, FSSpec or FSRef of the folder to show initially, location is the \((x, y)\) position on the screen where the dialog is shown, actionButtonLabel is a string to show instead of “Open” in the OK button, cancelButtonLabel is a string to show instead of “Cancel” in the cancel button, wanted is the type of value wanted as a return: str, unicode, FSSpec, FSRef and subtypes thereof are acceptable.

For a description of the other arguments please see the Apple Navigation Services documentation and the EasyDialogs source code.

Post a dialog asking the user for a file to save to, and return the file selected or **None** if the user cancelled. savedFileName is the default for the file name to save to (the return value). See AskFileForOpen() for a description of the other arguments.

Post a dialog asking the user to select a folder, and return the folder selected or **None** if the user cancelled. See AskFileForOpen() for a description of the arguments.

**See also:**

**Navigation Services Reference**

Programmer's reference documentation for the Navigation
Services, a part of the Carbon framework.
37.5.1. ProgressBar Objects

ProgressBar objects provide support for modeless progress-bar dialogs. Both determinate (thermometer style) and indeterminate (barber-pole style) progress bars are supported. The bar will be determinate if its maximum value is greater than zero; otherwise it will be indeterminate.

*Changed in version 2.2:* Support for indeterminate-style progress bars was added.

The dialog is displayed immediately after creation. If the dialog’s “Cancel” button is pressed, or if `Cmd-.` or `ESC` is typed, the dialog window is hidden and `KeyboardInterrupt` is raised (but note that this response does not occur until the progress bar is next updated, typically via a call to `inc()` or `set()`). Otherwise, the bar remains visible until the ProgressBar object is discarded.

ProgressBar objects possess the following attributes and methods:

**ProgressBar.** `curval`

The current value (of type integer or long integer) of the progress bar. The normal access methods coerce `curval` between 0 and `maxval`. This attribute should not be altered directly.

**ProgressBar.** `maxval`

The maximum value (of type integer or long integer) of the progress bar; the progress bar (thermometer style) is full when `curval` equals `maxval`. If `maxval` is 0, the bar will be indeterminate (barber-pole). This attribute should not be altered directly.

**ProgressBar.** `title([newstr])`

Sets the text in the title bar of the progress dialog to `newstr`. 
ProgressBar. **label**([*newstr*])  
Sets the text in the progress box of the progress dialog to *newstr*.

ProgressBar. **set**(*value*, *max*)  
Sets the progress bar’s *curval* to *value*, and also *maxval* to *max* if the latter is provided. *value* is first coerced between 0 and *maxval*. The thermometer bar is updated to reflect the changes, including a change from indeterminate to determinate or vice versa.

ProgressBar. **inc**(*n*)  
Increments the progress bar’s *curval* by *n*, or by 1 if *n* is not provided. (Note that *n* may be negative, in which case the effect is a decrement.) The progress bar is updated to reflect the change. If the bar is indeterminate, this causes one “spin” of the barber pole. The resulting *curval* is coerced between 0 and *maxval* if incrementing causes it to fall outside this range.
37.6. FrameWork — Interactive application framework

The FrameWork module contains classes that together provide a framework for an interactive Macintosh application. The programmer builds an application by creating subclasses that override various methods of the bases classes, thereby implementing the functionality wanted. Overriding functionality can often be done on various different levels, i.e. to handle clicks in a single dialog window in a non-standard way it is not necessary to override the complete event handling.

**Note:** This module has been removed in Python 3.x.

Work on the FrameWork has pretty much stopped, now that PyObjc is available for full Cocoa access from Python, and the documentation describes only the most important functionality, and not in the most logical manner at that. Examine the source or the examples for more details. The following are some comments posted on the MacPython newsgroup about the strengths and limitations of FrameWork:

The strong point of FrameWork is that it allows you to break into the control-flow at many different places. w, for instance, uses a different way to enable/disable menus and that plugs right in leaving the rest intact. The weak points of FrameWork are that it has no abstract command interface (but that shouldn’t be difficult), that its dialog support is minimal and that its control/toolbar support is non-existent.

The FrameWork module defines the following functions:

FrameWork.Application()
An object representing the complete application. See below for a description of the methods. The default \texttt{__init__()} routine creates an empty window dictionary and a menu bar with an apple menu.

\texttt{FrameWork.MenuBar()}  
An object representing the menubar. This object is usually not created by the user.

\texttt{FrameWork.Menu(bar, title[, after])}  
An object representing a menu. Upon creation you pass the \texttt{MenuBar} the menu appears in, the \texttt{title} string and a position (1-based) \texttt{after} where the menu should appear (default: at the end).

\texttt{FrameWork.MenuItem(menu, title[, shortcut, callback])}  
Create a menu item object. The arguments are the menu to create, the item title string and optionally the keyboard shortcut and a callback routine. The callback is called with the arguments menu-id, item number within menu (1-based), current front window and the event record.

Instead of a callable object the callback can also be a string. In this case menu selection causes the lookup of a method in the topmost window and the application. The method name is the callback string with \texttt{'domenu_'} prepended.

Calling the \texttt{MenuBar fixmenudimstate()} method sets the correct dimming for all menu items based on the current front window.

\texttt{FrameWork.Separator(menu)}  
Add a separator to the end of a menu.

\texttt{FrameWork.SubMenu(menu, label)}  
Create a submenu named \texttt{label} under menu \texttt{menu}. The menu
object is returned.

**Framework.** `Window(parent)`

Creates a (modeless) window. *Parent* is the application object to which the window belongs. The window is not displayed until later.

**Framework.** `DialogWindow(parent)`

Creates a modeless dialog window.

**Framework.** `windowbounds(width, height)`

Return a *(left, top, right, bottom)* tuple suitable for creation of a window of given width and height. The window will be staggered with respect to previous windows, and an attempt is made to keep the whole window on-screen. However, the window will however always be the exact size given, so parts may be offscreen.

**Framework.** `setwatchescursor()`

Set the mouse cursor to a watch.

**Framework.** `setarrowcursor()`

Set the mouse cursor to an arrow.
37.6.1. Application Objects

Application objects have the following methods, among others:

Application.makeusermenus()
Override this method if you need menus in your application. Append the menus to the attribute menubar.

Application.getabouttext()
Override this method to return a text string describing your application. Alternatively, override the do_about() method for more elaborate “about” messages.

Application.mainloop([mask[, wait]])
This routine is the main event loop, call it to set your application rolling. Mask is the mask of events you want to handle, wait is the number of ticks you want to leave to other concurrent application (default 0, which is probably not a good idea). While raising self to exit the mainloop is still supported it is not recommended: call self._quit() instead.

The event loop is split into many small parts, each of which can be overridden. The default methods take care of dispatching events to windows and dialogs, handling drags and resizes, Apple Events, events for non-FrameWork windows, etc.

In general, all event handlers should return 1 if the event is fully handled and 0 otherwise (because the front window was not a FrameWork window, for instance). This is needed so that update events and such can be passed on to other windows like the Sioux console window. Calling MacOS.HandleEvent() is not allowed within our dispatch or its callees, since this may result in an infinite loop if the code is called through the Python inner-loop
event handler.

Application. **asyncevents(onoff)**

Call this method with a nonzero parameter to enable asynchronous event handling. This will tell the inner interpreter loop to call the application event handler *async_dispatch* whenever events are available. This will cause FrameWork window updates and the user interface to remain working during long computations, but will slow the interpreter down and may cause surprising results in non-reentrant code (such as FrameWork itself). By default *async_dispatch* will immediately call *our_dispatch* but you may override this to handle only certain events asynchronously. Events you do not handle will be passed to Sioux and such.

The old on/off value is returned.

Application. **_quit()**

Terminate the running *mainloop()* call at the next convenient moment.

Application. **do_char(c, event)**

The user typed character *c*. The complete details of the event can be found in the *event* structure. This method can also be provided in a *Window* object, which overrides the application-wide handler if the window is frontmost.

Application. **do_dialogevent(event)**

Called early in the event loop to handle modeless dialog events. The default method simply dispatches the event to the relevant dialog (not through the *DialogWindow* object involved). Override if you need special handling of dialog events (keyboard shortcuts, etc).

Application. **idle(event)**
Called by the main event loop when no events are available. The null-event is passed (so you can look at mouse position, etc).
37.6.2. Window Objects

Window objects have the following methods, among others:

Window. **open()**
Override this method to open a window. Store the Mac OS window-id in `self.wid` and call the `do_postopen()` method to register the window with the parent application.

Window. **close()**
Override this method to do any special processing on window close. Call the `do_postclose()` method to cleanup the parent state.

Window. **do_postresize(width, height, macoswindowid)**
Called after the window is resized. Override if more needs to be done than calling `InvalRect`.

Window. **do_contentclick(local, modifiers, event)**
The user clicked in the content part of a window. The arguments are the coordinates (window-relative), the key modifiers and the raw event.

Window. **do_update(macoswindowid, event)**
An update event for the window was received. Redraw the window.

Window. **do_activate(activate, event)**
The window was activated (`activate == 1`) or deactivated (`activate == 0`). Handle things like focus highlighting, etc.
37.6.3. ControlsWindow Object

ControlsWindow objects have the following methods besides those of Window objects:

ControlsWindow.\texttt{do\_controlhit}(window, control, pcode, event)

Part \textit{pcode} of control \textit{control} was hit by the user. Tracking and such has already been taken care of.
37.6.4. ScrolledWindow Object

ScrolledWindow objects are ControlsWindow objects with the following extra methods:

**ScrolledWindow.** `scrollbars([wantx[, wanty]])`

Create (or destroy) horizontal and vertical scrollbars. The arguments specify which you want (default: both). The scrollbars always have minimum 0 and maximum 32767.

**ScrolledWindow.** `getscrollbarvalues()`

You must supply this method. It should return a tuple `(x, y)` giving the current position of the scrollbars (between 0 and 32767). You can return `None` for either to indicate the whole document is visible in that direction.

**ScrolledWindow.** `updatescrollbars()`

Call this method when the document has changed. It will call `getscrollbarvalues()` and update the scrollbars.

**ScrolledWindow.** `scrollbar_callback(which, what, value)`

Supplied by you and called after user interaction. `which` will be 'x' or 'y', `what` will be '-', '--', 'set', '++' or '+'. For 'set', `value` will contain the new scrollbar position.

**ScrolledWindow.** `scalebarvalues(absmin, absmax, curmin, curmax)`

Auxiliary method to help you calculate values to return from `getscrollbarvalues()`. You pass document minimum and maximum value and topmost (leftmost) and bottommost (rightmost) visible values and it returns the correct number or `None`.

**ScrolledWindow.** `do_activate(onoff, event)`
Takes care of dimming/highlighting scrollbars when a window becomes frontmost. If you override this method, call this one at the end of your method.

ScrolledWindow. **do_postresize**(width, height, window)

Moves scrollbars to the correct position. Call this method initially if you override it.

ScrolledWindow. **do_controlhit**(window, control, pcode, event)

Handles scrollbar interaction. If you override it call this method first, a nonzero return value indicates the hit was in the scrollbars and has been handled.
37.6.5. DialogWindow Objects

DialogWindow objects have the following methods besides those of Window objects:

**DialogWindow.open(resid)**

Create the dialog window, from the DLOG resource with id `resid`. The dialog object is stored in `self.wid`.

**DialogWindow.do_itemhit(item, event)**

Item number `item` was hit. You are responsible for redrawing toggle buttons, etc.
The `autoGIL` module provides a function `installAutoGIL()` that automatically locks and unlocks Python’s Global Interpreter Lock when running an event loop.

**Note:** This module has been removed in Python 3.x.

```python
exception autoGIL.AutoGILError
    Raised if the observer callback cannot be installed, for example because the current thread does not have a run loop.
```

```python
autoGIL.installAutoGIL()
    Install an observer callback in the event loop (CFRunLoop) for the current thread, that will lock and unlock the Global Interpreter Lock (GIL) at appropriate times, allowing other Python threads to run while the event loop is idle.
```

*Availability:* OSX 10.1 or later.
37.8. Mac OS Toolbox Modules

These are a set of modules that provide interfaces to various legacy Mac OS toolboxes. If applicable the module will define a number of Python objects for the various structures declared by the toolbox, and operations will be implemented as methods of the object. Other operations will be implemented as functions in the module. Not all operations possible in C will also be possible in Python (callbacks are often a problem), and parameters will occasionally be different in Python (input and output buffers, especially). All methods and functions have a \_doc\_ string describing their arguments and return values, and for additional description you are referred to Inside Macintosh or similar works.

These modules all live in a package called \texttt{carbon}. Despite that name they are not all part of the Carbon framework: CF is really in the CoreFoundation framework and Qt is in the QuickTime framework. The normal use pattern is

\begin{verbatim}
from Carbon import AE
\end{verbatim}

\textbf{Note:} Most of the OS X APIs that these modules use are deprecated or removed in recent versions of OS X. Many are not available when Python is executing in 64-bit mode. The Carbon modules have been removed in Python 3. You should avoid using them in Python 2.
37.8.1. Carbon.AE — Apple Events
37.8.3. Carbon.App — Appearance Manager
37.8.4. Carbon.Appearance — Appearance Manager constants
37.8.5. Carbon.CF — Core Foundation

The CFBase, CFArray, CFData, CFDictionary, CFString and CFURL objects are supported, some only partially.
37.8.7. Carbon.CarbonEvt — Carbon Event Manager
37.8.9. Carbon.Cm — Component Manager
37.8.11. Carbon.Control1Accessor — Control Manager accessors
37.8.12. Carbon.Controls — Control Manager constants
37.8.13. Carbon.CoreFoundation — CoreFoundation constants
Carbon.Dialogs — Dialog Manager constants
37.8.17. Carbon.Dlg — Dialog Manager
37.8.18. CarbonDrag — Drag and Drop Manager
37.8.19. **Carbon.Dragconst** — Drag and Drop Manager constants
37.8.20. *Carbon.Events* — Event Manager constants
37.8.22. Carbon.File — File Manager
37.8.23. Carbon.Files — File Manager constants
37.8.25. Carbon.Folder — Folder Manager
37.8.26. **Carbon.Folders** — Folder Manager constants
37.8.27. *Carbon.Fonts* — Font Manager constants
37.8.28. Carbon.Help — Help Manager
37.8.29. `Carbon.IBCarbon` — Carbon InterfaceBuilder
37.8.30. `Carbon.IBCarbonRuntime` — Carbon InterfaceBuilder constants
37.8.31. Carbon.Icon — Carbon Icon Manager
37.8.32. Carbon::Icons — Carbon Icon Manager constants
37.8.33. Carbon Launch — Carbon Launch Services
37.8.34. Carbon.LaunchServices — Carbon Launch Services constants
37.8.35. Carbon.List — List Manager
37.8.36. Carbon.Lists — List Manager constants
37.8.37. Carbon.MacHelp — Help Manager constants
37.8.38. Carbon.MediaDescr — Parsers and generators for Quicktime Media descriptors
37.8.40. *Carbon.Menus* — Menu Manager constants
37.8.41. Carbon.Mlte — MultiLingual Text Editor
37.8.42. Carbon OSA — Carbon OSA Interface
37.8.43. **Carbon.OSAconst** — Carbon OSA Interface constants
37.8.44. Carbon.QDOffscreen — QuickDraw Offscreen constants
37.8.46. Carbon.Qdoffs — QuickDraw Offscreen
| 37.8.47. Carbon.Qt — QuickTime |
37.8.48. Carbon.QuickDraw — QuickDraw constants
37.8.49. **Carbon.QuickTime** — **QuickTime constants**
37.8.51. Carbon.Resources — Resource Manager and Handles constants
This module is only fully available on Mac OS 9 and earlier under classic PPC MacPython. Very limited functionality is available under Carbon MacPython.

The Scrap Manager supports the simplest form of cut & paste operations on the Macintosh. It can be use for both inter- and intra-application clipboard operations.

The scrap module provides low-level access to the functions of the Scrap Manager. It contains the following functions:

```
Carbon.Scrap.InfoScrap()
```

Return current information about the scrap. The information is encoded as a tuple containing the fields (size, handle, count, state, path).

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>Size of the scrap in bytes.</td>
</tr>
<tr>
<td>handle</td>
<td>Resource object representing the scrap.</td>
</tr>
<tr>
<td>count</td>
<td>Serial number of the scrap contents.</td>
</tr>
<tr>
<td>state</td>
<td>Integer; positive if in memory, 0 if on disk, negative if uninitialized.</td>
</tr>
<tr>
<td>path</td>
<td>Filename of the scrap when stored on disk.</td>
</tr>
</tbody>
</table>

**See also:**

Scrap Manager

Apple’s documentation for the Scrap Manager gives a lot of useful information about using the Scrap Manager in applications.
37.8.54. `Carbon.Sound` — Sound Manager constants
37.8.55. Carbon. TE — TextEdit
37.8.56. Carbon::TextEdit — TextEdit

constants
37.9. ColorPicker — Color selection dialog

The ColorPicker module provides access to the standard color picker dialog.

**Note:** This module has been removed in Python 3.x.

ColorPicker. **getColor**(prompt, rgb)

Show a standard color selection dialog and allow the user to select a color. The user is given instruction by the prompt string, and the default color is set to rgb. rgb must be a tuple giving the red, green, and blue components of the color. GetColor() returns a tuple giving the user’s selected color and a flag indicating whether they accepted the selection of cancelled.
This chapter describes the current implementation of the Open Scripting Architecture (OSA, also commonly referred to as AppleScript) for Python, allowing you to control scriptable applications from your Python program, and with a fairly pythonic interface. Development on this set of modules has stopped.

For a description of the various components of AppleScript and OSA, and to get an understanding of the architecture and terminology, you should read Apple’s documentation. The “Applescript Language Guide” explains the conceptual model and the terminology, and documents the standard suite. The “Open Scripting Architecture” document explains how to use OSA from an application programmers point of view. In the Apple Help Viewer these books are located in the Developer Documentation, Core Technologies section.

As an example of scripting an application, the following piece of AppleScript will get the name of the frontmost Finder window and print it:

```
tell application "Finder"
    get name of window 1
end tell
```

In Python, the following code fragment will do the same:

```
import Finder

f = Finder.Finder()
print f.get(f.window(1).name)
```

As distributed the Python library includes packages that implement the standard suites, plus packages that interface to a small number of common applications.
To send AppleEvents to an application you must first create the Python package interfacing to the terminology of the application (what Script Editor calls the “Dictionary”). This can be done from within the PythonIDE or by running the gensuitemodule.py module as a standalone program from the command line.

The generated output is a package with a number of modules, one for every suite used in the program plus an __init__ module to glue it all together. The Python inheritance graph follows the AppleScript inheritance graph, so if a program’s dictionary specifies that it includes support for the Standard Suite, but extends one or two verbs with extra arguments then the output suite will contain a module Standard_Suite that imports and re-exports everything from StdSuites.Standard_Suite but overrides the methods that have extra functionality. The output of gensuitemodule is pretty readable, and contains the documentation that was in the original AppleScript dictionary in Python docstrings, so reading it is a good source of documentation.

The output package implements a main class with the same name as the package which contains all the AppleScript verbs as methods, with the direct object as the first argument and all optional parameters as keyword arguments. AppleScript classes are also implemented as Python classes, as are comparisons and all the other thingies.

The main Python class implementing the verbs also allows access to the properties and elements declared in the AppleScript class “application”. In the current release that is as far as the object orientation goes, so in the example above we need to use f.get(f.window(1).name) instead of the more Pythonic f.window(1).name.get().

If an AppleScript identifier is not a Python identifier the name is
mangled according to a small number of rules:

- spaces are replaced with underscores
- other non-alphanumeric characters are replaced with \_\text{xx}\_ where \text{xx} is the hexadecimal character value
- any Python reserved word gets an underscore appended

Python also has support for creating scriptable applications in Python, but The following modules are relevant to MacPython AppleScript support:

- 38.1. \texttt{gensuitemodule} — Generate OSA stub packages
- 38.2. \texttt{aetools} — OSA client support
- 38.3. \texttt{aepack} — Conversion between Python variables and AppleEvent data containers
- 38.4. \texttt{aetypes} — AppleEvent objects
- 38.5. \texttt{MiniAEFrame} — Open Scripting Architecture server support
  - 38.5.1. \texttt{AEServer Objects}

In addition, support modules have been pre-generated for Finder, Terminal, Explorer, Netscape, CodeWarrior, SystemEvents and StdSuites.
38.1. gensuitemodule — Generate OSA stub packages

The `gensuitemodule` module creates a Python package implementing stub code for the AppleScript suites that are implemented by a specific application, according to its AppleScript dictionary.

It is usually invoked by the user through the PythonIDE, but it can also be run as a script from the command line (pass `--help` for help on the options) or imported from Python code. For an example of its use see `Mac/scripts/genallsuites.py` in a source distribution, which generates the stub packages that are included in the standard library.

It defines the following public functions:

- `gensuitemodule.is_scriptable(application)`
  Returns true if `application`, which should be passed as a pathname, appears to be scriptable. Take the return value with a grain of salt: Internet Explorer appears not to be scriptable but definitely is.

- `gensuitemodule.processfile(application[, output, basepkgname, edit_modnames, creatorsignature, dump, verbose])`
  Create a stub package for `application`, which should be passed as a full pathname. For a `.app` bundle this is the pathname to the bundle, not to the executable inside the bundle; for an unbundled CFM application you pass the filename of the application binary.

  This function asks the application for its OSA terminology resources, decodes these resources and uses the resultant data to create the Python code for the package implementing the
client stubs.

output is the pathname where the resulting package is stored, if not specified a standard “save file as” dialog is presented to the user. basepkgname is the base package on which this package will build, and defaults to stdsuites. Only when generating stdsuites itself do you need to specify this. edit_modnames is a dictionary that can be used to change modulenames that are too ugly after name mangling. creator_signature can be used to override the 4-char creator code, which is normally obtained from the PkgInfo file in the package or from the CFM file creator signature. When dump is given it should refer to a file object, and processfile will stop after decoding the resources and dump the Python representation of the terminology resources to this file. verbose should also be a file object, and specifying it will cause processfile to tell you what it is doing.

gensuitemodule.processfile_fromresource(application[, output, basepkgname, edit_modnames, creatorsignature, dump, verbose])

This function does the same as processfile, except that it uses a different method to get the terminology resources. It opens application as a resource file and reads all "aete" and "aeut" resources from this file.
38.2. aetools — OSA client support

The aetools module contains the basic functionality on which Python AppleScript client support is built. It also imports and re-exports the core functionality of the aetypes and aepack modules. The stub packages generated by gensuitemodule import the relevant portions of aetools, so usually you do not need to import it yourself. The exception to this is when you cannot use a generated suite package and need lower-level access to scripting.

The aetools module itself uses the AppleEvent support provided by the Carbon.AE module. This has one drawback: you need access to the window manager, see section Running scripts with a GUI for details. This restriction may be lifted in future releases.

**Note:** This module has been removed in Python 3.x.

The aetools module defines the following functions:

- **aetools.packevent** *(ae, parameters, attributes)*
  Stores parameters and attributes in a pre-created Carbon.AE.AEDesc object. parameters and attributes are dictionaries mapping 4-character OSA parameter keys to Python objects. The objects are packed using aepack.pack().

- **aetools.unpackevent** *(ae[, formodulename])*
  Recursively unpacks a Carbon.AE.AEDesc event to Python objects. The function returns the parameter dictionary and the attribute dictionary. The formodulename argument is used by generated stub packages to control where AppleScript classes are looked up.
aetools. **keystub** *(arguments, keydict)*  
Converts a Python keyword argument dictionary `arguments` to the format required by `packevent` by replacing the keys, which are Python identifiers, by the four-character OSA keys according to the mapping specified in `keydict`. Used by the generated suite packages.

aetools. **enumsubst** *(arguments, key, edict)*  
If the `arguments` dictionary contains an entry for `key` convert the value for that entry according to dictionary `edict`. This converts human-readable Python enumeration names to the OSA 4-character codes. Used by the generated suite packages.

The *aetools* module defines the following class:

```python
class aetools.TalkTo([signature=None, start=0, timeout=0])
```

Base class for the proxy used to talk to an application. `signature` overrides the class attribute `_signature` (which is usually set by subclasses) and is the 4-char creator code defining the application to talk to. `start` can be set to true to enable running the application on class instantiation. `timeout` can be specified to change the default timeout used while waiting for an AppleEvent reply.

**TalkTo. **`_start`**()
Test whether the application is running, and attempt to start it if not.

**TalkTo. **`send(code, subcode[, parameters, attributes])`
Create the AppleEvent `Carbon.AE.AEDesc` for the verb with the OSA designation `code, subcode` (which are the usual 4-character strings), pack the `parameters` and `attributes` into it, send it to the target application, wait for the reply, unpack the reply with
unpackevent and return the reply appleevent, the unpacked return values as a dictionary and the return attributes.
38.3. `aepack` — Conversion between Python variables and AppleEvent data containers

The `aepack` module defines functions for converting (packing) Python variables to AppleEvent descriptors and back (unpacking). Within Python the AppleEvent descriptor is handled by Python objects of built-in type `AEDesc`, defined in module `Carbon.AE`.

**Note:** This module has been removed in Python 3.x.

The `aepack` module defines the following functions:

```python
aepack.pack(x[, forcetype])
```

Returns an `AEDesc` object containing a conversion of Python value `x`. If `forcetype` is provided it specifies the descriptor type of the result. Otherwise, a default mapping of Python types to Apple Event descriptor types is used, as follows:

<table>
<thead>
<tr>
<th>Python type</th>
<th>descriptor type</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSSpec</td>
<td>typeFSS</td>
</tr>
<tr>
<td>FSRef</td>
<td>typeFSRef</td>
</tr>
<tr>
<td>Alias</td>
<td>typeAlias</td>
</tr>
<tr>
<td>integer</td>
<td>typeLong (32 bit integer)</td>
</tr>
<tr>
<td>float</td>
<td>typeFloat (64 bit floating point)</td>
</tr>
<tr>
<td>string</td>
<td>typeText</td>
</tr>
<tr>
<td>unicode</td>
<td>typeUnicodeText</td>
</tr>
<tr>
<td>list</td>
<td>typeAEList</td>
</tr>
<tr>
<td>dictionary</td>
<td>typeAERecord</td>
</tr>
</tbody>
</table>
If $x$ is a Python instance then this function attempts to call an \texttt{\_\_aepack\_\_()} method. This method should return an \texttt{AEDesc} object.

If the conversion $x$ is not defined above, this function returns the Python string representation of a value (the \texttt{repr()} function) encoded as a text descriptor.

\texttt{aepack.unpack(x[, formodulename])}

$x$ must be an object of type \texttt{AEDesc}. This function returns a Python object representation of the data in the Apple Event descriptor $x$. Simple AppleEvent data types (integer, text, float) are returned as their obvious Python counterparts. Apple Event lists are returned as Python lists, and the list elements are recursively unpacked. Object references (ex. line 3 of document 1) are returned as instances of \texttt{aetypes.ObjectSpecifier}, unless \texttt{formodulename} is specified. AppleEvent descriptors with descriptor type typeFSS are returned as \texttt{FSSpec} objects. AppleEvent record descriptors are returned as Python dictionaries, with 4-character string keys and elements recursively unpacked.

The optional \texttt{formodulename} argument is used by the stub packages generated by \texttt{gensuitemodule}, and ensures that the OSA classes for object specifiers are looked up in the correct module. This ensures that if, say, the Finder returns an object specifier for a window you get an instance of \texttt{Finder.Window} and not a generic \texttt{aetypes.Window}. The former knows about all the properties and elements a window has in the Finder, while the latter knows no such things.

\textbf{See also:}
Module **Carbon.AE**

Built-in access to Apple Event Manager routines.

Module **aetypes**

Python definitions of codes for Apple Event descriptor types.
38.4. `aetypes` — AppleEvent objects

The `aetypes` defines classes used to represent Apple Event data descriptors and Apple Event object specifiers.

Apple Event data is contained in descriptors, and these descriptors are typed. For many descriptors the Python representation is simply the corresponding Python type: `typeText` in OSA is a Python string, `typeFloat` is a float, etc. For OSA types that have no direct Python counterpart this module declares classes. Packing and unpacking instances of these classes is handled automatically by `aepack`.

An object specifier is essentially an address of an object implemented in an Apple Event server. An Apple Event specifier is used as the direct object for an Apple Event or as the argument of an optional parameter. The `aetypes` module contains the base classes for OSA classes and properties, which are used by the packages generated by `gensuitemodule` to populate the classes and properties in a given suite.

For reasons of backward compatibility, and for cases where you need to script an application for which you have not generated the stub package this module also contains object specifiers for a number of common OSA classes such as `Document`, `Window`, `Character`, etc.

Note: This module has been removed in Python 3.x.

The `AEObjects` module defines the following classes to represent Apple Event descriptor data:

```python
class aetypes. Unknown(type, data)
    The representation of OSA descriptor data for which the `aepack`
and aetypes modules have no support, i.e. anything that is not represented by the other classes here and that is not equivalent to a simple Python value.

```python
class aetypes.Enum(enum)
    An enumeration value with the given 4-character string value.

class aetypes.InsertionLoc(of, pos)
    Position pos in object of.

class aetypes.Boolean(bool)
    A boolean.

class aetypes.StyledText(style, text)
    Text with style information (font, face, etc) included.

class aetypes.AEText(script, style, text)
    Text with script system and style information included.

class aetypes.IntlText(script, language, text)
    Text with script system and language information included.

class aetypes.IntlWritingCode(script, language)
    Script system and language information.

class aetypes.QDPoint(v, h)
    A quickdraw point.

class aetypes.QDRectangle(v0, h0, v1, h1)
    A quickdraw rectangle.

class aetypes.RGBColor(r, g, b)
    A color.

class aetypes.Type(type)
    An OSA type value with the given 4-character name.
```
class aetypes. **Keyword**(name)
An OSA keyword with the given 4-character name.

class aetypes. **Range**(start, stop)
A range.

class aetypes. **Ordinal**(abso)
Non-numeric absolute positions, such as "firs", first, or "midd", middle.

class aetypes. **Logical**(logc, term)
The logical expression of applying operator logc to term.

class aetypes. **Comparison**(obj1, relo, obj2)
The comparison relo of obj1 to obj2.

The following classes are used as base classes by the generated stub packages to represent AppleScript classes and properties in Python:

class aetypes. **ComponentItem**(which[, fr])
Abstract baseclass for an OSA class. The subclass should set the class attribute want to the 4-character OSA class code. Instances of subclasses of this class are equivalent to AppleScript Object Specifiers. Upon instantiation you should pass a selector in which, and optionally a parent object in fr.

class aetypes. **NProperty**(fr)
Abstract baseclass for an OSA property. The subclass should set the class attributes want and which to designate which property we are talking about. Instances of subclasses of this class are Object Specifiers.

class aetypes. **ObjectSpecifier**(want, form, seld[, fr])
Base class of `ComponentItem` and `NProperty`, a general OSA Object Specifier. See the Apple Open Scripting Architecture documentation for the parameters. Note that this class is not abstract.
38.5. MiniAEFrame — Open Scripting Architecture server support

The module MiniAEFrame provides a framework for an application that can function as an Open Scripting Architecture (OSA) server, i.e. receive and process AppleEvents. It can be used in conjunction with FrameWork or standalone. As an example, it is used in PythonCGISlave.

The MiniAEFrame module defines the following classes:

**class** MiniAEFrame.**AEServer**  
A class that handles AppleEvent dispatch. Your application should subclass this class together with either MiniApplication or FrameWork.Application. Your __init__() method should call the __init__() method for both classes.

**class** MiniAEFrame.**MiniApplication**  
A class that is more or less compatible with FrameWork.Application but with less functionality. Its event loop supports the apple menu, command-dot and AppleEvents; other events are passed on to the Python interpreter and/or Sioux. Useful if your application wants to use AEServer but does not provide its own windows, etc.
38.5.1. AEServer Objects

AEServer.installahandler(\textit{classe}, \textit{type}, \textit{callback})

Installs an AppleEvent handler. \textit{classe} and \textit{type} are the four-character OSA Class and Type designators, '*****' wildcards are allowed. When a matching AppleEvent is received the parameters are decoded and your callback is invoked.

AEServer.callback(\_\textit{object}, **\textit{kwargs})

Your callback is called with the OSA Direct Object as first positional parameter. The other parameters are passed as keyword arguments, with the 4-character designator as name. Three extra keyword parameters are passed: \_\textit{class} and \_\textit{type} are the Class and Type designators and \_\textit{attributes} is a dictionary with the AppleEvent attributes.

The return value of your method is packed with \texttt{aetools.packevent()} and sent as reply.

Note that there are some serious problems with the current design. AppleEvents which have non-identifier 4-character designators for arguments are not implementable, and it is not possible to return an error to the originator. This will be addressed in a future release.
39. SGI IRIX Specific Services

The modules described in this chapter provide interfaces to features that are unique to SGI's IRIX operating system (versions 4 and 5).

- **39.1. al** — Audio functions on the SGI
  - **39.1.1. Configuration Objects**
  - **39.1.2. Port Objects**
- **39.2. AL** — Constants used with the al module
- **39.3. cd** — CD-ROM access on SGI systems
  - **39.3.1. Player Objects**
  - **39.3.2. Parser Objects**
- **39.4. fl** — FORMS library for graphical user interfaces
  - **39.4.1. Functions Defined in Module fl**
  - **39.4.2. Form Objects**
  - **39.4.3. FORMS Objects**
- **39.5. FL** — Constants used with the fl module
- **39.6. flp** — Functions for loading stored FORMS designs
- **39.7. fm** — *Font Manager* interface
- **39.8. gl** — *Graphics Library* interface
- **39.9. DEVICE** — Constants used with the gl module
- **39.10. GL** — Constants used with the gl module
- **39.11. imgfile** — Support for SGI imglib files
- **39.12. jpeg** — Read and write JPEG files
39.1. **al — Audio functions on the SGI**

*Deprecated since version 2.6:* The `al` module has been removed in Python 3.

This module provides access to the audio facilities of the SGI Indy and Indigo workstations. See section 3A of the IRIX man pages for details. You’ll need to read those man pages to understand what these functions do! Some of the functions are not available in IRIX releases before 4.0.5. Again, see the manual to check whether a specific function is available on your platform.

All functions and methods defined in this module are equivalent to the C functions with `AL` prefixed to their name.

Symbolic constants from the C header file `<audio.h>` are defined in the standard module `AL`, see below.

**Warning:** The current version of the audio library may dump core when bad argument values are passed rather than returning an error status. Unfortunately, since the precise circumstances under which this may happen are undocumented and hard to check, the Python interface can provide no protection against this kind of problems. (One example is specifying an excessive queue size — there is no documented upper limit.)

The module defines the following functions:

```python
al.openport(name, direction[, config])
```

The name and direction arguments are strings. The optional
config argument is a configuration object as returned by newconfig(). The return value is an audio port object; methods of audio port objects are described below.

al. newconfig()
   The return value is a new audio configuration object; methods of audio configuration objects are described below.

al. queryparams(device)
   The device argument is an integer. The return value is a list of integers containing the data returned by ALqueryparams().

al. getparams(device, list)
   The device argument is an integer. The list argument is a list such as returned by queryparams(); it is modified in place (!).

al. setparams(device, list)
   The device argument is an integer. The list argument is a list such as returned by queryparams().
39.1.1. Configuration Objects

Configuration objects returned by `newconfig()` have the following methods:

```python
audio configuration.getqueuesize()
    Return the queue size.

audio configuration.setqueuesize(size)
    Set the queue size.

audio configuration.getwidth()
    Get the sample width.

audio configuration.setwidth(width)
    Set the sample width.

audio configuration.getchannels()
    Get the channel count.

audio configuration.setchannels(nchannels)
    Set the channel count.

audio configuration.getsampfmt()
    Get the sample format.

audio configuration.setsampfmt(sampfmt)
    Set the sample format.

audio configuration.getfloatmax()
    Get the maximum value for floating sample formats.

audio configuration.setfloatmax(floatmax)
    Set the maximum value for floating sample formats.
```
39.1.2. Port Objects

Port objects, as returned by `openport()`, have the following methods:

```python
audio port.closeport()
    Close the port.
```

```python
audio port.getfd()
    Return the file descriptor as an int.
```

```python
audio port.getfilled()
    Return the number of filled samples.
```

```python
audio port.getfillable()
    Return the number of fillable samples.
```

```python
audio port.readsamps(nsamples)
    Read a number of samples from the queue, blocking if necessary. Return the data as a string containing the raw data, (e.g., 2 bytes per sample in big-endian byte order (high byte, low byte) if you have set the sample width to 2 bytes).
```

```python
audio port.writesamps(samples)
    Write samples into the queue, blocking if necessary. The samples are encoded as described for the `readsamps()` return value.
```

```python
audio port.getfillpoint()
    Return the ‘fill point’.
```

```python
audio port.setfillpoint(fillpoint)
    Set the ‘fill point’.
```

```python
audio port.getconfig()
    Return a configuration object containing the current configuration of the port.
```
audio port.setconfig(config)
   Set the configuration from the argument, a configuration object.

audio port.getstatus(list)
   Get status information on last error.
39.2. AL — Constants used with the al module

_Deprecated since version 2.6:_ The _AL_ module has been removed in Python 3.

This module defines symbolic constants needed to use the built-in module _al_ (see above); they are equivalent to those defined in the C header file _<audio.h>_ except that the name prefix _AL_ is omitted. Read the module source for a complete list of the defined names. Suggested use:

```python
import al
from AL import *
```
39.3. cd — CD-ROM access on SGI systems

**Deprecated since version 2.6:** The cd module has been removed in Python 3.

This module provides an interface to the Silicon Graphics CD library. It is available only on Silicon Graphics systems.

The way the library works is as follows. A program opens the CD-ROM device with `open()` and creates a parser to parse the data from the CD with `createparser()`. The object returned by `open()` can be used to read data from the CD, but also to get status information for the CD-ROM device, and to get information about the CD, such as the table of contents. Data from the CD is passed to the parser, which parses the frames, and calls any callback functions that have previously been added.

An audio CD is divided into *tracks* or *programs* (the terms are used interchangeably). Tracks can be subdivided into *indices*. An audio CD contains a *table of contents* which gives the starts of the tracks on the CD. Index 0 is usually the pause before the start of a track. The start of the track as given by the table of contents is normally the start of index 1.

Positions on a CD can be represented in two ways. Either a frame number or a tuple of three values, minutes, seconds and frames. Most functions use the latter representation. Positions can be both relative to the beginning of the CD, and to the beginning of the track.

Module `cd` defines the following functions and constants:
cd. `createparser()`
Create and return an opaque parser object. The methods of the parser object are described below.

cd. `msftoframe(minutes, seconds, frames)`
Converts a `(minutes, seconds, frames)` triple representing time in absolute time code into the corresponding CD frame number.

cd. `open([device[, mode]])`
Open the CD-ROM device. The return value is an opaque player object; methods of the player object are described below. The device is the name of the SCSI device file, e.g. `/dev/scsi/sc0d4l0`, or None. If omitted or None, the hardware inventory is consulted to locate a CD-ROM drive. The mode, if not omitted, should be the string 'r'.

The module defines the following variables:

`exception cd.error`
Exception raised on various errors.

`cd.DATASIZE`
The size of one frame's worth of audio data. This is the size of the audio data as passed to the callback of type audio.

`cd.BLOCKSIZE`
The size of one uninterpreted frame of audio data.

The following variables are states as returned by `getstatus()`:

`cd.READY`
The drive is ready for operation loaded with an audio CD.

`cd.NODISC`
The drive does not have a CD loaded.
The drive is loaded with a CD-ROM. Subsequent play or read operations will return I/O errors.

An error occurred while trying to read the disc or its table of contents.

The drive is in CD player mode playing an audio CD through its audio jacks.

The drive is in CD layer mode with play paused.

The equivalent of PAUSED on older (non 3301) model Toshiba CD-ROM drives. Such drives have never been shipped by SGI.

Integer constants describing the various types of parser callbacks that can be set by the addcallback() method of CD parser objects (see below).
39.3.1. Player Objects

Player objects (returned by `open()`) have the following methods:

**CD player.allowremoval()**
Unlocks the eject button on the CD-ROM drive permitting the user to eject the caddy if desired.

**CD player.bestreadsize()**
Returns the best value to use for the `num_frames` parameter of the `readda()` method. Best is defined as the value that permits a continuous flow of data from the CD-ROM drive.

**CD player.close()**
Frees the resources associated with the player object. After calling `close()`, the methods of the object should no longer be used.

**CD player.eject()**
Ejects the caddy from the CD-ROM drive.

**CD player.getstatus()**
Returns information pertaining to the current state of the CD-ROM drive. The returned information is a tuple with the following values: `state`, `track`, `rtime`, `atime`, `ttme`, `first`, `last`, `scsi_audio`, `cur_block`. `rtime` is the time relative to the start of the current track; `atime` is the time relative to the beginning of the disc; `ttme` is the total time on the disc. For more information on the meaning of the values, see the man page `CDgetstatus(3dm)`. The value of `state` is one of the following: `ERROR`, `NODISC`, `READY`, `PLAYING`, `PAUSED`, `STILL`, or `CDROM`.

**CD player.gettrackinfo(track)**
Returns information about the specified track. The returned
information is a tuple consisting of two elements, the start time of
the track and the duration of the track.

**CD player.msftoblock(min, sec, frame)**
Converts a minutes, seconds, frames triple representing a time in
absolute time code into the corresponding logical block number
for the given CD-ROM drive. You should use `msftoframe()` rather
than `msftoblock()` for comparing times. The logical block number
differs from the frame number by an offset required by certain
CD-ROM drives.

**CD player.play(start, play)**
Starts playback of an audio CD in the CD-ROM drive at the
specified track. The audio output appears on the CD-ROM drive's
headphone and audio jacks (if fitted). Play stops at the end of the
disc. `start` is the number of the track at which to start playing the
CD; if `play` is 0, the CD will be set to an initial paused state. The
method `togglepause()` can then be used to commence play.

**CD player.playabs(minutes, seconds, frames, play)**
Like `play()`, except that the start is given in minutes, seconds,
and frames instead of a track number.

**CD player.playtrack(start, play)**
Like `play()`, except that playing stops at the end of the track.

**CD player.playtrackabs(track, minutes, seconds, frames, play)**
Like `play()`, except that playing begins at the specified absolute
time and ends at the end of the specified track.

**CD player.preventremoval()**
Locks the eject button on the CD-ROM drive thus preventing the
user from arbitrarily ejecting the caddy.

**CD player.readda(num_frames)**
Reads the specified number of frames from an audio CD mounted in the CD-ROM drive. The return value is a string representing the audio frames. This string can be passed unaltered to the parseframe() method of the parser object.

**CD player.seek(minutes, seconds, frames)**
Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to an absolute time code location specified in *minutes*, *seconds*, and *frames*. The return value is the logical block number to which the pointer has been set.

**CD player.seekblock(block)**
Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified logical block number. The return value is the logical block number to which the pointer has been set.

**CD player.seektrack(track)**
Sets the pointer that indicates the starting point of the next read of digital audio data from a CD-ROM. The pointer is set to the specified track. The return value is the logical block number to which the pointer has been set.

**CD player.stop()**
Stops the current playing operation.

**CD player.togglepause()**
Pauses the CD if it is playing, and makes it play if it is paused.
39.3.2. Parser Objects

Parser objects (returned by `createparser()`) have the following methods:

**CD parser.addcallback(type, func, arg)**

Adds a callback for the parser. The parser has callbacks for eight different types of data in the digital audio data stream. Constants for these types are defined at the `cd` module level (see above). The callback is called as follows: `func(arg, type, data)`, where `arg` is the user supplied argument, `type` is the particular type of callback, and `data` is the data returned for this `type` of callback. The type of the data depends on the `type` of callback as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>audio</td>
<td>String which can be passed unmodified to <code>al.writesamps()</code></td>
</tr>
<tr>
<td>pnum</td>
<td>Integer giving the program (track) number.</td>
</tr>
<tr>
<td>index</td>
<td>Integer giving the index number.</td>
</tr>
<tr>
<td>ptime</td>
<td>Tuple consisting of the program time in minutes, seconds, and frames.</td>
</tr>
<tr>
<td>atime</td>
<td>Tuple consisting of the absolute time in minutes, seconds, and frames.</td>
</tr>
<tr>
<td>catalog</td>
<td>String of 13 characters, giving the catalog number of the CD.</td>
</tr>
<tr>
<td>ident</td>
<td>String of 12 characters, giving the ISRC identification number of the recording. The string consists of two characters country code, three characters owner code, two characters giving the year, and five characters giving a serial number.</td>
</tr>
<tr>
<td>control</td>
<td>Integer giving the control bits from the CD subcode data</td>
</tr>
</tbody>
</table>

**CD parser.deleteparser()**
Deletes the parser and frees the memory it was using. The object should not be used after this call. This call is done automatically when the last reference to the object is removed.

**CD parser.parseframe(frame)**

 Parses one or more frames of digital audio data from a CD such as returned by `readda()`. It determines which subcodes are present in the data. If these subcodes have changed since the last frame, then `parseframe()` executes a callback of the appropriate type passing to it the subcode data found in the frame. Unlike the C function, more than one frame of digital audio data can be passed to this method.

**CD parser.removecallback(type)**

 Removes the callback for the given `type`.

**CD parser.resetparser()**

 Resets the fields of the parser used for tracking subcodes to an initial state. `resetparser()` should be called after the disc has been changed.
39.4. **f1 — FORMS library for graphical user interfaces**

*Deprecated since version 2.6:* The `f1` module has been removed in Python 3.

This module provides an interface to the FORMS Library by Mark Overmars. The source for the library can be retrieved by anonymous FTP from host `ftp.cs.ruu.nl`, directory `SGI/FORMS`. It was last tested with version 2.0b.

Most functions are literal translations of their C equivalents, dropping the initial `f1_` from their name. Constants used by the library are defined in module `FL` described below.

The creation of objects is a little different in Python than in C: instead of the ‘current form’ maintained by the library to which new FORMS objects are added, all functions that add a FORMS object to a form are methods of the Python object representing the form. Consequently, there are no Python equivalents for the C functions `fl_addto_form()` and `fl_end_form()`, and the equivalent of `fl_bgn_form()` is called `f1.make_form()`.

Watch out for the somewhat confusing terminology: FORMS uses the word `object` for the buttons, sliders etc. that you can place in a form. In Python, ‘object’ means any value. The Python interface to FORMS introduces two new Python object types: form objects (representing an entire form) and FORMS objects (representing one button, slider etc.). Hopefully this isn’t too confusing.

There are no ‘free objects’ in the Python interface to FORMS, nor is there an easy way to add object classes written in Python. The
FORMS interface to GL event handling is available, though, so you can mix FORMS with pure GL windows.

Please note: importing f1 implies a call to the GL function foreground() and to the FORMS routine f1_init().
Module \texttt{f1} defines the following functions. For more information about what they do, see the description of the equivalent C function in the FORMS documentation:

\texttt{f1.make_form(type, width, height)}

Create a form with given type, width and height. This returns a \textit{form} object, whose methods are described below.

\texttt{f1.do_forms()}

The standard FORMS main loop. Returns a Python object representing the FORMS object needing interaction, or the special value \texttt{FL.EVENT}.

\texttt{f1.check_forms()}

Check for FORMS events. Returns what \texttt{do_forms()} above returns, or \texttt{None} if there is no event that immediately needs interaction.

\texttt{f1.set_event_call_back(function)}

Set the event callback function.

\texttt{f1.set_graphics_mode(rgbmode, doublebuffering)}

Set the graphics modes.

\texttt{f1.get_rgbmode()}

Return the current rgb mode. This is the value of the C global variable \texttt{fl_rgbmode}.

\texttt{f1.show_message(str1, str2, str3)}

Show a dialog box with a three-line message and an OK button.

\texttt{f1.show_question(str1, str2, str3)}
Show a dialog box with a three-line message and YES and NO buttons. It returns 1 if the user pressed YES, 0 if NO.

```python
fl.show_choice(str1, str2, str3, but1[, but2[, but3]])
```
Show a dialog box with a three-line message and up to three buttons. It returns the number of the button clicked by the user (1, 2 or 3).

```python
fl.show_input(prompt, default)
```
Show a dialog box with a one-line prompt message and text field in which the user can enter a string. The second argument is the default input string. It returns the string value as edited by the user.

```python
fl.show_file_selector(message, directory, pattern, default)
```
Show a dialog box in which the user can select a file. It returns the absolute filename selected by the user, or None if the user presses Cancel.

```python
fl.get_directory()
fl.get_pattern()
fl.get_filename()
```
These functions return the directory, pattern and filename (the tail part only) selected by the user in the last show_file_selector() call.

```python
fl.qdevice(dev)
fl.unqdevice(dev)
fl.isqueued(dev)
fl.qtest()
fl.qread()
fl.qreset()
fl.qenter(dev, val)
fl.get_mouse()
fl.tie(button, valuator1, valuator2)
```
These functions are the FORMS interfaces to the corresponding GL functions. Use these if you want to handle some GL events yourself when using `fl.do_events()`. When a GL event is detected that FORMS cannot handle, `fl.do_forms()` returns the special value `FL.EVENT` and you should call `fl.qread()` to read the event from the queue. Don’t use the equivalent GL functions!

`fl.color()`  
`fl.mapcolor()`  
`fl.getmcolor()`  
See the description in the FORMS documentation of `fl.color()`, `fl.mapcolor()` and `fl.getmcolor()`. 
39.4.2. Form Objects

Form objects (returned by `make_form()` above) have the following methods. Each method corresponds to a C function whose name is prefixed with `fl_`; and whose first argument is a form pointer; please refer to the official FORMS documentation for descriptions.

All the `add_*()` methods return a Python object representing the FORMS object. Methods of FORMS objects are described below. Most kinds of FORMS object also have some methods specific to that kind; these methods are listed here.

```python
form.show_form(placement, bordertype, name)
    Show the form.

form.hide_form()
    Hide the form.

form.redraw_form()
    Redraw the form.

form.set_form_position(x, y)
    Set the form’s position.

form.freeze_form()
    Freeze the form.

form.unfreeze_form()
    Unfreeze the form.

form.activate_form()
    Activate the form.

form.deactivate_form()
```
Deactivate the form.

form. **bgn_group()**
Begin a new group of objects; return a group object.

form. **end_group()**
End the current group of objects.

form. **find_first()**
Find the first object in the form.

form. **find_last()**
Find the last object in the form.

form. **add_box(type, x, y, w, h, name)**
Add a box object to the form. No extra methods.

form. **add_text(type, x, y, w, h, name)**
Add a text object to the form. No extra methods.

form. **add_clock(type, x, y, w, h, name)**
Add a clock object to the form. — Method: **get_clock()**.

form. **add_button(type, x, y, w, h, name)**
Add a button object to the form. — Methods: **get_button()**, **set_button()**.

form. **add_lightbutton(type, x, y, w, h, name)**
Add a lightbutton object to the form. — Methods: **get_button()**, **set_button()**.

form. **add_roundbutton(type, x, y, w, h, name)**
Add a roundbutton object to the form. — Methods: **get_button()**, **set_button()**.

form. **add_slider(type, x, y, w, h, name)**
Add a slider object to the form. — Methods: set_slider_value(), get_slider_value(), set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(), set_slider_precision(), set_slider_step().

form.add_valslider(type, x, y, w, h, name)
Add a valslider object to the form. — Methods: set_slider_value(), get_slider_value(), set_slider_bounds(), get_slider_bounds(), set_slider_return(), set_slider_size(), set_slider_precision(), set_slider_step().

form.add_dial(type, x, y, w, h, name)
Add a dial object to the form. — Methods: set_dial_value(), get_dial_value(), set_dial_bounds(), get_dial_bounds().

form.add_positioner(type, x, y, w, h, name)
Add a positioner object to the form. — Methods: set_positioner_xvalue(), set_positioner_yvalue(), set_positioner_xbounds(), set_positioner_ybounds(), get_positioner_xvalue(), get_positioner_yvalue(), get_positioner_xbounds(), get_positioner_ybounds().

form.add_counter(type, x, y, w, h, name)
Add a counter object to the form. — Methods: set_counter_value(), get_counter_value(), set_counter_bounds(), set_counter_step(), set_counter_precision(), set_counter_return().

form.add_input(type, x, y, w, h, name)
Add an input object to the form. — Methods: set_input(), get_input(), set_input_color(), set_input_return().

form.add_menu(type, x, y, w, h, name)
Add a menu object to the form. — Methods: set_menu(), get_menu(), addto_menu().

form. add_choice(type, x, y, w, h, name)
Add a choice object to the form. — Methods: set_choice(), get_choice(), clear_choice(), addto_choice(), replace_choice(), delete_choice(), get_choice_text(), set_choice_fontsize(), set_choice_fontstyle().

form. add_browser(type, x, y, w, h, name)
Add a browser object to the form. — Methods: set_browser_topline(), clear_browser(), add_browser_line(), addto_browser(), insert_browser_line(), delete_browser_line(), replace_browser_line(), get_browser_line(), load_browser(), get_browser_maxline(), select_browser_line(), deselect_browser_line(), deselect_browser(), isselected_browser_line(), get_browser(), set_browser_fontsize(), set_browser_fontstyle(), set_browser_specialkey().

form. add_timer(type, x, y, w, h, name)
Add a timer object to the form. — Methods: set_timer(), get_timer().

Form objects have the following data attributes; see the FORMS documentation:

<table>
<thead>
<tr>
<th>Name</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>window</td>
<td>int (read-only)</td>
<td>GL window id</td>
</tr>
<tr>
<td>w</td>
<td>float</td>
<td>form width</td>
</tr>
<tr>
<td>h</td>
<td>float</td>
<td>form height</td>
</tr>
<tr>
<td>x</td>
<td>float</td>
<td>form x origin</td>
</tr>
<tr>
<td>y</td>
<td>float</td>
<td>form y origin</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>----------------</td>
<td>-----</td>
<td>----------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>deactivated</strong></td>
<td>int</td>
<td>nonzero if form is deactivated</td>
</tr>
<tr>
<td><strong>visible</strong></td>
<td>int</td>
<td>nonzero if form is visible</td>
</tr>
<tr>
<td><strong>frozen</strong></td>
<td>int</td>
<td>nonzero if form is frozen</td>
</tr>
<tr>
<td><strong>doublebuf</strong></td>
<td>int</td>
<td>nonzero if double buffering on</td>
</tr>
</tbody>
</table>
39.4.3. FORMS Objects

Besides methods specific to particular kinds of FORMS objects, all FORMS objects also have the following methods:

**FORMS object.set_call_back(function, argument)**
Set the object's callback function and argument. When the object needs interaction, the callback function will be called with two arguments: the object, and the callback argument. (FORMS objects without a callback function are returned by `fl.do_forms()` or `fl.check_forms()` when they need interaction.) Call this method without arguments to remove the callback function.

**FORMS object.delete_object()**
Delete the object.

**FORMS object.show_object()**
Show the object.

**FORMS object.hide_object()**
Hide the object.

**FORMS object.redraw_object()**
Redraw the object.

**FORMS object.freeze_object()**
Freeze the object.

**FORMS object.unfreeze_object()**
Unfreeze the object.

FORMS objects have these data attributes; see the FORMS documentation:

<table>
<thead>
<tr>
<th>Name</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>objclass</td>
<td>int (read-only)</td>
<td>object class</td>
</tr>
<tr>
<td>type</td>
<td>int (read-only)</td>
<td>object type</td>
</tr>
<tr>
<td>boxtype</td>
<td>int</td>
<td>box type</td>
</tr>
<tr>
<td>x</td>
<td>float</td>

</tbody>
</table>
39.5. **FL — Constants used with the f1 module**

*Deprecated since version 2.6:* The `FL` module has been removed in Python 3.

This module defines symbolic constants needed to use the built-in module `f1` (see above); they are equivalent to those defined in the C header file `<forms.h>` except that the name prefix `FL_` is omitted. Read the module source for a complete list of the defined names. Suggested use:

```python
import f1
from FL import *
```
39.6. \texttt{flp} — Functions for loading stored FORMS designs

\textit{Deprecated since version 2.6:} The \texttt{flp} module has been removed in Python 3.

This module defines functions that can read form definitions created by the ‘form designer’ (\texttt{fdesign}) program that comes with the FORMS library (see module \texttt{f1} above).

For now, see the file \texttt{flp.doc} in the Python library source directory for a description.

XXX A complete description should be inserted here!
39.7. fm — Font Manager interface

Deprecation notice: The fm module has been removed in Python 3.

This module provides access to the IRIS Font Manager library. It is available only on Silicon Graphics machines. See also: 4Sight User's Guide, section 1, chapter 5: “Using the IRIS Font Manager.”

This is not yet a full interface to the IRIS Font Manager. Among the unsupported features are: matrix operations; cache operations; character operations (use string operations instead); some details of font info; individual glyph metrics; and printer matching.

It supports the following operations:

- **fm.init()**
  Initialization function. Calls fminit(). It is normally not necessary to call this function, since it is called automatically the first time the fm module is imported.

- **fm.findfont(fontname)**
  Return a font handle object. Calls fmfindfont(fontname).

- **fm.enumerate()**
  Returns a list of available font names. This is an interface to fmenumerate().

- **fm.prstr(string)**
  Render a string using the current font (see the setfont() font handle method below). Calls fmprstr(string).

- **fm.setpath(string)**
Sets the font search path. Calls fmsetpath(string). (XXX Does not work!?!)

```
fm.fontpath()
```

Returns the current font search path.

Font handle objects support the following operations:

```
font handle.scalefont(factor)
```

Returns a handle for a scaled version of this font. Calls fmscalefont(fh, factor).

```
font handle.setfont()
```

Makes this font the current font. Note: the effect is undone silently when the font handle object is deleted. Calls fmsetfont(fh).

```
font handle.getfontname()
```

Returns this font's name. Calls fmgetfontname(fh).

```
font handle.getcomment()
```

Returns the comment string associated with this font. Raises an exception if there is none. Calls fmgetcomment(fh).

```
font handle.getfontinfo()
```

Returns a tuple giving some pertinent data about this font. This is an interface to fmgetfontinfo(). The returned tuple contains the following numbers: (printermatched, fixed_width, xorig, yorig, xsize, ysize, height, nglyphs).

```
font handle.getstrwidth(string)
```

Returns the width, in pixels, of string when drawn in this font. Calls fmgetstrwidth(fh, string).
39.8. g1 — Graphics Library interface

*Deprecated since version 2.6:* The g1 module has been removed in Python 3.

This module provides access to the Silicon Graphics Graphics Library. It is available only on Silicon Graphics machines.

**Warning:** Some illegal calls to the GL library cause the Python interpreter to dump core. In particular, the use of most GL calls is unsafe before the first window is opened.

The module is too large to document here in its entirety, but the following should help you to get started. The parameter conventions for the C functions are translated to Python as follows:

- All (short, long, unsigned) int values are represented by Python integers.

- All float and double values are represented by Python floating point numbers. In most cases, Python integers are also allowed.

- All arrays are represented by one-dimensional Python lists. In most cases, tuples are also allowed.

- All string and character arguments are represented by Python strings, for instance, `winopen('Hi There!')` and `rotate(900, 'z')`.

- All (short, long, unsigned) integer arguments or return values that are only used to specify the length of an array argument are
omitted. For example, the C call

```c
lmdef(deftype, index, np, props)
```

is translated to Python as

```python
lmdef(deftype, index, props)
```

- Output arguments are omitted from the argument list; they are transmitted as function return values instead. If more than one value must be returned, the return value is a tuple. If the C function has both a regular return value (that is not omitted because of the previous rule) and an output argument, the return value comes first in the tuple. Examples: the C call

```c
getmcolor(i, &red, &green, &blue)
```

is translated to Python as

```python
red, green, blue = getmcolor(i)
```

The following functions are non-standard or have special argument conventions:

- **gl. varray(argument)**
  Equivalent to but faster than a number of `v3d()` calls. The argument is a list (or tuple) of points. Each point must be a tuple of coordinates `(x, y, z)` or `(x, y)`. The points may be 2- or 3-dimensional but must all have the same dimension. Float and int values may be mixed however. The points are always converted to 3D double precision points by assuming `z = 0.0` if necessary (as indicated in the man page), and for each point `v3d()` is called.

- **gl. nvarray()**
  Equivalent to but faster than a number of `n3f` and `v3f` calls. The
argument is an array (list or tuple) of pairs of normals and points. Each pair is a tuple of a point and a normal for that point. Each point or normal must be a tuple of coordinates \((x, y, z)\). Three coordinates must be given. Float and int values may be mixed. For each pair, \(n3f()\) is called for the normal, and then \(v3f()\) is called for the point.

\[\text{gl.} \ vnarray()\]
Similar to \(nvarray()\) but the pairs have the point first and the normal second.

\[\text{gl.} \ nurbssurface(s_k, t_k, ctl, s_ord, t_ord, type)\]
Defines a nurbs surface. The dimensions of \(ctl[][]\) are computed as follows: \([\text{len}(s_k) - s_{ord}], [\text{len}(t_k) - t_{ord}]\).

\[\text{gl.} \ nurbscurve(knots, ctlpoints, order, type)\]
Defines a nurbs curve. The length of \(ctlpoints\) is \(\text{len}(knots) - order\).

\[\text{gl.} \ pw1curve(points, type)\]
Defines a piecewise-linear curve. \(points\) is a list of points. \(type\) must be \(N\_ST\).

\[\text{gl.} \ pick(n)\]
\[\text{gl.} \ select(n)\]
The only argument to these functions specifies the desired size of the pick or select buffer.

\[\text{gl.} \ endpick()\]
\[\text{gl.} \ endselect()\]
These functions have no arguments. They return a list of integers representing the used part of the pick/select buffer. No method is provided to detect buffer overrun.

Here is a tiny but complete example GL program in Python:
import gl, GL, time

def main():
    gl.foreground()
    gl.prefposition(500, 900, 500, 900)
    w = gl.winopen('CrissCross')
    gl.ortho2(0.0, 400.0, 0.0, 400.0)
    gl.color(GL.WHITE)
    gl.clear()
    gl.color(GL.RED)
    gl.bgnline()
    gl.v2f(0.0, 0.0)
    gl.v2f(400.0, 0.0)
    gl.endline()
    gl.bgnline()
    gl.v2f(0.0, 0.0)
    gl.v2f(400.0, 400.0)
    gl.endline()
    time.sleep(5)

See also:

PyOpenGL: The Python OpenGL Binding

An interface to OpenGL is also available; see information about the PyOpenGL project online at http://pyopengl.sourceforge.net/. This may be a better option if support for SGI hardware from before about 1996 is not required.
39.9. **DEVICE** — Constants used with the gl module

*Deprecated since version 2.6:* The **DEVICE** module has been removed in Python 3.

This module defines the constants used by the Silicon Graphics Graphics Library that C programmers find in the header file `<gl/device.h>`. Read the module source file for details.
39.10. GL — Constants used with the gl module

Deprecation warning: The `GL` module has been removed in Python 3.

This module contains constants used by the Silicon Graphics Graphics Library from the C header file `<gl/gl.h>`. Read the module source file for details.
39.11. imgfile — Support for SGI imglib files

*Deprecated since version 2.6:* The `imgfile` module has been removed in Python 3.

The `imgfile` module allows Python programs to access SGI imglib image files (also known as `.rgb` files). The module is far from complete, but is provided anyway since the functionality that there is enough in some cases. Currently, colormap files are not supported.

The module defines the following variables and functions:

- **exception** `imgfile.error`  
  This exception is raised on all errors, such as unsupported file type, etc.

- **`imgfile.getsizes(file)`**  
  This function returns a tuple `(x, y, z)` where `x` and `y` are the size of the image in pixels and `z` is the number of bytes per pixel. Only 3 byte RGB pixels and 1 byte greyscale pixels are currently supported.

- **`imgfile.read(file)`**  
  This function reads and decodes the image on the specified file, and returns it as a Python string. The string has either 1 byte greyscale pixels or 4 byte RGBA pixels. The bottom left pixel is the first in the string. This format is suitable to pass to `gl.lrectwrite()`, for instance.

- **`imgfile.readscaled(file, x, y, filter[, blur])`**  
  This function is identical to `read` but it returns an image that is
scaled to the given $x$ and $y$ sizes. If the \texttt{filter} and \texttt{blur} parameters are omitted scaling is done by simply dropping or duplicating pixels, so the result will be less than perfect, especially for computer-generated images.

Alternatively, you can specify a filter to use to smooth the image after scaling. The filter forms supported are \texttt{impulse'}, \texttt{box'}, \texttt{triangle'}, \texttt{quadratic} and \texttt{gaussian}. If a filter is specified \texttt{blur} is an optional parameter specifying the blurriness of the filter. It defaults to 1.0.

\texttt{readscaled()} makes no attempt to keep the aspect ratio correct, so that is the users' responsibility.

\texttt{imgfile.ttob(flag)}

This function sets a global flag which defines whether the scan lines of the image are read or written from bottom to top (flag is zero, compatible with SGI GL) or from top to bottom (flag is one, compatible with X). The default is zero.

\texttt{imgfile.write(file, data, x, y, z)}

This function writes the RGB or greyscale data in \texttt{data} to image file \texttt{file}. \texttt{x} and \texttt{y} give the size of the image, \texttt{z} is 1 for 1 byte greyscale images or 3 for RGB images (which are stored as 4 byte values of which only the lower three bytes are used). These are the formats returned by \texttt{gl.lrectread()}. 
39.12. jpeg — Read and write JPEG files

*Deprecated since version 2.6: The jpeg module has been removed in Python 3.*

The module `jpeg` provides access to the jpeg compressor and decompressor written by the Independent JPEG Group (IJG). JPEG is a standard for compressing pictures; it is defined in ISO 10918. For details on JPEG or the Independent JPEG Group software refer to the JPEG standard or the documentation provided with the software.

A portable interface to JPEG image files is available with the Python Imaging Library (PIL) by Fredrik Lundh. Information on PIL is available at [http://www.pythonware.com/products/pil/](http://www.pythonware.com/products/pil/).

The `jpeg` module defines an exception and some functions.

*exception* `jpeg.error`

Exception raised by `compress()` and `decompress()` in case of errors.

`jpeg.compress(data, w, h, b)`

Treat data as a pixmap of width `w` and height `h`, with `b` bytes per pixel. The data is in SGI GL order, so the first pixel is in the lower-left corner. This means that `gl.lrectread()` return data can immediately be passed to `compress()`. Currently only 1 byte and 4 byte pixels are allowed, the former being treated as greyscale and the latter as RGB color. `compress()` returns a string that contains the compressed picture, in JFIF format.
**jpeg.decompress(data)**

Data is a string containing a picture in JFIF format. It returns a tuple `(data, width, height, bytesperpixel)`. Again, the data is suitable to pass to `gl.lrectwrite()`.

**jpeg.setoption(name, value)**

Set various options. Subsequent `compress()` and `decompress()` calls will use these options. The following options are available:

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>'forcegray'</td>
<td>Force output to be grayscale, even if input is RGB.</td>
</tr>
<tr>
<td>'quality'</td>
<td>Set the quality of the compressed image to a value between 0 and 100 (default is 75). This only affects compression.</td>
</tr>
<tr>
<td>'optimize'</td>
<td>Perform Huffman table optimization. Takes longer, but results in smaller compressed image. This only affects compression.</td>
</tr>
<tr>
<td>'smooth'</td>
<td>Perform inter-block smoothing on uncompressed image. Only useful for low-quality images. This only affects decompression.</td>
</tr>
</tbody>
</table>

40. SunOS Specific Services

The modules described in this chapter provide interfaces to features that are unique to SunOS 5 (also known as Solaris version 2).

- 40.1. sunaudiodev — Access to Sun audio hardware
  - 40.1.1. Audio Device Objects
- 40.2. SUNAUDIODEV — Constants used with sunaudiodev
40.1. sunaudiodev — Access to Sun audio hardware

*Deprecated since version 2.6:* The `sunaudiodev` module has been removed in Python 3.

This module allows you to access the Sun audio interface. The Sun audio hardware is capable of recording and playing back audio data in u-LAW format with a sample rate of 8K per second. A full description can be found in the `audio(7I)` manual page.

The module `SUNAUDIODEV` defines constants which may be used with this module.

This module defines the following variables and functions:

* `exception sunaudiodev.error`
  This exception is raised on all errors. The argument is a string describing what went wrong.

* `sunaudiodev.open(mode)`
  This function opens the audio device and returns a Sun audio device object. This object can then be used to do I/O on. The `mode` parameter is one of 'r' for record-only access, 'w' for play-only access, 'rw' for both and 'control' for access to the control device. Since only one process is allowed to have the recorder or player open at the same time it is a good idea to open the device only for the activity needed. See `audio(7I)` for details.

As per the manpage, this module first looks in the environment variable `AUDIODEV` for the base audio device filename. If not found, it falls back to `/dev/audio`. The control device is calculated
by appending “ctl” to the base audio device.
40.1.1. Audio Device Objects

The audio device objects are returned by `open()` define the following methods (except `control` objects which only provide `getinfo()`, `setinfo()`, `fileno()`, and `drain()`):

**audio device.close()**
This method explicitly closes the device. It is useful in situations where deleting the object does not immediately close it since there are other references to it. A closed device should not be used again.

**audio device.fileno()**
Returns the file descriptor associated with the device. This can be used to set up `SIGPOLL` notification, as described below.

**audio device.drain()**
This method waits until all pending output is processed and then returns. Calling this method is often not necessary: destroying the object will automatically close the audio device and this will do an implicit drain.

**audio device.flush()**
This method discards all pending output. It can be used avoid the slow response to a user’s stop request (due to buffering of up to one second of sound).

**audio device.getinfo()**
This method retrieves status information like input and output volume, etc. and returns it in the form of an audio status object. This object has no methods but it contains a number of attributes describing the current device status. The names and meanings of the attributes are described in `<sun/audioioio.h>` and in the `audio(7I)` manual page. Member names are slightly different from
their C counterparts: a status object is only a single structure. Members of the play substructure have o_ prepended to their name and members of the record structure have i_. So, the C member play.sample_rate is accessed as o_sample_rate, record.gain as i_gain and monitor_gain plainly as monitor_gain.

audio device.ibufcount()
This method returns the number of samples that are buffered on the recording side, i.e. the program will not block on a read() call of so many samples.

audio device.obufcount()
This method returns the number of samples buffered on the playback side. Unfortunately, this number cannot be used to determine a number of samples that can be written without blocking since the kernel output queue length seems to be variable.

audio device.read(size)
This method reads size samples from the audio input and returns them as a Python string. The function blocks until enough data is available.

audio device.setinfo(status)
This method sets the audio device status parameters. The status parameter is a device status object as returned by getinfo() and possibly modified by the program.

audio device.write(samples)
Write is passed a Python string containing audio samples to be played. If there is enough buffer space free it will immediately return, otherwise it will block.

The audio device supports asynchronous notification of various events, through the SIGPOLL signal. Here’s an example of how you
might enable this in Python:

```python
def handle_sigpoll(signum, frame):
    print 'I got a SIGPOLL update'

import fcntl, signal, STROPTS

signal.signal(signal.SIGPOLL, handle_sigpoll)
fcntl.ioctl(audio_obj.fileno(), STROPTS.I_SETSIG, STROPTS.S_MSG)
```
40.2. **SUNAUDIODEV** — Constants used with **sunaudiodev**

*Deprecated since version 2.6:* The **SUNAUDIODEV** module has been removed in Python 3.

This is a companion module to **sunaudiodev** which defines useful symbolic constants like **MIN_GAIN**, **MAX_GAIN**, **SPEAKER**, etc. The names of the constants are the same names as used in the C include file `<sun/audioio.h>`, with the leading string **AUDIO** stripped.
41. Undocumented Modules

Here’s a quick listing of modules that are currently undocumented, but that should be documented. Feel free to contribute documentation for them! (Send via email to docs@python.org.)

The idea and original contents for this chapter were taken from a posting by Fredrik Lundh; the specific contents of this chapter have been substantially revised.
41.1. Miscellaneous useful utilities

Some of these are very old and/or not very robust; marked with “hmm.”

ihooks
— Import hook support (for rexec; may become obsolete). Removed in Python 3.x.
41.2. Platform specific modules

These modules are used to implement the `os.path` module, and are not documented beyond this mention. There's little need to document these.

**ntpath**
- Implementation of `os.path` on Win32, Win64, WinCE, and OS/2 platforms.

**posixpath**
- Implementation of `os.path` on POSIX.

**bsddb185**
- Backwards compatibility module for systems which still use the Berkeley DB 1.85 module. It is normally only available on certain BSD Unix-based systems. It should never be used directly.
41.3. Multimedia

**audiodev**
— Platform-independent API for playing audio data. Removed in Python 3.x.

**linuxaudiodev**
— Play audio data on the Linux audio device. Replaced in Python 2.3 by the **ossaudiodev** module. Removed in Python 3.x.

**sunaudio**
— Interpret Sun audio headers (may become obsolete or a tool/demo). Removed in Python 3.x.

**toaiff**
— Convert “arbitrary” sound files to AIFF files; should probably become a tool or demo. Requires the external program **sox**. Removed in Python 3.x.
41.4. Undocumented Mac OS modules

41.4.1. applesingle — AppleSingle decoder

*Deprecated since version 2.6.*

41.4.2. buildtools — Helper module for BuildApplet and Friends

*Deprecated since version 2.4.*

41.4.3. cfmyfile — Code Fragment Resource module

*cfmyfile* is a module that understands Code Fragments and the accompanying “cfrg” resources. It can parse them and merge them, and is used by BuildApplication to combine all plugin modules to a single executable.

*Deprecated since version 2.4.*

41.4.4. icopen — Internet Config replacement for open()

Importing *icopen* will replace the built-in *open()* with a version that uses Internet Config to set file type and creator for new files.
41.4.5. `macerrors` — Mac OS Errors

`macerrors` contains constant definitions for many Mac OS error codes.

41.4.6. `macresource` — Locate script resources

`macresource` helps scripts finding their resources, such as dialogs and menus, without requiring special case code for when the script is run under MacPython, as a MacPython applet or under OSX Python.

41.4.7. `Nav` — NavServices calls

A low-level interface to Navigation Services.

41.4.8. `PixMapWrapper` — Wrapper for PixMap objects

`PixMapWrapper` wraps a PixMap object with a Python object that allows access to the fields by name. It also has methods to convert
to and from PIL images.

* Deprecated since version 2.6.*

### 41.4.9. videoreader — Read QuickTime movies

*videoreader* reads and decodes QuickTime movies and passes a stream of images to your program. It also provides some support for audio tracks.

* Deprecated since version 2.6.*

### 41.4.10. w — Widgets built on Framework

The *w* widgets are used extensively in the IDE.

* Deprecated since version 2.6.*
41.5. Obsolete

These modules are not normally available for import; additional work must be done to make them available.

These extension modules written in C are not built by default. Under Unix, these must be enabled by uncommenting the appropriate lines in Modules/Setup in the build tree and either rebuilding Python if the modules are statically linked, or building and installing the shared object if using dynamically-loaded extensions.

**timing**

— Measure time intervals to high resolution (use `time.clock()` instead). Removed in Python 3.x.
41.6. SGI-specific Extension modules

The following are SGI specific, and may be out of touch with the current version of reality.

c1
— Interface to the SGI compression library.

sv
— Interface to the “simple video” board on SGI Indigo (obsolete hardware). Removed in Python 3.x.
1. Extending Python with C or C++

It is quite easy to add new built-in modules to Python, if you know how to program in C. Such extension modules can do two things that can’t be done directly in Python: they can implement new built-in object types, and they can call C library functions and system calls.

To support extensions, the Python API (Application Programmers Interface) defines a set of functions, macros and variables that provide access to most aspects of the Python run-time system. The Python API is incorporated in a C source file by including the header "Python.h".

The compilation of an extension module depends on its intended use as well as on your system setup; details are given in later chapters.

**Note:** The C extension interface is specific to CPython, and extension modules do not work on other Python implementations. In many cases, it is possible to avoid writing C extensions and preserve portability to other implementations. For example, if your use case is calling C library functions or system calls, you should consider using the `ctypes` module or the `cffi` library rather than writing custom C code. These modules let you write Python code to interface with C code and are more portable between implementations of Python than writing and compiling a C extension module.
1.1. A Simple Example

Let’s create an extension module called spam (the favorite food of Monty Python fans...) and let’s say we want to create a Python interface to the C library function system(). [1] This function takes a null-terminated character string as argument and returns an integer. We want this function to be callable from Python as follows:

```python
>>> import spam
>>> status = spam.system("ls -l")
```

Begin by creating a file spammodule.c. (Historically, if a module is called spam, the C file containing its implementation is called spammodule.c; if the module name is very long, like spammify, the module name can be just spammify.c.)

The first line of our file can be:

```c
#include <Python.h>
```

which pulls in the Python API (you can add a comment describing the purpose of the module and a copyright notice if you like).

**Note:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you *must* include Python.h before any standard headers are included.

All user-visible symbols defined by Python.h have a prefix of Py or PY, except those defined in standard header files. For convenience, and since they are used extensively by the Python interpreter, "Python.h" includes a few standard header files: <stdio.h>, <string.h>, <errno.h>, and <stdlib.h>. If the latter header file does
not exist on your system, it declares the functions `malloc()`, `free()` and `realloc()` directly.

The next thing we add to our module file is the C function that will be called when the Python expression `spam.system(string)` is evaluated (we’ll see shortly how it ends up being called):

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    return Py_BuildValue("i", sts);
}
```

There is a straightforward translation from the argument list in Python (for example, the single expression "ls -l") to the arguments passed to the C function. The C function always has two arguments, conventionally named `self` and `args`.

For module functions, the `self` argument is `NULL` or a pointer selected while initializing the module (see `Py_InitModule4()`). For a method, it would point to the object instance.

The `args` argument will be a pointer to a Python tuple object containing the arguments. Each item of the tuple corresponds to an argument in the call’s argument list. The arguments are Python objects — in order to do anything with them in our C function we have to convert them to C values. The function `PyArg_ParseTuple()` in the Python API checks the argument types and converts them to C values. It uses a template string to determine the required types of the arguments as well as the types of the C variables into which to store the converted values. More about this later.
PyArg_ParseTuple() returns true (nonzero) if all arguments have the right type and its components have been stored in the variables whose addresses are passed. It returns false (zero) if an invalid argument list was passed. In the latter case it also raises an appropriate exception so the calling function can return NULL immediately (as we saw in the example).
1.2. Intermezzo: Errors and Exceptions

An important convention throughout the Python interpreter is the following: when a function fails, it should set an exception condition and return an error value (usually a NULL pointer). Exceptions are stored in a static global variable inside the interpreter; if this variable is NULL no exception has occurred. A second global variable stores the “associated value” of the exception (the second argument to raise). A third variable contains the stack traceback in case the error originated in Python code. These three variables are the C equivalents of the Python variables `sys.exc_type`, `sys.exc_value` and `sys.exc_traceback` (see the section on module `sys` in the Python Library Reference). It is important to know about them to understand how errors are passed around.

The Python API defines a number of functions to set various types of exceptions.

The most common one is `PyErr_SetString()`. Its arguments are an exception object and a C string. The exception object is usually a predefined object like `PyExc_ZeroDivisionError`. The C string indicates the cause of the error and is converted to a Python string object and stored as the “associated value” of the exception.

Another useful function is `PyErr_SetFromErrno()`, which only takes an exception argument and constructs the associated value by inspection of the global variable `errno`. The most general function is `PyErr_SetObject()`, which takes two object arguments, the exception and its associated value. You don’t need to `Py_INCREF()` the objects passed to any of these functions.

You can test non-destructively whether an exception has been set with `PyErr_Occurred()`. This returns the current exception object, or
NULL if no exception has occurred. You normally don’t need to call
PyErr_Occurred() to see whether an error occurred in a function call,
since you should be able to tell from the return value.

When a function $f$ that calls another function $g$ detects that the latter
fails, $f$ should itself return an error value (usually NULL or -1). It
should not call one of the PyErr_*() functions — one has already
been called by $g$. $f$’s caller is then supposed to also return an error
indication to its caller, again without calling PyErr_*(), and so on —
the most detailed cause of the error was already reported by the
function that first detected it. Once the error reaches the Python
interpreter’s main loop, this aborts the currently executing Python
code and tries to find an exception handler specified by the Python
programmer.

(There are situations where a module can actually give a more
detailed error message by calling another PyErr_*() function, and in
such cases it is fine to do so. As a general rule, however, this is not
necessary, and can cause information about the cause of the error to
be lost: most operations can fail for a variety of reasons.)

To ignore an exception set by a function call that failed, the exception
condition must be cleared explicitly by calling PyErr_Clear(). The
only time C code should call PyErr_Clear() is if it doesn’t want to
pass the error on to the interpreter but wants to handle it completely
by itself (possibly by trying something else, or pretending nothing
went wrong).

Every failing malloc() call must be turned into an exception — the
direct caller of malloc() (or realloc()) must call PyErr_NoMemory()
and return a failure indicator itself. All the object-creating functions
(for example, PyInt_FromLong()) already do this, so this note is only
relevant to those who call malloc() directly.
Also note that, with the important exception of `PyArg_ParseTuple()` and friends, functions that return an integer status usually return a positive value or zero for success and -1 for failure, like Unix system calls.

Finally, be careful to clean up garbage (by making `Py_XDECREF()` or `Py_DECREF()` calls for objects you have already created) when you return an error indicator!

The choice of which exception to raise is entirely yours. There are predeclared C objects corresponding to all built-in Python exceptions, such as `PyExc_ZeroDivisionError`, which you can use directly. Of course, you should choose exceptions wisely — don’t use `PyExc_TypeError` to mean that a file couldn’t be opened (that should probably be `PyExc_IOError`). If something’s wrong with the argument list, the `PyArg_ParseTuple()` function usually raises `PyExc_TypeError`. If you have an argument whose value must be in a particular range or must satisfy other conditions, `PyExc_ValueError` is appropriate.

You can also define a new exception that is unique to your module. For this, you usually declare a static object variable at the beginning of your file:

```c
static PyObject *SpamError;
```

and initialize it in your module’s initialization function (`initspam()`) with an exception object (leaving out the error checking for now):

```c
PyMODINIT_FUNC
initspam(void)
{
    PyObject *m;

    m = Py_InitModule("spam", SpamMethods);
    if (m == NULL)
```
Note that the Python name for the exception object is `spam.error`. The `PyErr_NewException()` function may create a class with the base class being `Exception` (unless another class is passed in instead of `NULL`), described in Built-in Exceptions.

Note also that the `SpamError` variable retains a reference to the newly created exception class; this is intentional! Since the exception could be removed from the module by external code, an owned reference to the class is needed to ensure that it will not be discarded, causing `SpamError` to become a dangling pointer. Should it become a dangling pointer, C code which raises the exception could cause a core dump or other unintended side effects.

We discuss the use of `PyMODINIT_FUNC` as a function return type later in this sample.

The `spam.error` exception can be raised in your extension module using a call to `PyErr_SetString()` as shown below:

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    if (sts < 0) {
        PyErr_SetString(SpamError, "System command failed");
        return NULL;
    }
```
return PyLong_FromLong(sts);
}
1.3. Back to the Example

Going back to our example function, you should now be able to understand this statement:

```c
if (!PyArg_ParseTuple(args, "s", &command))
    return NULL;
```

It returns `NULL` (the error indicator for functions returning object pointers) if an error is detected in the argument list, relying on the exception set by `PyArg_ParseTuple()`. Otherwise the string value of the argument has been copied to the local variable `command`. This is a pointer assignment and you are not supposed to modify the string to which it points (so in Standard C, the variable `command` should properly be declared as `const char *command`).

The next statement is a call to the Unix function `system()`, passing it the string we just got from `PyArg_ParseTuple()`:

```c
sts = system(command);
```

Our `spam.system()` function must return the value of `sts` as a Python object. This is done using the function `Py_BuildValue()`, which is something like the inverse of `PyArg_ParseTuple()`: it takes a format string and an arbitrary number of C values, and returns a new Python object. More info on `Py_BuildValue()` is given later.

```c
return Py_BuildValue("i", sts);
```

In this case, it will return an integer object. (Yes, even integers are objects on the heap in Python!)

If you have a C function that returns no useful argument (a function
returning `void`), the corresponding Python function must return `None`. You need this idiom to do so (which is implemented by the `Py_RETURN_NONE` macro):

```c
Py_INCREF(Py_None);
return Py_None;
```

`Py_None` is the C name for the special Python object `None`. It is a genuine Python object rather than a `NULL` pointer, which means “error” in most contexts, as we have seen.
1.4. The Module’s Method Table and Initialization Function

I promised to show how `spam_system()` is called from Python programs. First, we need to list its name and address in a “method table”:

```c
static PyMethodDef SpamMethods[] = {
    ...,
    {"system", spam_system, METH_VARARGS, "Execute a shell command."},
    ...,
    {NULL, NULL, 0, NULL}, /* Sentinel */
};
```

Note the third entry (METH_VARARGS). This is a flag telling the interpreter the calling convention to be used for the C function. It should normally always be METH_VARARGS or METH_VARARGS | METH_KEYWORDS; a value of 0 means that an obsolete variant of `PyArg_ParseTuple()` is used.

When using only METH_VARARGS, the function should expect the Python-level parameters to be passed in as a tuple acceptable for parsing via `PyArg_ParseTuple()`; more information on this function is provided below.

The METH_KEYWORDS bit may be set in the third field if keyword arguments should be passed to the function. In this case, the C function should accept a third `PyObject *` parameter which will be a dictionary of keywords. Use `PyArg_ParseTupleAndKeywords()` to parse the arguments to such a function.

The method table must be passed to the interpreter in the module’s initialization function. The initialization function must be named
initname(), where name is the name of the module, and should be the only non-static item defined in the module file:

```c
PyMODINIT_FUNC
initspam(void)
{
    (void) Py_InitModule("spam", SpamMethods);
}
```

Note that PyMODINIT_FUNC declares the function as void return type, declares any special linkage declarations required by the platform, and for C++ declares the function as extern "C".

When the Python program imports module spam for the first time, initspam() is called. (See below for comments about embedding Python.) It calls Py_InitModule(), which creates a “module object” (which is inserted in the dictionary sys.modules under the key "spam"), and inserts built-in function objects into the newly created module based upon the table (an array of PyMethodDef structures) that was passed as its second argument. Py_InitModule() returns a pointer to the module object that it creates (which is unused here). It may abort with a fatal error for certain errors, or return NULL if the module could not be initialized satisfactorily.

When embedding Python, the initspam() function is not called automatically unless there's an entry in the _PyImport_Inittab table. The easiest way to handle this is to statically initialize your statically-linked modules by directly calling initspam() after the call to Py_Initialize():

```c
int
main(int argc, char *argv[])
{
    /* Pass argv[0] to the Python interpreter */
    Py_SetProgramName(argv[0]);
```
/* Initialize the Python interpreter. Required. */
Py_Initialize();

/* Add a static module */
initspam();
...

An example may be found in the file `Demo/embed/demo.c` in the Python source distribution.

**Note:** Removing entries from `sys.modules` or importing compiled modules into multiple interpreters within a process (or following a `fork()` without an intervening `exec()`) can create problems for some extension modules. Extension module authors should exercise caution when initializing internal data structures. Note also that the `reload()` function can be used with extension modules, and will call the module initialization function (`initspam()` in the example), but will not load the module again if it was loaded from a dynamically loadable object file (.so on Unix, .dll on Windows).

A more substantial example module is included in the Python source distribution as `Modules/xxmodule.c`. This file may be used as a template or simply read as an example.
1.5. Compilation and Linkage

There are two more things to do before you can use your new extension: compiling and linking it with the Python system. If you use dynamic loading, the details may depend on the style of dynamic loading your system uses; see the chapters about building extension modules (chapter Building C and C++ Extensions with distutils) and additional information that pertains only to building on Windows (chapter Building C and C++ Extensions on Windows) for more information about this.

If you can’t use dynamic loading, or if you want to make your module a permanent part of the Python interpreter, you will have to change the configuration setup and rebuild the interpreter. Luckily, this is very simple on Unix: just place your file (spammodule.c for example) in the Modules/ directory of an unpacked source distribution, add a line to the file Modules/Setup.local describing your file:

    spam spammodule.o

and rebuild the interpreter by running make in the toplevel directory. You can also run make in the Modules/ subdirectory, but then you must first rebuild Makefile there by running ‘make Makefile’. (This is necessary each time you change the Setup file.)

If your module requires additional libraries to link with, these can be listed on the line in the configuration file as well, for instance:

    spam spammodule.o -lx11
1.6. Calling Python Functions from C

So far we have concentrated on making C functions callable from Python. The reverse is also useful: calling Python functions from C. This is especially the case for libraries that support so-called “callback” functions. If a C interface makes use of callbacks, the equivalent Python often needs to provide a callback mechanism to the Python programmer; the implementation will require calling the Python callback functions from a C callback. Other uses are also imaginable.

Fortunately, the Python interpreter is easily called recursively, and there is a standard interface to call a Python function. (I won’t dwell on how to call the Python parser with a particular string as input — if you’re interested, have a look at the implementation of the \texttt{-c} command line option in \texttt{Modules/main.c} from the Python source code.)

Calling a Python function is easy. First, the Python program must somehow pass you the Python function object. You should provide a function (or some other interface) to do this. When this function is called, save a pointer to the Python function object (be careful to \texttt{Py_INCREF()} it!) in a global variable — or wherever you see fit. For example, the following function might be part of a module definition:

```c
static PyObject *my_callback = NULL;

static PyObject *
my_set_callback(PyObject *dummy, PyObject *args)
{
    PyObject *result = NULL;
    PyObject *temp;

    if (PyArg_ParseTuple(args, "O:set_callback", &temp)) {
        if (!PyCallable_Check(temp)) {
            PyErr_SetString(PyExc_TypeError, "parameter must be
```
This function must be registered with the interpreter using the `METH_VARARGS` flag; this is described in section The Module's Method Table and Initialization Function. The `PyArg_ParseTuple()` function and its arguments are documented in section Extracting Parameters in Extension Functions.

The macros `Py_XINCREF()` and `Py_XDECREF()` increment/decrement the reference count of an object and are safe in the presence of `NULL` pointers (but note that `temp` will not be `NULL` in this context). More info on them in section Reference Counts.

Later, when it is time to call the function, you call the C function `PyObject_CallObject()`. This function has two arguments, both pointers to arbitrary Python objects: the Python function, and the argument list. The argument list must always be a tuple object, whose length is the number of arguments. To call the Python function with no arguments, pass in `NULL`, or an empty tuple; to call it with one argument, pass a singleton tuple. `Py_BuildValue()` returns a tuple when its format string consists of zero or more format codes between parentheses. For example:

```c
int arg;
PyObject *arglist;
PyObject *result;
...
arg = 123;
```
... /* Time to call the callback */
arglist = Py_BuildValue("(i)", arg);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);

PyObject_CallObject() returns a Python object pointer: this is the return value of the Python function. PyObject_CallObject() is “reference-count-neutral” with respect to its arguments. In the example a new tuple was created to serve as the argument list, which is Py_DECREF()-ed immediately after the PyObject_CallObject() call.

The return value of PyObject_CallObject() is “new”: either it is a brand new object, or it is an existing object whose reference count has been incremented. So, unless you want to save it in a global variable, you should somehow Py_DECREF() the result, even (especially!) if you are not interested in its value.

Before you do this, however, it is important to check that the return value isn’t NULL. If it is, the Python function terminated by raising an exception. If the C code that called PyObject_CallObject() is called from Python, it should now return an error indication to its Python caller, so the interpreter can print a stack trace, or the calling Python code can handle the exception. If this is not possible or desirable, the exception should be cleared by calling PyErr_Clear(). For example:

```c
if (result == NULL)
    return NULL; /* Pass error back */
...use result...
Py_DECREF(result);
```

Depending on the desired interface to the Python callback function, you may also have to provide an argument list to PyObject_CallObject(). In some cases the argument list is also
provided by the Python program, through the same interface that specified the callback function. It can then be saved and used in the same manner as the function object. In other cases, you may have to construct a new tuple to pass as the argument list. The simplest way to do this is to call `Py_BuildValue()`. For example, if you want to pass an integral event code, you might use the following code:

```python
PyObject *arglist;
...
arglist = Py_BuildValue("(l)", eventcode);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

Note the placement of `Py_DECREF(arglist)` immediately after the call, before the error check! Also note that strictly speaking this code is not complete: `Py_BuildValue()` may run out of memory, and this should be checked.

You may also call a function with keyword arguments by using `PyObject_Call()`, which supports arguments and keyword arguments. As in the above example, we use `Py_BuildValue()` to construct the dictionary.

```python
PyObject *dict;
...
dict = Py_BuildValue("{s:i}", "name", val);
result = PyObject_CallObject(my_callback, NULL, dict);
Py_DECREF(dict);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```
1.7. Extracting Parameters in Extension Functions

The `PyArg_ParseTuple()` function is declared as follows:

```c
int PyArg_ParseTuple(PyObject *arg, char *format, ...);
```

The `arg` argument must be a tuple object containing an argument list passed from Python to a C function. The `format` argument must be a format string, whose syntax is explained in Parsing arguments and building values in the Python/C API Reference Manual. The remaining arguments must be addresses of variables whose type is determined by the format string.

Note that while `PyArg_ParseTuple()` checks that the Python arguments have the required types, it cannot check the validity of the addresses of C variables passed to the call: if you make mistakes there, your code will probably crash or at least overwrite random bits in memory. So be careful!

Note that any Python object references which are provided to the caller are borrowed references; do not decrement their reference count!

Some example calls:

```c
int ok;
int i, j;
long k, l;
const char *s;
int size;

ok = PyArg_ParseTuple(args, """); /* No arguments */
   /* Python call: f() */
```
ok = PyArg_ParseTuple(args, "s", &s); /* A string */
   /* Possible Python call: f('whoops!') */
ok = PyArg_ParseTuple(args, "lls", &k, &l, &s); /* Two longs and a string */
   /* Possible Python call: f(1, 2, 'three') */
ok = PyArg_ParseTuple(args, "(ii)s#", &i, &j, &s, &size); /* A pair of ints and a string, whose size is also returned */
   /* Possible Python call: f((1, 2), 'three') */
{
    const char *file;
    const char *mode = "r";
    int bufsize = 0;
    ok = PyArg_ParseTuple(args, "s|si", &file, &mode, &bufsize); /* A string, and optionally another string and an integer */
    /* Possible Python calls:
       f('spam')
       f('spam', 'w')
       f('spam', 'wb', 100000) */
}
{
    int left, top, right, bottom, h, v;
    ok = PyArg_ParseTuple(args, "((ii)(ii))(ii)",
                           &left, &top, &right, &bottom, &h, &v);
    /* A rectangle and a point */
    /* Possible Python call:
       f(((0, 0), (400, 300)), (10, 10)) */
}
{
    Py_complex c;
    ok = PyArg_ParseTuple(args, "D:myfunction", &c);
    /* a complex, also providing a function name for errors */
    /* Possible Python call: myfunction(1+2j) */
}
1.8. Keyword Parameters for Extension Functions

The `PyArg_ParseTupleAndKeywords()` function is declared as follows:

```c
int PyArg_ParseTupleAndKeywords(PyObject *arg, PyObject *kwdict, char *format, char *kwlist[], ...);
```

The `arg` and `format` parameters are identical to those of the `PyArg_ParseTuple()` function. The `kwdict` parameter is the dictionary of keywords received as the third parameter from the Python runtime. The `kwlist` parameter is a `NULL`-terminated list of strings which identify the parameters; the names are matched with the type information from `format` from left to right. On success, `PyArg_ParseTupleAndKeywords()` returns true, otherwise it returns false and raises an appropriate exception.

**Note:** Nested tuples cannot be parsed when using keyword arguments! Keyword parameters passed in which are not present in the `kwlist` will cause `TypeError` to be raised.

Here is an example module which uses keywords, based on an example by Geoff Philbrick (philbrick@hks.com):

```c
#include "Python.h"

static PyObject *
keywdarg_parrot(PyObject *self, PyObject *args, PyObject *keywd)
{
    int voltage;
    char *state = "a stiff";
    char *action = "voom";
    char *type = "Norwegian Blue";

    static char *kwlist[] = {
        "voltage", "state", "action", "typ
if (!PyArg_ParseTupleAndKeywords(args, keywds, "i|sss", kwlist, &voltage, &state, &action, &type, &action)
    return NULL;

printf("-- This parrot wouldn't %s if you put %i Volts through it.
       action, voltage);
printf("-- Lovely plumage, the %s -- It's %s!\n", type, state);
Py_INCREF(Py_None);
    return Py_None;
}

static PyMethodDef keywdarg_methods[] = {
    /* The cast of the function is necessary since PyCFunction
       * only take two PyObject* parameters, and keywdarg_parrot( *
       * three.
       */
    {"parrot", (PyCFunction)keywdarg_parrot, METH_VARARGS | METH_KEYWORDS,
     "Print a lovely skit to standard output."},
    {NULL, NULL, 0, NULL} /* sentinel */
};

void initkeywdarg(void)
{
    /* Create the module and add the functions */
    Py_InitModule("keywdarg", keywdarg_methods);
}
1.9. Building Arbitrary Values

This function is the counterpart to \texttt{PyArg_ParseTuple()}. It is declared as follows:

\begin{verbatim}
PyObject *Py_BuildValue(char *format, ...);
\end{verbatim}

It recognizes a set of format units similar to the ones recognized by \texttt{PyArg_ParseTuple()}, but the arguments (which are input to the function, not output) must not be pointers, just values. It returns a new Python object, suitable for returning from a C function called from Python.

One difference with \texttt{PyArg_ParseTuple()}: while the latter requires its first argument to be a tuple (since Python argument lists are always represented as tuples internally), \texttt{Py_BuildValue()} does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns \texttt{None}; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

Examples (to the left the call, to the right the resulting Python value):

\begin{verbatim}
Py_BuildValue(""")                        None
Py_BuildValue("i", 123)                      123
Py_BuildValue("iii", 123, 456, 789)         (123, 456, 789)
Py_BuildValue("s", "hello")                'hello'
Py_BuildValue("ss", "hello", "world")     ('hello', 'world')
Py_BuildValue("s#", "hello", 4)            'hell'
Py_BuildValue("()")                         ()
Py_BuildValue("(i)", 123)                    (123,)
Py_BuildValue("(ii)", 123, 456)             (123, 456)
Py_BuildValue("(i,i)", 123, 456)            (123, 456)
Py_BuildValue("[i,i]", 123, 456)             [123, 456]
Py_BuildValue("{s:i,s:i}"),              
\end{verbatim}
<table>
<thead>
<tr>
<th>String</th>
<th>Dictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;abc&quot;, 123, &quot;def&quot;, 456</td>
<td>{'abc': 123, 'def': 456}</td>
</tr>
<tr>
<td><code>Py_BuildValue(&quot;((ii)(ii))(ii)&quot;, 1, 2, 3, 4, 5, 6)</code></td>
<td><code>(((1, 2), (3, 4)), (5, 6))</code></td>
</tr>
</tbody>
</table>
1.10. Reference Counts

In languages like C or C++, the programmer is responsible for dynamic allocation and deallocation of memory on the heap. In C, this is done using the functions `malloc()` and `free()`. In C++, the operators `new` and `delete` are used with essentially the same meaning and we'll restrict the following discussion to the C case.

Every block of memory allocated with `malloc()` should eventually be returned to the pool of available memory by exactly one call to `free()`. It is important to call `free()` at the right time. If a block's address is forgotten but `free()` is not called for it, the memory it occupies cannot be reused until the program terminates. This is called a memory leak. On the other hand, if a program calls `free()` for a block and then continues to use the block, it creates a conflict with re-use of the block through another `malloc()` call. This is called using freed memory. It has the same bad consequences as referencing uninitialized data — core dumps, wrong results, mysterious crashes.

Common causes of memory leaks are unusual paths through the code. For instance, a function may allocate a block of memory, do some calculation, and then free the block again. Now a change in the requirements for the function may add a test to the calculation that detects an error condition and can return prematurely from the function. It's easy to forget to free the allocated memory block when taking this premature exit, especially when it is added later to the code. Such leaks, once introduced, often go undetected for a long time: the error exit is taken only in a small fraction of all calls, and most modern machines have plenty of virtual memory, so the leak only becomes apparent in a long-running process that uses the leaking function frequently. Therefore, it's important to prevent leaks
from happening by having a coding convention or strategy that minimizes this kind of errors.

Since Python makes heavy use of `malloc()` and `free()`, it needs a strategy to avoid memory leaks as well as the use of freed memory. The chosen method is called *reference counting*. The principle is simple: every object contains a counter, which is incremented when a reference to the object is stored somewhere, and which is decremented when a reference to it is deleted. When the counter reaches zero, the last reference to the object has been deleted and the object is freed.

An alternative strategy is called *automatic garbage collection*. (Sometimes, reference counting is also referred to as a garbage collection strategy, hence my use of “automatic” to distinguish the two.) The big advantage of automatic garbage collection is that the user doesn’t need to call `free()` explicitly. (Another claimed advantage is an improvement in speed or memory usage — this is no hard fact however.) The disadvantage is that for C, there is no truly portable automatic garbage collector, while reference counting can be implemented portably (as long as the functions `malloc()` and `free()` are available — which the C Standard guarantees). Maybe some day a sufficiently portable automatic garbage collector will be available for C. Until then, we’ll have to live with reference counts.

While Python uses the traditional reference counting implementation, it also offers a cycle detector that works to detect reference cycles. This allows applications to not worry about creating direct or indirect circular references; these are the weakness of garbage collection implemented using only reference counting. Reference cycles consist of objects which contain (possibly indirect) references to themselves, so that each object in the cycle has a reference count which is non-zero. Typical reference counting implementations are not able to reclaim the memory belonging to any objects in a
reference cycle, or referenced from the objects in the cycle, even though there are no further references to the cycle itself.

The cycle detector is able to detect garbage cycles and can reclaim them so long as there are no finalizers implemented in Python (__del__() methods). When there are such finalizers, the detector exposes the cycles through the gc module (specifically, the garbage variable in that module). The gc module also exposes a way to run the detector (the collect() function), as well as configuration interfaces and the ability to disable the detector at runtime. The cycle detector is considered an optional component; though it is included by default, it can be disabled at build time using the --without-cycle-gc option to the configure script on Unix platforms (including Mac OS X) or by removing the definition of WITH_CYCLE_GC in the pyconfig.h header on other platforms. If the cycle detector is disabled in this way, the gc module will not be available.

1.10.1. Reference Counting in Python

There are two macros, Py_INCREF(x) and Py_DECREF(x), which handle the incrementing and decrementing of the reference count. Py_DECREF() also frees the object when the count reaches zero. For flexibility, it doesn’t call free() directly — rather, it makes a call through a function pointer in the object’s type object. For this purpose (and others), every object also contains a pointer to its type object.

The big question now remains: when to use Py_INCREF(x) and Py_DECREF(x)? Let’s first introduce some terms. Nobody “owns” an object; however, you can own a reference to an object. An object’s reference count is now defined as the number of owned references to it. The owner of a reference is responsible for calling Py_DECREF() when the reference is no longer needed. Ownership of a reference
can be transferred. There are three ways to dispose of an owned reference: pass it on, store it, or call `Py_DECREF()`. Forgetting to dispose of an owned reference creates a memory leak.

It is also possible to borrow [2] a reference to an object. The borrower of a reference should not call `Py_DECREF()`. The borrower must not hold on to the object longer than the owner from which it was borrowed. Using a borrowed reference after the owner has disposed of it risks using freed memory and should be avoided completely. [3]

The advantage of borrowing over owning a reference is that you don’t need to take care of disposing of the reference on all possible paths through the code — in other words, with a borrowed reference you don’t run the risk of leaking when a premature exit is taken. The disadvantage of borrowing over owning is that there are some subtle situations where in seemingly correct code a borrowed reference can be used after the owner from which it was borrowed has in fact disposed of it.

A borrowed reference can be changed into an owned reference by calling `Py_INCREF()`. This does not affect the status of the owner from which the reference was borrowed — it creates a new owned reference, and gives full owner responsibilities (the new owner must dispose of the reference properly, as well as the previous owner).

**1.10.2. Ownership Rules**

Whenever an object reference is passed into or out of a function, it is part of the function’s interface specification whether ownership is transferred with the reference or not.

Most functions that return a reference to an object pass on ownership with the reference. In particular, all functions whose function it is to create a new object, such as `PyInt_FromLong()` and
Py_BuildValue(), pass ownership to the receiver. Even if the object is not actually new, you still receive ownership of a new reference to that object. For instance, PyInt_FromLong() maintains a cache of popular values and can return a reference to a cached item.

Many functions that extract objects from other objects also transfer ownership with the reference, for instance PyObject_GetAttrString(). The picture is less clear, here, however, since a few common routines are exceptions: PyTuple_GetItem(), PyList_GetItem(), PyDict_GetItem(), and PyDict_GetItemString() all return references that you borrow from the tuple, list or dictionary.

The function PyImport_AddModule() also returns a borrowed reference, even though it may actually create the object it returns: this is possible because an owned reference to the object is stored in sys.modules.

When you pass an object reference into another function, in general, the function borrows the reference from you — if it needs to store it, it will use Py_INCREF() to become an independent owner. There are exactly two important exceptions to this rule: PyTuple_SetItem() and PyList_SetItem(). These functions take over ownership of the item passed to them — even if they fail! (Note that PyDict_SetItem() and friends don’t take over ownership — they are “normal.”)

When a C function is called from Python, it borrows references to its arguments from the caller. The caller owns a reference to the object, so the borrowed reference’s lifetime is guaranteed until the function returns. Only when such a borrowed reference must be stored or passed on, it must be turned into an owned reference by calling Py_INCREF().

The object reference returned from a C function that is called from Python must be an owned reference — ownership is transferred
from the function to its caller.

## 1.10.3. Thin Ice

There are a few situations where seemingly harmless use of a borrowed reference can lead to problems. These all have to do with implicit invocations of the interpreter, which can cause the owner of a reference to dispose of it.

The first and most important case to know about is using `Py_DECREF()` on an unrelated object while borrowing a reference to a list item. For instance:

```c
void bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    PyList_SetItem(list, 1, PyInt_FromLong(0L));
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

This function first borrows a reference to `list[0]`, then replaces `list[1]` with the value `0`, and finally prints the borrowed reference. Looks harmless, right? But it's not!

Let’s follow the control flow into `PyList_SetItem()`. The list owns references to all its items, so when item 1 is replaced, it has to dispose of the original item 1. Now let’s suppose the original item 1 was an instance of a user-defined class, and let’s further suppose that the class defined a `__del__()` method. If this class instance has a reference count of 1, disposing of it will call its `__del__()` method.

Since it is written in Python, the `__del__()` method can execute arbitrary Python code. Could it perhaps do something to invalidate the reference to `item` in `bug()`? You bet! Assuming that the list
passed into `bug()` is accessible to the `__del__()` method, it could execute a statement to the effect of `del list[0]`, and assuming this was the last reference to that object, it would free the memory associated with it, thereby invalidating `item`.

The solution, once you know the source of the problem, is easy: temporarily increment the reference count. The correct version of the function reads:

```c
void no_bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_INCREF(item);
    PyList_SetItem(list, 1, PyInt_FromLong(0L));
    PyObject_Print(item, stdout, 0);
    Py_DECREF(item);
}
```

This is a true story. An older version of Python contained variants of this bug and someone spent a considerable amount of time in a C debugger to figure out why his `__del__()` methods would fail...

The second case of problems with a borrowed reference is a variant involving threads. Normally, multiple threads in the Python interpreter can’t get in each other’s way, because there is a global lock protecting Python’s entire object space. However, it is possible to temporarily release this lock using the macro `Py_BEGIN_ALLOW_THREADS`, and to re-acquire it using `Py_END_ALLOW_THREADS`. This is common around blocking I/O calls, to let other threads use the processor while waiting for the I/O to complete. Obviously, the following function has the same problem as the previous one:

```c
void bug(PyObject *list)
```
In general, functions that take object references as arguments do not expect you to pass them NULL pointers, and will dump core (or cause later core dumps) if you do so. Functions that return object references generally return NULL only to indicate that an exception occurred. The reason for not testing for NULL arguments is that functions often pass the objects they receive on to other function — if each function were to test for NULL, there would be a lot of redundant tests and the code would run more slowly.

It is better to test for NULL only at the “source:” when a pointer that may be NULL is received, for example, from malloc() or from a function that may raise an exception.

The macros Py_INCREF() and Py_DECREF() do not check for NULL pointers — however, their variants Py_XINCREF() and Py_XDECREF() do.

The macros for checking for a particular object type (Pytype_Check()) don’t check for NULL pointers — again, there is much code that calls several of these in a row to test an object against various different expected types, and this would generate redundant tests. There are no variants with NULL checking.

The C function calling mechanism guarantees that the argument list passed to C functions (args in the examples) is never NULL — in fact it guarantees that it is always a tuple.
It is a severe error to ever let a NULL pointer “escape” to the Python user.
1.11. Writing Extensions in C++

It is possible to write extension modules in C++. Some restrictions apply. If the main program (the Python interpreter) is compiled and linked by the C compiler, global or static objects with constructors cannot be used. This is not a problem if the main program is linked by the C++ compiler. Functions that will be called by the Python interpreter (in particular, module initialization functions) have to be declared using `extern "C"`. It is unnecessary to enclose the Python header files in `extern "C" {...}` — they use this form already if the symbol `__cplusplus` is defined (all recent C++ compilers define this symbol).
1.12. Providing a C API for an Extension Module

Many extension modules just provide new functions and types to be used from Python, but sometimes the code in an extension module can be useful for other extension modules. For example, an extension module could implement a type “collection” which works like lists without order. Just like the standard Python list type has a C API which permits extension modules to create and manipulate lists, this new collection type should have a set of C functions for direct manipulation from other extension modules.

At first sight this seems easy: just write the functions (without declaring them static, of course), provide an appropriate header file, and document the C API. And in fact this would work if all extension modules were always linked statically with the Python interpreter. When modules are used as shared libraries, however, the symbols defined in one module may not be visible to another module. The details of visibility depend on the operating system; some systems use one global namespace for the Python interpreter and all extension modules (Windows, for example), whereas others require an explicit list of imported symbols at module link time (AIX is one example), or offer a choice of different strategies (most Unices). And even if symbols are globally visible, the module whose functions one wishes to call might not have been loaded yet!

Portability therefore requires not to make any assumptions about symbol visibility. This means that all symbols in extension modules should be declared static, except for the module’s initialization function, in order to avoid name clashes with other extension modules (as discussed in section The Module’s Method Table and Initialization Function). And it means that symbols that should be accessible from other extension modules must be exported in a
different way.

Python provides a special mechanism to pass C-level information (pointers) from one extension module to another one: Capsules. A Capsule is a Python data type which stores a pointer (void *). Capsules can only be created and accessed via their C API, but they can be passed around like any other Python object. In particular, they can be assigned to a name in an extension module’s namespace. Other extension modules can then import this module, retrieve the value of this name, and then retrieve the pointer from the Capsule.

There are many ways in which Capsules can be used to export the C API of an extension module. Each function could get its own Capsule, or all C API pointers could be stored in an array whose address is published in a Capsule. And the various tasks of storing and retrieving the pointers can be distributed in different ways between the module providing the code and the client modules.

Whichever method you choose, it's important to name your Capsules properly. The function `PyCapsule_New()` takes a name parameter (const char *); you're permitted to pass in a NULL name, but we strongly encourage you to specify a name. Properly named Capsules provide a degree of runtime type-safety; there is no feasible way to tell one unnamed Capsule from another.

In particular, Capsules used to expose C APIs should be given a name following this convention:

```
modulename.attributename
```

The convenience function `PyCapsule_Import()` makes it easy to load a C API provided via a Capsule, but only if the Capsule’s name matches this convention. This behavior gives C API users a high degree of certainty that the Capsule they load contains the correct C
The following example demonstrates an approach that puts most of the burden on the writer of the exporting module, which is appropriate for commonly used library modules. It stores all C API pointers (just one in the example!) in an array of `void` pointers which becomes the value of a Capsule. The header file corresponding to the module provides a macro that takes care of importing the module and retrieving its C API pointers; client modules only have to call this macro before accessing the C API.

The exporting module is a modification of the `spam` module from section A Simple Example. The function `spam.system()` does not call the C library function `system()` directly, but a function `PySpam_System()`, which would of course do something more complicated in reality (such as adding “spam” to every command). This function `PySpam_System()` is also exported to other extension modules.

The function `PySpam_System()` is a plain C function, declared `static` like everything else:

```c
static int
PySpam_System(const char *command)
{
    return system(command);
}
```

The function `spam_system()` is modified in a trivial way:

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
```
In the beginning of the module, right after the line

```
#include "Python.h"
```

two more lines must be added:

```
#define SPAM_MODULE
#include "spammodule.h"
```

The `#define` is used to tell the header file that it is being included in the exporting module, not a client module. Finally, the module's initialization function must take care of initializing the C API pointer array:

```c
PyMODINIT_FUNC
initspam(void)
{
    PyObject *m;
    static void *PySpam_API[PySpam_API_pointers];
    PyObject *c_api_object;

    m = Py_InitModule("spam", SpamMethods);
    if (m == NULL)
        return;

    /* Initialize the C API pointer array */
    PySpam_API[PySpam_System_NUM] = (void *)PySpam_System;

    /* Create a Capsule containing the API pointer array's addr */
    c_api_object = PyCapsule_New((void *)PySpam_API, "spam._C_API",
                                 (void *)PySpam_API_pointers);
    if (c_api_object != NULL)
        PyModule_AddObject(m, "_C_API", c_api_object);
}
```

Note that `PySpam_API` is declared `static`; otherwise the pointer array
would disappear when \texttt{initspam()} terminates!

The bulk of the work is in the header file \texttt{spammodule.h}, which looks like this:

```c
#ifndef Py_SPAMMODULE_H
#define Py_SPAMMODULE_H
#ifdef __cplusplus
extern "C" {
#endif

/* Header file for spammodule */

/* C API functions */
#define PySpam_System_NUM 0
#define PySpam_System_RETURN int
#define PySpam_System_PROTO (const char *command)

/* Total number of C API pointers */
#define PySpam_API_pointers 1

#ifdef SPAM_MODULE
/* This section is used when compiling spammodule.c */

static PySpam_System_RETURN PySpam_System PySpam_System_PROTO;
#else
/* This section is used in modules that use spammodule's API */

static void **PySpam_API;

#define PySpam_System \
  (*(PySpam_System_RETURN (*)PySpam_System_PROTO) PySpam_API[PyS

/* Return -1 on error, 0 on success. 
 * PyCapsule_Import will set an exception if there's an error. */

static int import_spam(void)
{
  PySpam_API = (void **)PyCapsule_Import("spam._C_API", 0);
  return (PySpam_API != NULL) ? 0 : -1;
}
```
```
All that a client module must do in order to have access to the function `PySpam_System()` is to call the function (or rather macro) `import_spam()` in its initialization function:

```python
PyMODINIT_FUNC
initclient(void)
{
    PyObject *m;

    m = Py_InitModule("client", ClientMethods);
    if (m == NULL)
        return;
    if (import_spam() < 0)
        return;
    /* additional initialization can happen here */
}
```

The main disadvantage of this approach is that the file `spammodule.h` is rather complicated. However, the basic structure is the same for each function that is exported, so it has to be learned only once.

Finally it should be mentioned that Capsules offer additional functionality, which is especially useful for memory allocation and deallocation of the pointer stored in a Capsule. The details are described in the Python/C API Reference Manual in the section Capsules and in the implementation of Capsules (files `Include/pycapsule.h` and `Objects/pycapsule.c` in the Python source code distribution).

Footnotes
An interface for this function already exists in the standard module `os` — it was chosen as a simple and straightforward example.

The metaphor of “borrowing” a reference is not completely correct: the owner still has a copy of the reference. Checking that the reference count is at least 1 **does not work** — the reference count itself could be in freed memory and may thus be reused for another object!

These guarantees don’t hold when you use the “old” style calling convention — this is still found in much existing code.
2. Defining New Types

As mentioned in the last chapter, Python allows the writer of an extension module to define new types that can be manipulated from Python code, much like strings and lists in core Python.

This is not hard; the code for all extension types follows a pattern, but there are some details that you need to understand before you can get started.

**Note:** The way new types are defined changed dramatically (and for the better) in Python 2.2. This document documents how to define new types for Python 2.2 and later. If you need to support older versions of Python, you will need to refer to older versions of this documentation.
2.1. The Basics

The Python runtime sees all Python objects as variables of type `PyObject*`. A `PyObject` is not a very magnificent object - it just contains the refcount and a pointer to the object’s “type object”. This is where the action is; the type object determines which (C) functions get called when, for instance, an attribute gets looked up on an object or it is multiplied by another object. These C functions are called “type methods”.

So, if you want to define a new object type, you need to create a new type object.

This sort of thing can only be explained by example, so here’s a minimal, but complete, module that defines a new type:

```c
#include <Python.h>

typedef struct {
    PyObject_HEAD
    /* Type-specific fields go here. */
} noddy_NoddyObject;

static PyTypeObject noddy_NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0,           /*ob_size*/
    "noddy.Noddy",
    sizeof(noddy_NoddyObject), /*tp_basicsize*/
    0,           /*tp_itemsize*/
    0,           /*tp_dealloc*/
    0,           /*tp_print*/
    0,           /*tp_getattr*/
    0,           /*tp_setattr*/
    0,           /*tp_compare*/
    0,           /*tp_as_number*/
    0,           /*tp_as_sequence*/
    0,           /*tp_as_mapping*/
    0,           /*tp_hash */
    0,           /*tp_call*/
```
Now that's quite a bit to take in at once, but hopefully bits will seem familiar from the last chapter.

The first bit that will be new is:

```c
typedef struct {
    PyObject_HEAD
} noddy_NoddyObject;
```

This is what a Noddy object will contain—in this case, nothing more than every Python object contains, namely a refcount and a pointer to a type object. These are the fields the `PyObject_HEAD` macro brings
in. The reason for the macro is to standardize the layout and to enable special debugging fields in debug builds. Note that there is no semicolon after the `PyObject_HEAD` macro; one is included in the macro definition. Be wary of adding one by accident; it’s easy to do from habit, and your compiler might not complain, but someone else’s probably will! (On Windows, MSVC is known to call this an error and refuse to compile the code.)

For contrast, let’s take a look at the corresponding definition for standard Python integers:

```c
typedef struct {
    PyObject_HEAD
    long ob_ival;
} PyIntObject;
```

Moving on, we come to the crunch — the type object.

```c
static PyTypeObject noddy_NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0, /*ob_size*/
    "noddy.Noddy", /*tp_name*/
    sizeof(noddy_NoddyObject), /*tp_basicsize*/
    0, /*tp_itemsize*/
    0, /*tp_dealloc*/
    0, /*tp_print*/
    0, /*tp_getattr*/
    0, /*tp_setattr*/
    0, /*tp_compare*/
    0, /*tp_repr*/
    0, /*tp_as_number*/
    0, /*tp_as_sequence*/
    0, /*tp_as_mapping*/
    0, /*tp_hash */
    0, /*tp_call*/
    0, /*tp_str*/
    0, /*tp_getattro*/
    0, /*tp_setattro*/
    0, /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT, /*tp_flags*/
    "Noddy objects", /* tp_doc */
};
```
Now if you go and look up the definition of `PyTypeObject` in `object.h` you'll see that it has many more fields that the definition above. The remaining fields will be filled with zeros by the C compiler, and it's common practice to not specify them explicitly unless you need them.

This is so important that we're going to pick the top of it apart still further:

```c
PyObject_HEAD_INIT(NULL)
```

This line is a bit of a wart; what we'd like to write is:

```c
PyObject_HEAD_INIT(&PyType_Type)
```

as the type of a type object is “type”, but this isn't strictly conforming C and some compilers complain. Fortunately, this member will be filled in for us by `PyType_Ready()`.

```c
0, /* ob_size */
```

The `ob_size` field of the header is not used; its presence in the type structure is a historical artifact that is maintained for binary compatibility with extension modules compiled for older versions of Python. Always set this field to zero.

```c
"noddy.Noddy", /* tp_name */
```

The name of our type. This will appear in the default textual representation of our objects and in some error messages, for example:

```python
>>> "" + noddy.new_noddy()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: cannot add type "noddy.Noddy" to string
```
Note that the name is a dotted name that includes both the module name and the name of the type within the module. The module in this case is `noddy` and the type is `Noddy`, so we set the type name to `noddy.Noddy`. One side effect of using an undotted name is that the pydoc documentation tool will not list the new type in the module documentation.

```c
sizeof(noddy_NoddyObject), /* tp_baseasize */
```

This is so that Python knows how much memory to allocate when you call `PyObject_New()`.

**Note:** If you want your type to be subclassable from Python, and your type has the same `tp_baseasize` as its base type, you may have problems with multiple inheritance. A Python subclass of your type will have to list your type first in its `__bases__`, or else it will not be able to call your type’s `__new__()` method without getting an error. You can avoid this problem by ensuring that your type has a larger value for `tp_baseasize` than its base type does. Most of the time, this will be true anyway, because either your base type will be `object`, or else you will be adding data members to your base type, and therefore increasing its size.

```c
0, /* tp_itemsize */
```

This has to do with variable length objects like lists and strings. Ignore this for now.

Skipping a number of type methods that we don’t provide, we set the class flags to `Py_TPFLAGS_DEFAULT`.

```c
Py_TPFLAGS_DEFAULT, /*tp_flags*/
```

All types should include this constant in their flags. It enables all of
the members defined by the current version of Python.

We provide a doc string for the type in `tp_doc`.

```
"Noddy objects", /* tp_doc */
```

Now we get into the type methods, the things that make your objects different from the others. We aren't going to implement any of these in this version of the module. We'll expand this example later to have more interesting behavior.

For now, all we want to be able to do is to create new `Noddy` objects. To enable object creation, we have to provide a `tp_new` implementation. In this case, we can just use the default implementation provided by the API function `PyType_GenericNew()`. We'd like to just assign this to the `tp_new` slot, but we can't, for portability sake, On some platforms or compilers, we can't statically initialize a structure member with a function defined in another C module, so, instead, we'll assign the `tp_new` slot in the module initialization function just before calling `PyType_Ready()`:

```c
noddy_NoddyType.tp_new = PyType_GenericNew;
if (PyType_Ready(&noddy_NoddyType) < 0)
    return;
```

All the other type methods are `NULL`, so we'll go over them later — that's for a later section!

Everything else in the file should be familiar, except for some code in `initnoddy()`:

```c
if (PyType_Ready(&noddy_NoddyType) < 0)
    return;
```

This initializes the `Noddy` type, filing in a number of members,
including `ob_type` that we initially set to `NULL`.

```c
PyModule_AddObject(m, "Noddy", (PyObject *)&noddy_NoddyType);
```

This adds the type to the module dictionary. This allows us to create `Noddy` instances by calling the `Noddy` class:

```python
>>> import noddy
>>> mynoddy = noddy.Noddy()
```

That's it! All that remains is to build it; put the above code in a file called `noddy.c` and

```python
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
      ext_modules=[Extension("noddy", ["noddy.c"])]
)
```

in a file called `setup.py`; then typing

```
$ python setup.py build
```

at a shell should produce a file `noddy.so` in a subdirectory; move to that directory and fire up Python — you should be able to import `noddy` and play around with Noddy objects.

That wasn't so hard, was it?

Of course, the current Noddy type is pretty uninteresting. It has no data and doesn't do anything. It can't even be subclassed.

### 2.1.1. Adding data and methods to the Basic example

Let's expend the basic example to add some data and methods. Let's also make the type usable as a base class. We'll create a new
module, noddy2 that adds these capabilities:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;  /* first name */
    PyObject *last;  /* last name */
    int number;
} Noddy;

static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
    }

    self->last = PyString_FromString("");
    if (self->last == NULL) {
        Py_DECREF(self);
        return NULL;
    }

    self->number = 0;

    return (PyObject *)self;
}
```c
static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", kwlist
                                        &first, &last,
                                        &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }

    return 0;
}

static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
        "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,
        "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
        "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject * Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;
```
if (format == NULL) {
    format = PyString_FromString("%s %s");
    if (format == NULL)
        return NULL;
}

if (self->first == NULL) {
    PyErr_SetString(PyExc_AttributeError, "first");
    return NULL;
}

if (self->last == NULL) {
    PyErr_SetString(PyExc_AttributeError, "last");
    return NULL;
}

args = Py_BuildValue("OO", self->first, self->last);
if (args == NULL)
    return NULL;

result = PyString_Format(format, args);
Py_DECREF(args);

return result;

static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0,                                    /*ob_size*/
    "noddy.Noddy",                        /*tp_name*/
    sizeof(Noddy),                       /*tp_basicsize*/
    0,                                    /*tp_itemsize*/
    (destructor)Noddy_dealloc,            /*tp_dealloc*/
    0,                                    /*tp_print*/
    0,                                    /*tp_getattr*/
    0,                                    /*tp_setattr*/
    0,                                    /*tp_compare*/
    0,                                    /*tp_repr*/
    0,                                    /*tp_as_number*/
    0,                                    /*tp_as_sequence*/
    0,                                    /*tp_as_mapping*/
    0,                                    /*tp_hashval*/
    0,                                    /*tp_accept*/
    0,                                    /*tp_is_gc*/
    0,                                    /*tp_bases*/
    0,                                    /*tp_mro*/
    0,                                    /*tp_cache*/
    0,                                    /*tp�名*
static PyMethodDef module_methods[] = {
    {NULL} /* Sentinel */
};

#ifndef PyMODINIT_FUNC /* declarations for DLL import/export */
#define PyMODINIT_FUNC void
#endif
PyMODINIT_FUNC
initnoddy2(void)
{
    PyObject* m;

    if (PyType_Ready(&NoddyType) < 0)
        return;

    m = Py_InitModule3("noddy2", module_methods,
                       "Example module that creates an extension type.");

    if (m == NULL)
This version of the module has a number of changes.

We’ve added an extra include:

```c
#include <structmember.h>
```

This include provides declarations that we use to handle attributes, as described a bit later.

The name of the `Noddy` object structure has been shortened to `Noddy`. The type object name has been shortened to `NoddyType`.

The `Noddy` type now has three data attributes, `first`, `last`, and `number`. The `first` and `last` variables are Python strings containing first and last names. The `number` attribute is an integer.

The object structure is updated accordingly:

```c
typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;
```

Because we now have data to manage, we have to be more careful about object allocation and deallocation. At a minimum, we need a deallocation method:

```c
static void
Noddy_dealloc(Noddy* self)
{ return;
    Py_INCREF(&NoddyType);
    PyModule_AddObject(m, "Noddy", (PyObject *)&NoddyType);
}
which is assigned to the \texttt{tp\_dealloc} member:

\begin{verbatim}
(destructor)Noddy\_dealloc, /*tp\_dealloc*/
\end{verbatim}

This method decrements the reference counts of the two Python attributes. We use \texttt{Py\_XDECREF()} here because the \texttt{first} and \texttt{last} members could be \texttt{NULL}. It then calls the \texttt{tp\_free} member of the object's type to free the object's memory. Note that the object's type might not be \texttt{NoddyType}, because the object may be an instance of a subclass.

We want to make sure that the first and last names are initialized to empty strings, so we provide a new method:

\begin{verbatim}
static PyObject *
Noddy\_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;
    self = (Noddy *)type->tp\_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString\_From\_String(""");
        if (self->first == NULL)
            \{ Py\_DECREF(self);
            return NULL;
        \}
        self->last = PyString\_From\_String(""");
        if (self->last == NULL)
            \{ Py\_DECREF(self);
            return NULL;
        \}
        self->number = 0;
    }
}\end{verbatim}
```c
return (PyObject *)self;
```

and install it in the `tp_new` member:

```c
Noddy_new,   /* tp_new */
```

The new member is responsible for creating (as opposed to initializing) objects of the type. It is exposed in Python as the `__new__()` method. See the paper titled “Unifying types and classes in Python” for a detailed discussion of the `__new__()` method. One reason to implement a new method is to assure the initial values of instance variables. In this case, we use the new method to make sure that the initial values of the members `first` and `last` are not `NULL`. If we didn’t care whether the initial values were `NULL`, we could have used `PyType_GenericNew()` as our new method, as we did before. `PyType_GenericNew()` initializes all of the instance variable members to `NULL`.

The new method is a static method that is passed the type being instantiated and any arguments passed when the type was called, and that returns the new object created. New methods always accept positional and keyword arguments, but they often ignore the arguments, leaving the argument handling to initializer methods. Note that if the type supports subclassing, the type passed may not be the type being defined. The new method calls the `tp_alloc` slot to allocate memory. We don’t fill the `tp_alloc` slot ourselves. Rather `PyType_Ready()` fills it for us by inheriting it from our base class, which is `object` by default. Most types use the default allocation.

**Note:** If you are creating a co-operative `tp_new` (one that calls a base type’s `tp_new` or `__new__()`, you must *not* try to determine
what method to call using method resolution order at runtime. Always statically determine what type you are going to call, and call its `tp_new` directly, or via `type->tp_base->tp_new`. If you do not do this, Python subclasses of your type that also inherit from other Python-defined classes may not work correctly. (Specifically, you may not be able to create instances of such subclasses without getting a `TypeError`.)

We provide an initialization function:

```c
static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", kwlist
                                        &first, &last,
                                        &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCRREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCRREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }

    return 0;
}
```

by filling the `tp_init` slot.
The `tp_init` slot is exposed in Python as the `__init__()` method. It is used to initialize an object after it's created. Unlike the new method, we can't guarantee that the initializer is called. The initializer isn't called when unpickling objects and it can be overridden. Our initializer accepts arguments to provide initial values for our instance. Initializers always accept positional and keyword arguments.

Initializers can be called multiple times. Anyone can call the `__init__()` method on our objects. For this reason, we have to be extra careful when assigning the new values. We might be tempted, for example to assign the `first` member like this:

```python
if (first) {
    Py_XDECREF(self->first);
    Py_INCREF(first);
    self->first = first;
}
```

But this would be risky. Our type doesn't restrict the type of the `first` member, so it could be any kind of object. It could have a destructor that causes code to be executed that tries to access the `first` member. To be paranoid and protect ourselves against this possibility, we almost always reassign members before decrementing their reference counts. When don't we have to do this?

- when we absolutely know that the reference count is greater than 1
- when we know that deallocation of the object [1] will not cause any calls back into our type's code
- when decrementing a reference count in a `tp_dealloc` handler when garbage-collections is not supported [2]

We want to expose our instance variables as attributes. There are a number of ways to do that. The simplest way is to define member
definitions:

```c
static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
     "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,
     "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};
```

and put the definitions in the `tp_members` slot:

```
Noddy_members, /* tp_members */
```

Each member definition has a member name, type, offset, access flags and documentation string. See the [Generic Attribute Management](#) section below for details.

A disadvantage of this approach is that it doesn’t provide a way to restrict the types of objects that can be assigned to the Python attributes. We expect the first and last names to be strings, but any Python objects can be assigned. Further, the attributes can be deleted, setting the C pointers to `NULL`. Even though we can make sure the members are initialized to non-`NULL` values, the members can be set to `NULL` if the attributes are deleted.

We define a single method, `name()`, that outputs the objects name as the concatenation of the first and last names.

```c
static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");

```
The method is implemented as a C function that takes a Noddy (or Noddy subclass) instance as the first argument. Methods always take an instance as the first argument. Methods often take positional and keyword arguments as well, but in this case we don’t take any and don’t need to accept a positional argument tuple or keyword argument dictionary. This method is equivalent to the Python method:

```python
def name(self):
    return "%s %s" % (self.first, self.last)
```

Note that we have to check for the possibility that our `first` and `last` members are `NULL`. This is because they can be deleted, in which case they are set to `NULL`. It would be better to prevent deletion of these attributes and to restrict the attribute values to be strings. We'll see how to do that in the next section.
Now that we've defined the method, we need to create an array of method definitions:

```c
static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};
```

and assign them to the `tp_methods` slot:

```c
Noddy_methods,  /* tp_methods */
```

Note that we used the `METH_NOARGS` flag to indicate that the method is passed no arguments.

Finally, we'll make our type usable as a base class. We've written our methods carefully so far so that they don't make any assumptions about the type of the object being created or used, so all we need to do is to add the `Py_TPFLAGS_BASETYPE` to our class flag definition:

```c
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE, /*tp_flags*/
```

We rename `initnoddy()` to `initnoddy2()` and update the module name passed to `Py_InitModule3()`.

Finally, we update our `setup.py` file to build the new module:

```python
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
    ext_modules=[
        Extension("noddy", ["noddy.c"]),
        Extension("noddy2", ["noddy2.c"])])
```
In this section, we’ll provide finer control over how the `first` and `last` attributes are set in the `Noddy` example. In the previous version of our module, the instance variables `first` and `last` could be set to non-string values or even deleted. We want to make sure that these attributes always contain strings.

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static void
Noddy_dealloc(Noddy * self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("\n");
        if (self->first == NULL)
        {
            Py_DECREF(self);
            return NULL;
        }

        self->last = PyString_FromString("\n");
        if (self->last == NULL)
        {
```
Py_DECREF(self);
    return NULL;
}

self->number = 0;
}

return (PyObject *)self;

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;
    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi", kwlis
     &first, &last, &self->number))
    {
        return -1;
    }

        if (first) {
            tmp = self->first;
            Py_INCREF(first);
            self->first = first;
            Py_DECREF(tmp);
        }

        if (last) {
            tmp = self->last;
            Py_INCREF(last);
            self->last = last;
            Py_DECREF(tmp);
        }

        return 0;
}

static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_getfirst(Noddy *self, void *closure)
```c
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the first attribute");
        return -1;
    }

    if (! PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The first attribute value must be a string");
        return -1;
    }

    Py_DECREF(self->first);
    Py_INCREF(value);
    self->first = value;

    return 0;
}

static PyObject *
Noddy_getlast(Noddy *self, void *closure)
{
    Py_INCREF(self->last);
    return self->last;
}

static int
Noddy_setlast(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the last attribute");
        return -1;
    }

    if (! PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The last attribute value must be a string");
        return -1;
    }
```
Py_DECREF(self->last);
Py_INCREF(value);
self->last = value;

return 0;
}

static PyGetSetDef Noddy_getseters[] = {
    {"first",
     (getter)Noddy_getfirst, (setter)Noddy_setfirst,
     "first name",
     NULL},
    {"last",
     (getter)Noddy_getlast, (setter)Noddy_setlast,
     "last name",
     NULL},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    args = Py_BuildValue("OO", self->first, self->last);
    if (args == NULL)
        return NULL;

    result = PyString_Format(format, args);
    Py_DECREF(args);

    return result;
}

static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
     "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};
static PyTypeObject NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0, /*ob_size*/
    "noddy.Noddy", /*tp_name*/
    sizeof(Noddy), /*tp_basicsize*/
    0, /*tp_itemsize*/
    (destroyer)Noddy_dealloc, /*tp_dealloc*/
    0, /*tp_print*/
    0, /*tp_getattr*/
    0, /*tp_setattr*/
    0, /*tp_compare*/
    0, /*tp_repr*/
    0, /*tp_as_number*/
    0, /*tp_as_sequence*/
    0, /*tp_as_mapping*/
    0, /*tp_hash */
    0, /*tp_call*/
    0, /*tp_str*/
    0, /*tp_getattro*/
    0, /*tp_setattro*/
    0, /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE, /*tp_flags*/
    "Noddy objects", /* tp_doc */
    0, /* tp_traverse */
    0, /* tp_clear */
    0, /* tp_richcompare */
    0, /* tp_weaklistoffset */
    0, /* tp_iter */
    0, /* tp_iternext */
    Noddy_methods, /* tp_methods */
    Noddy_members, /* tp_members */
    Noddy_getseters, /* tp_getset */
    0, /* tp_base */
    0, /* tp_dict */
    0, /* tp_descr_get */
    0, /* tp_descr_set */
    0, /* tp_dictoffset */
    (initproc)Noddy_init, /* tp_init */
    0, /* tp_alloc */
    Noddy_new, /* tp_new */
};

static PyMethodDef module_methods[] = {
    {NULL} /* Sentinel */
};
To provide greater control, over the first and last attributes, we'll use custom getter and setter functions. Here are the functions for getting and setting the first attribute:

```c
Noddy_getfirst(Noddy *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the first attribute");
        return -1;
    }

    if (!PyString_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The first attribute value must be a string");
        return -1;
    }
```
PyDECREF(self->first);
Py_INCREF(value);
self->first = value;

return 0;
}

The getter function is passed a Noddy object and a “closure”, which is void pointer. In this case, the closure is ignored. (The closure supports an advanced usage in which definition data is passed to the getter and setter. This could, for example, be used to allow a single set of getter and setter functions that decide the attribute to get or set based on data in the closure.)

The setter function is passed the Noddy object, the new value, and the closure. The new value may be NULL, in which case the attribute is being deleted. In our setter, we raise an error if the attribute is deleted or if the attribute value is not a string.

We create an array of PyGetSetDef structures:

```c
static PyGetSetDef Noddy_getseters[] = {
    {"first",
     (getter)Noddy_getfirst, (setter)Noddy_setfirst,
     "first name",
     NULL},
    {"last",
     (getter)Noddy_getlast, (setter)Noddy_setlast,
     "last name",
     NULL},
    {NULL} /* Sentinel */
};
```

and register it in the tp_getset slot:

```c
Noddy_getseters, /* tp_getset */
```

to register our attribute getters and setters.
The last item in a `PyGetSetDef` structure is the closure mentioned above. In this case, we aren’t using the closure, so we just pass `NULL`.

We also remove the member definitions for these attributes:

```c
static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};
```

We also need to update the `tp_init` handler to only allow strings [3] to be passed:

```c
static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi", kwlist
            &first, &last,
            &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }

    return 0;
}
```
With these changes, we can assure that the first and last members are never NULL so we can remove checks for NULL values in almost all cases. This means that most of the Py_XDECREF() calls can be converted to Py_DECREF() calls. The only place we can’t change these calls is in the deallocator, where there is the possibility that the initialization of these members failed in the constructor.

We also rename the module initialization function and module name in the initialization function, as we did before, and we add an extra definition to the setup.py file.

### 2.1.3. Supporting cyclic garbage collection

Python has a cyclic-garbage collector that can identify unneeded objects even when their reference counts are not zero. This can happen when objects are involved in cycles. For example, consider:

```python
>>> l = []
>>> l.append(l)
>>> del l
```

In this example, we create a list that contains itself. When we delete it, it still has a reference from itself. Its reference count doesn’t drop to zero. Fortunately, Python’s cyclic-garbage collector will eventually figure out that the list is garbage and free it.

In the second version of the Noddy example, we allowed any kind of object to be stored in the first or last attributes. [4] This means that Noddy objects can participate in cycles:

```python
>>> import noddy2
>>> n = noddy2.Noddy()
>>> l = [n]
>>> n.first = l
```
This is pretty silly, but it gives us an excuse to add support for the cyclic-garbage collector to the **Noddy** example. To support cyclic garbage collection, types need to fill two slots and set a class flag that enables these slots:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static int
Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    int vret;

    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }

    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }

    return 0;
}

static int
Noddy_clear(Noddy *self)
{
    PyObject *tmp;

    tmp = self->first;
    self->first = NULL;
    Py_XDECREF(tmp);

    tmp = self->last;
    self->last = NULL;
```
Py_XDECREF(
tmp);

return 0;
}

static void
Noddy_dealloc(Noddy* self)
{
    Noddy_clear(self);
    self->ob_type->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kwds)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyString_FromString("");
        if (self->first == NULL)
        {
            Py_DECREF(self);
            return NULL;
        }
    }

    self->last = PyString_FromString("");
    if (self->last == NULL)
    {
        Py_DECREF(self);
        return NULL;
    }

    self->number = 0;
}

return (PyObject *)self;
}

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number", NULL};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", kwlist,

return -1;

if (first) {
    tmp = self->first;
    Py_INCREF(first);
    self->first = first;
    Py_XDECREF(tmp);
}

if (last) {
    tmp = self->last;
    Py_INCREF(last);
    self->last = last;
    Py_XDECREF(tmp);
}

return 0;

static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
     "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,
     "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
{
    static PyObject *format = NULL;
    PyObject *args, *result;

    if (format == NULL) {
        format = PyString_FromString("%s %s");
        if (format == NULL)
            return NULL;
    }

    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

    return NULL;
}
if (self->last == NULL) {
    PyErr_SetString(PyExc_AttributeError, "last");
    return NULL;
}

args = Py_BuildValue("OO", self->first, self->last);
if (args == NULL)
    return NULL;

result = PyString_Format(format, args);
Py_DECREF(args);

return result;

static PyMethodDef Noddy_methods[] = {
    {"name",  (PyCFunction)Noddy_name, METH_NOARGS,
        "Return the name, combining the first and last name"},
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyObject_HEAD_INIT(NULL)
    0,               /*ob_size*/
    "noddy.Noddy",  /*tp_name*/
    sizeof(Noddy),  /*tp_basicsize*/
    0,               /*tp_itemsize*/
    (destructor)Noddy_dealloc, /*tp_dealloc*/
    0,               /*tp_print*/
    0,               /*tp_getattr*/
    0,               /*tp_setattr*/
    0,               /*tp_compare*/
    0,               /*tp_repr*/
    0,               /*tp_as_number*/
    0,               /*tp_as_sequence*/
    0,               /*tp_as_mapping*/
    0,               /*tp_hash */
    0,               /*tp_call*/
    0,               /*tp_str*/
    0,               /*tp_getattro*/
    0,               /*tp_setattro*/
    0,               /*tp_as_buffer*/
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | Py_TPFLAGS_HAVE_GC,
    "Noddy objects",     /* tp_doc */
};
The traversal method provides access to subobjects that could
participate in cycles:

```c
static int Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    int vret;

    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }
    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }
    return 0;
}
```

For each subobject that can participate in cycles, we need to call the `visit()` function, which is passed to the traversal method. The `visit()` function takes as arguments the subobject and the extra argument `arg` passed to the traversal method. It returns an integer value that must be returned if it is non-zero.

Python 2.4 and higher provide a `Py_VISIT()` macro that automates calling visit functions. With `Py_VISIT()`, `Noddy_traverse()` can be simplified:

```c
static int Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}
```

**Note:** Note that the `tp_traverse` implementation must name its
arguments exactly visit and arg in order to use Py_VISIT(). This is to encourage uniformity across these boring implementations.

We also need to provide a method for clearing any subobjects that can participate in cycles. We implement the method and reimplement the deallocator to use it:

```c
static int
Noddy_clear(Noddy *self)
{
    PyObject *tmp;

    tmp = self->first;
    self->first = NULL;
    Py_XDECREF(tmp);

    tmp = self->last;
    self->last = NULL;
    Py_XDECREF(tmp);

    return 0;
}

static void
Noddy_dealloc(Noddy *self)
{
    Noddy_clear(self);
    self->ob_type->tp_free((PyObject*)self);
}
```

Notice the use of a temporary variable in Noddy_clear(). We use the temporary variable so that we can set each member to NULL before decrementing its reference count. We do this because, as was discussed earlier, if the reference count drops to zero, we might cause code to run that calls back into the object. In addition, because we now support garbage collection, we also have to worry about code being run that triggers garbage collection. If garbage collection is run, our tp_traverse handler could get called. We can’t take a chance of having Noddy_traverse() called when a member’s reference count has dropped to zero and its value hasn’t been set to
NULL.

Python 2.4 and higher provide a `Py_CLEAR()` that automates the careful decrementing of reference counts. With `Py_CLEAR()`, the `Noddy_clear()` function can be simplified:

```c
static int
Noddy_clear(Noddy *self)
{
    Py_CLEAR(self->first);
    Py_CLEAR(self->last);
    return 0;
}
```

Finally, we add the `Py_TPFLAGS_HAVE_GC` flag to the class flags:

```
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | Py_TPFLAGS_HAVE_GC,
```

That's pretty much it. If we had written custom `tp_alloc` or `tp_free` slots, we'd need to modify them for cyclic-garbage collection. Most extensions will use the versions automatically provided.

2.1.4. Subclassing other types

It is possible to create new extension types that are derived from existing types. It is easiest to inherit from the built-in types, since an extension can easily use the `PyTypeObject` it needs. It can be difficult to share these `PyTypeObject` structures between extension modules.

In this example we will create a `Shoddy` type that inherits from the built-in `list` type. The new type will be completely compatible with regular lists, but will have an additional `increment()` method that increases an internal counter.

```python
>>> import shoddy
```
```python
>>> s = shoddy.Shoddy(range(3))
>>> s.extend(s)
>>> print len(s)
6
>>> print s.increment()
1
>>> print s.increment()
2
```

```c
#include <Python.h>

typedef struct {
  PyListObject list;
  int state;
} Shoddy;

static PyObject *
Shoddy_increment(Shoddy *self, PyObject *unused)
{
  self->state++;
  return PyInt_FromLong(self->state);
}

static PyMethodDef Shoddy_methods[] = {
  {"increment", (PyCFunction)shoddy_increment, METH_NOARGS,
   PyDoc_STR("increment state counter")},
  {NULL, NULL},
};

static int
Shoddy_init(Shoddy *self, PyObject *args, PyObject *kwds)
{
  if (PyList_Type.tp_init((PyObject *)self, args, kwds) < 0)
    return -1;
  self->state = 0;
  return 0;
}

static PyTypeObject ShoddyType = {
  PyObject_HEAD_INIT(NULL)
  0, /* ob_size */
  "shoddy.Shoddy", /* tp_name */
  sizeof(Shoddy), /* tp_basicsize */
```
ShoddyType.tp_base = &PyList_Type;

PyMODINIT_FUNC
initshoddy(void)
{
    PyObject *m;

    ShoddyType.tp_base = &PyList_Type;
    if (PyType_Ready(&ShoddyType) < 0)
        return;
}
As you can see, the source code closely resembles the Noddy examples in previous sections. We will break down the main differences between them.

define struct {
    PyListObject list;
    int state;
} Shoddy;

The primary difference for derived type objects is that the base type's object structure must be the first value. The base type will already include the `PyObject_HEAD()` at the beginning of its structure.

When a Python object is a Shoddy instance, its PyObject* pointer can be safely cast to both PyListObject* and Shoddy*.

```c
static int Shoddy_init(Shoddy *self, PyObject *args, PyObject *kwds) {
    if (PyList_Type.tp_init((PyObject *)self, args, kwds) < 0)
        return -1;
    self->state = 0;
    return 0;
}
```

In the `__init__` method for our type, we can see how to call through to the `__init__` method of the base type.

This pattern is important when writing a type with custom `new` and `dealloc` methods. The `new` method should not actually create the memory for the object with `tp_alloc`, that will be handled by the base
class when calling its \texttt{tp\_new}.

When filling out the \texttt{PyTypeObject()} for the \texttt{Shoddy} type, you see a slot for \texttt{tp\_base()}. Due to cross platform compiler issues, you can’t fill that field directly with the \texttt{PyList\_Type()}; it can be done later in the module’s \texttt{init()} function.

```python
PyMODINIT_FUNC
initshoddy(void)
{
    PyObject *m;

    ShoddyType.tp_base = &PyList_Type;
    if (PyType_Ready(&ShoddyType) < 0)
        return;

    m = Py_InitModule3("shoddy", NULL, "Shoddy module");
    if (m == NULL)
        return;

    Py_INCREF(&ShoddyType);
    PyModule_AddObject(m, "Shoddy", (PyObject *) &ShoddyType);
}
```

Before calling \texttt{PyType\_Ready()}, the type structure must have the \texttt{tp\_base} slot filled in. When we are deriving a new type, it is not necessary to fill out the \texttt{tp\_alloc} slot with \texttt{PyType\_Generic\_New()} – the allocate function from the base type will be inherited.

After that, calling \texttt{PyType\_Ready()} and adding the type object to the module is the same as with the basic \texttt{Noddy} examples.
This section aims to give a quick fly-by on the various type methods you can implement and what they do.

Here is the definition of `PyTypeObject`, with some fields only used in debug builds omitted:

```c
typedef struct _typeobject {
    PyObject_VAR_HEAD
    char *tp_name; /* For printing, in format "<module>.<name>" */
    int tp_basicsize, tp_itemsize; /* For allocation */

    /* Methods to implement standard operations */

destructor tp_dealloc;
printfunc tp_print;
getattrofunc tp_getattr;
setattrofunc tp_setattr;
cmpfunc tp_compare;
reprfunc tp_repr;

    /* Method suites for standard classes */

PyNumberMethods *tp_as_number;
 PySequenceMethods *tp_as_sequence;
 PyMappingMethods *tp_as_mapping;

    /* More standard operations (here for binary compatibility) */

hashfunc tp_hash;
ternaryfunc tp_call;
reprfunc tp_str;
geattrofunc tp_getattro;
setattrofunc tp_setattro;

    /* Functions to access object as input/output buffer */
PyBufferProcs *tp_as_buffer;

    /* Flags to define presence of optional/expanded features */
long tp_flags;
```
char *tp_doc; /* Documentation string */

/* Assigned meaning in release 2.0 */
/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* Assigned meaning in release 2.1 */
/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
long tp_weaklistoffset;

/* Added in release 2.2 */
/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;
descrsetfunc tp_descr_set;
long tp_dictoffset;
initproc tp_init;
allocfunc tp_alloc;
newfunc tp_new;
freefunc tp_free; /* Low-level free-memory routine */
inquiry tp_is_gc; /* For PyObject_IS_GC */
PyObject *tp_bases;
PyObject *tp_mro; /* method resolution order */
PyObject *tp_cache;
PyObject *tp_subclasses;
PyObject *tp_weaklist;

} PyTypeObject;

Now that’s a lot of methods. Don’t worry too much though - if you have a type you want to define, the chances are very good that you
will only implement a handful of these.

As you probably expect by now, we're going to go over this and give more information about the various handlers. We won't go in the order they are defined in the structure, because there is a lot of historical baggage that impacts the ordering of the fields; be sure your type initialization keeps the fields in the right order! It's often easiest to find an example that includes all the fields you need (even if they're initialized to 0) and then change the values to suit your new type.

```c
char *tp_name; /* For printing */
```

The name of the type - as mentioned in the last section, this will appear in various places, almost entirely for diagnostic purposes. Try to choose something that will be helpful in such a situation!

```c
int tp_basicsize, tp_itemsize; /* For allocation */
```

These fields tell the runtime how much memory to allocate when new objects of this type are created. Python has some built-in support for variable length structures (think: strings, lists) which is where the `tp_itemsize` field comes in. This will be dealt with later.

```c
char *tp_doc;
```

Here you can put a string (or its address) that you want returned when the Python script references `obj.__doc__` to retrieve the doc string.

Now we come to the basic type methods—the ones most extension types will implement.

### 2.2.1. Finalization and De-allocation
This function is called when the reference count of the instance of your type is reduced to zero and the Python interpreter wants to reclaim it. If your type has memory to free or other clean-up to perform, put it here. The object itself needs to be freed here as well. Here is an example of this function:

```c
static void
newdatatype_dealloc(newdatatypeobject * obj)
{
    free(obj->obj_UnderlyingDatatypePtr);
    obj->ob_type->tp_free(obj);
}
```

One important requirement of the deallocator function is that it leaves any pending exceptions alone. This is important since deallocators are frequently called as the interpreter unwinds the Python stack; when the stack is unwound due to an exception (rather than normal returns), nothing is done to protect the deallocators from seeing that an exception has already been set. Any actions which a deallocator performs which may cause additional Python code to be executed may detect that an exception has been set. This can lead to misleading errors from the interpreter. The proper way to protect against this is to save a pending exception before performing the unsafe action, and restoring it when done. This can be done using the `PyErr_Fetch()` and `PyErr_Restore()` functions:

```c
static void
my_dealloc(PyObject *obj)
{
    MyObject *self = (MyObject *) obj;
    PyObject *cbresult;

    if (self->my_callback != NULL) {
        PyObject *err_type, *err_value, *err_traceback;
        int have_error = PyErr_Occurred() ? 1 : 0;

        if (have_error) 
```
2.2.2. Object Presentation

In Python, there are three ways to generate a textual representation of an object: the `repr()` function (or equivalent back-tick syntax), the `str()` function, and the `print` statement. For most objects, the `print` statement is equivalent to the `str()` function, but it is possible to special-case printing to a `FILE*` if necessary; this should only be done if efficiency is identified as a problem and profiling suggests that creating a temporary string object to be written to a file is too expensive.

These handlers are all optional, and most types at most need to implement the `tp_str` and `tp_repr` handlers.

```c
reprfunc tp_repr;
reprfunc tp_str;
printfunc tp_print;
```

The `tp_repr` handler should return a string object containing a representation of the instance for which it is called. Here is a simple example:
static PyObject *
newdatatype_repr(newdatatypeobject * obj)
{
    return PyString_FromFormat("Repr-ified_newdatatype{{size:\%d}}", obj->obj_UnderlyingDatatypePtr->)
}

If no \texttt{tp\_repr} handler is specified, the interpreter will supply a representation that uses the type's \texttt{tp\_name} and a uniquely-identifying value for the object.

The \texttt{tp\_str} handler is to \texttt{str()} what the \texttt{tp\_repr} handler described above is to \texttt{repr()}; that is, it is called when Python code calls \texttt{str()} on an instance of your object. Its implementation is very similar to the \texttt{tp\_repr} function, but the resulting string is intended for human consumption. If \texttt{tp\_str} is not specified, the \texttt{tp\_repr} handler is used instead.

Here is a simple example:

static PyObject *
newdatatype_str(newdatatypeobject * obj)
{
    return PyString_FromFormat("Stringified_newdatatype{{size:\%d}}", obj->obj_UnderlyingDatatypePtr->)
}

The print function will be called whenever Python needs to “print” an instance of the type. For example, if ‘node’ is an instance of type TreeNode, then the print function is called when Python code calls:

```
print node
```

There is a flags argument and one flag, \texttt{PY\_PRINT\_RAW}, and it suggests that you print without string quotes and possibly without interpreting escape sequences.
The print function receives a file object as an argument. You will likely want to write to that file object.

Here is a sample print function:

```c
static int
newdatatype_print(newdatatypeobject *obj, FILE *fp, int flags)
{
    if (flags & Py_PRINT_RAW) {
        fprintf(fp, "<\{newdatatype object--size: %d}\>",
                obj->obj_UnderlyingDatatypePtr->size);
    } else {
        fprintf(fp, ""<\{newdatatype object--size: %d}\>\"",
                obj->obj_UnderlyingDatatypePtr->size);
    }
    return 0;
}
```

### 2.2.3. Attribute Management

For every object which can support attributes, the corresponding type must provide the functions that control how the attributes are resolved. There needs to be a function which can retrieve attributes (if any are defined), and another to set attributes (if setting attributes is allowed). Removing an attribute is a special case, for which the new value passed to the handler is `NULL`.

Python supports two pairs of attribute handlers; a type that supports attributes only needs to implement the functions for one pair. The difference is that one pair takes the name of the attribute as a `char*`, while the other accepts a `PyObject*`. Each type can use whichever pair makes more sense for the implementation's convenience.

```c
getattrfunc tp_getattr; /* char * version */
setattrfunc tp_setattr;
/* ... */
getattrofunc tp_getattrofunc; /* PyObject * version */
setattrofunc tp_setattrofunc;
```
If accessing attributes of an object is always a simple operation (this will be explained shortly), there are generic implementations which can be used to provide the PyObject* version of the attribute management functions. The actual need for type-specific attribute handlers almost completely disappeared starting with Python 2.2, though there are many examples which have not been updated to use some of the new generic mechanism that is available.

### 2.2.3.1. Generic Attribute Management

*New in version 2.2.*

Most extension types only use *simple* attributes. So, what makes the attributes simple? There are only a couple of conditions that must be met:

1. The name of the attributes must be known when `PyType_Ready()` is called.
2. No special processing is needed to record that an attribute was looked up or set, nor do actions need to be taken based on the value.

Note that this list does not place any restrictions on the values of the attributes, when the values are computed, or how relevant data is stored.

When `PyType_Ready()` is called, it uses three tables referenced by the type object to create *descriptors* which are placed in the dictionary of the type object. Each descriptor controls access to one attribute of the instance object. Each of the tables is optional; if all three are `NULL`, instances of the type will only have attributes that are inherited from their base type, and should leave the `tp_getattro` and `tp_setattro` fields `NULL` as well, allowing the base type to handle attributes.
The tables are declared as three fields of the type object:

```c
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
```

If `tp_methods` is not `NULL`, it must refer to an array of `PyMethodDef` structures. Each entry in the table is an instance of this structure:

```c
typedef struct PyMethodDef {
    const char *ml_name; /* method name */
    PyCFunction ml_meth; /* implementation function */
    int ml_flags; /* flags */
    const char *ml_doc; /* docstring */
} PyMethodDef;
```

One entry should be defined for each method provided by the type; no entries are needed for methods inherited from a base type. One additional entry is needed at the end; it is a sentinel that marks the end of the array. The `ml_name` field of the sentinel must be `NULL`.

XXX Need to refer to some unified discussion of the structure fields, shared with the next section.

The second table is used to define attributes which map directly to data stored in the instance. A variety of primitive C types are supported, and access may be read-only or read-write. The structures in the table are defined as:

```c
typedef struct PyMemberDef {
    char *name;
    int type;
    int offset;
    int flags;
    char *doc;
} PyMemberDef;
```

For each entry in the table, a descriptor will be constructed and added to the type which will be able to extract a value from the
instance structure. The type field should contain one of the type codes defined in the structmember.h header; the value will be used to determine how to convert Python values to and from C values. The flags field is used to store flags which control how the attribute can be accessed.

XXX Need to move some of this to a shared section!

The following flag constants are defined in structmember.h; they may be combined using bitwise-OR.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>READONLY</td>
<td>Never writable.</td>
</tr>
<tr>
<td>RO</td>
<td>Shorthand for READONLY.</td>
</tr>
<tr>
<td>READ_RESTRICTED</td>
<td>Not readable in restricted mode.</td>
</tr>
<tr>
<td>WRITE_RESTRICTED</td>
<td>Not writable in restricted mode.</td>
</tr>
<tr>
<td>RESTRICTED</td>
<td>Not readable or writable in restricted mode.</td>
</tr>
</tbody>
</table>

An interesting advantage of using the tp_members table to build descriptors that are used at runtime is that any attribute defined this way can have an associated doc string simply by providing the text in the table. An application can use the introspection API to retrieve the descriptor from the class object, and get the doc string using its __doc__ attribute.

As with the tp_methods table, a sentinel entry with a name value of NULL is required.

2.2.3.2. Type-specific Attribute Management

For simplicity, only the char* version will be demonstrated here; the type of the name parameter is the only difference between the char* and PyObject* flavors of the interface. This example effectively does
the same thing as the generic example above, but does not use the generic support added in Python 2.2. The value in showing this is two-fold: it demonstrates how basic attribute management can be done in a way that is portable to older versions of Python, and explains how the handler functions are called, so that if you do need to extend their functionality, you'll understand what needs to be done.

The `tp_getattr` handler is called when the object requires an attribute look-up. It is called in the same situations where the `__getattr__()` method of a class would be called.

A likely way to handle this is (1) to implement a set of functions (such as `newdatatype_getSize()`, and `newdatatype_setSize()` in the example below), (2) provide a method table listing these functions, and (3) provide a getattr function that returns the result of a lookup in that table. The method table uses the same structure as the `tp_methods` field of the type object.

Here is an example:

```c
static PyMethodDef newdatatype_methods[] = {
    {"getSize", (PyCFunction)newdatatype_getSize, METH_VARARGS,
     "Return the current size."},
    {"setSize", (PyCFunction)newdatatype_setSize, METH_VARARGS,
     "Set the size."},
    {NULL, NULL, 0, NULL} /* sentinel */
};

static PyObject *
newdatatype_getattr(newdatatypeobject *obj, char *name)
{
    return Py_FindMethod(newdatatype_methods, (PyObject *)obj,
}
```

The `tp_setattr` handler is called when the `__setattr__()`, `__delattr__()`, or `__setattr__()`, or `__delattr__() `method of a class instance would be called. When an
attribute should be deleted, the third parameter will be NULL. Here is an example that simply raises an exception; if this were really all you wanted, the `tp_setattr` handler should be set to `NULL`.

```c
static int
newdatatype_setattr(newdatatypeobject *obj, char *name, PyObject *)
{
    (void)PyErr_Format(PyExc_RuntimeError, "Read-only attribute
return -1;
}
```

### 2.2.4. Object Comparison

```c
cmpfunc tp_compare;
```

The `tp_compare` handler is called when comparisons are needed and the object does not implement the specific rich comparison method which matches the requested comparison. (It is always used if defined and the `PyObject_Compare()` or `PyObject_Cmp()` functions are used, or if `cmp()` is used from Python.) It is analogous to the `__cmp__()` method. This function should return `-1` if `obj1` is less than `obj2`, `0` if they are equal, and `1` if `obj1` is greater than `obj2`. (It was previously allowed to return arbitrary negative or positive integers for less than and greater than, respectively; as of Python 2.2, this is no longer allowed. In the future, other return values may be assigned a different meaning.)

A `tp_compare` handler may raise an exception. In this case it should return a negative value. The caller has to test for the exception using `PyErr_Occurred()`.

Here is a sample implementation:

```c
static int
newdatatype_compare(newdatatypeobject * obj1, newdatatypeobject
```
2.2.5. Abstract Protocol Support

Python supports a variety of abstract ‘protocols;‘ the specific interfaces provided to use these interfaces are documented in Abstract Objects Layer.

A number of these abstract interfaces were defined early in the development of the Python implementation. In particular, the number, mapping, and sequence protocols have been part of Python since the beginning. Other protocols have been added over time. For protocols which depend on several handler routines from the type implementation, the older protocols have been defined as optional blocks of handlers referenced by the type object. For newer protocols there are additional slots in the main type object, with a flag bit being set to indicate that the slots are present and should be checked by the interpreter. (The flag bit does not indicate that the slot values are non-NULL. The flag may be set to indicate the presence of a slot, but a slot may still be unfilled.)

```c
PyNumberMethods       *tp_as_number;
PySequenceMethods     *tp_as_sequence;
PyMappingMethods      *tp_as_mapping;
```
If you wish your object to be able to act like a number, a sequence, or a mapping object, then you place the address of a structure that implements the C type `PyNumberMethods`, `PySequenceMethods`, or `PyMappingMethods`, respectively. It is up to you to fill in this structure with appropriate values. You can find examples of the use of each of these in the `objects` directory of the Python source distribution.

```c
hashfunc tp_hash;
```

This function, if you choose to provide it, should return a hash number for an instance of your data type. Here is a moderately pointless example:

```c
static long
newdatatype_hash(newdatatypeobject *obj)
{
    long result;
    result = obj->obj_UnderlyingDatatypePtr->size;
    result = result * 3;
    return result;
}
```

```c
ternaryfunc tp_call;
```

This function is called when an instance of your data type is “called”, for example, if `obj1` is an instance of your data type and the Python script contains `obj1('hello')`, the `tp_call` handler is invoked.

This function takes three arguments:

1. `arg1` is the instance of the data type which is the subject of the call. If the call is `obj1('hello')`, then `arg1` is `obj1`.
2. `arg2` is a tuple containing the arguments to the call. You can use `PyArg_ParseTuple()` to extract the arguments.
3. `arg3` is a dictionary of keyword arguments that were passed. If
this is non-NULL and you support keyword arguments, use\nPyArg_ParseTupleAndKeywords() to extract the arguments. If you\ndo not want to support keyword arguments and this is non-\nNULL, raise a TypeError with a message saying that keyword\narguments are not supported.

Here is a desultory example of the implementation of the call\nfunction.

```c
/* Implement the call function.\n *   obj1 is the instance receiving the call.\n *   obj2 is a tuple containing the arguments to the call, in\n *   case 3 strings.\n */
static PyObject *\nnewdatatype_call(newdatatypeobject *obj, PyObject *args, PyObje\n{
    PyObject *result;
    char *arg1;
    char *arg2;
    char *arg3;

    if (!PyArg_ParseTuple(args, "sss:call", &arg1, &arg2, &arg3\n        return NULL;
    }
    result = PyString_FromFormat(\n        "Returning -- value: [%d] arg1: [%s] arg2: [%s] arg3\n    obj->obj_UnderlyingDatatypePtr->size,\n    arg1, arg2, arg3);
    printf("%s", PyString_AS_STRING(result));\n    return result;
}
```

XXX some fields need to be added here...

```c
/* Added in release 2.2 */
/* Iterators */
getiterfunc tp_iter;
ithernextfunc tp_iternext;
```

These functions provide support for the iterator protocol. Any object
which wishes to support iteration over its contents (which may be generated during iteration) must implement the \texttt{tp\_iter} handler. Objects which are returned by a \texttt{tp\_iter} handler must implement both the \texttt{tp\_iter} and \texttt{tp\_iternext} handlers. Both handlers take exactly one parameter, the instance for which they are being called, and return a new reference. In the case of an error, they should set an exception and return \texttt{NULL}.

For an object which represents an iterable collection, the \texttt{tp\_iter} handler must return an iterator object. The iterator object is responsible for maintaining the state of the iteration. For collections which can support multiple iterators which do not interfere with each other (as lists and tuples do), a new iterator should be created and returned. Objects which can only be iterated over once (usually due to side effects of iteration) should implement this handler by returning a new reference to themselves, and should also implement the \texttt{tp\_iternext} handler. File objects are an example of such an iterator.

Iterator objects should implement both handlers. The \texttt{tp\_iter} handler should return a new reference to the iterator (this is the same as the \texttt{tp\_iter} handler for objects which can only be iterated over destructively). The \texttt{tp\_iternext} handler should return a new reference to the next object in the iteration if there is one. If the iteration has reached the end, it may return \texttt{NULL} without setting an exception or it may set \texttt{StopIteration}; avoiding the exception can yield slightly better performance. If an actual error occurs, it should set an exception and return \texttt{NULL}.

\section*{2.2.6. Weak Reference Support}

One of the goals of Python's weak-reference implementation is to allow any type to participate in the weak reference mechanism
without incurring the overhead on those objects which do not benefit by weak referencing (such as numbers).

For an object to be weakly referencable, the extension must include a `PyObject*` field in the instance structure for the use of the weak reference mechanism; it must be initialized to `NULL` by the object’s constructor. It must also set the `tp_weaklistoffset` field of the corresponding type object to the offset of the field. For example, the instance type is defined with the following structure:

```c
typedef struct {
    PyObject_HEAD
    PyClassObject  *in_class;  /* The class object */
    PyObject       *in_dict;   /* A dictionary */
    PyObject       *in_weakreflist; /* List of weak references */
} PyInstanceObject;
```

The statically-declared type object for instances is defined this way:

```c
PyTypeObject PyInstance_Type = {
    PyObject_HEAD_INIT(&PyType_Type)
    0,
    "module.instance",
    /* Lots of stuff omitted for brevity... */
    Py_TPFLAGS_DEFAULT,
    0,
    0,
    0,
    0,
    0,
    offsetof(PyInstanceObject, in_weakreflist), /* tp_weaklistoffset */
};
```

The type constructor is responsible for initializing the weak reference list to `NULL`:

```c
static PyObject *
instance_new() {
```
The only further addition is that the destructor needs to call the weak reference manager to clear any weak references. This is only required if the weak reference list is non-NULL:

```c
static void instance_dealloc(PyInstanceObject *inst)
{
    /* Allocate temporaries if needed, but do not begin destruction just yet. */
    if (inst->in_weakreflist != NULL)
        PyObject_ClearWeakRefs((PyObject *) inst);
    /* Proceed with object destruction normally. */
}
```

### 2.2.7. More Suggestions

Remember that you can omit most of these functions, in which case you provide 0 as a value. There are type definitions for each of the functions you must provide. They are in `object.h` in the Python include directory that comes with the source distribution of Python.

In order to learn how to implement any specific method for your new data type, do the following: Download and unpack the Python source distribution. Go to the `objects` directory, then search the C source files for `tp_` plus the function you want (for example, `tp_print` or `tp_compare`). You will find examples of the function you want to implement.

When you need to verify that an object is an instance of the type you
are implementing, use the `PyObject_TypeCheck()` function. A sample of its use might be something like the following:

```c
if (!PyObject_TypeCheck(some_object, &MyType)) {
    PyErr_SetString(PyExc_TypeError, "arg #1 not a mything");
    return NULL;
}
```

Footnotes

[1] This is true when we know that the object is a basic type, like a string or a float.
   We relied on this in the `tp_dealloc` handler in this example, because our type doesn't support garbage collection. Even if a type supports garbage collection, there are calls that can be made to “untrack” the object from garbage collection, however, these calls are advanced and not covered here.

We now know that the first and last members are strings, so perhaps we could be less careful about decrementing their reference counts, however, we accept instances of string subclasses. Even though deallocating normal strings won’t call back into our objects, we can’t guarantee that deallocating an instance of a string subclass won’t call back into our objects.

Even in the third version, we aren’t guaranteed to avoid cycles.

[3] Instances of string subclasses are allowed and string subclasses could allow cycles even if normal strings don’t.
3. Building C and C++ Extensions with distutils

Starting in Python 1.4, Python provides, on Unix, a special make file for building make files for building dynamically-linked extensions and custom interpreters. Starting with Python 2.0, this mechanism (known as related to Makefile.pre.in, and Setup files) is no longer supported. Building custom interpreters was rarely used, and extension modules can be built using distutils.

Building an extension module using distutils requires that distutils is installed on the build machine, which is included in Python 2.x and available separately for Python 1.5. Since distutils also supports creation of binary packages, users don’t necessarily need a compiler and distutils to install the extension.

A distutils package contains a driver script, setup.py. This is a plain Python file, which, in the most simple case, could look like this:

```python
from distutils.core import setup, Extension

module1 = Extension('demo',
                     sources = ['demo.c'])

setup (name = 'PackageName',
        version = '1.0',
        description = 'This is a demo package',
        ext_modules = [module1])
```

With this setup.py, and a file demo.c, running

```bash
python setup.py build
```

will compile demo.c, and produce an extension module named demo in the build directory. Depending on the system, the module file will
end up in a subdirectory `build/lib.system`, and may have a name like `demo.so` or `demo.pyd`.

In the `setup.py`, all execution is performed by calling the `setup` function. This takes a variable number of keyword arguments, of which the example above uses only a subset. Specifically, the example specifies meta-information to build packages, and it specifies the contents of the package. Normally, a package will contain of addition modules, like Python source modules, documentation, subpackages, etc. Please refer to the distutils documentation in *Distributing Python Modules (Legacy version)* to learn more about the features of distutils; this section explains building extension modules only.

It is common to pre-compute arguments to `setup()`, to better structure the driver script. In the example above, the `ext_modules` argument to `setup()` is a list of extension modules, each of which is an instance of the `Extension`. In the example, the instance defines an extension named `demo` which is build by compiling a single source file, `demo.c`.

In many cases, building an extension is more complex, since additional preprocessor defines and libraries may be needed. This is demonstrated in the example below.

```python
from distutils.core import setup, Extension

module1 = Extension('demo',
    define_macros = [('MAJOR_VERSION', '1'), ('MINOR_VERSION', '0')],
    include_dirs = ['/usr/local/include'],
    libraries = ['tcl83'],
    library_dirs = ['/usr/local/lib'],
    sources = ['demo.c'])

setup (name = 'PackageName',
        version = '1.0',
        ...)
```
In this example, `setup()` is called with additional meta-information, which is recommended when distribution packages have to be built. For the extension itself, it specifies preprocessor defines, include directories, library directories, and libraries. Depending on the compiler, distutils passes this information in different ways to the compiler. For example, on Unix, this may result in the compilation commands:

```bash
gcc -DNDEBUG -g -03 -Wall -Wstrict-prototypes -fPIC -DMAJOR_VERSION
```

```bash
gcc -shared build/temp.linux-i686-2.2/demo.o -L/usr/local/lib
```

These lines are for demonstration purposes only; distutils users should trust that distutils gets the invocations right.
3.1. Distributing your extension modules

When an extension has been successfully build, there are three ways to use it.

End-users will typically want to install the module, they do so by running

```
python setup.py install
```

Module maintainers should produce source packages; to do so, they run

```
python setup.py sdist
```

In some cases, additional files need to be included in a source distribution; this is done through a `MANIFEST.in` file; see the distutils documentation for details.

If the source distribution has been build successfully, maintainers can also create binary distributions. Depending on the platform, one of the following commands can be used to do so.

```
python setup.py bdist_wininst
python setup.py bdist_rpm
python setup.py bdist_dumb
```
This chapter briefly explains how to create a Windows extension module for Python using Microsoft Visual C++, and follows with more detailed background information on how it works. The explanatory material is useful for both the Windows programmer learning to build Python extensions and the Unix programmer interested in producing software which can be successfully built on both Unix and Windows.

Module authors are encouraged to use the distutils approach for building extension modules, instead of the one described in this section. You will still need the C compiler that was used to build Python; typically Microsoft Visual C++.

**Note:** This chapter mentions a number of filenames that include an encoded Python version number. These filenames are represented with the version number shown as XY; in practice, 'X' will be the major version number and 'Y' will be the minor version number of the Python release you’re working with. For example, if you are using Python 2.2.1, XY will actually be 22.
4.1. A Cookbook Approach

There are two approaches to building extension modules on Windows, just as there are on Unix: use the distutils package to control the build process, or do things manually. The distutils approach works well for most extensions; documentation on using distutils to build and package extension modules is available in Distributing Python Modules (Legacy version). If you find you really need to do things manually, it may be instructive to study the project file for the winsound standard library module.
4.2. Differences Between Unix and Windows

Unix and Windows use completely different paradigms for run-time loading of code. Before you try to build a module that can be dynamically loaded, be aware of how your system works.

In Unix, a shared object (.so) file contains code to be used by the program, and also the names of functions and data that it expects to find in the program. When the file is joined to the program, all references to those functions and data in the file's code are changed to point to the actual locations in the program where the functions and data are placed in memory. This is basically a link operation.

In Windows, a dynamic-link library (.dll) file has no dangling references. Instead, an access to functions or data goes through a lookup table. So the DLL code does not have to be fixed up at runtime to refer to the program’s memory; instead, the code already uses the DLL's lookup table, and the lookup table is modified at runtime to point to the functions and data.

In Unix, there is only one type of library file (.a) which contains code from several object files (.o). During the link step to create a shared object file (.so), the linker may find that it doesn’t know where an identifier is defined. The linker will look for it in the object files in the libraries; if it finds it, it will include all the code from that object file.

In Windows, there are two types of library, a static library and an import library (both called .lib). A static library is like a Unix .a file; it contains code to be included as necessary. An import library is basically used only to reassure the linker that a certain identifier is legal, and will be present in the program when the DLL is loaded. So the linker uses the information from the import library to build the
lookup table for using identifiers that are not included in the DLL. When an application or a DLL is linked, an import library may be generated, which will need to be used for all future DLLs that depend on the symbols in the application or DLL.

Suppose you are building two dynamic-load modules, B and C, which should share another block of code A. On Unix, you would not pass A.a to the linker for B.so and C.so; that would cause it to be included twice, so that B and C would each have their own copy. In Windows, building A.dll will also build A.lib. You do pass A.lib to the linker for B and C. A.lib does not contain code; it just contains information which will be used at runtime to access A’s code.

In Windows, using an import library is sort of like using import spam; it gives you access to spam’s names, but does not create a separate copy. On Unix, linking with a library is more like from spam import *; it does create a separate copy.
4.3. Using DLLs in Practice

Windows Python is built in Microsoft Visual C++; using other compilers may or may not work (though Borland seems to). The rest of this section is MSVC++ specific.

When creating DLLs in Windows, you must pass pythonXY.lib to the linker. To build two DLLs, spam and ni (which uses C functions found in spam), you could use these commands:

```
cl /LD /I/python/include spam.c ..;/libs/pythonXY.lib
cl /LD /I/python/include ni.c spam.lib ..;/libs/pythonXY.lib
```

The first command created three files: spam.obj, spam.dll and spam.lib. Spam.dll does not contain any Python functions (such as `PyArg_ParseTuple()`), but it does know how to find the Python code thanks to pythonXY.lib.

The second command created ni.dll (and .obj and .lib), which knows how to find the necessary functions from spam, and also from the Python executable.

Not every identifier is exported to the lookup table. If you want any other modules (including Python) to be able to see your identifiers, you have to say `_declspec(dllexport)`, as in `void _declspec(dllexport) initspam(void)` or `PyObject _declspec(dllexport) *NiGetSpamData(void)`.

Developer Studio will throw in a lot of import libraries that you do not really need, adding about 100K to your executable. To get rid of them, use the Project Settings dialog, Link tab, to specify `ignore default libraries`. Add the correct msvcrxx.lib to the list of libraries.
5. Embedding Python in Another Application

The previous chapters discussed how to extend Python, that is, how to extend the functionality of Python by attaching a library of C functions to it. It is also possible to do it the other way around: enrich your C/C++ application by embedding Python in it. Embedding provides your application with the ability to implement some of the functionality of your application in Python rather than C or C++. This can be used for many purposes; one example would be to allow users to tailor the application to their needs by writing some scripts in Python. You can also use it yourself if some of the functionality can be written in Python more easily.

Embedding Python is similar to extending it, but not quite. The difference is that when you extend Python, the main program of the application is still the Python interpreter, while if you embed Python, the main program may have nothing to do with Python — instead, some parts of the application occasionally call the Python interpreter to run some Python code.

So if you are embedding Python, you are providing your own main program. One of the things this main program has to do is initialize the Python interpreter. At the very least, you have to call the function Py_Initialize(). There are optional calls to pass command line arguments to Python. Then later you can call the interpreter from any part of the application.

There are several different ways to call the interpreter: you can pass a string containing Python statements to PyRun_SimpleString(), or you can pass a stdio file pointer and a file name (for identification in error messages only) to PyRun_SimpleFile(). You can also call the lower-level operations described in the previous chapters to
construct and use Python objects.

A simple demo of embedding Python can be found in the directory Demo/embed/ of the source distribution.

See also:

Python/C API Reference Manual
The details of Python’s C interface are given in this manual. A great deal of necessary information can be found here.
5.1. Very High Level Embedding

The simplest form of embedding Python is the use of the very high level interface. This interface is intended to execute a Python script without needing to interact with the application directly. This can for example be used to perform some operation on a file.

```c
#include <Python.h>

int main(int argc, char *argv[])
{
    Py_SetProgramName(argv[0]); /* optional but recommended */
    Py_Initialize();
    PyRun_SimpleString("from time import time,ctime
"                  "print 'Today is',ctime(time())\n");
    Py_Finalize();
    return 0;
}
```

The `Py_SetProgramName()` function should be called before `Py_Initialize()` to inform the interpreter about paths to Python run-time libraries. Next, the Python interpreter is initialized with `Py_Initialize()`, followed by the execution of a hard-coded Python script that prints the date and time. Afterwards, the `Py_Finalize()` call shuts the interpreter down, followed by the end of the program. In a real program, you may want to get the Python script from another source, perhaps a text-editor routine, a file, or a database. Getting the Python code from a file can better be done by using the `PyRun_SimpleFile()` function, which saves you the trouble of allocating memory space and loading the file contents.
5.2. Beyond Very High Level Embedding: An overview

The high level interface gives you the ability to execute arbitrary pieces of Python code from your application, but exchanging data values is quite cumbersome to say the least. If you want that, you should use lower level calls. At the cost of having to write more C code, you can achieve almost anything.

It should be noted that extending Python and embedding Python is quite the same activity, despite the different intent. Most topics discussed in the previous chapters are still valid. To show this, consider what the extension code from Python to C really does:

1. Convert data values from Python to C,
2. Perform a function call to a C routine using the converted values, and
3. Convert the data values from the call from C to Python.

When embedding Python, the interface code does:

1. Convert data values from C to Python,
2. Perform a function call to a Python interface routine using the converted values, and
3. Convert the data values from the call from Python to C.

As you can see, the data conversion steps are simply swapped to accommodate the different direction of the cross-language transfer. The only difference is the routine that you call between both data conversions. When extending, you call a C routine, when embedding, you call a Python routine.

This chapter will not discuss how to convert data from Python to C and vice versa. Also, proper use of references and dealing with
errors is assumed to be understood. Since these aspects do not differ from extending the interpreter, you can refer to earlier chapters for the required information.
5.3. Pure Embedding

The first program aims to execute a function in a Python script. Like in the section about the very high level interface, the Python interpreter does not directly interact with the application (but that will change in the next section).

The code to run a function defined in a Python script is:

```c
#include <Python.h>

int main(int argc, char *argv[]) {
    PyObject *pName, *pModule, *pDict, *pFunc;
    PyObject *pArgs, *pValue;
    int i;

    if (argc < 3) {
        fprintf(stderr, "Usage: call pythonfile funcname [args]\n        return 1;
    }

    Py_Initialize();
    pName = PyString_FromString(argv[1]);
    /* Error checking of pName left out */

    pModule = PyImport_Import(pName);
    Py_DECREF(pName);

    if (pModule != NULL) {
        pFunc = PyObject_GetAttrString(pModule, argv[2]);
        /* pFunc is a new reference */

        if (pFunc && PyCallable_Check(pFunc)) {
            pArgs = PyTuple_New(argc - 3);
            for (i = 0; i < argc - 3; ++i) {
                pValue = PyInt_FromLong(atoi(argv[i + 3]));
                if (!pValue) {
                    Py_DECREF(pArgs);
                    Py_DECREF(pModule);
                    fprintf(stderr, "Cannot convert argument\n";
```
This code loads a Python script using `argv[1]`, and calls the function named in `argv[2]`. Its integer arguments are the other values of the `argv` array. If you compile and link this program (let's call the finished executable `call`), and use it to execute a Python script, such as:

```python
def multiply(a,b):
    print "Will compute", a, "times", b
```
```python
c = 0
for i in range(0, a):
    c = c + b
return c
```

then the result should be:

```
$ call multiply multiply 3 2
Will compute 3 times 2
Result of call: 6
```

Although the program is quite large for its functionality, most of the code is for data conversion between Python and C, and for error reporting. The interesting part with respect to embedding Python starts with

```c
Py_Initialize();
pName = PyString_FromString(argv[1]);
/* Error checking of pName left out */
pModule = PyImport_Import(pName);
```

After initializing the interpreter, the script is loaded using `PyImport_Import()`. This routine needs a Python string as its argument, which is constructed using the `PyString_FromString()` data conversion routine.

```c
pFunc = PyObject_GetAttrString(pModule, argv[2]);
/* pFunc is a new reference */
if (pFunc && PyCallable_Check(pFunc)) {
    ...
}
Py_XDECREF(pFunc);
```

Once the script is loaded, the name we're looking for is retrieved using `PyObject_GetAttrString()`. If the name exists, and the object returned is callable, you can safely assume that it is a function. The program then proceeds by constructing a tuple of arguments as normal. The call to the Python function is then made with:
pValue = PyObject_CallObject(pFunc, pArgs);

Upon return of the function, `pValue` is either `NULL` or it contains a reference to the return value of the function. Be sure to release the reference after examining the value.
5.4. Extending Embedded Python

Until now, the embedded Python interpreter had no access to functionality from the application itself. The Python API allows this by extending the embedded interpreter. That is, the embedded interpreter gets extended with routines provided by the application. While it sounds complex, it is not so bad. Simply forget for a while that the application starts the Python interpreter. Instead, consider the application to be a set of subroutines, and write some glue code that gives Python access to those routines, just like you would write a normal Python extension. For example:

```c
static int numargs=0;

/* Return the number of arguments of the application command line */
static PyObject*
emb_numargs(PyObject *self, PyObject *args)
{
    if(!PyArg_ParseTuple(args, ":numargs"))
        return NULL;
    return Py_BuildValue("i", numargs);
}

static PyMethodDef EmbMethods[] = {
    {"numargs", emb_numargs, METH_VARARGS,
    "Return the number of arguments received by the process."}
    {NULL, NULL, 0, NULL}
};
```

Insert the above code just above the `main()` function. Also, insert the following two statements directly after `Py_Initialize()`:

```c
numargs = argc;
Py_InitModule("emb", EmbMethods);
```

These two lines initialize the `numargs` variable, and make the `emb.numargs()` function accessible to the embedded Python
interpreter. With these extensions, the Python script can do things like

```python
import emb
print "Number of arguments", emb.numargs()
```

In a real application, the methods will expose an API of the application to Python.
5.5. Embedding Python in C++

It is also possible to embed Python in a C++ program; precisely how this is done will depend on the details of the C++ system used; in general you will need to write the main program in C++, and use the C++ compiler to compile and link your program. There is no need to recompile Python itself using C++. 
5.6. Compiling and Linking under Unix-like systems

It is not necessarily trivial to find the right flags to pass to your compiler (and linker) in order to embed the Python interpreter into your application, particularly because Python needs to load library modules implemented as C dynamic extensions (.so files) linked against it.

To find out the required compiler and linker flags, you can execute the `pythonX.Y-config` script which is generated as part of the installation process (a `python-config` script may also be available). This script has several options, of which the following will be directly useful to you:

- `pythonX.Y-config --cflags` will give you the recommended flags when compiling:

  ```bash
  $ /opt/bin/python2.7-config --cflags
  -I/opt/include/python2.7 -fno-strict-aliasing -DNDEBUG -g -O3 -Wall -Wstrict-prototypes
  ```

- `pythonX.Y-config --ldflags` will give you the recommended flags when linking:

  ```bash
  $ /opt/bin/python2.7-config --ldflags
  -L/opt/lib/python2.7/config -lpthread -ldl -lutil -lm -lpython2.7
  ```

**Note:** To avoid confusion between several Python installations (and especially between the system Python and your own compiled Python), it is recommended that you use the absolute path to `pythonX.Y-config`, as in the above example.
If this procedure doesn’t work for you (it is not guaranteed to work for all Unix-like platforms; however, we welcome bug reports) you will have to read your system’s documentation about dynamic linking and/or examine Python’s Makefile (use \texttt{sysconfig.get_makefile_filename()} to find its location) and compilation options. In this case, the \texttt{sysconfig} module is a useful tool to programmatically extract the configuration values that you will want to combine together. For example:

\begin{verbatim}
>>> import sysconfig
>>> sysconfig.get_config_var('LIBS')
'-lpthread -ldl -lutil'
>>> sysconfig.get_config_var('LINKFORSHARED')
'-Xlinker -export-dynamic'
\end{verbatim}
The Application Programmer’s Interface to Python gives C and C++ programmers access to the Python interpreter at a variety of levels. The API is equally usable from C++, but for brevity it is generally referred to as the Python/C API. There are two fundamentally different reasons for using the Python/C API. The first reason is to write extension modules for specific purposes; these are C modules that extend the Python interpreter. This is probably the most common use. The second reason is to use Python as a component in a larger application; this technique is generally referred to as embedding Python in an application.

Writing an extension module is a relatively well-understood process, where a “cookbook” approach works well. There are several tools that automate the process to some extent. While people have embedded Python in other applications since its early existence, the process of embedding Python is less straightforward than writing an extension.

Many API functions are useful independent of whether you’re embedding or extending Python; moreover, most applications that embed Python will need to provide a custom extension as well, so it’s probably a good idea to become familiar with writing an extension before attempting to embed Python in a real application.
Include Files

All function, type and macro definitions needed to use the Python/C API are included in your code by the following line:

```
#include "Python.h"
```

This implies inclusion of the following standard headers: `<stdio.h>`, `<string.h>`, `<errno.h>`, `<limits.h>`, `<assert.h>` and `<stdlib.h>` (if available).

**Note:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you *must* include `Python.h` before any standard headers are included.

All user visible names defined by `Python.h` (except those defined by the included standard headers) have one of the prefixes `Py` or `_Py`. Names beginning with `_Py` are for internal use by the Python implementation and should not be used by extension writers. Structure member names do not have a reserved prefix.

**Important:** user code should never define names that begin with `Py` or `_Py`. This confuses the reader, and jeopardizes the portability of the user code to future Python versions, which may define additional names beginning with one of these prefixes.

The header files are typically installed with Python. On Unix, these are located in the directories `prefix/include/pythonversion/` and `exec_prefix/include/pythonversion/`, where `prefix` and `exec_prefix` are defined by the corresponding parameters to Python’s `configure` script and `version` is `sys.version[:3]`. On Windows, the headers are installed in `prefix/include`, where `prefix`
is the installation directory specified to the installer.

To include the headers, place both directories (if different) on your compiler’s search path for includes. Do *not* place the parent directories on the search path and then use `#include <pythonX.Y/Python.h>`; this will break on multi-platform builds since the platform independent headers under `prefix` include the platform specific headers from `exec_prefix`.

C++ users should note that though the API is defined entirely using C, the header files do properly declare the entry points to be `extern "C"`, so there is no need to do anything special to use the API from C++.
Objects, Types and Reference Counts

Most Python/C API functions have one or more arguments as well as a return value of type `PyObject*`. This type is a pointer to an opaque data type representing an arbitrary Python object. Since all Python object types are treated the same way by the Python language in most situations (e.g., assignments, scope rules, and argument passing), it is only fitting that they should be represented by a single C type. Almost all Python objects live on the heap: you never declare an automatic or static variable of type `PyObject`, only pointer variables of type `PyObject*` can be declared. The sole exception are the type objects; since these must never be deallocated, they are typically static `PyTypeObject` objects.

All Python objects (even Python integers) have a type and a reference count. An object’s type determines what kind of object it is (e.g., an integer, a list, or a user-defined function; there are many more as explained in The standard type hierarchy). For each of the well-known types there is a macro to check whether an object is of that type; for instance, `PyList_Check(a)` is true if (and only if) the object pointed to by a is a Python list.

Reference Counts

The reference count is important because today’s computers have a finite (and often severely limited) memory size; it counts how many different places there are that have a reference to an object. Such a place could be another object, or a global (or static) C variable, or a local variable in some C function. When an object’s reference count becomes zero, the object is deallocated. If it contains references to other objects, their reference count is decremented. Those other objects may be deallocated in turn, if this decrement makes their
reference count become zero, and so on. (There’s an obvious problem with objects that reference each other here; for now, the solution is “don’t do that.”)

Reference counts are always manipulated explicitly. The normal way is to use the macro \texttt{Py_INCREF()} to increment an object’s reference count by one, and \texttt{Py_DECREF()} to decrement it by one. The \texttt{Py_DECREF()} macro is considerably more complex than the incref one, since it must check whether the reference count becomes zero and then cause the object’s deallocator to be called. The deallocator is a function pointer contained in the object’s type structure. The type-specific deallocator takes care of decrementing the reference counts for other objects contained in the object if this is a compound object type, such as a list, as well as performing any additional finalization that’s needed. There’s no chance that the reference count can overflow; at least as many bits are used to hold the reference count as there are distinct memory locations in virtual memory (assuming $\text{sizeof}(\text{Py_ssize_t}) \geq \text{sizeof(void*)}$). Thus, the reference count increment is a simple operation.

It is not necessary to increment an object’s reference count for every local variable that contains a pointer to an object. In theory, the object’s reference count goes up by one when the variable is made to point to it and it goes down by one when the variable goes out of scope. However, these two cancel each other out, so at the end the reference count hasn’t changed. The only real reason to use the reference count is to prevent the object from being deallocated as long as our variable is pointing to it. If we know that there is at least one other reference to the object that lives at least as long as our variable, there is no need to increment the reference count temporarily. An important situation where this arises is in objects that are passed as arguments to C functions in an extension module that are called from Python; the call mechanism guarantees to hold a reference to every argument for the duration of the call.
However, a common pitfall is to extract an object from a list and hold on to it for a while without incrementing its reference count. Some other operation might conceivably remove the object from the list, decrementing its reference count and possible deallocating it. The real danger is that innocent-looking operations may invoke arbitrary Python code which could do this; there is a code path which allows control to flow back to the user from a \texttt{Py\_DECREF()}, so almost any operation is potentially dangerous.

A safe approach is to always use the generic operations (functions whose name begins with \texttt{PyObject\_}, \texttt{PyNumber\_}, \texttt{PySequence\_} or \texttt{PyMapping\_}). These operations always increment the reference count of the object they return. This leaves the caller with the responsibility to call \texttt{Py\_DECREF()} when they are done with the result; this soon becomes second nature.

### Reference Count Details

The reference count behavior of functions in the Python/C API is best explained in terms of \textit{ownership of references}. Ownership pertains to references, never to objects (objects are not owned: they are always shared). “Owning a reference” means being responsible for calling \texttt{Py\_DECREF} on it when the reference is no longer needed. Ownership can also be transferred, meaning that the code that receives ownership of the reference then becomes responsible for eventually decref’ing it by calling \texttt{Py\_DECREF()} or \texttt{Py\_XDECREF()} when it’s no longer needed—or passing on this responsibility (usually to its caller). When a function passes ownership of a reference on to its caller, the caller is said to receive a \textit{new} reference. When no ownership is transferred, the caller is said to \textit{borrow} the reference. Nothing needs to be done for a borrowed reference.

Conversely, when a calling function passes in a reference to an
object, there are two possibilities: the function steals a reference to the object, or it does not. Stealing a reference means that when you pass a reference to a function, that function assumes that it now owns that reference, and you are not responsible for it any longer.

Few functions steal references; the two notable exceptions are `PyList_SetItem()` and `PyTuple_SetItem()`, which steal a reference to the item (but not to the tuple or list into which the item is put!). These functions were designed to steal a reference because of a common idiom for populating a tuple or list with newly created objects; for example, the code to create the tuple `(1, 2, "three")` could look like this (forgetting about error handling for the moment; a better way to code this is shown below):

```python
PyObject *t;
t = PyTuple_New(3);
PyTuple_SetItem(t, 0, PyInt_FromLong(1L));
PyTuple_SetItem(t, 1, PyInt_FromLong(2L));
PyTuple_SetItem(t, 2, PyString_FromString("three"));
```

Here, `PyInt_FromLong()` returns a new reference which is immediately stolen by `PyTuple_SetItem()`. When you want to keep using an object although the reference to it will be stolen, use `Py_INCREF()` to grab another reference before calling the reference-stealing function.

Incidentally, `PyTuple_SetItem()` is the only way to set tuple items; `PySequence_SetItem()` and `PyObject_SetItem()` refuse to do this since tuples are an immutable data type. You should only use `PyTuple_SetItem()` for tuples that you are creating yourself.

Equivalent code for populating a list can be written using `PyList_New()` and `PyList_SetItem()`.

However, in practice, you will rarely use these ways of creating and
populating a tuple or list. There's a generic function, `Py_BuildValue()`, that can create most common objects from C values, directed by a *format string*. For example, the above two blocks of code could be replaced by the following (which also takes care of the error checking):

```c
PyObject *tuple, *list;
tuple = Py_BuildValue("(iis)", 1, 2, "three");
list = Py_BuildValue("[iis]", 1, 2, "three");
```

It is much more common to use `PyObject_SetItem()` and friends with items whose references you are only borrowing, like arguments that were passed in to the function you are writing. In that case, their behaviour regarding reference counts is much saner, since you don’t have to increment a reference count so you can give a reference away (“have it be stolen”). For example, this function sets all items of a list (actually, any mutable sequence) to a given item:

```c
int
set_all(PyObject *target, PyObject *item)
{
    int i, n;

    n = PyObject_Length(target);
    if (n < 0)
        return -1;
    for (i = 0; i < n; i++) {
        PyObject *index = PyInt_FromLong(i);
        if (!index)
            return -1;
        if (PyObject_SetItem(target, index, item) < 0) {
            Py_DECREF(index);
            return -1;
        }
    }
    Py_DECREF(index);
    return 0;
}
```
The situation is slightly different for function return values. While passing a reference to most functions does not change your ownership responsibilities for that reference, many functions that return a reference to an object give you ownership of the reference. The reason is simple: in many cases, the returned object is created on the fly, and the reference you get is the only reference to the object. Therefore, the generic functions that return object references, like `PyObject_GetItem()` and `PySequence_GetItem()`, always return a new reference (the caller becomes the owner of the reference).

It is important to realize that whether you own a reference returned by a function depends on which function you call only — the plumage (the type of the object passed as an argument to the function) doesn’t enter into it! Thus, if you extract an item from a list using `PyList_GetItem()`, you don’t own the reference — but if you obtain the same item from the same list using `PySequence_GetItem()` (which happens to take exactly the same arguments), you do own a reference to the returned object.

Here is an example of how you could write a function that computes the sum of the items in a list of integers; once using `PyList_GetItem()`, and once using `PySequence_GetItem()`.

```c
long sum_list(PyObject *list)
{
    int i, n;
    long total = 0;
    PyObject *item;

    n = PyList_Size(list);
    if (n < 0)
        return -1; /* Not a list */
    for (i = 0; i < n; i++) {
        item = PyList_GetItem(list, i); /* Can't fail */
        if (!PyInt_Check(item)) continue; /* Skip non-integers */
        total += PyInt_AsLong(item);
    }
}
```
Types

There are few other data types that play a significant role in the Python/C API; most are simple C types such as `int`, `long`, `double` and `char*`. A few structure types are used to describe static tables used to list the functions exported by a module or the data attributes of a new object type, and another is used to describe the value of a complex number. These will be discussed together with the functions that use them.
The Python programmer only needs to deal with exceptions if specific error handling is required; unhandled exceptions are automatically propagated to the caller, then to the caller’s caller, and so on, until they reach the top-level interpreter, where they are reported to the user accompanied by a stack traceback.

For C programmers, however, error checking always has to be explicit. All functions in the Python/C API can raise exceptions, unless an explicit claim is made otherwise in a function’s documentation. In general, when a function encounters an error, it sets an exception, discards any object references that it owns, and returns an error indicator. If not documented otherwise, this indicator is either `NULL` or `-1`, depending on the function’s return type. A few functions return a Boolean true/false result, with false indicating an error. Very few functions return no explicit error indicator or have an ambiguous return value, and require explicit testing for errors with `PyErr_Occurred()`. These exceptions are always explicitly documented.

Exception state is maintained in per-thread storage (this is equivalent to using global storage in an unthreaded application). A thread can be in one of two states: an exception has occurred, or not. The function `PyErr_Occurred()` can be used to check for this: it returns a borrowed reference to the exception type object when an exception has occurred, and `NULL` otherwise. There are a number of functions to set the exception state: `PyErr_SetString()` is the most common (though not the most general) function to set the exception state, and `PyErr_Clear()` clears the exception state.

The full exception state consists of three objects (all of which can be `NULL`): the exception type, the corresponding exception value, and
the traceback. These have the same meanings as the Python objects `sys.exc_type`, `sys.exc_value`, and `sys.exc_traceback`; however, they are not the same: the Python objects represent the last exception being handled by a Python `try ... except` statement, while the C level exception state only exists while an exception is being passed on between C functions until it reaches the Python bytecode interpreter’s main loop, which takes care of transferring it to `sys.exc_type` and friends.

Note that starting with Python 1.5, the preferred, thread-safe way to access the exception state from Python code is to call the function `sys.exc_info()`, which returns the per-thread exception state for Python code. Also, the semantics of both ways to access the exception state have changed so that a function which catches an exception will save and restore its thread’s exception state so as to preserve the exception state of its caller. This prevents common bugs in exception handling code caused by an innocent-looking function overwriting the exception being handled; it also reduces the often unwanted lifetime extension for objects that are referenced by the stack frames in the traceback.

As a general principle, a function that calls another function to perform some task should check whether the called function raised an exception, and if so, pass the exception state on to its caller. It should discard any object references that it owns, and return an error indicator, but it should not set another exception — that would overwrite the exception that was just raised, and lose important information about the exact cause of the error.

A simple example of detecting exceptions and passing them on is shown in the `sum_sequence()` example above. It so happens that this example doesn’t need to clean up any owned references when it detects an error. The following example function shows some error cleanup. First, to remind you why you like Python, we show the
equivalent Python code:

def incr_item(dict, key):
    try:
        item = dict[key]
    except KeyError:
        item = 0
    dict[key] = item + 1

Here is the corresponding C code, in all its glory:

```c
int
incr_item(PyObject *dict, PyObject *key)
{
    /* Objects all initialized to NULL for Py_XDECREF */
    PyObject *item = NULL, *const_one = NULL, *incremented_item
    int rv = -1; /* Return value initialized to -1 (failure) */

    item = PyObject_GetItem(dict, key);
    if (item == NULL) {
        /* Handle KeyError only: */
        if (!PyErr_ExceptionMatches(PyExc_KeyError))
            goto error;

        /* Clear the error and use zero: */
        PyErr_Clear();
        item = PyInt_FromLong(0L);
        if (item == NULL)
            goto error;
    }
    const_one = PyInt_FromLong(1L);
    if (const_one == NULL)
        goto error;

    incremented_item = PyNumber_Add(item, const_one);
    if (incremented_item == NULL)
        goto error;

    if (PyObject_SetItem(dict, key, incremented_item) < 0)
        goto error;
    rv = 0; /* Success */
    /* Continue with cleanup code */

error:
    /* Cleanup code, shared by success and failure path */
```
This example represents an endorsed use of the `goto` statement in C! It illustrates the use of `PyErr_ExceptionMatches()` and `PyErr_Clear()` to handle specific exceptions, and the use of `Py_XDECRREF()` to dispose of owned references that may be `NULL` (note the 'x' in the name; `Py_DECREF()` would crash when confronted with a `NULL` reference). It is important that the variables used to hold owned references are initialized to `NULL` for this to work; likewise, the proposed return value is initialized to `-1` (failure) and only set to success after the final call made is successful.
The one important task that only embedders (as opposed to extension writers) of the Python interpreter have to worry about is the initialization, and possibly the finalization, of the Python interpreter. Most functionality of the interpreter can only be used after the interpreter has been initialized.

The basic initialization function is `Py_Initialize()`. This initializes the table of loaded modules, and creates the fundamental modules `__builtin__`, `__main__`, `sys`, and `exceptions`. It also initializes the module search path (`sys.path`).

`Py_Initialize()` does not set the “script argument list” (`sys.argv`). If this variable is needed by Python code that will be executed later, it must be set explicitly with a call to `PySys_SetArgvEx(argc, argv, updatepath)` after the call to `Py_Initialize()`.

On most systems (in particular, on Unix and Windows, although the details are slightly different), `Py_Initialize()` calculates the module search path based upon its best guess for the location of the standard Python interpreter executable, assuming that the Python library is found in a fixed location relative to the Python interpreter executable. In particular, it looks for a directory named `lib/pythonX.Y` relative to the parent directory where the executable named `python` is found on the shell command search path (the environment variable `PATH`).

For instance, if the Python executable is found in `/usr/local/bin/python`, it will assume that the libraries are in `/usr/local/lib/pythonX.Y`. (In fact, this particular path is also the “fallback” location, used when no executable file named `python` is
found along **PATH**.) The user can override this behavior by setting the environment variable **PYTHONHOME**, or insert additional directories in front of the standard path by setting **PYTHONPATH**.

The embedding application can steer the search by calling `Py_SetProgramName(file)` before calling `Py_Initialize()`. Note that **PYTHONHOME** still overrides this and **PYTHONPATH** is still inserted in front of the standard path. An application that requires total control has to provide its own implementation of `Py_GetPath()`, `Py_GetPrefix()`, `Py_GetExecPrefix()`, and `Py_GetProgramFullPath()` (all defined in Modules/getpath.c).

Sometimes, it is desirable to “uninitialize” Python. For instance, the application may want to start over (make another call to `Py_Initialize()`) or the application is simply done with its use of Python and wants to free memory allocated by Python. This can be accomplished by calling `Py_Finalize()`. The function `Py_IsInitialized()` returns true if Python is currently in the initialized state. More information about these functions is given in a later chapter. Notice that `Py_Finalize()` does not free all memory allocated by the Python interpreter, e.g. memory allocated by extension modules currently cannot be released.
Debugging Builds

Python can be built with several macros to enable extra checks of the interpreter and extension modules. These checks tend to add a large amount of overhead to the runtime so they are not enabled by default.

A full list of the various types of debugging builds is in the file Misc/SpecialBuilds.txt in the Python source distribution. Builds are available that support tracing of reference counts, debugging the memory allocator, or low-level profiling of the main interpreter loop. Only the most frequently-used builds will be described in the remainder of this section.

Compiling the interpreter with the Py_DEBUG macro defined produces what is generally meant by “a debug build” of Python. Py_DEBUG is enabled in the Unix build by adding --with-pydebug to the ./configure command. It is also implied by the presence of the not-Python-specific _DEBUG macro. When Py_DEBUG is enabled in the Unix build, compiler optimization is disabled.

In addition to the reference count debugging described below, the following extra checks are performed:

- Extra checks are added to the object allocator.
- Extra checks are added to the parser and compiler.
- Downcasts from wide types to narrow types are checked for loss of information.
- A number of assertions are added to the dictionary and set implementations. In addition, the set object acquires a test_c_api() method.
- Sanity checks of the input arguments are added to frame creation.
The storage for long ints is initialized with a known invalid pattern to catch reference to uninitialized digits.
Low-level tracing and extra exception checking are added to the runtime virtual machine.
Extra checks are added to the memory arena implementation.
Extra debugging is added to the thread module.

There may be additional checks not mentioned here.

Defining `Py_TRACE_REFS` enables reference tracing. When defined, a circular doubly linked list of active objects is maintained by adding two extra fields to every `PyObject`. Total allocations are tracked as well. Upon exit, all existing references are printed. (In interactive mode this happens after every statement run by the interpreter.) Implied by `Py_DEBUG`.

Please refer to `Misc/SpecialBuilds.txt` in the Python source distribution for more detailed information.
The Very High Level Layer

The functions in this chapter will let you execute Python source code given in a file or a buffer, but they will not let you interact in a more detailed way with the interpreter.

Several of these functions accept a start symbol from the grammar as a parameter. The available start symbols are `Py_eval_input`, `Py_file_input`, and `Py_single_input`. These are described following the functions which accept them as parameters.

Note also that several of these functions take `FILE*` parameters. One particular issue which needs to be handled carefully is that the `FILE` structure for different C libraries can be different and incompatible. Under Windows (at least), it is possible for dynamically linked extensions to actually use different libraries, so care should be taken that `FILE*` parameters are only passed to these functions if it is certain that they were created by the same library that the Python runtime is using.

```c
int Py_Main(int argc, char **argv)
```

The main program for the standard interpreter. This is made available for programs which embed Python. The `argc` and `argv` parameters should be prepared exactly as those which are passed to a C program's `main()` function. It is important to note that the argument list may be modified (but the contents of the strings pointed to by the argument list are not). The return value will be 0 if the interpreter exits normally (ie, without an exception), 1 if the interpreter exits due to an exception, or 2 if the parameter list does not represent a valid Python command line.

Note that if an otherwise unhandled `SystemExit` is raised, this function will not return 1, but exit the process, as long as
Py_InspectFlag is not set.

int PyRun<AnyFile(FILE *fp, const char *filename)
    This is a simplified interface to PyRun<AnyFileExFlags() below, leaving closeit set to 0 and flags set to NULL.

int PyRun<AnyFileFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
    This is a simplified interface to PyRun<AnyFileExFlags() below, leaving the closeit argument set to 0.

int PyRun<AnyFileEx(FILE *fp, const char *filename, int closeit)
    This is a simplified interface to PyRun<AnyFileExFlags() below, leaving the flags argument set to NULL.

int PyRun<AnyFileExFlags(FILE *fp, const char *filename, int closeit, PyCompilerFlags *flags)
    If fp refers to a file associated with an interactive device (console or terminal input or Unix pseudo-terminal), return the value of PyRun_InteractiveLoop(), otherwise return the result of PyRun_SimpleFile(). If filename is NULL, this function uses "???", as the filename.

int PyRun_SimpleString(const char *command)
    This is a simplified interface to PyRun_SimpleStringFlags() below, leaving the PyCompilerFlags* argument set to NULL.

int PyRun_SimpleStringFlags(const char *command, PyCompilerFlags *flags)
    Executes the Python source code from command in the __main__ module according to the flags argument. If __main__ does not already exist, it is created. Returns 0 on success or -1 if an exception was raised. If there was an error, there is no way to get the exception information. For the meaning of flags, see below.
Note that if an otherwise unhandled `SystemExit` is raised, this function will not return `-1`, but exit the process, as long as `Py_InspectFlag` is not set.

```c
int PyRun_SimpleFile(FILE *fp, const char *filename)
    This is a simplified interface to `PyRun_SimpleFileExFlags()` below, leaving `closeit` set to 0 and `flags` set to `NULL`.
```

```c
int PyRun_SimpleFileFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
    This is a simplified interface to `PyRun_SimpleFileExFlags()` below, leaving `closeit` set to 0.
```

```c
int PyRun_SimpleFileEx(FILE *fp, const char *filename, int closeit)
    This is a simplified interface to `PyRun_SimpleFileExFlags()` below, leaving `flags` set to `NULL`.
```

```c
int PyRun_SimpleFileExFlags(FILE *fp, const char *filename, int closeit, PyCompilerFlags *flags)
    Similar to `PyRun_SimpleStringFlags()`, but the Python source code is read from `fp` instead of an in-memory string. `filename` should be the name of the file. If `closeit` is true, the file is closed before `PyRun_SimpleFileExFlags` returns.
```

```c
int PyRun_InteractiveOne(FILE *fp, const char *filename)
    This is a simplified interface to `PyRun_InteractiveOneFlags()` below, leaving `flags` set to `NULL`.
```

```c
int PyRun_InteractiveOneFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
    Read and execute a single statement from a file associated with an interactive device according to the `flags` argument. The user will be prompted using `sys.ps1` and `sys.ps2`. Returns 0 when the input was executed successfully, -1 if there was an exception, or
an error code from the errcode.h include file distributed as part of Python if there was a parse error. (Note that errcode.h is not included by Python.h, so must be included specifically if needed.)

int PyRun_InteractiveLoop(FILE *fp, const char *filename)
This is a simplified interface to PyRun_InteractiveLoopFlags() below, leaving flags set to NULL.

int PyRun_InteractiveLoopFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
Read and execute statements from a file associated with an interactive device until EOF is reached. The user will be prompted using sys.ps1 and sys.ps2. Returns 0 at EOF.

struct _node* PyParser_SimpleParseString(const char *str, int start)
This is a simplified interface to PyParser_SimpleParseStringFlagsFilename() below, leaving filename set to NULL and flags set to 0.

struct _node* PyParser_SimpleParseStringFlags(const char *str, int start, int flags)
This is a simplified interface to PyParser_SimpleParseStringFlagsFilename() below, leaving filename set to NULL.

struct _node* PyParser_SimpleParseStringFlagsFilename(const char *str, const char *filename, int start, int flags)
Parse Python source code from str using the start token start according to the flags argument. The result can be used to create a code object which can be evaluated efficiently. This is useful if a code fragment must be evaluated many times.

struct _node* PyParser_SimpleParseFile(FILE *fp, const char *filename, int start)
This is a simplified interface to `PyParser_SimpleParseFileFlags()` below, leaving `flags` set to 0.

```c
struct_node* PyParser_SimpleParseFileFlags(FILE *fp, const char *filename, int start, int flags)
```

Similar to `PyParser_SimpleParseStringFlagsFilename()`, but the Python source code is read from `fp` instead of an in-memory string.

```c
PyObject* PyRun_String(const char *str, int start, PyObject *globals, PyObject *locals)
```

*Return value: New reference.*

This is a simplified interface to `PyRun_StringFlags()` below, leaving `flags` set to NULL.

```c
PyObject* PyRun_StringFlags(const char *str, int start, PyObject *globals, PyObject *locals, PyCompilerFlags *flags)
```

*Return value: New reference.*

Execute Python source code from `str` in the context specified by the dictionaries `globals` and `locals` with the compiler flags specified by `flags`. The parameter `start` specifies the start token that should be used to parse the source code.

Returns the result of executing the code as a Python object, or `NULL` if an exception was raised.

```c
PyObject* PyRun_File(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals)
```

*Return value: New reference.*

This is a simplified interface to `PyRun_FileExFlags()` below, leaving `closeit` set to 0 and `flags` set to NULL.

```c
PyObject* PyRun_FileEx(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, int closeit)
```

*Return value: New reference.*
This is a simplified interface to `PyRun_FileExFlags()` below, leaving `flags` set to `NULL`.

```
PyObject* PyRun_FileFlags(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, PyCompilerFlags *flags)
   This is a simplified interface to `PyRun_FileExFlags()` below, leaving `closeit` set to 0.
```

```
PyObject* PyRun_FileExFlags(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, int closeit, PyCompilerFlags *flags)
   Similar to `PyRun_StringFlags()`, but the Python source code is read from `fp` instead of an in-memory string. `filename` should be the name of the file. If `closeit` is true, the file is closed before `PyRun_FileExFlags()` returns.
```

```
PyObject* Py_CompileString(const char *str, const char *filename, int start)
   This is a simplified interface to `Py_CompileStringFlags()` below, leaving `flags` set to `NULL`.
```

```
PyObject* Py_CompileStringFlags(const char *str, const char *filename, int start, PyCompilerFlags *flags)
   Parse and compile the Python source code in `str`, returning the resulting code object. The start token is given by `start`; this can be used to constrain the code which can be compiled and should be `Py_eval_input`, `Py_file_input`, or `Py_single_input`. The filename specified by `filename` is used to construct the code object and may appear in traceback or `SyntaxError` exception messages. This returns `NULL` if the code cannot be parsed or compiled.
```
PyObject* PyEval_EvalCode(PyCodeObject *co, PyObject *globals, PyObject *locals)

This is a simplified interface to PyEval_EvalCodeEx(), with just the code object, and the dictionaries of global and local variables. The other arguments are set to NULL.

PyObject* PyEval_EvalCodeEx(PyCodeObject *co, PyObject *globals, PyObject *locals, PyObject **args, int argcount, PyObject **kws, int kwcount, PyObject **defs, int defcount, PyObject *closure)

Evaluate a precompiled code object, given a particular environment for its evaluation. This environment consists of dictionaries of global and local variables, arrays of arguments, keywords and defaults, and a closure tuple of cells.

PyObject* PyEval_EvalFrame(PyFrameObject *f)

Evaluate an execution frame. This is a simplified interface to PyEval_EvalFrameEx, for backward compatibility.

PyObject* PyEval_EvalFrameEx(PyFrameObject *f, int throwflag)

This is the main, unvarnished function of Python interpretation. It is literally 2000 lines long. The code object associated with the execution frame f is executed, interpreting bytecode and executing calls as needed. The additional throwflag parameter can mostly be ignored - if true, then it causes an exception to immediately be thrown; this is used for the throw() methods of generator objects.

int PyEval_MergeCompilerFlags(PyCompilerFlags *cf)

This function changes the flags of the current evaluation frame, and returns true on success, false on failure.

int Py_eval_input

The start symbol from the Python grammar for isolated
expressions; for use with Py_CompileString().

int Py_file_input
The start symbol from the Python grammar for sequences of statements as read from a file or other source; for use with Py_CompileString(). This is the symbol to use when compiling arbitrarily long Python source code.

int Py_single_input
The start symbol from the Python grammar for a single statement; for use with Py_CompileString(). This is the symbol used for the interactive interpreter loop.

struct PyCompilerFlags
This is the structure used to hold compiler flags. In cases where code is only being compiled, it is passed as int flags, and in cases where code is being executed, it is passed as PyCompilerFlags *flags. In this case, from __future__ import can modify flags.

Whenever PyCompilerFlags *flags is NULL, cf_flags is treated as equal to 0, and any modification due to from __future__ import is discarded.

\[
\textbf{struct} \hspace{1em} \text{PyCompilerFlags} \{ \\
\hspace{2em} \text{int} \hspace{1em} \text{cf_flags}; \\
\}
\]

int CO_FUTURE_DIVISION
This bit can be set in flags to cause division operator / to be interpreted as “true division” according to PEP 238.
Reference Counting

The macros in this section are used for managing reference counts of Python objects.

```c
void Py_INCREF(PyObject *o)
```
Increment the reference count for object o. The object must not be `NULL`; if you aren't sure that it isn't `NULL`, use `Py_XINCREF()`.

```c
void Py_XINCREF(PyObject *o)
```
Increment the reference count for object o. The object may be `NULL`, in which case the macro has no effect.

```c
void Py_DECREF(PyObject *o)
```
Decrement the reference count for object o. The object must not be `NULL`; if you aren't sure that it isn't `NULL`, use `Py_XDECREF()`. If the reference count reaches zero, the object's type's deallocation function (which must not be `NULL`) is invoked.

**Warning:** The deallocation function can cause arbitrary Python code to be invoked (e.g. when a class instance with a `__del__()` method is deallocated). While exceptions in such code are not propagated, the executed code has free access to all Python global variables. This means that any object that is reachable from a global variable should be in a consistent state before `Py_DECREF()` is invoked. For example, code to delete an object from a list should copy a reference to the deleted object in a temporary variable, update the list data structure, and then call `Py_DECREF()` for the temporary variable.

```c
void Py_XDECREF(PyObject *o)
```
Decrement the reference count for object o. The object may be `NULL`, in which case the macro has no effect; otherwise the
effect is the same as for `Py_DECREF()`, and the same warning applies.

```c
void Py_CLEAR(PyObject *o)
```

Decrement the reference count for object `o`. The object may be `NULL`, in which case the macro has no effect; otherwise the effect is the same as for `Py_DECREF()`, except that the argument is also set to `NULL`. The warning for `Py_DECREF()` does not apply with respect to the object passed because the macro carefully uses a temporary variable and sets the argument to `NULL` before decrementing its reference count.

It is a good idea to use this macro whenever decrementing the value of a variable that might be traversed during garbage collection.

*New in version 2.4.*

The following functions are for runtime dynamic embedding of Python: `Py_IncRef(PyObject *o)`, `Py_DecRef(PyObject *o)`. They are simply exported function versions of `Py_XINCREF()` and `Py_XDECREF()`, respectively.

The following functions or macros are only for use within the interpreter core: `_Py_Dealloc()`, `_Py_ForgetReference()`, `_Py_NewReference()`, as well as the global variable `_Py_RefTotal`.
Exception Handling

The functions described in this chapter will let you handle and raise Python exceptions. It is important to understand some of the basics of Python exception handling. It works somewhat like the Unix \texttt{errno} variable: there is a global indicator (per thread) of the last error that occurred. Most functions don't clear this on success, but will set it to indicate the cause of the error on failure. Most functions also return an error indicator, usually \texttt{NULL} if they are supposed to return a pointer, or \texttt{-1} if they return an integer (exception: the \texttt{PyArg_*()} functions return \texttt{1} for success and \texttt{0} for failure).

When a function must fail because some function it called failed, it generally doesn't set the error indicator; the function it called already set it. It is responsible for either handling the error and clearing the exception or returning after cleaning up any resources it holds (such as object references or memory allocations); it should \textit{not} continue normally if it is not prepared to handle the error. If returning due to an error, it is important to indicate to the caller that an error has been set. If the error is not handled or carefully propagated, additional calls into the Python/C API may not behave as intended and may fail in mysterious ways.

The error indicator consists of three Python objects corresponding to the Python variables \texttt{sys.exc_type, sys.exc_value} and \texttt{sys.exc_traceback}. API functions exist to interact with the error indicator in various ways. There is a separate error indicator for each thread.

\texttt{void PyErr_PrintEx(int set_sys_last_vars)}

Print a standard traceback to \texttt{sys.stderr} and clear the error indicator. Call this function only when the error indicator is set. (Otherwise it will cause a fatal error!)
If `set_sys_last_vars` is nonzero, the variables `sys.last_type`, `sys.last_value` and `sys.last_traceback` will be set to the type, value and traceback of the printed exception, respectively.

```c
void PyErr_Print()
    Alias for PyErr_PrintEx(1).
```

```c
PyObject* PyErr_Occurred()
    Return value: Borrowed reference.
    Test whether the error indicator is set. If set, return the exception type (the first argument to the last call to one of the PyErr_Set*() functions or to PyErr_Restore()). If not set, return NULL. You do not own a reference to the return value, so you do not need to Py_DECREF() it.

    **Note:** Do not compare the return value to a specific exception; use PyErr_ExceptionMatches() instead, shown below. (The comparison could easily fail since the exception may be an instance instead of a class, in the case of a class exception, or it may be a subclass of the expected exception.)
```

```c
int PyErr_ExceptionMatches(PyObject *exc)
    Equivalent to PyErr_GivenExceptionMatches(PyErr_Occurred(), exc). This should only be called when an exception is actually set; a memory access violation will occur if no exception has been raised.
```

```c
int PyErr_GivenExceptionMatches(PyObject *given, PyObject *exc)
    Return true if the `given` exception matches the exception in `exc`. If `exc` is a class object, this also returns true when `given` is an instance of a subclass. If `exc` is a tuple, all exceptions in the tuple (and recursively in subtuples) are searched for a match.
```
void PyErr_NormalizeException(PyObject**exc, PyObject**val, PyObject**tb)
    Under certain circumstances, the values returned by PyErr_Fetch() below can be “unnormalized”, meaning that *exc is a class object but *val is not an instance of the same class. This function can be used to instantiate the class in that case. If the values are already normalized, nothing happens. The delayed normalization is implemented to improve performance.

void PyErr_Clear()
    Clear the error indicator. If the error indicator is not set, there is no effect.

void PyErr_Fetch(PyObject **ptype, PyObject **pvalue, PyObject **ptraceback)
    Retrieve the error indicator into three variables whose addresses are passed. If the error indicator is not set, set all three variables to NULL. If it is set, it will be cleared and you own a reference to each object retrieved. The value and traceback object may be NULL even when the type object is not.

Note: This function is normally only used by code that needs to handle exceptions or by code that needs to save and restore the error indicator temporarily.

void PyErr_Restore(PyObject *type, PyObject *value, PyObject *traceback)
    Set the error indicator from the three objects. If the error indicator is already set, it is cleared first. If the objects are NULL, the error indicator is cleared. Do not pass a NULL type and non-NULL value or traceback. The exception type should be a class. Do not pass an invalid exception type or value. (Violating these rules will cause subtle problems later.) This call takes away a reference to each object: you must own a reference to each object before the
call and after the call you no longer own these references. (If you don’t understand this, don’t use this function. I warned you.)

**Note:** This function is normally only used by code that needs to save and restore the error indicator temporarily; use `PyErr_Fetch()` to save the current exception state.

void **PyErr_SetString**(PyObject *type, const char *message)

This is the most common way to set the error indicator. The first argument specifies the exception type; it is normally one of the standard exceptions, e.g. `PyExc_RuntimeError`. You need not increment its reference count. The second argument is an error message; it is converted to a string object.

void **PyErr_SetObject**(PyObject *type, PyObject *value)

This function is similar to `PyErr_SetString()` but lets you specify an arbitrary Python object for the “value” of the exception.

PyObject* **PyErr_Format**(PyObject *exception, const char *format, ...)

*Return value: Always NULL.*

This function sets the error indicator and returns `NULL`. `exception` should be a Python exception class. The `format` and subsequent parameters help format the error message; they have the same meaning and values as in `PyString_FromFormat()`.

void **PyErr_SetNone**(PyObject *type)

This is a shorthand for `PyErr_SetObject(type, Py_None)`.

int **PyErr_BadArgument**()

This is a shorthand for `PyErr_SetString(PyExc_TypeError, message)`, where `message` indicates that a built-in operation was invoked with an illegal argument. It is mostly for internal use.
PyObject* PyErr_NoMemory()

Return value: Always NULL.
This is a shorthand for PyErr_SetNone(PyExc_MemoryError); it returns NULL so an object allocation function can write return PyErr_NoMemory(); when it runs out of memory.

PyObject* PyErr_SetFromErrno(PyObject *type)

Return value: Always NULL.
This is a convenience function to raise an exception when a C library function has returned an error and set the C variable errno. It constructs a tuple object whose first item is the integer errno value and whose second item is the corresponding error message (gotten from strerror()), and then calls PyErr_SetObject(type, object). On Unix, when the errno value is EINTR, indicating an interrupted system call, this calls PyErr_CheckSignals(), and if that set the error indicator, leaves it set to that. The function always returns NULL, so a wrapper function around a system call can write return PyErr_SetFromErrno(type); when the system call returns an error.

PyObject* PyErr_SetFromErrnoWithFilenameObject(PyObject *type, PyObject *filenameObject)

Similar to PyErr_SetFromErrno(), with the additional behavior that if filenameObject is not NULL, it is passed to the constructor of type as a third parameter. In the case of exceptions such as IOError and OSError, this is used to define the filename attribute of the exception instance.

PyObject* PyErr_SetFromErrnoWithFilename(PyObject *type, const char *filename)

Return value: Always NULL.
Similar to PyErr_SetFromErrnoWithFilenameObject(), but the
filename is given as a C string.

PyObject* PyErr_SetFromWindowsErr(int ierr)

*Return value:* Always **NULL**.

This is a convenience function to raise **WindowsError**. If called with `ierr` of 0, the error code returned by a call to `GetLastError()` is used instead. It calls the Win32 function `FormatMessage()` to retrieve the Windows description of error code given by `ierr` or `GetLastError()`, then it constructs a tuple object whose first item is the `ierr` value and whose second item is the corresponding error message (gotten from `FormatMessage()`), and then calls `PyErr_SetObject(PyExc_WindowsError, object)`. This function always returns **NULL**. Availability: Windows.

PyObject* PyErr_SetExcFromWindowsErr(PyObject *type, int ierr)

*Return value:* Always **NULL**.

Similar to `PyErr_SetFromWindowsErr()`, with an additional parameter specifying the exception type to be raised. Availability: Windows.

*New in version 2.3.*

PyObject* PyErr_SetFromWindowsErrWithFilenameObject(int ierr, PyObject *filenameObject)

Similar to `PyErr_SetFromWindowsErr()`, with the additional behavior that if `filenameObject` is not **NULL**, it is passed to the constructor of **WindowsError** as a third parameter. Availability: Windows.

PyObject* PyErr_SetFromWindowsErrWithFilename(int ierr, const char *filename)

*Return value:* Always **NULL**.

Similar to `PyErr_SetFromWindowsErrWithFilenameObject()`, but the filename is given as a C string. Availability: Windows.
PyObject*
PyErr_SetExcFromWindowsErrWithFilenameObject(PyObject *type, int ierr, PyObject *filename)

Similar to PyErr_SetFromWindowsErrWithFilenameObject(), with an additional parameter specifying the exception type to be raised. Availability: Windows.

*New in version 2.3.*

PyObject*
PyErr_SetExcFromWindowsErrWithFilename(PyObject *type, int ierr, const char *filename)

*Return value: Always NULL.*

Similar to PyErr_SetFromWindowsErrWithFilename(), with an additional parameter specifying the exception type to be raised. Availability: Windows.

*New in version 2.3.*

void PyErr_BadInternalCall()

This is a shorthand for PyErr_SetString(PyExc_SystemError, message), where message indicates that an internal operation (e.g. a Python/C API function) was invoked with an illegal argument. It is mostly for internal use.

int PyErr_WarnEx(PyObject *category, char *message, int stacklevel)

Issue a warning message. The category argument is a warning category (see below) or NULL; the message argument is a message string. stacklevel is a positive number giving a number of stack frames; the warning will be issued from the currently executing line of code in that stack frame. A stacklevel of 1 is the function calling PyErr_WarnEx(), 2 is the function above that, and so forth.
This function normally prints a warning message to `sys.stderr`; however, it is also possible that the user has specified that warnings are to be turned into errors, and in that case this will raise an exception. It is also possible that the function raises an exception because of a problem with the warning machinery (the implementation imports the `warnings` module to do the heavy lifting). The return value is 0 if no exception is raised, or -1 if an exception is raised. (It is not possible to determine whether a warning message is actually printed, nor what the reason is for the exception; this is intentional.) If an exception is raised, the caller should do its normal exception handling (for example, `Py_DECREF()` owned references and return an error value).

Warning categories must be subclasses of `Warning`; the default warning category is `RuntimeWarning`. The standard Python warning categories are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. Their names are `PyExc_Warning`, `PyExc_UserWarning`, `PyExc_UnicodeWarning`, `PyExc_DeprecationWarning`, `PyExc_SyntaxWarning`, `PyExc_RuntimeWarning`, and `PyExc_FutureWarning`. `PyExc_Warning` is a subclass of `PyExc_Exception`; the other warning categories are subclasses of `PyExc_Warning`.

For information about warning control, see the documentation for the `warnings` module and the `-W` option in the command line documentation. There is no C API for warning control.

```c
int PyErr_Warn(PyObject *category, char *message)
```
Issue a warning message. The `category` argument is a warning category (see below) or `NULL`; the `message` argument is a message string. The warning will appear to be issued from the function calling `PyErr_Warn()`, equivalent to calling
PyErr_WarnEx() with a stacklevel of 1.

Deprecated; use PyErr_WarnEx() instead.

int PyErr_WARNExplicit(PyObject *category, const char *message, const char *filename, int lineno, const char *module, PyObject *registry)

Issue a warning message with explicit control over all warning attributes. This is a straightforward wrapper around the Python function warnings.warn_explicit(), see there for more information. The module and registry arguments may be set to NULL to get the default effect described there.

int PyErr_WARNPy3k(char *message, int stacklevel)

Issue a DeprecationWarning with the given message and stacklevel if the Py_Py3kWarningFlag flag is enabled.

New in version 2.6.

int PyErr_CheckSignals()

This function interacts with Python’s signal handling. It checks whether a signal has been sent to the processes and if so, invokes the corresponding signal handler. If the signal module is supported, this can invoke a signal handler written in Python. In all cases, the default effect for SIGINT is to raise the KeyboardInterrupt exception. If an exception is raised the error indicator is set and the function returns -1; otherwise the function returns 0. The error indicator may or may not be cleared if it was previously set.

void PyErr_SetInterrupt()

This function simulates the effect of a SIGINT signal arriving — the next time PyErr_CheckSignals() is called, KeyboardInterrupt will be raised. It may be called without holding the interpreter
int PySignal_SetWakeupFd(int fd)

This utility function specifies a file descriptor to which a '0' byte will be written whenever a signal is received. It returns the previous such file descriptor. The value -1 disables the feature; this is the initial state. This is equivalent to signal.set_wakeup_fd() in Python, but without any error checking. fd should be a valid file descriptor. The function should only be called from the main thread.

New in version 2.6.

PyObject* PyErr_NewException(char *name, PyObject *base, PyObject *dict)

This utility function creates and returns a new exception class. The name argument must be the name of the new exception, a C string of the form module.classname. The base and dict arguments are normally NULL. This creates a class object derived from Exception (accessible in C as PyExc_Exception).

The __module__ attribute of the new class is set to the first part (up to the last dot) of the name argument, and the class name is set to the last part (after the last dot). The base argument can be used to specify alternate base classes; it can either be only one class or a tuple of classes. The dict argument can be used to specify a dictionary of class variables and methods.

PyObject* PyErr_NewExceptionWithDoc(char *name, char *doc, PyObject *base, PyObject *dict)

Same as PyErr_NewException(), except that the new exception class can easily be given a docstring: If doc is non-NULL, it will be used as the docstring for the exception class.
New in version 2.7.

void PyErr_WriteUnraisable(PyObject *obj)

This utility function prints a warning message to sys.stderr when an exception has been set but it is impossible for the interpreter to actually raise the exception. It is used, for example, when an exception occurs in an _del__() method.

The function is called with a single argument obj that identifies the context in which the unraisable exception occurred. If possible, the repr of obj will be printed in the warning message.
Unicode Exception Objects

The following functions are used to create and modify Unicode exceptions from C.

**PyObject** * PyUnicodeDecodeError_Create(const char *encoding, const char *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeDecodeError` object with the attributes `encoding`, `object`, `length`, `start`, `end` and `reason`.

**PyObject** * PyUnicodeEncodeError_Create(const char *encoding, const Py_UNICODE *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeEncodeError` object with the attributes `encoding`, `object`, `length`, `start`, `end` and `reason`.

**PyObject** * PyUnicodeTranslateError_Create(const Py_UNICODE *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeTranslateError` object with the attributes `object`, `length`, `start`, `end` and `reason`.

**PyObject** * PyUnicodeDecodeError_GetEncoding(PyObject *exc)

**PyObject** * PyUnicodeEncodeError_GetEncoding(PyObject *exc)

Return the `encoding` attribute of the given exception object.

**PyObject** * PyUnicodeDecodeError_GetObject(PyObject *exc)

**PyObject** * PyUnicodeEncodeError_GetObject(PyObject *exc)

**PyObject** * PyUnicodeTranslateError_GetObject(PyObject *exc)

Return the `object` attribute of the given exception object.

int PyUnicodeDecodeError_GetStart(PyObject *exc, Py_ssize_t *start)
int PyUnicodeEncodeError_GetStart(PyObject *exc,
Py_ssize_t *start
int PyUnicodeTranslateError_GetStart(PyObject *exc, Py_ssize_t *start)
    Get the start attribute of the given exception object and place it into *start. start must not be NULL. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_SetStart(PyObject *exc, Py_ssize_t start)
int PyUnicodeEncodeError_SetStart(PyObject *exc, Py_ssize_t start)
int PyUnicodeTranslateError_SetStart(PyObject *exc, Py_ssize_t start)
    Set the start attribute of the given exception object to start. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_GetEnd(PyObject *exc, Py_ssize_t *end)
int PyUnicodeEncodeError_GetEnd(PyObject *exc, Py_ssize_t *end)
int PyUnicodeTranslateError_GetEnd(PyObject *exc, Py_ssize_t *end)
    Get the end attribute of the given exception object and place it into *end. end must not be NULL. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_SetEnd(PyObject *exc, Py_ssize_t end)
int PyUnicodeEncodeError_SetEnd(PyObject *exc, Py_ssize_t end)
int PyUnicodeTranslateError_SetEnd(PyObject *exc, Py_ssize_t end)
    Set the end attribute of the given exception object to end. Return 0 on success, -1 on failure.

PyObject* PyUnicodeDecodeError_GetReason(PyObject *exc)
PyObject* PyUnicodeEncodeError_GetReason(PyObject *exc)
PyObject* PyUnicodeTranslateError_GetReason(PyObject *exc)
Return the *reason* attribute of the given exception object.

```c
int PyUnicodeDecodeError_SetReason(PyObject *exc, const char *reason)

int PyUnicodeEncodeError_SetReason(PyObject *exc, const char *reason)

int PyUnicodeTranslateError_SetReason(PyObject *exc, const char *reason)
```

Set the *reason* attribute of the given exception object to *reason*. Return 0 on success, -1 on failure.
Recursion Control

These two functions provide a way to perform safe recursive calls at the C level, both in the core and in extension modules. They are needed if the recursive code does not necessarily invoke Python code (which tracks its recursion depth automatically).

```c
int Py_EnterRecursiveCall(const char *where)
```

Marks a point where a recursive C-level call is about to be performed.

If `USE_STACKCHECK` is defined, this function checks if the OS stack overflowed using `PyOS_CheckStack()`. In this case, it sets a `MemoryError` and returns a nonzero value.

The function then checks if the recursion limit is reached. If this is the case, a `RuntimeError` is set and a nonzero value is returned. Otherwise, zero is returned.

*where* should be a string such as " in instance check" to be concatenated to the `RuntimeError` message caused by the recursion depth limit.

```c
void Py_LeaveRecursiveCall()
```

Ends a `Py_EnterRecursiveCall()`. Must be called once for each successful invocation of `Py_EnterRecursiveCall()`. 

**Standard Exceptions**

All standard Python exceptions are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. For completeness, here are all the variables:

<table>

</tbody>
</table>

Notes:

1. This is a base class for other standard exceptions.

2. This is the same as `weakref.ReferenceError`.

3. Only defined on Windows; protect code that uses this by testing that the preprocessor macro `MS_WINDOWS` is defined.

4. *New in version 2.5.*
String Exceptions

*Changed in version 2.6:* All exceptions to be raised or caught must be derived from `BaseException`. Trying to raise a string exception now raises `TypeError`. 
The functions in this chapter perform various utility tasks, ranging from helping C code be more portable across platforms, using Python modules from C, and parsing function arguments and constructing Python values from C values.

- Operating System Utilities
- System Functions
- Process Control
- Importing Modules
- Data marshalling support
- Parsing arguments and building values
- String conversion and formatting
- Reflection
- Codec registry and support functions
  - Codec lookup API
  - Registry API for Unicode encoding error handlers
int Py_FdIsInteractive(FILE *fp, const char *filename)

Return true (nonzero) if the standard I/O file fp with name filename is deemed interactive. This is the case for files for which isatty(fileno(fp)) is true. If the global flag Py_InteractiveFlag is true, this function also returns true if the filename pointer is NULL or if the name is equal to one of the strings '<stdin>' or '???'.

void PyOS_AfterFork()

Function to update some internal state after a process fork; this should be called in the new process if the Python interpreter will continue to be used. If a new executable is loaded into the new process, this function does not need to be called.

int PyOS_CheckStack()

Return true when the interpreter runs out of stack space. This is a reliable check, but is only available when USE_STACKCHECK is defined (currently on Windows using the Microsoft Visual C++ compiler). USE_STACKCHECK will be defined automatically; you should never change the definition in your own code.

PyOS_sighandler_t PyOS_getsig(int i)

Return the current signal handler for signal i. This is a thin wrapper around either sigaction() or signal(). Do not call those functions directly! PyOS_sighandler_t is a typedef alias for void (*)(int).

PyOS_sighandler_t PyOS_setsig(int i, PyOS_sighandler_t h)

Set the signal handler for signal i to be h; return the old signal handler. This is a thin wrapper around either sigaction() or signal(). Do not call those functions directly! PyOS_sighandler_t
is a typedef alias for `void (*)(int)`.
System Functions

These are utility functions that make functionality from the `sys` module accessible to C code. They all work with the current interpreter thread’s `sys` module’s dict, which is contained in the internal thread state structure.

`PyObject *PySys_GetObject(char *name)`

*Return value: Borrowed reference.*
Return the object `name` from the `sys` module or `NULL` if it does not exist, without setting an exception.

`FILE *PySys_GetFile(char *name, FILE *def)`

Return the `FILE*` associated with the object `name` in the `sys` module, or `def` if `name` is not in the module or is not associated with a `FILE*`.

`int PySys_SetObject(char *name, PyObject *v)`

Set `name` in the `sys` module to `v` unless `v` is `NULL`, in which case `name` is deleted from the sys module. Returns `0` on success, `-1` on error.

`void PySys_ResetWarnOptions()`

Reset `sys.warnoptions` to an empty list.

`void PySys_AddWarnOption(char *s)`

Append `s` to `sys.warnoptions`.

`void PySys_SetPath(char *path)`

Set `sys.path` to a list object of paths found in `path` which should be a list of paths separated with the platform’s search path delimiter (`:` on Unix, `;` on Windows).
void PySys_WriteStdout(const char *format, ...)
Write the output string described by format to sys.stdout. No exceptions are raised, even if truncation occurs (see below).

format should limit the total size of the formatted output string to 1000 bytes or less – after 1000 bytes, the output string is truncated. In particular, this means that no unrestricted “%s” formats should occur; these should be limited using “%.<N>s” where <N> is a decimal number calculated so that <N> plus the maximum size of other formatted text does not exceed 1000 bytes. Also watch out for “%f”, which can print hundreds of digits for very large numbers.

If a problem occurs, or sys.stdout is unset, the formatted message is written to the real (C level) stdout.

void PySys_WriteStderr(const char *format, ...)
As above, but write to sys.stderr or stderr instead.
void Py_FatalError(const char *message)

Print a fatal error message and kill the process. No cleanup is performed. This function should only be invoked when a condition is detected that would make it dangerous to continue using the Python interpreter; e.g., when the object administration appears to be corrupted. On Unix, the standard C library function abort() is called which will attempt to produce a core file.

void Py_Exit(int status)

Exit the current process. This calls Py_Finalize() and then calls the standard C library function exit(status).

int Py_AtExit(void (*func)())

Register a cleanup function to be called by Py_Finalize(). The cleanup function will be called with no arguments and should return no value. At most 32 cleanup functions can be registered. When the registration is successful, Py_AtExit() returns 0; on failure, it returns -1. The cleanup function registered last is called first. Each cleanup function will be called at most once. Since Python's internal finalization will have completed before the cleanup function, no Python APIs should be called by func.
Importing Modules

**PyObject** `PyImport_ImportModule`(const char *name)

*Return value: New reference.*

This is a simplified interface to `PyImport_ImportModuleEx()` below, leaving the `globals` and `locals` arguments set to `NULL` and `level` set to 0. When the `name` argument contains a dot (when it specifies a submodule of a package), the `fromlist` argument is set to the list `['*']` so that the return value is the named module rather than the top-level package containing it as would otherwise be the case. (Unfortunately, this has an additional side effect when `name` in fact specifies a subpackage instead of a submodule: the submodules specified in the package’s `__all__` variable are loaded.) Return a new reference to the imported module, or `NULL` with an exception set on failure. Before Python 2.4, the module may still be created in the failure case — examine `sys.modules` to find out. Starting with Python 2.4, a failing import of a module no longer leaves the module in `sys.modules`.

*Changed in version 2.4:* Failing imports remove incomplete module objects.

*Changed in version 2.6:* Always uses absolute imports.

**PyObject** `PyImport_ImportModuleNoBlock`(const char *name)

This version of `PyImport_ImportModule()` does not block. It’s intended to be used in C functions that import other modules to execute a function. The import may block if another thread holds the import lock. The function `PyImport_ImportModuleNoBlock()` never blocks. It first tries to fetch the module from `sys.modules` and falls back to `PyImport_ImportModule()` unless the lock is held, in which case the function will raise an `ImportError`. 
New in version 2.6.

PyObject* PyImport_ImportModuleEx(char *name,  
PyObject *globals, PyObject *locals, PyObject *fromlist)

Import a module. This is best described by referring to the built-in Python function __import__() as the standard __import__() function calls this function directly.

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure (before Python 2.4, the module may still be created in this case). Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.

Changed in version 2.4: Failing imports remove incomplete module objects.

Changed in version 2.6: The function is an alias for PyImport_ImportModuleLevel() with -1 as level, meaning relative import.

PyObject* PyImport_ImportModuleLevel(char *name,  
PyObject *globals, PyObject *locals, PyObject *fromlist, int level)

Import a module. This is best described by referring to the built-in Python function __import__() as the standard __import__() function calls this function directly.

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure. Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.
New in version 2.5.

PyObject* PyImport_Import(PyObject *name)

This is a higher-level interface that calls the current “import hook function”. It invokes the __import__() function from the __builtins__ of the current globals. This means that the import is done using whatever import hooks are installed in the current environment, e.g. by rexec or ihooks.

Changed in version 2.6: Always uses absolute imports.

PyObject* PyImport_ReloadModule(PyObject *m)

Reload a module. This is best described by referring to the built-in Python function reload(), as the standard reload() function calls this function directly. Return a new reference to the reloaded module, or NULL with an exception set on failure (the module still exists in this case).

PyObject* PyImport_AddModule(const char *name)

Return value: Borrowed reference.
Return the module object corresponding to a module name. The name argument may be of the form package.module. First check the modules dictionary if there’s one there, and if not, create a new one and insert it in the modules dictionary. Return NULL with an exception set on failure.

Note: This function does not load or import the module; if the module wasn’t already loaded, you will get an empty module object. Use PyImport_ImportModule() or one of its variants to import a module. Package structures implied by a dotted name for name are not created if not already present.
PyObject* PyImport_ExecCodeModule(char *name, PyObject *co)

*Return value: New reference.*

Given a module name (possibly of the form `package.module`) and a code object read from a Python bytecode file or obtained from the built-in function `compile()`, load the module. Return a new reference to the module object, or `NULL` with an exception set if an error occurred. Before Python 2.4, the module could still be created in error cases. Starting with Python 2.4, `name` is removed from `sys.modules` in error cases, and even if `name` was already in `sys.modules` on entry to `PyImport_ExecCodeModule()`. Leaving incompletely initialized modules in `sys.modules` is dangerous, as imports of such modules have no way to know that the module object is an unknown (and probably damaged with respect to the module author’s intents) state.

The module’s `__file__` attribute will be set to the code object’s `co_filename`.

This function will reload the module if it was already imported. See `PyImport_ReloadModule()` for the intended way to reload a module.

If `name` points to a dotted name of the form `package.module`, any package structures not already created will still not be created.

*Changed in version 2.4: name is removed from sys.modules in error cases.*

PyObject* PyImport_ExecCodeModuleEx(char *name, PyObject *co, char *pathname)

*Return value: New reference.*

Like `PyImport_ExecCodeModule()`, but the `__file__` attribute of the module object is set to `pathname` if it is non-`NULL`. 
long PyImport_GetMagicNumber()
    Return the magic number for Python bytecode files (a.k.a. .pyc and .pyo files). The magic number should be present in the first four bytes of the bytecode file, in little-endian byte order.

PyObject* PyImport_GetModuleDict()
    Return value: Borrowed reference.
    Return the dictionary used for the module administration (a.k.a. sys.modules). Note that this is a per-interpreter variable.

PyObject* PyImport_GetImporter(PyObject *path)
    Return an importer object for a sys.path/pkg.__path__ item path, possibly by fetching it from the sys.path_importer_cache dict. If it wasn’t yet cached, traverse sys.path_hooks until a hook is found that can handle the path item. Return None if no hook could; this tells our caller it should fall back to the built-in import mechanism. Cache the result in sys.path_importer_cache. Return a new reference to the importer object.

    New in version 2.6.

void _PyImport_Init()
    Initialize the import mechanism. For internal use only.

void PyImport_Cleanup()
    Empty the module table. For internal use only.

void _PyImport_Fini()
    Finalize the import mechanism. For internal use only.

PyObject* _PyImport_FindExtension(char *, char *)
    For internal use only.

PyObject* _PyImport_FixupExtension(char *, char *)
    For internal use only.
int PyImport_ImportFrozenModule(char *name)
    Load a frozen module named name. Return 1 for success, 0 if the module is not found, and -1 with an exception set if the initialization failed. To access the imported module on a successful load, use PyImport_ImportModule(). (Note the misnomer — this function would reload the module if it was already imported.)

struct _frozen
    This is the structure type definition for frozen module descriptors, as generated by the freeze utility (see Tools/freeze/ in the Python source distribution). Its definition, found in Include/import.h, is:

```
struct _frozen {
    char *name;
    unsigned char *code;
    int size;
};
```

struct _frozen* PyImport_FrozenModules
    This pointer is initialized to point to an array of struct _frozen records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

int PyImport_AppendInittab(const char *name, void (*initfunc)(void))
    Add a single module to the existing table of built-in modules. This is a convenience wrapper around PyImport_ExtendInittab(), returning -1 if the table could not be extended. The new module can be imported by the name name, and uses the function initfunc as the initialization function called on the first attempted import. This should be called before Py_Initialize().
struct _inittab

Structure describing a single entry in the list of built-in modules. Each of these structures gives the name and initialization function for a module built into the interpreter. Programs which embed Python may use an array of these structures in conjunction with PyImport_ExtendInittab() to provide additional built-in modules. The structure is defined in `Include/import.h` as:

```c
struct _inittab {
    char *name;
    void (*initfunc)(void);
};
```

int PyImport_ExtendInittab(struct _inittab *newtab)

Add a collection of modules to the table of built-in modules. The `newtab` array must end with a sentinel entry which contains `NULL` for the `name` field; failure to provide the sentinel value can result in a memory fault. Returns 0 on success or -1 if insufficient memory could be allocated to extend the internal table. In the event of failure, no modules are added to the internal table. This should be called before `Py_Initialize()`. 
Data marshalling support

These routines allow C code to work with serialized objects using the same data format as the `marshal` module. There are functions to write data into the serialization format, and additional functions that can be used to read the data back. Files used to store marshalled data must be opened in binary mode.

Numeric values are stored with the least significant byte first.

The module supports two versions of the data format: version 0 is the historical version, version 1 (new in Python 2.4) shares interned strings in the file, and upon unmarshalling. Version 2 (new in Python 2.5) uses a binary format for floating point numbers. `Py_MARSHAL_VERSION` indicates the current file format (currently 2).

```c
void PyMarshal_WriteLongToFile(long value, FILE *file, int version)
    Marshal a long integer, value, to file. This will only write the least-significant 32 bits of value; regardless of the size of the native long type.

    Changed in version 2.4: version indicates the file format.
```

```c
void PyMarshal_WriteObjectToFile(PyObject *value, FILE *file, int version)
    Marshal a Python object, value, to file.

    Changed in version 2.4: version indicates the file format.
```

```c
PyObject* PyMarshal_WriteObjectToString(PyObject *value, int version)
    Return a string object containing the marshalled representation of
```
value.

*Changed in version 2.4*: `version` indicates the file format.

The following functions allow marshalled values to be read back in.

XXX What about error detection? It appears that reading past the end of the file will always result in a negative numeric value (where that's relevant), but it's not clear that negative values won't be handled properly when there's no error. What's the right way to tell? Should only non-negative values be written using these routines?

```c
long PyMarshal_ReadLongFromFile(FILE *file)
    Return a C `long` from the data stream in a `FILE*` opened for reading. Only a 32-bit value can be read in using this function, regardless of the native size of `long`.
```

```c
int PyMarshal_ReadShortFromFile(FILE *file)
    Return a C `short` from the data stream in a `FILE*` opened for reading. Only a 16-bit value can be read in using this function, regardless of the native size of `short`.
```

```c
PyObject* PyMarshal_ReadObjectFromFile(FILE *file)
    Return a Python object from the data stream in a `FILE*` opened for reading. On error, sets the appropriate exception (`EOFError` or `TypeError`) and returns `NULL`.
```

```c
PyObject* PyMarshal_ReadLastObjectFromFile(FILE *file)
    Return a Python object from the data stream in a `FILE*` opened for reading. Unlike `PyMarshal_ReadObjectFromFile()`, this function assumes that no further objects will be read from the file, allowing it to aggressively load file data into memory so that the de-serialization can operate from data in memory rather than reading
a byte at a time from the file. Only use these variant if you are certain that you won’t be reading anything else from the file. On error, sets the appropriate exception (\texttt{EOFError} or \texttt{TypeError}) and returns \texttt{NULL}.

\textbf{PyObject*} \texttt{PyMarshal_ReadObjectFromString(char *string, Py_ssize_t len)}

\textit{Return value: New reference.}

Return a Python object from the data stream in a character buffer containing \texttt{len} bytes pointed to by \texttt{string}. On error, sets the appropriate exception (\texttt{EOFError} or \texttt{TypeError}) and returns \texttt{NULL}.

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \texttt{len}. This might require changes in your code for properly supporting 64-bit systems.
Parsing arguments and building values

These functions are useful when creating your own extensions functions and methods. Additional information and examples are available in Extending and Embedding the Python Interpreter.

The first three of these functions described, `PyArg_ParseTuple()`, `PyArg_ParseTupleAndKeywords()`, and `PyArg_Parse()`, all use format strings which are used to tell the function about the expected arguments. The format strings use the same syntax for each of these functions.

A format string consists of zero or more “format units.” A format unit describes one Python object; it is usually a single character or a parenthesized sequence of format units. With a few exceptions, a format unit that is not a parenthesized sequence normally corresponds to a single address argument to these functions. In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that matches the format unit; and the entry in [square] brackets is the type of the C variable(s) whose address should be passed.

These formats allow accessing an object as a contiguous chunk of memory. You don’t have to provide raw storage for the returned unicode or bytes area. Also, you won’t have to release any memory yourself, except with the `es`, `es#`, `et` and `et#` formats.

`s` (string or Unicode) [const char *]
Convert a Python string or Unicode object to a C pointer to a character string. You must not provide storage for the string itself; a pointer to an existing string is stored into the character pointer variable whose address you pass. The C string is NUL-
terminated. The Python string must not contain embedded NULL bytes; if it does, a `TypeError` exception is raised. Unicode objects are converted to C strings using the default encoding. If this conversion fails, a `UnicodeError` is raised.

`s#` (string, Unicode or any read buffer compatible object) [const char *, int (or `Py_ssize_t`, see below)]

This variant on `s` stores into two C variables, the first one a pointer to a character string, the second one its length. In this case the Python string may contain embedded null bytes. Unicode objects pass back a pointer to the default encoded string version of the object if such a conversion is possible. All other read-buffer compatible objects pass back a reference to the raw internal data representation.

Starting with Python 2.5 the type of the length argument can be controlled by defining the macro `PY_SSIZE_T_CLEAN` before including `Python.h`. If the macro is defined, length is a `Py_ssize_t` rather than an int.

`s*` (string, Unicode, or any buffer compatible object) [Py_buffer]

Similar to `s#`, this code fills a Py_buffer structure provided by the caller. The buffer gets locked, so that the caller can subsequently use the buffer even inside a `Py_BEGIN_ALLOW_THREADS` block; the caller is responsible for calling `PyBuffer_Release` with the structure after it has processed the data.

*New in version 2.6.*

`z` (string, Unicode or `None`) [const char *]

Like `s`, but the Python object may also be `None`, in which case the C pointer is set to `NULL`.

`z#` (string, Unicode, `None` or any read buffer compatible object) [const char *, int]
This is to \texttt{s\#} as \texttt{z} is to \texttt{s}.

\texttt{z*} (string, Unicode, \texttt{None} or any buffer compatible object) [Py_buffer]

This is to \texttt{s*} as \texttt{z} is to \texttt{s}.

\textit{New in version 2.6.}

\texttt{u} (Unicode) [Py\_UNICODE \*]

Convert a Python Unicode object to a C pointer to a NUL-terminated buffer of 16-bit Unicode (UTF-16) data. As with \texttt{s}, there is no need to provide storage for the Unicode data buffer; a pointer to the existing Unicode data is stored into the \texttt{Py\_UNICODE} pointer variable whose address you pass.

\texttt{u\#} (Unicode) [Py\_UNICODE \*, int]

This variant on \texttt{u} stores into two C variables, the first one a pointer to a Unicode data buffer, the second one its length. Non-Unicode objects are handled by interpreting their read-buffer pointer as pointer to a \texttt{Py\_UNICODE} array.

\texttt{es} (string, Unicode or character buffer compatible object) [const char *encoding, char **buffer]

This variant on \texttt{s} is used for encoding Unicode and objects convertible to Unicode into a character buffer. It only works for encoded data without embedded NUL bytes.

This format requires two arguments. The first is only used as input, and must be a \texttt{const char*} which points to the name of an encoding as a NUL-terminated string, or \texttt{NULL}, in which case the default encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a \texttt{char**}; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument.

\texttt{PyArg\_ParseTuple()} will allocate a buffer of the needed size, copy
the encoded data into this buffer and adjust *buffer to reference the newly allocated storage. The caller is responsible for calling PyMem_Free() to free the allocated buffer after use.

et (string, Unicode or character buffer compatible object) [const char *encoding, char **buffer]
Same as es except that 8-bit string objects are passed through without recoding them. Instead, the implementation assumes that the string object uses the encoding passed in as parameter.

es# (string, Unicode or character buffer compatible object) [const char *encoding, char **buffer, int *buffer_length]
This variant on s# is used for encoding Unicode and objects convertible to Unicode into a character buffer. Unlike the es format, this variant allows input data which contains NUL characters.

It requires three arguments. The first is only used as input, and must be a const char* which points to the name of an encoding as a NUL-terminated string, or NULL, in which case the default encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a char**; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument. The third argument must be a pointer to an integer; the referenced integer will be set to the number of bytes in the output buffer.

There are two modes of operation:

If *buffer points a NULL pointer, the function will allocate a buffer of the needed size, copy the encoded data into this buffer and set *buffer to reference the newly allocated storage. The caller is responsible for calling PyMem_Free() to free the allocated buffer after usage.
If *buffer points to a non-NULL pointer (an already allocated buffer), PyArg_ParseTuple() will use this location as the buffer and interpret the initial value of *buffer_length as the buffer size. It will then copy the encoded data into the buffer and NUL-terminate it. If the buffer is not large enough, a TypeError will be set. Note: starting from Python 3.6 a ValueError will be set. In both cases, *buffer_length is set to the length of the encoded data without the trailing NUL byte.

et# (string, Unicode or character buffer compatible object) [const char *encoding, char **buffer, int *buffer_length]
Same as es# except that string objects are passed through without recoding them. Instead, the implementation assumes that the string object uses the encoding passed in as parameter.

b (integer) [unsigned char]
Convert a nonnegative Python integer to an unsigned tiny int, stored in a C unsigned char.

B (integer) [unsigned char]
Convert a Python integer to a tiny int without overflow checking, stored in a C unsigned char.

New in version 2.3.

h (integer) [short int]
Convert a Python integer to a C short int.

H (integer) [unsigned short int]
Convert a Python integer to a C unsigned short int, without overflow checking.

New in version 2.3.

i (integer) [int]
Convert a Python integer to a plain C \texttt{int}.

\texttt{I} (integer) [\texttt{unsigned int}]
Convert a Python integer to a C \texttt{unsigned int}, without overflow checking.

\textit{New in version 2.3.}

\texttt{l} (integer) [\texttt{long int}]
Convert a Python integer to a C \texttt{long int}.

\texttt{k} (integer) [\texttt{unsigned long}]
Convert a Python integer or long integer to a C \texttt{unsigned long} without overflow checking.

\textit{New in version 2.3.}

\texttt{L} (integer) [\texttt{PY_LONG_LONG}]
Convert a Python integer to a C \texttt{long long}. This format is only available on platforms that support \texttt{long long} (or \texttt{\_int64} on Windows).

\texttt{K} (integer) [\texttt{unsigned PY_LONG_LONG}]
Convert a Python integer or long integer to a C \texttt{unsigned long long} without overflow checking. This format is only available on platforms that support \texttt{unsigned long long} (or \texttt{unsigned \_int64} on Windows).

\textit{New in version 2.3.}

\texttt{n} (integer) [\texttt{Py_ssize_t}]
Convert a Python integer or long integer to a C \texttt{Py_ssize_t}.

\textit{New in version 2.5.}

\texttt{c} (string of length 1) [\texttt{char}]
Convert a Python character, represented as a string of length 1,
to a C char.

f (float) [float]
    Convert a Python floating point number to a C float.

d (float) [double]
    Convert a Python floating point number to a C double.

p (complex) [Py_complex]
    Convert a Python complex number to a C Py_complex structure.

0 (object) [PyObject *]
    Store a Python object (without any conversion) in a C object pointer. The C program thus receives the actual object that was passed. The object’s reference count is not increased. The pointer stored is not NULL.

0! (object) [typeobject, PyObject *]
    Store a Python object in a C object pointer. This is similar to 0, but takes two C arguments: the first is the address of a Python type object, the second is the address of the C variable (of type PyObject*) into which the object pointer is stored. If the Python object does not have the required type, TypeError is raised.

0& (object) [converter, anything]
    Convert a Python object to a C variable through a converter function. This takes two arguments: the first is a function, the second is the address of a C variable (of arbitrary type), converted to void *.

    status = converter(object, address);

where object is the Python object to be converted and address is the void* argument that was passed to the PyArg_Parse*() function. The returned status should be 1 for a successful conversion and 0 if the conversion has failed. When the
conversion fails, the converter function should raise an exception and leave the content of address unmodified.

\texttt{s} (string) [PyStringObject *]
Like o but requires that the Python object is a string object. Raises \texttt{TypeError} if the object is not a string object. The C variable may also be declared as \texttt{PyObject *}.

\texttt{u} (Unicode string) [PyUnicodeObject *]
Like o but requires that the Python object is a Unicode object. Raises \texttt{TypeError} if the object is not a Unicode object. The C variable may also be declared as \texttt{PyObject *}.

\texttt{t\#} (read-only character buffer) [char *, int]
Like \texttt{s\#}, but accepts any object which implements the read-only buffer interface. The char* variable is set to point to the first byte of the buffer, and the int is set to the length of the buffer. Only single-segment buffer objects are accepted; \texttt{TypeError} is raised for all others.

\texttt{w} (read-write character buffer) [char *]
Similar to \texttt{s}, but accepts any object which implements the read-write buffer interface. The caller must determine the length of the buffer by other means, or use \texttt{w\#} instead. Only single-segment buffer objects are accepted; \texttt{TypeError} is raised for all others.

\texttt{w\#} (read-write character buffer) [char *, Py_ssize_t]
Like \texttt{s\#}, but accepts any object which implements the read-write buffer interface. The char * variable is set to point to the first byte of the buffer, and the Py_ssize_t is set to the length of the buffer. Only single-segment buffer objects are accepted; \texttt{TypeError} is raised for all others.

\texttt{w*} (read-write byte-oriented buffer) [Py_buffer]
This is to \texttt{w} what \texttt{s*} is to \texttt{s}. 

New in version 2.6.

(items) (tuple) [matching-items]

The object must be a Python sequence whose length is the number of format units in items. The C arguments must correspond to the individual format units in items. Format units for sequences may be nested.

Note: Prior to Python version 1.5.2, this format specifier only accepted a tuple containing the individual parameters, not an arbitrary sequence. Code which previously caused TypeError to be raised here may now proceed without an exception. This is not expected to be a problem for existing code.

It is possible to pass Python long integers where integers are requested; however no proper range checking is done — the most significant bits are silently truncated when the receiving field is too small to receive the value (actually, the semantics are inherited from downcasts in C — your mileage may vary).

A few other characters have a meaning in a format string. These may not occur inside nested parentheses. They are:

\|

Indicates that the remaining arguments in the Python argument list are optional. The C variables corresponding to optional arguments should be initialized to their default value — when an optional argument is not specified, PyArg_ParseTuple() does not touch the contents of the corresponding C variable(s).

; The list of format units ends here; the string after the colon is used as the function name in error messages (the “associated value” of the exception that PyArg_ParseTuple() raises).
The list of format units ends here; the string after the semicolon is used as the error message instead of the default error message. : and ; mutually exclude each other.

Note that any Python object references which are provided to the caller are borrowed references; do not decrement their reference count!

Additional arguments passed to these functions must be addresses of variables whose type is determined by the format string; these are used to store values from the input tuple. There are a few cases, as described in the list of format units above, where these parameters are used as input values; they should match what is specified for the corresponding format unit in that case.

For the conversion to succeed, the arg object must match the format and the format must be exhausted. On success, the PyArg_Parse*() functions return true, otherwise they return false and raise an appropriate exception. When the PyArg_Parse*() functions fail due to conversion failure in one of the format units, the variables at the addresses corresponding to that and the following format units are left untouched.

int PyArg_ParseTuple(PyObject *args, const char *format, ...)
   Parse the parameters of a function that takes only positional parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.

int PyArg_VaParse(PyObject *args, const char *format, va_list vargs)
   Identical to PyArg_ParseTuple(), except that it accepts a va_list rather than a variable number of arguments.

int PyArg_ParseTupleAndKeywords(PyObject *args, PyObject *kw, const char *format, char *keywords[], ...)
Parse the parameters of a function that takes both positional and keyword parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.

```c
int PyArg_ParseTupleAndKeywords(PyObject *args, PyObject *kw, const char *format, char *keywords[], va_list vargs)

Identical to PyArg_ParseTupleAndKeywords(), except that it accepts a va_list rather than a variable number of arguments.
```

```c
int PyArg_Parse(PyObject *args, const char *format, ...)  

Function used to deconstruct the argument lists of “old-style” functions — these are functions which use the METH_OLDARGS parameter parsing method. This is not recommended for use in parameter parsing in new code, and most code in the standard interpreter has been modified to no longer use this for that purpose. It does remain a convenient way to decompose other tuples, however, and may continue to be used for that purpose.
```

```c
int PyArg_UnpackTuple(PyObject *args, const char *name, Py_ssize_t min, Py_ssize_t max, ...)  

A simpler form of parameter retrieval which does not use a format string to specify the types of the arguments. Functions which use this method to retrieve their parameters should be declared as METH_VARARGS in function or method tables. The tuple containing the actual parameters should be passed as args; it must actually be a tuple. The length of the tuple must be at least min and no more than max; min and max may be equal. Additional arguments must be passed to the function, each of which should be a pointer to a PyObject* variable; these will be filled in with the values from args; they will contain borrowed references. The variables which correspond to optional parameters not given by args will not be filled in; these should be initialized by the caller. This function returns true on success and false if args is not a
tuple or contains the wrong number of elements; an exception will be set if there was a failure.

This is an example of the use of this function, taken from the sources for the _weakref helper module for weak references:

```c
static PyObject *
weakref_ref(PyObject *self, PyObject *args)
{
    PyObject *object;
    PyObject *callback = NULL;
    PyObject *result = NULL;

    if (PyArg_UnpackTuple(args, "ref", 1, 2, &object, &callback))
        result = PyWeakref_NewRef(object, callback);

    return result;
}
```

The call to `PyArg_UnpackTuple()` in this example is entirely equivalent to this call to `PyArg_ParseTuple()`:

```c
PyArg_ParseTuple(args, "O|O:ref", &object, &callback)
```

*New in version 2.2.*

*Changed in version 2.5:* This function used an `int` type for `min` and `max`. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** `Py_BuildValue` (const char *format, ...)

*Return value: New reference.*

Create a new value based on a format string similar to those accepted by the `PyArg_Parse*()` family of functions and a sequence of values. Returns the value or `NULL` in the case of an error; an exception will be raised if `NULL` is returned.

`Py_BuildValue()` does not always build a tuple. It builds a tuple
only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

When memory buffers are passed as parameters to supply data to build objects, as for the `s` and `s#` formats, the required data is copied. Buffers provided by the caller are never referenced by the objects created by `Py_BuildValue()`. In other words, if your code invokes `malloc()` and passes the allocated memory to `Py_BuildValue()`, your code is responsible for calling `free()` for that memory once `Py_BuildValue()` returns.

In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that the format unit will return; and the entry in [square] brackets is the type of the C value(s) to be passed.

The characters space, tab, colon and comma are ignored in format strings (but not within format units such as `s#`). This can be used to make long format strings a tad more readable.

`s` (string) [char *]
Convert a null-terminated C string to a Python object. If the C string pointer is `NULL`, `None` is used.

`s#` (string) [char *, int]
Convert a C string and its length to a Python object. If the C string pointer is `NULL`, the length is ignored and `None` is returned.

`z` (string or `None`) [char *]
Same as `s`. 
z# (string or None) [char *, int]
   Same as s#.

u (Unicode string) [Py_UNICODE *]
   Convert a null-terminated buffer of Unicode (UCS-2 or UCS-4) data to a Python Unicode object. If the Unicode buffer pointer is NULL, None is returned.

u# (Unicode string) [Py_UNICODE *, int]
   Convert a Unicode (UCS-2 or UCS-4) data buffer and its length to a Python Unicode object. If the Unicode buffer pointer is NULL, the length is ignored and None is returned.

i (integer) [int]
   Convert a plain C int to a Python integer object.

b (integer) [char]
   Convert a plain C char to a Python integer object.

h (integer) [short int]
   Convert a plain C short int to a Python integer object.

l (integer) [long int]
   Convert a C long int to a Python integer object.

B (integer) [unsigned char]
   Convert a C unsigned char to a Python integer object.

H (integer) [unsigned short int]
   Convert a C unsigned short int to a Python integer object.

I (integer/long) [unsigned int]
   Convert a C unsigned int to a Python integer object or a Python long integer object, if it is larger than sys.maxint.
Convert a C unsigned long to a Python integer object or a Python long integer object, if it is larger than \texttt{sys.maxint}.

\texttt{L} (long) [PY\_LONG\_LONG]

Convert a C long \texttt{long} to a Python long integer object. Only available on platforms that support \texttt{long long}.

\texttt{K} (long) [unsigned PY\_LONG\_LONG]

Convert a C unsigned long \texttt{long} to a Python long integer \texttt{long} object. Only available on platforms that support unsigned \texttt{long long}.

\texttt{n} (int) [Py\_ssize\_t]

Convert a C Py\_ssize\_t to a Python integer or long integer.

\textit{New in version 2.5.}

\texttt{c} (string of length 1) [char]

Convert a C int representing a character to a Python string of length 1.

\texttt{d} (float) [double]

Convert a C \texttt{double} to a Python floating point number.

\texttt{f} (float) [float]

Same as \texttt{d}.

\texttt{D} (complex) [Py\_complex \*]

Convert a C Py\_complex structure to a Python complex number.

\texttt{o} (object) [PyObject \*]

Pass a Python object untouched (except for its reference count, which is incremented by one). If the object passed in is a \texttt{NULL} pointer, it is assumed that this was caused because the call producing the argument found an error and set an
exception. Therefore, `Py_BuildValue()` will return `NULL` but won't raise an exception. If no exception has been raised yet, `SystemError` is set.

S (object) [PyObject *]
Same as `O`.

N (object) [PyObject *]
Same as `O`, except it doesn't increment the reference count on the object. Useful when the object is created by a call to an object constructor in the argument list.

O\& (object) [converter, anything]
Convert `anything` to a Python object through a `converter` function. The function is called with `anything` (which should be compatible with `void *`) as its argument and should return a "new" Python object, or `NULL` if an error occurred.

(items) (tuple) [matching-items]
Convert a sequence of C values to a Python tuple with the same number of items.

[items] (list) [matching-items]
Convert a sequence of C values to a Python list with the same number of items.

{items} (dictionary) [matching-items]
Convert a sequence of C values to a Python dictionary. Each pair of consecutive C values adds one item to the dictionary, serving as key and value, respectively.

If there is an error in the format string, the `SystemError` exception is set and `NULL` returned.

`PyObject* Py_VaBuildValue(const char *format, va_list vars)`
Identical to `Py_BuildValue()`, except that it accepts a `va_list`
rather than a variable number of arguments.
String conversion and formatting

Functions for number conversion and formatted string output.

```c
int PyOS_snprintf(char *str, size_t size, const char *format, ...)  
Output not more than size bytes to str according to the format string format and the extra arguments. See the Unix man page snprintf(2).
```

```c
int PyOS_vsnprintf(char *str, size_t size, const char *format, va_list va)  
Output not more than size bytes to str according to the format string format and the variable argument list va. Unix man page vsnprintf(2).
```

PyOS_snprintf() and PyOS_vsnprintf() wrap the Standard C library functions snprintf() and vsnprintf(). Their purpose is to guarantee consistent behavior in corner cases, which the Standard C functions do not.

The wrappers ensure that str[\*size-1] is always '\0' upon return. They never write more than size bytes (including the trailing '\0' into str. Both functions require that str != NULL, size > 0 and format != NULL.

If the platform doesn’t have vsnprintf() and the buffer size needed to avoid truncation exceeds size by more than 512 bytes, Python aborts with a Py_FatalError.

The return value (rv) for these functions should be interpreted as follows:

- When 0 <= rv < size, the output conversion was successful and rv characters were written to str (excluding the trailing '\0')
byte at \texttt{str\texttt{\[*rv\]}}.

- When \texttt{rv >= size}, the output conversion was truncated and a buffer with \texttt{rv + 1} bytes would have been needed to succeed. \texttt{str\texttt{\[*size-1\]}} is '\texttt{\0}' in this case.
- When \texttt{rv < 0}, "something bad happened." \texttt{str\texttt{\[*size-1\]}} is '\texttt{\0}' in this case too, but the rest of \texttt{str} is undefined. The exact cause of the error depends on the underlying platform.

The following functions provide locale-independent string to number conversions.

\texttt{double PyOS\_string\_to\_double(const char \*s, char **endptr, PyObject \*overflow\_exception)}

Convert a string \texttt{s} to a \texttt{double}, raising a Python exception on failure. The set of accepted strings corresponds to the set of strings accepted by Python's \texttt{float()} constructor, except that \texttt{s} must not have leading or trailing whitespace. The conversion is independent of the current locale.

If \texttt{endptr} is \texttt{NULL}, convert the whole string. Raise ValueError and return \texttt{-1.0} if the string is not a valid representation of a floating-point number.

If \texttt{endptr} is not \texttt{NULL}, convert as much of the string as possible and set \texttt{*endptr} to point to the first unconverted character. If no initial segment of the string is the valid representation of a floating-point number, set \texttt{*endptr} to point to the beginning of the string, raise ValueError, and return \texttt{-1.0}.

If \texttt{s} represents a value that is too large to store in a float (for example, "1e500" is such a string on many platforms) then if \texttt{overflow\_exception} is \texttt{NULL} return \texttt{Py\_HUGE\_VAL} (with an appropriate sign) and don't set any exception. Otherwise, \texttt{overflow\_exception} must point to a Python exception object;
raise that exception and return -1.0. In both cases, set *endptr to point to the first character after the converted value.

If any other error occurs during the conversion (for example an out-of-memory error), set the appropriate Python exception and return -1.0.

*New in version 2.7.*

double **PyOS_ascii_strtod**(const char *nptr, char **endptr)

Convert a string to a double. This function behaves like the Standard C function **strtod()** does in the C locale. It does this without changing the current locale, since that would not be thread-safe.

**PyOS_ascii_strtod()** should typically be used for reading configuration files or other non-user input that should be locale independent.

See the Unix man page **strtod(2)** for details.

*New in version 2.4.*

**Deprecation: since version 2.7:** Use **PyOS_string_to_double()** instead.

char* **PyOS_ascii_formatd**(char *buffer, size_t buf_len, const char *format, double d)

Convert a double to a string using the '.' as the decimal separator. **format** is a printf()-style format string specifying the number format. Allowed conversion characters are 'e', 'E', 'f', 'F', 'g' and 'G'.

The return value is a pointer to buffer with the converted string or
NULL if the conversion failed.

New in version 2.4.

Deprecated since version 2.7: This function is removed in Python 2.7 and 3.1. Use PyOS_double_to_string() instead.

char* PyOS_double_to_string(double val, char format_code, int precision, int flags, int *ptype)

Convert a double val to a string using supplied format_code, precision, and flags.

format_code must be one of 'e', 'E', 'f', 'F', 'g', 'G' or 'r'. For 'r', the supplied precision must be 0 and is ignored. The 'r' format code specifies the standard repr() format.

flags can be zero or more of the values Py_DTSF_SIGN, Py_DTSF_ADD_DOT_0, or Py_DTSF_ALT, or-ed together:

- **Py_DTSF_SIGN** means to always precede the returned string with a sign character, even if val is non-negative.
- **Py_DTSF_ADD_DOT_0** means to ensure that the returned string will not look like an integer.
- **Py_DTSF_ALT** means to apply “alternate” formatting rules. See the documentation for the PyOS_snprintf() '#' specifier for details.

If ptype is non-NULL, then the value it points to will be set to one of Py_DTST_FINITE, Py_DTST_INFINITY, or Py_DTST_NAN, signifying that val is a finite number, an infinite number, or not a number, respectively.

The return value is a pointer to buffer with the converted string or NULL if the conversion failed. The caller is responsible for freeing the returned string by calling PyMem_Free().
New in version 2.7.

double PyOS_ascii_atof(const char *nptr)
    Convert a string to a double in a locale-independent way.

See the Unix man page atof(2) for details.

New in version 2.4.

**Deprecated since version 3.1:** Use PyOS_string_to_double() instead.

char* PyOS_stricmp(char *s1, char *s2)
    Case insensitive comparison of strings. The function works almost identically to strcmp() except that it ignores the case.

New in version 2.6.

char* PyOS_strnicmp(char *s1, char *s2, Py_ssize_t size)
    Case insensitive comparison of strings. The function works almost identically to strncmp() except that it ignores the case.

New in version 2.6.
Reflection

PyObject* PyEval_GetBuiltin()  
*Return value: Borrowed reference.*  
Return a dictionary of the builtins in the current execution frame,  
or the interpreter of the thread state if no frame is currently executing.

PyObject* PyEval_GetLocals()  
*Return value: Borrowed reference.*  
Return a dictionary of the local variables in the current execution frame, or *NULL* if no frame is currently executing.

PyObject* PyEval_GetGlobals()  
*Return value: Borrowed reference.*  
Return a dictionary of the global variables in the current execution frame, or *NULL* if no frame is currently executing.

PyFrameObject* PyEval_GetFrame()  
*Return value: Borrowed reference.*  
Return the current thread state's frame, which is *NULL* if no frame is currently executing.

int PyFrame_GetLineNumber(PyFrameObject *frame)  
Return the line number that *frame* is currently executing.

int PyEval_GetRestricted()  
If there is a current frame and it is executing in restricted mode,  
return true, otherwise false.

const char* PyEval_GetFuncName(PyObject *func)  
Return the name of *func* if it is a function, class or instance object, else the name of *funcs* type.

const char* PyEval_GetFuncDesc(PyObject *func)
Return a description string, depending on the type of `func`. Return values include “()” for functions and methods, ” constructor”, ” instance”, and ” object”. Concatenated with the result of `PyEval_GetFuncName()`, the result will be a description of `func`.
Codec registry and support functions

int PyCodec_Register(PyObject *search_function)

Register a new codec search function.

As side effect, this tries to load the encodings package, if not yet done, to make sure that it is always first in the list of search functions.

int PyCodec_KnownEncoding(const char *encoding)

Return 1 or 0 depending on whether there is a registered codec for the given encoding.

PyObject* PyCodec_Encode(PyObject *object, const char *encoding, const char *errors)

Generic codec based encoding API.

object is passed through the encoder function found for the given encoding using the error handling method defined by errors. errors may be NULL to use the default method defined for the codec. Raises a LookupError if no encoder can be found.

PyObject* PyCodec_Decode(PyObject *object, const char *encoding, const char *errors)

Generic codec based decoding API.

object is passed through the decoder function found for the given encoding using the error handling method defined by errors. errors may be NULL to use the default method defined for the codec. Raises a LookupError if no encoder can be found.
Codec lookup API

In the following functions, the `encoding` string is looked up converted to all lower-case characters, which makes encodings looked up through this mechanism effectively case-insensitive. If no codec is found, a `KeyError` is set and `NULL` returned.

```c
PyObject* PyCodec_Encoder(const char *encoding)
    Get an encoder function for the given `encoding`.

PyObject* PyCodec_Decoder(const char *encoding)
    Get a decoder function for the given `encoding`.

PyObject* PyCodec_IncrementalEncoder(const char *encoding, const char *errors)
    Get an IncrementalEncoder object for the given `encoding`.

PyObject* PyCodec_IncrementalDecoder(const char *encoding, const char *errors)
    Get an IncrementalDecoder object for the given `encoding`.

PyObject* PyCodec_StreamReader(const char *encoding, PyObject *stream, const char *errors)
    Get a StreamReader factory function for the given `encoding`.

PyObject* PyCodec_StreamWriter(const char *encoding, PyObject *stream, const char *errors)
    Get a StreamWriter factory function for the given `encoding`.
```
Registry API for Unicode encoding error handlers

int PyCodec_RegisterError(const char *name, PyObject *error)

Register the error handling callback function error under the given name. This callback function will be called by a codec when it encounters unencodable characters/undecodable bytes and name is specified as the error parameter in the call to the encode/decode function.

The callback gets a single argument, an instance of UnicodeEncodeError, UnicodeDecodeError or UnicodeTranslateError that holds information about the problematic sequence of characters or bytes and their offset in the original string (see Unicode Exception Objects for functions to extract this information). The callback must either raise the given exception, or return a two-item tuple containing the replacement for the problematic sequence, and an integer giving the offset in the original string at which encoding/decoding should be resumed.

Return 0 on success, -1 on error.

PyObject* PyCodec_LookupError(const char *name)

Lookup the error handling callback function registered under name. As a special case NULL can be passed, in which case the error handling callback for “strict” will be returned.

PyObject* PyCodec STRICTErrors(PyObject *exc)

Raise exc as an exception.

PyObject* PyCodec IgnoreErrors(PyObject *exc)

Ignore the unicode error, skipping the faulty input.
PyObject* PyCodec_ReplaceErrors(PyObject *exc)
Replace the unicode encode error with \? or \u+FFFF.

PyObject* PyCodec_XMLCharRefReplaceErrors(PyObject *exc)
Replace the unicode encode error with XML character references.

PyObject* PyCodec_BackslashReplaceErrors(PyObject *exc)
Replace the unicode encode error with backslash escapes (\x, \u and \U).
Abstract Objects Layer

The functions in this chapter interact with Python objects regardless of their type, or with wide classes of object types (e.g. all numerical types, or all sequence types). When used on object types for which they do not apply, they will raise a Python exception.

It is not possible to use these functions on objects that are not properly initialized, such as a list object that has been created by `PyList_New()`, but whose items have not been set to some non-NULL value yet.

- Object Protocol
- Number Protocol
- Sequence Protocol
- Mapping Protocol
- Iterator Protocol
- Old Buffer Protocol
Object Protocol

int PyObject_Print(PyObject *o, FILE *fp, int flags)
Print an object o, on file fp. Returns -1 on error. The flags argument is used to enable certain printing options. The only option currently supported is Py_PRINT_RAW; if given, the str() of the object is written instead of the repr().

int PyObject_HasAttr(PyObject *o, PyObject *attr_name)
Returns 1 if o has the attribute attr_name, and 0 otherwise. This is equivalent to the Python expression hasattr(o, attr_name). This function always succeeds.

int PyObject_HasAttrString(PyObject *o, const char *attr_name)
Returns 1 if o has the attribute attr_name, and 0 otherwise. This is equivalent to the Python expression hasattr(o, attr_name). This function always succeeds.

PyObject* PyObject_GetAttr(PyObject *o, PyObject *attr_name)
Retrieve an attribute named attr_name from object o. Returns the attribute value on success, or NULL on failure. This is the equivalent of the Python expression o.attr_name.

PyObject* PyObject_GetAttrString(PyObject *o, const char *attr_name)
Retrieve an attribute named attr_name from object o. Returns the attribute value on success, or NULL on failure. This is the equivalent of the Python expression o.attr_name.

PyObject* PyObject_GenericGetAttr(PyObject *o, PyObject *name)
Generic attribute getter function that is meant to be put into a type object's `tp_getattro` slot. It looks for a descriptor in the dictionary of classes in the object's MRO as well as an attribute in the object's `__dict__` (if present). As outlined in Implementing Descriptors, data descriptors take preference over instance attributes, while non-data descriptors don't. Otherwise, an `AttributeError` is raised.

```c
int PyObject_SetAttr(PyObject *o, PyObject *attr_name, PyObject *v)
```

Set the value of the attribute named `attr_name`, for object `o`, to the value `v`. Raise an exception and return `-1` on failure; return `0` on success. This is the equivalent of the Python statement `o.attr_name = v`.

If `v` is `NULL`, the attribute is deleted, however this feature is deprecated in favour of using `PyObject_DelAttr()`.

```c
int PyObject_SetAttrString(PyObject *o, const char *attr_name, PyObject *v)
```

Set the value of the attribute named `attr_name`, for object `o`, to the value `v`. Raise an exception and return `-1` on failure; return `0` on success. This is the equivalent of the Python statement `o.attr_name = v`.

If `v` is `NULL`, the attribute is deleted, however this feature is deprecated in favour of using `PyObject_DelAttrString()`.

```c
int PyObject_GenericSetAttr(PyObject *o, PyObject *name, PyObject *value)
```

Generic attribute setter and deleter function that is meant to be put into a type object's `tp_setattro` slot. It looks for a data descriptor in the dictionary of classes in the object's MRO, and if found it takes preference over setting or deleting the attribute in
the instance dictionary. Otherwise, the attribute is set or deleted in the object's `__dict__` (if present). On success, `0` is returned, otherwise an `AttributeError` is raised and `-1` is returned.

```c
int PyObject_DelAttr(PyObject *o, PyObject *attr_name)
    Delete attribute named `attr_name`, for object `o`. Returns `-1` on failure. This is the equivalent of the Python statement `del o.attr_name`.
```

```c
int PyObject_DelAttrString(PyObject *o, const char *attr_name)
    Delete attribute named `attr_name`, for object `o`. Returns `-1` on failure. This is the equivalent of the Python statement `del o.attr_name`.
```

```c
PyObject* PyObject_RichCompare(PyObject *o1, PyObject *o2, int opid)
    Compare the values of `o1` and `o2` using the operation specified by `opid`, which must be one of `Py_LT`, `Py_LE`, `Py_EQ`, `Py_NE`, `Py_GT`, or `Py_GE`, corresponding to `<`, `<=`, `==`, `!=`, `>`, or `>=` respectively. This is the equivalent of the Python expression `o1 op o2`, where `op` is the operator corresponding to `opid`. Returns the value of the comparison on success, or `NULL` on failure.
```

```c
int PyObject_RichCompareBool(PyObject *o1, PyObject *o2, int opid)
    Compare the values of `o1` and `o2` using the operation specified by `opid`, which must be one of `Py_LT`, `Py_LE`, `Py_EQ`, `Py_NE`, `Py_GT`, or `Py_GE`, corresponding to `<`, `<=`, `==`, `!=`, `>`, or `>=` respectively. Returns `-1` on error, `0` if the result is false, `1` otherwise. This is the equivalent of the Python expression `o1 op o2`, where `op` is the operator corresponding to `opid`.
```
**Note:** If \( o1 \) and \( o2 \) are the same object, `PyObject_RichCompareBool()` will always return 1 for `Py_EQ` and 0 for `Py_NE`.

```c
int PyObject_Cmp(PyObject *o1, PyObject *o2, int *result)
```

Compare the values of \( o1 \) and \( o2 \) using a routine provided by \( o1 \), if one exists, otherwise with a routine provided by \( o2 \). The result of the comparison is returned in \( result \). Returns -1 on failure. This is the equivalent of the Python statement `result = cmp(o1, o2)`.

```c
int PyObject_Compare(PyObject *o1, PyObject *o2)
```

Compare the values of \( o1 \) and \( o2 \) using a routine provided by \( o1 \), if one exists, otherwise with a routine provided by \( o2 \). Returns the result of the comparison on success. On error, the value returned is undefined; use `PyErr_Occurred()` to detect an error. This is equivalent to the Python expression `cmp(o1, o2)`.

```c
PyObject* PyObject_Repr(PyObject *o)
```

*Return value: New reference.*

Compute a string representation of object \( o \). Returns the string representation on success, `NULL` on failure. This is the equivalent of the Python expression `repr(o)`. Called by the `repr()` built-in function and by reverse quotes.

```c
PyObject* PyObject_Str(PyObject *o)
```

*Return value: New reference.*

Compute a string representation of object \( o \). Returns the string representation on success, `NULL` on failure. This is the equivalent of the Python expression `str(o)`. Called by the `str()` built-in function and by the `print` statement.

```c
PyObject* PyObjectBytes(PyObject *o)
```

Compute a bytes representation of object \( o \). In 2.x, this is just an
alias for `PyObject_Str()`.

**PyObject* `PyObject_Unicode(PyObject *o)`**

*Return value: New reference.*

Compute a Unicode string representation of object `o`. Returns the Unicode string representation on success, `NULL` on failure. This is the equivalent of the Python expression `unicode(o)`. Called by the `unicode()` built-in function.

```c
int PyObject_IsInstance(PyObject *inst, PyObject *cls)
```

Returns `1` if `inst` is an instance of the class `cls` or a subclass of `cls`, or `0` if not. On error, returns `-1` and sets an exception. If `cls` is a type object rather than a class object, `PyObject_IsInstance()` returns `1` if `inst` is of type `cls`. If `cls` is a tuple, the check will be done against every entry in `cls`. The result will be `1` when at least one of the checks returns `1`, otherwise it will be `0`. If `inst` is not a class instance and `cls` is neither a type object, nor a class object, nor a tuple, `inst` must have a `__class__` attribute — the class relationship of the value of that attribute with `cls` will be used to determine the result of this function.

*New in version 2.1.*

*Changed in version 2.2:* Support for a tuple as the second argument added.

Subclass determination is done in a fairly straightforward way, but includes a wrinkle that implementors of extensions to the class system may want to be aware of. If `A` and `B` are class objects, `B` is a subclass of `A` if it inherits from `A` either directly or indirectly. If either is not a class object, a more general mechanism is used to determine the class relationship of the two objects. When testing if `B` is a subclass of `A`, if `A` is `B`, `PyObject_IsSubclass()` returns true. If `A` and `B` are different objects, `B`'s `__bases__` attribute is searched in a
depth-first fashion for A — the presence of the __bases__ attribute is considered sufficient for this determination.

```c
int PyObject_IsSubclass(PyObject *derived, PyObject *cls)

Returns 1 if the class derived is identical to or derived from the class cls, otherwise returns 0. In case of an error, returns -1. If cls is a tuple, the check will be done against every entry in cls. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0. If either derived or cls is not an actual class object (or tuple), this function uses the generic algorithm described above.

New in version 2.1.

Changed in version 2.3: Older versions of Python did not support a tuple as the second argument.
```

```c
int PyCallable_Check(PyObject *o)

Determine if the object o is callable. Return 1 if the object is callable and 0 otherwise. This function always succeeds.

PyObject* PyObject_Call(PyObject *callable_object, PyObject *args, PyObject *kw)

Call a callable Python object callable_object, with arguments given by the tuple args, and named arguments given by the dictionary kw. If no named arguments are needed, kw may be NULL. args must not be NULL, use an empty tuple if no arguments are needed. Returns the result of the call on success, or NULL on failure. This is the equivalent of the Python expression apply(callable_object, args, kw) or callable_object(*args, **kw).

New in version 2.2.
PyObject* PyObject_CallObject(PyObject *callable_object, PyObject *args)

*Return value: New reference.*

Call a callable Python object *callable_object*, with arguments given by the tuple *args*. If no arguments are needed, then *args* may be *NULL*. Returns the result of the call on success, or *NULL* on failure. This is the equivalent of the Python expression `apply(callable_object, args)` or `callable_object(*args)`.

PyObject* PyObject_CallFunction(PyObject *callable, char *format, ...)

*Return value: New reference.*

Call a callable Python object *callable*, with a variable number of C arguments. The C arguments are described using a `Py_BuildValue()` style format string. The format may be *NULL*, indicating that no arguments are provided. Returns the result of the call on success, or *NULL* on failure. This is the equivalent of the Python expression `apply(callable, args)` or `callable(*args)`. Note that if you only pass `PyObject * args`, `PyObject_CallFunctionObjArgs()` is a faster alternative.

PyObject* PyObject_CallMethod(PyObject *o, char *method, char *format, ...)

*Return value: New reference.*

Call the method named *method* of object *o* with a variable number of C arguments. The C arguments are described by a `Py_BuildValue()` format string that should produce a tuple. The format may be *NULL*, indicating that no arguments are provided. Returns the result of the call on success, or *NULL* on failure. This is the equivalent of the Python expression `o.method(args)`. Note that if you only pass `PyObject * args`, `PyObject_CallMethodObjArgs()` is a faster alternative.

PyObject* PyObject_CallFunctionObjArgs(PyObject *callable, ...)
Call a callable Python object callable, with a variable number of PyObject* arguments. The arguments are provided as a variable number of parameters followed by NULL. Returns the result of the call on success, or NULL on failure.

New in version 2.2.

PyObject* PyObject_CallMethodObjArgs(PyObject *o, PyObject *name, ..., NULL)
Calls a method of the object o, where the name of the method is given as a Python string object in name. It is called with a variable number of PyObject* arguments. The arguments are provided as a variable number of parameters followed by NULL. Returns the result of the variable number of parameters followed by NULL.

New in version 2.2.

long PyObject_Hash(PyObject *o)
Compute and return the hash value of an object o. On failure, return -1. This is the equivalent of the Python expression hash(o).

long PyObject_HashNotImplemented(PyObject *o)
Set a TypeError indicating that type(o) is not hashable and return -1. This function receives special treatment when stored in a tp_hash slot, allowing a type to explicitly indicate to the interpreter that it is not hashable.

New in version 2.6.

int PyObject_IsTrue(PyObject *o)
Returns 1 if the object o is considered to be true, and 0
otherwise. This is equivalent to the Python expression `not not o`. On failure, return `-1`.

```c
int PyObject_Not(PyObject *o)
```

Returns 0 if the object `o` is considered to be true, and 1 otherwise. This is equivalent to the Python expression `not o`. On failure, return `-1`.

```c
PyObject* PyObject_Type(PyObject *o)
```

*Return value: New reference.*

When `o` is non-NULL, returns a type object corresponding to the object type of object `o`. On failure, raises `SystemError` and returns `NULL`. This is equivalent to the Python expression `type(o)`. This function increments the reference count of the return value. There's really no reason to use this function instead of the common expression `o->ob_type`, which returns a pointer of type `PyTypeObject*`, except when the incremented reference count is needed.

```c
int PyObject_TypeCheck(PyObject *o, PyTypeObject *type)
```

Return true if the object `o` is of type `type` or a subtype of `type`. Both parameters must be non-NULL.

*New in version 2.2.*

```c
Py_ssize_t PyObject_Length(PyObject *o)
Py_ssize_t PyObject_Size(PyObject *o)
```

Return the length of object `o`. If the object `o` provides either the sequence and mapping protocols, the sequence length is returned. On error, `-1` is returned. This is the equivalent to the Python expression `len(o)`.

*Changed in version 2.5:* These functions returned an `int` type. This might require changes in your code for properly supporting
64-bit systems.

**PyObject** PyObject**_GetItem**(PyObject *o, PyObject *key)

*Return value: New reference.*

Return element of o corresponding to the object key or NULL on failure. This is the equivalent of the Python expression o[key].

**int** PyObject**_SetItem**(PyObject *o, PyObject *key, PyObject *v)

Map the object key to the value v. Raise an exception and return -1 on failure; return 0 on success. This is the equivalent of the Python statement o[key] = v.

**int** PyObject**_DelItem**(PyObject *o, PyObject *key)

Delete the mapping for key from o. Returns -1 on failure. This is the equivalent of the Python statement del o[key].

**int** PyObject**_AsFileDescriptor**(PyObject *o)

Derives a file descriptor from a Python object. If the object is an integer or long integer, its value is returned. If not, the object’s fileno() method is called if it exists; the method must return an integer or long integer, which is returned as the file descriptor value. Returns -1 on failure.

**PyObject*** PyObject**_Dir**(PyObject *o)

*Return value: New reference.*

This is equivalent to the Python expression dir(o), returning a (possibly empty) list of strings appropriate for the object argument, or NULL if there was an error. If the argument is NULL, this is like the Python dir(), returning the names of the current locals; in this case, if no execution frame is active then NULL is returned but PyErr_occurred() will return false.

**PyObject*** PyObject**_GetIter**(PyObject *o)

*Return value: New reference.*
This is equivalent to the Python expression `iter(o)`. It returns a new iterator for the object argument, or the object itself if the object is already an iterator. Raises `TypeError` and returns `NULL` if the object cannot be iterated.
Number Protocol

```c
int PyNumber_Check(PyObject *o)

    Returns 1 if the object o provides numeric protocols, and false otherwise. This function always succeeds.
```

```c
PyObject* PyNumber_Add(PyObject *o1, PyObject *o2)

    Returns the result of adding o1 and o2, or NULL on failure. This is the equivalent of the Python expression o1 + o2.
```

```c
PyObject* PyNumber_Subtract(PyObject *o1, PyObject *o2)

    Returns the result of subtracting o2 from o1, or NULL on failure. This is the equivalent of the Python expression o1 - o2.
```

```c
PyObject* PyNumber_Multiply(PyObject *o1, PyObject *o2)

    Returns the result of multiplying o1 and o2, or NULL on failure. This is the equivalent of the Python expression o1 * o2.
```

```c
PyObject* PyNumber_Divide(PyObject *o1, PyObject *o2)

    Returns the result of dividing o1 by o2, or NULL on failure. This is the equivalent of the Python expression o1 / o2.
```

```c
PyObject* PyNumber_FloorDivide(PyObject *o1, PyObject *o2)

    Return the floor of o1 divided by o2, or NULL on failure. This is equivalent to the “classic” division of integers.

    New in version 2.2.
```

```c
PyObject* PyNumber_TrueDivide(PyObject *o1, PyObject *o2)
```
Return a reasonable approximation for the mathematical value of $o1$ divided by $o2$, or NULL on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers.

New in version 2.2.

PyObject* PyNumber_Remainder(PyObject *o1, PyObject *o2)
Returns the remainder of dividing $o1$ by $o2$, or NULL on failure. This is the equivalent of the Python expression $o1 \% o2$.

PyObject* PyNumber_Divmod(PyObject *o1, PyObject *o2)
See the built-in function divmod(). Returns NULL on failure. This is the equivalent of the Python expression divmod(o1, o2).

PyObject* PyNumber_Power(PyObject *o1, PyObject *o2, PyObject *o3)
See the built-in function pow(). Returns NULL on failure. This is the equivalent of the Python expression pow(o1, o2, o3), where o3 is optional. If o3 is to be ignored, pass Py_None in its place (passing NULL for o3 would cause an illegal memory access).

PyObject* PyNumber_Negative(PyObject *o)
Returns the negation of o on success, or NULL on failure. This is the equivalent of the Python expression -o.

PyObject* PyNumber_Positive(PyObject *o)
Returns \( o \) on success, or \( NULL \) on failure. This is the equivalent of the Python expression \(+o\).

\section*{PyObject* PyNumber_Absolute(PyObject *o)}

\textit{Return value: New reference.}

Returns the absolute value of \( o \), or \( NULL \) on failure. This is the equivalent of the Python expression \( \text{abs}(o) \).

\section*{PyObject* PyNumber_Invert(PyObject *o)}

\textit{Return value: New reference.}

Returns the bitwise negation of \( o \) on success, or \( NULL \) on failure. This is the equivalent of the Python expression \( \sim o \).

\section*{PyObject* PyNumber_Lshift(PyObject *o1, PyObject *o2)}

\textit{Return value: New reference.}

Returns the result of left shifting \( o1 \) by \( o2 \) on success, or \( NULL \) on failure. This is the equivalent of the Python expression \( o1 \ll o2 \).

\section*{PyObject* PyNumber_Rshift(PyObject *o1, PyObject *o2)}

\textit{Return value: New reference.}

Returns the result of right shifting \( o1 \) by \( o2 \) on success, or \( NULL \) on failure. This is the equivalent of the Python expression \( o1 \gg o2 \).

\section*{PyObject* PyNumber_And(PyObject *o1, PyObject *o2)}

\textit{Return value: New reference.}

Returns the “bitwise and” of \( o1 \) and \( o2 \) on success and \( NULL \) on failure. This is the equivalent of the Python expression \( o1 \& o2 \).

\section*{PyObject* PyNumber_Xor(PyObject *o1, PyObject *o2)}

\textit{Return value: New reference.}

Returns the “bitwise exclusive or” of \( o1 \) by \( o2 \) on success, or \( NULL \) on failure. This is the equivalent of the Python expression \( o1 \oplus o2 \).
PyObject* PyNumber_Or(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the “bitwise or” of o1 and o2 on success, or NULL on failure. This is the equivalent of the Python expression `o1 | o2`.

PyObject* PyNumber_InPlaceAdd(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of adding o1 and o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement `o1 += o2`.

PyObject* PyNumber_InPlaceSubtract(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of subtracting o2 from o1, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement `o1 -= o2`.

PyObject* PyNumber_InPlaceMultiply(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of multiplying o1 and o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement `o1 *= o2`.

PyObject* PyNumber_InPlaceDivide(PyObject *o1, PyObject *o2)

*Return value: New reference.*

Returns the result of dividing o1 by o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement `o1 /= o2`.

PyObject* PyNumber_InPlaceFloorDivide(PyObject *o1, PyObject *o2)
Returns the mathematical floor of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 /= o2.

New in version 2.2.

PyObject* PyNumber_InPlaceTrueDivide(PyObject *o1, PyObject *o2)

Return a reasonable approximation for the mathematical value of o1 divided by o2, or NULL on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers. The operation is done in-place when o1 supports it.

New in version 2.2.

PyObject* PyNumber_InPlaceRemainder(PyObject *o1, PyObject *o2)

Returns the remainder of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 %= o2.

PyObject* PyNumber_InPlacePower(PyObject *o1, PyObject *o2, PyObject *o3)

See the built-in function pow(). Returns NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 **= o2 when o3 is Py_None, or an in-place variant of pow(o1, o2, o3) otherwise. If o3 is to be ignored, pass Py_None in its place (passing NULL for
o3 would cause an illegal memory access).

**PyObject* PyNumber_InPlaceLshift(PyObject *o1, PyObject *o2)**

*Return value: New reference.*

Returns the result of left shifting o1 by o2 on success, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 <<= o2.

**PyObject* PyNumber_InPlaceRshift(PyObject *o1, PyObject *o2)**

*Return value: New reference.*

Returns the result of right shifting o1 by o2 on success, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 >>= o2.

**PyObject* PyNumber_InPlaceAnd(PyObject *o1, PyObject *o2)**

*Return value: New reference.*

Returns the “bitwise and” of o1 and o2 on success and NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 &= o2.

**PyObject* PyNumber_InPlaceXor(PyObject *o1, PyObject *o2)**

*Return value: New reference.*

Returns the “bitwise exclusive or” of o1 by o2 on success, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 ^= o2.

**PyObject* PyNumber_InPlaceOr(PyObject *o1, PyObject *o2)**

*Return value: New reference.*

Returns the “bitwise or” of o1 and o2 on success, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 |= o2.

**int PyNumber_Coerce(PyObject **p1, PyObject **p2)**

This function takes the addresses of two variables of type
PyObject*. If the objects pointed to by *p1 and *p2 have the same type, increment their reference count and return 0 (success). If the objects can be converted to a common numeric type, replace *p1 and *p2 by their converted value (with ‘new’ reference counts), and return 0. If no conversion is possible, or if some other error occurs, return -1 (failure) and don’t increment the reference counts. The call PyNumber_Coerce(&o1, &o2) is equivalent to the Python statement o1, o2 = coerce(o1, o2).

int PyNumber_CoerceEx(PyObject **p1, PyObject **p2)
This function is similar to PyNumber_Coerce(), except that it returns 1 when the conversion is not possible and when no error is raised. Reference counts are still not increased in this case.

PyObject* PyNumber_Int(PyObject *o)
Returns the o converted to an integer object on success, or NULL on failure. If the argument is outside the integer range a long object will be returned instead. This is the equivalent of the Python expression int(o).

PyObject* PyNumber_Long(PyObject *o)
Returns the o converted to a long integer object on success, or NULL on failure. This is the equivalent of the Python expression long(o).

PyObject* PyNumber_Float(PyObject *o)
Returns the o converted to a float object on success, or NULL on failure. This is the equivalent of the Python expression float(o).

PyObject* PyNumber_Index(PyObject *o)
Returns the o converted to a Python int or long on success or
NULL with a TypeError exception raised on failure.

New in version 2.5.

PyObject* PyNumber_ToBase(PyObject *n, int base)
Returns the integer n converted to base as a string with a base marker of '0b', '0o', or '0x' if applicable. When base is not 2, 8, 10, or 16, the format is 'x#num' where x is the base. If n is not an int object, it is converted with PyNumber_Index() first.

New in version 2.6.

Py_ssize_t PyNumber_AsSsize_t(PyObject *o, PyObject *exc)
Returns o converted to a Py_ssize_t value if o can be interpreted as an integer. If o can be converted to a Python int or long but the attempt to convert to a Py_ssize_t value would raise an OverflowError, then the exc argument is the type of exception that will be raised (usually IndexError or OverflowError). If exc is NULL, then the exception is cleared and the value is clipped to PY_SSIZE_T_MIN for a negative integer or PY_SSIZE_T_MAX for a positive integer.

New in version 2.5.

int PyIndex_Check(PyObject *o)
Returns 1 if o is an index integer (has the nb_index slot of the tp_as_number structure filled in), and 0 otherwise.

New in version 2.5.
Reference Manual » Abstract Objects Layer »
Sequence Protocol

int PySequence_Check(PyObject *o)
    Return 1 if the object provides sequence protocol, and 0 otherwise. This function always succeeds.

Py_ssize_t PySequence_Size(PyObject *o)  
Py_ssize_t PySequence_Length(PyObject *o)
    Returns the number of objects in sequence o on success, and -1 on failure. For objects that do not provide sequence protocol, this is equivalent to the Python expression `len(o)`.

  Changed in version 2.5: These functions returned an int type. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PySequence_Concat(PyObject *o1, PyObject *o2)
    Return the concatenation of o1 and o2 on success, and NULL on failure. This is the equivalent of the Python expression `o1 + o2`.

PyObject* PySequence_Repeat(PyObject *o, Py_ssize_t count)
    Return the result of repeating sequence object o count times, or NULL on failure. This is the equivalent of the Python expression `o * count`.

  Changed in version 2.5: This function used an int type for count. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PySequence_InPlaceConcat(PyObject *o1, PyObject *o2)
Return the concatenation of \( o1 \) and \( o2 \) on success, and \textit{NULL} on failure. The operation is done \textit{in-place} when \( o1 \) supports it. This is the equivalent of the Python expression \( o1 += o2 \).

\textbf{PyObject* PySequence\_InPlaceRepeat(PyObject *o, Py\_ssize\_t count)}

\textit{Return value: New reference.}
Return the result of repeating sequence object \( o \) \textit{count} times, or \textit{NULL} on failure. The operation is done \textit{in-place} when \( o \) supports it. This is the equivalent of the Python expression \( o *= count \).

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \textit{count}. This might require changes in your code for properly supporting 64-bit systems.

\textbf{PyObject* PySequence\_GetItem(PyObject *o, Py\_ssize\_t i)}

\textit{Return value: New reference.}
Return the \textit{i}th element of \( o \), or \textit{NULL} on failure. This is the equivalent of the Python expression \( o[i] \).

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \textit{i}. This might require changes in your code for properly supporting 64-bit systems.

\textbf{PyObject* PySequence\_GetSlice(PyObject *o, Py\_ssize\_t i1, Py\_ssize\_t i2)}

\textit{Return value: New reference.}
Return the slice of sequence object \( o \) between \( i1 \) and \( i2 \), or \textit{NULL} on failure. This is the equivalent of the Python expression \( o[i1:i2] \).

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \textit{i1} and \textit{i2}. This might require changes in your code for properly supporting 64-bit systems.
int PySequence_SetItem(PyObject *o, Py_ssize_t i, PyObject *v)
    Assign object v to the i\(^{th}\) element of o. Raise an exception and return -1 on failure; return 0 on success. This is the equivalent of the Python statement \(o[i] = v\). This function does not steal a reference to v.

    If v is NULL, the element is deleted, however this feature is deprecated in favour of using PySequence_DelItem().

    Changed in version 2.5: This function used an int type for i. This might require changes in your code for properly supporting 64-bit systems.

int PySequence_DelItem(PyObject *o, Py_ssize_t i)
    Delete the i\(^{th}\) element of object o. Returns -1 on failure. This is the equivalent of the Python statement del o[i].

    Changed in version 2.5: This function used an int type for i. This might require changes in your code for properly supporting 64-bit systems.

int PySequence_SetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2, PyObject *v)
    Assign the sequence object v to the slice in sequence object o from i1 to i2. Raise an exception and return -1 on failure; return 0 on success. This is the equivalent of the Python statement \(o[i1:i2] = v\).

    If v is NULL, the slice is deleted, however this feature is deprecated in favour of using PySequence_DelSlice().

    Changed in version 2.5: This function used an int type for i1 and i2. This might require changes in your code for properly supporting 64-bit systems.
int PySequence_DelSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)
    Delete the slice in sequence object o from i1 to i2. Returns -1 on failure. This is the equivalent of the Python statement del o[i1:i2].

    Changed in version 2.5: This function used an int type for i1 and i2. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PySequence_Count(PyObject *o, PyObject *value)
    Return the number of occurrences of value in o, that is, return the number of keys for which o[key] == value. On failure, return -1. This is equivalent to the Python expression o.count(value).

    Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.

int PySequence_Contains(PyObject *o, PyObject *value)
    Determine if o contains value. If an item in o is equal to value, return 1, otherwise return 0. On error, return -1. This is equivalent to the Python expression value in o.

Py_ssize_t PySequence_Index(PyObject *o, PyObject *value)
    Return the first index i for which o[i] == value. On error, return -1. This is equivalent to the Python expression o.index(value).

    Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PySequence_List(PyObject *o)
Return a list object with the same contents as the arbitrary sequence o. The returned list is guaranteed to be new.

**PyObject** PySequence_Tuple(PyObject *o)

*Return value: New reference.*

Return a tuple object with the same contents as the arbitrary sequence o or NULL on failure. If o is a tuple, a new reference will be returned, otherwise a tuple will be constructed with the appropriate contents. This is equivalent to the Python expression tuple(o).

**PyObject** PySequence_Fast(PyObject *o, const char *m)

*Return value: New reference.*

Return the sequence o as a list, unless it is already a tuple or list, in which case o is returned. Use PySequence_Fast_GET_ITEM() to access the members of the result. Returns NULL on failure. If the object is not a sequence, raises TypeError with m as the message text.

**PyObject** PySequence_Fast_GET_ITEM(PyObject *o, Py_ssize_t i)

*Return value: Borrowed reference.*

Return the i-th element of o, assuming that o was returned by PySequence_Fast(), o is not NULL, and that i is within bounds.

*Changed in version 2.5:* This function used an int type for i. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** PySequence_Fast_ITEMS(PyObject *o)

Return the underlying array of PyObject pointers. Assumes that o was returned by PySequence_Fast() and o is not NULL.

Note, if a list gets resized, the reallocation may relocate the items array. So, only use the underlying array pointer in contexts where the sequence cannot change.
New in version 2.4.

PyObject* PySequence_ITEM(PyObject *o, Py_ssize_t i)

Return the \textit{i}th element of \textit{o} or \texttt{NULL} on failure. Macro form of \*PySequence_GetItem() but without checking that \*PySequence_Check() on \textit{o} is true and without adjustment for negative indices.

New in version 2.3.

\textit{Changed in version 2.5}: This function used an \texttt{int} type for \textit{i}. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PySequence_Fast_GET_SIZE(PyObject *o)

Returns the length of \textit{o}, assuming that \textit{o} was returned by \*PySequence_Fast() and that \textit{o} is not \texttt{NULL}. The size can also be gotten by calling \texttt{PySequence_Size()} on \textit{o}, but \texttt{PySequence_Fast_GET_SIZE()} is faster because it can assume \textit{o} is a list or tuple.
Mapping Protocol

```c
int PyMapping_Check(PyObject *o)
    Return 1 if the object provides mapping protocol, and 0 otherwise. This function always succeeds.
```

```c
Py_ssize_t PyMapping_Size(PyObject *o)
Py_ssize_t PyMapping_Length(PyObject *o)
    Returns the number of keys in object o on success, and -1 on failure. For objects that do not provide mapping protocol, this is equivalent to the Python expression `len(o)`.
```

*Changed in version 2.5:* These functions returned an `int` type. This might require changes in your code for properly supporting 64-bit systems.

```c
int PyMapping_DelItemString(PyObject *o, char *key)
    Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement `del o[key]`.
```

```c
int PyMapping_DelItem(PyObject *o, PyObject *key)
    Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement `del o[key]`.
```

```c
int PyMapping_HasKeyString(PyObject *o, char *key)
    On success, return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to `o[key]`, returning `True` on success and `False` on an exception. This function always succeeds.
```

```c
int PyMapping_HasKey(PyObject *o, PyObject *key)
    Return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to `o[key]`, returning `True` on success and `False` on an exception. This function always succeeds.
```
PyObject* PyMapping_Keys(PyObject *o)

*Return value: New reference.*
On success, return a list of the keys in object o. On failure, return *NULL*. This is equivalent to the Python expression `o.keys()`.

PyObject* PyMapping_Values(PyObject *o)

*Return value: New reference.*
On success, return a list of the values in object o. On failure, return *NULL*. This is equivalent to the Python expression `o.values()`.

PyObject* PyMapping_Items(PyObject *o)

*Return value: New reference.*
On success, return a list of the items in object o, where each item is a tuple containing a key-value pair. On failure, return *NULL*. This is equivalent to the Python expression `o.items()`.

PyObject* PyMapping_GetItemString(PyObject *o, char *key)

*Return value: New reference.*
Return element of o corresponding to the object key or *NULL* on failure. This is the equivalent of the Python expression `o[key]`.

int PyMapping_SetItemString(PyObject *o, char *key, PyObject *v)

Map the object key to the value v in object o. Returns -1 on failure. This is the equivalent of the Python statement `o[key] = v`. 
Iterator Protocol

New in version 2.2.

There are two functions specifically for working with iterators.

```c
int PyIter_Check(PyObject *o)
    Return true if the object o supports the iterator protocol.
```

This function can return a false positive in the case of old-style classes because those classes always define a `tp_iter_next` slot with logic that either invokes a `next()` method or raises a `TypeError`.

```c
PyObject* PyIter_Next(PyObject *o)
    Return the next value from the iteration o. The object must be an iterator (it is up to the caller to check this). If there are no remaining values, returns `NULL` with no exception set. If an error occurs while retrieving the item, returns `NULL` and passes along the exception.
```

To write a loop which iterates over an iterator, the C code should look something like this:

```c
PyObject *iterator = PyObject_GetIter(obj);
PyObject *item;

if (iterator == NULL) {
    /* propagate error */
}

while (item = PyIter_Next(iterator)) {
    /* do something with item */
    ...
    /* release reference when done */
    Py_DECREF(item);
```
Py_DECREF(iterator);

if (PyErr_Occurred()) {
    /* propagate error */
} else {
    /* continue doing useful work */
}
This section describes the legacy buffer protocol, which has been introduced in Python 1.6. It is still supported but deprecated in the Python 2.x series. Python 3 introduces a new buffer protocol which fixes weaknesses and shortcomings of the protocol, and has been backported to Python 2.6. See Buffers and Memoryview Objects for more information.

```c
int PyObject_AsCharBuffer(PyObject *obj, const char **buffer, Py_ssize_t *buffer_len)
```

Returns a pointer to a read-only memory location usable as character-based input. The `obj` argument must support the single-segment character buffer interface. On success, returns 0, sets `buffer` to the memory location and `buffer_len` to the buffer length. Returns -1 and sets a `TypeError` on error.

*New in version 1.6.*

*Changed in version 2.5:* This function used an `int *` type for `buffer_len`. This might require changes in your code for properly supporting 64-bit systems.

```c
int PyObject_AsReadBuffer(PyObject *obj, const void **buffer, Py_ssize_t *buffer_len)
```

Returns a pointer to a read-only memory location containing arbitrary data. The `obj` argument must support the single-segment readable buffer interface. On success, returns 0, sets `buffer` to the memory location and `buffer_len` to the buffer length. Returns -1 and sets a `TypeError` on error.

*New in version 1.6.*

*Changed in version 2.5:* This function used an `int *` type for
buffer_len. This might require changes in your code for properly supporting 64-bit systems.

int PyObject_CheckReadBuffer(PyObject *o)
Returns 1 if o supports the single-segment readable buffer interface. Otherwise returns 0.

New in version 2.2.

int PyObject_AsWriteBuffer(PyObject *obj, void **buffer, Py_ssize_t *buffer_len)
Returns a pointer to a writeable memory location. The obj argument must support the single-segment, character buffer interface. On success, returns 0, sets buffer to the memory location and buffer_len to the buffer length. Returns -1 and sets a TypeError on error.

New in version 1.6.

Changed in version 2.5: This function used an int * type for buffer_len. This might require changes in your code for properly supporting 64-bit systems.
Concrete Objects Layer

The functions in this chapter are specific to certain Python object types. Passing them an object of the wrong type is not a good idea; if you receive an object from a Python program and you are not sure that it has the right type, you must perform a type check first; for example, to check that an object is a dictionary, use `PyDict_Check()`. The chapter is structured like the “family tree” of Python object types.

**Warning:** While the functions described in this chapter carefully check the type of the objects which are passed in, many of them do not check for *NULL* being passed instead of a valid object. Allowing *NULL* to be passed in can cause memory access violations and immediate termination of the interpreter.
Fundamental Objects

This section describes Python type objects and the singleton object `None`.

- Type Objects
- The `None` Object
Numeric Objects

- Plain Integer Objects
- Boolean Objects
- Long Integer Objects
- Floating Point Objects
- Complex Number Objects
  - Complex Numbers as C Structures
  - Complex Numbers as Python Objects
Sequence Objects

Generic operations on sequence objects were discussed in the previous chapter; this section deals with the specific kinds of sequence objects that are intrinsic to the Python language.

- **Byte Array Objects**
  - Type check macros
  - Direct API functions
  - Macros
- **String/Bytes Objects**
- **Unicode Objects and Codecs**
  - Unicode Objects
    - Unicode Type
    - Unicode Character Properties
    - Plain Py_UNICODE
    - wchar_t Support
  - Built-in Codecs
    - Generic Codecs
    - UTF-8 Codecs
    - UTF-32 Codecs
    - UTF-16 Codecs
    - UTF-7 Codecs
    - Unicode-Escape Codecs
    - Raw-Unicode-Escape Codecs
    - Latin-1 Codecs
    - ASCII Codecs
    - Character Map Codecs
    - MBCS codecs for Windows
    - Methods & Slots
  - Methods and Slot Functions
- **Buffers and Memoryview Objects**
  - The new-style Py_buffer struct
- Buffer related functions
- MemoryView objects
- Old-style buffer objects

- Tuple Objects
- List Objects
Mapping Objects

- Dictionary Objects
Other Objects

- Class and Instance Objects
- Function Objects
- Method Objects
- File Objects
- Module Objects
- Iterator Objects
- Descriptor Objects
- Slice Objects
- Weak Reference Objects
- Capsules
- CObjects
- Cell Objects
- Generator Objects
- DateTime Objects
- Set Objects
- Code Objects
Type Objects

**PyTypeObject**
The C structure of the objects used to describe built-in types.

**PyObject* PyType_Type**
This is the type object for type objects; it is the same object as `type` and `types.TypeType` in the Python layer.

```c
int PyType_Check(PyObject *o)
```
Return true if the object `o` is a type object, including instances of types derived from the standard type object. Return false in all other cases.

```c
int PyType_CheckExact(PyObject *o)
```
Return true if the object `o` is a type object, but not a subtype of the standard type object. Return false in all other cases.

*New in version 2.2.*

```c
unsigned int PyType_ClearCache()
```
Clear the internal lookup cache. Return the current version tag.

*New in version 2.6.*

```c
void PyType_Modified(PyTypeObject *type)
```
Invalidate the internal lookup cache for the type and all of its subtypes. This function must be called after any manual modification of the attributes or base classes of the type.

*New in version 2.6.*

```c
int PyType_HasFeature(PyObject *o, int feature)
```
Return true if the type object `o` sets the feature `feature`. Type features are denoted by single bit flags.
int PyType_IS_GC(PyObject *o)
    Return true if the type object includes support for the cycle detector; this tests the type flag Py_TPFLAGS_HAVE_GC.

    New in version 2.0.

int PyType_IsSubtype(PyTypeObject *a, PyTypeObject *b)
    Return true if a is a subtype of b.

    New in version 2.2.

This function only checks for actual subtypes, which means that __subclasscheck__() is not called on b. Call PyObject_IsSubclass() to do the same check that issubclass() would do.

PyObject* PyType_GenericAlloc(PyTypeObject *type, Py_ssize_t nitems)

    New in version 2.2.

    Changed in version 2.5: This function used an int type for nitems. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyType_GenericNew(PyTypeObject *type, PyObject *args, PyObject *kwds)

    New in version 2.2.

int PyType_Ready(PyTypeObject *type)
    Finalize a type object. This should be called on all type objects to finish their initialization. This function is responsible for adding inherited slots from a type's base class. Return 0 on success, or return -1 and sets an exception on error.
New in version 2.2.
The None Object

Note that the PyTypeObject for None is not directly exposed in the Python/C API. Since None is a singleton, testing for object identity (using == in C) is sufficient. There is no PyNone_Check() function for the same reason.

PyObject* Py_None
The Python None object, denoting lack of value. This object has no methods. It needs to be treated just like any other object with respect to reference counts.

Py_RETURN_NONE
Properly handle returning Py_None from within a C function.

New in version 2.4.
Plain Integer Objects

**PyIntObject**
This subtype of **PyObject** represents a Python integer object.

**PyTypeObject** **PyInt_Type**
This instance of **PyTypeObject** represents the Python plain integer type. This is the same object as **int** and **types.IntType**.

`int PyInt_Check(PyObject *o)`
Return true if `o` is of type **PyInt_Type** or a subtype of **PyInt_Type**.

*Changed in version 2.2:* Allowed subtypes to be accepted.

`int PyInt_CheckExact(PyObject *o)`
Return true if `o` is of type **PyInt_Type**, but not a subtype of **PyInt_Type**.

*New in version 2.2.*

**PyObject**`* PyInt_FromString(char *str, char **pend, int base)`

*Return value: New reference.*
Return a new **PyIntObject** or **PyLongObject** based on the string value in `str`, which is interpreted according to the radix in `base`. If `pend` is non-`NULL`, `*pend` will point to the first character in `str` which follows the representation of the number. If `base` is 0, the radix will be determined based on the leading characters of `str`: if `str` starts with '0x' or '0X', radix 16 will be used; if `str` starts with '0', radix 8 will be used; otherwise radix 10 will be used. If `base` is not 0, it must be between 2 and 36, inclusive. Leading spaces are ignored. If there are no digits, **ValueError** will be raised. If the string represents a number too large to be contained within the machine’s **long int** type and overflow warnings are being
suppressed, a `PyLongObject` will be returned. If overflow warnings are not being suppressed, `NULL` will be returned in this case.

`PyObject* PyInt_FromLong(long ival)`  
*Return value: New reference.*  
Create a new integer object with a value of `ival`.

The current implementation keeps an array of integer objects for all integers between `-5` and `256`, when you create an int in that range you actually just get back a reference to the existing object. So it should be possible to change the value of `1`. I suspect the behaviour of Python in this case is undefined. :-)

`PyObject* PyInt_FromSsize_t(Py_ssize_t ival)`  
*Return value: New reference.*  
Create a new integer object with a value of `ival`. If the value is larger than `LONG_MAX` or smaller than `LONG_MIN`, a long integer object is returned.  

*New in version 2.5.*

`PyObject* PyInt_FromSize_t(size_t ival)`  
Create a new integer object with a value of `ival`. If the value exceeds `LONG_MAX`, a long integer object is returned.  

*New in version 2.5.*

`long PyInt_AsLong(PyObject *io)`  
Will first attempt to cast the object to a `PyIntObject`, if it is not already one, and then return its value. If there is an error, `-1` is returned, and the caller should check `PyErr_Occurred()` to find out whether there was an error, or whether the value just happened to be `-1`.

`long PyInt_AS_LONG(PyObject *io)`
Return the value of the object \textit{io}. No error checking is performed.

\texttt{unsigned long \textbf{PyInt\_AsUnsignedLongMask}(PyObject *\textit{io})}

Will first attempt to cast the object to a \texttt{PyIntObject} or \texttt{PyLongObject}, if it is not already one, and then return its value as unsigned long. This function does not check for overflow.

\textit{New in version 2.3.}

\texttt{unsigned PY\_LONG\_LONG \textbf{PyInt\_AsUnsignedLongLongMask}(PyObject *\textit{io})}

Will first attempt to cast the object to a \texttt{PyIntObject} or \texttt{PyLongObject}, if it is not already one, and then return its value as unsigned long long, without checking for overflow.

\textit{New in version 2.3.}

\texttt{Py\_ssize\_t \textbf{PyInt\_AsSsize\_t}(PyObject *\textit{io})}

Will first attempt to cast the object to a \texttt{PyIntObject} or \texttt{PyLongObject}, if it is not already one, and then return its value as \texttt{Py\_ssize\_t}.

\textit{New in version 2.5.}

\texttt{long \textbf{PyInt\_GetMax}()}

Return the system's idea of the largest integer it can handle (\texttt{LONG\_MAX}, as defined in the system header files).

\texttt{int \textbf{PyInt\_ClearFreeList}()}

Clear the integer free list. Return the number of items that could not be freed.

\textit{New in version 2.6.}
Boolean Objects

Booleans in Python are implemented as a subclass of integers. There are only two booleans, `Py_False` and `Py_True`. As such, the normal creation and deletion functions don’t apply to booleans. The following macros are available, however.

```c
int PyBool_Check(PyObject *o)
    Return true if o is of type PyBool_Type.
```

*New in version 2.3.*

```c
PyObject* Py_False
    The Python False object. This object has no methods. It needs to be treated just like any other object with respect to reference counts.
```

```c
PyObject* Py_True
    The Python True object. This object has no methods. It needs to be treated just like any other object with respect to reference counts.
```

```c
Py_RETURN_FALSE
    Return Py_False from a function, properly incrementing its reference count.
```

*New in version 2.4.*

```c
Py_RETURN_TRUE
    Return Py_True from a function, properly incrementing its reference count.
```

*New in version 2.4.*

```c
PyObject* PyBool_FromLong(long v)
```
Return a new reference to `Py_True` or `Py_False` depending on the truth value of `v`.

New in version 2.3.
Long Integer Objects

**PyLongObject**
This subtype of `PyObject` represents a Python long integer object.

**PyTypeObject** **PyLong_Type**
This instance of `PyTypeObject` represents the Python long integer type. This is the same object as `long` and `types.LongType`.

```c
int PyLong_Check(PyObject *p)
Return true if its argument is a PyLongObject or a subtype of PyLongObject.
```

*Changed in version 2.2*: Allowed subtypes to be accepted.

```c
int PyLong_CheckExact(PyObject *p)
Return true if its argument is a PyLongObject, but not a subtype of PyLongObject.
```

*New in version 2.2.*

```c
PyObject* PyLong_FromLong(long v)
Return a new PyLongObject object from v, or NULL on failure.
```

```c
PyObject* PyLong_FromUnsignedLong(unsigned long v)
Return a new PyLongObject object from a C unsigned long, or NULL on failure.
```

```c
PyObject* PyLong_FromSsize_t(Py_ssize_t v)
Return a new PyLongObject object from a C Py_ssize_t, or NULL on failure.
```
New in version 2.6.

PyObject* PyLong_FromSize_t(size_t v)
  
  
  Return a new PyLongObject object from a C size_t, or NULL on failure.

New in version 2.6.

PyObject* PyLong_FromLongLong(PY_LONG_LONG v)
  
  
  Return a new PyLongObject object from a C long long, or NULL on failure.

PyObject* PyLong_FromUnsignedLongLong(unsigned PY_LONG_LONG v)
  
  
  Return a new PyLongObject object from a C unsigned long long, or NULL on failure.

PyObject* PyLong_FromDouble(double v)
  
  
  Return a new PyLongObject object from the integer part of v, or NULL on failure.

PyObject* PyLong_FromString(char *str, char **pend, int base)
  
  
  Return a new PyLongObject based on the string value in str, which is interpreted according to the radix in base. If pend is non-NULL, *pend will point to the first character in str which follows the representation of the number. If base is 0, the radix will be determined based on the leading characters of str: if str starts with '0x' or '0X', radix 16 will be used; if str starts with '0', radix 8 will be used; otherwise radix 10 will be used. If base is not 0, it
must be between 2 and 36, inclusive. Leading spaces are ignored. If there are no digits, ValueError will be raised.

PyObject* PyLong_FromUnicode(Py_UNICODE *u, Py_ssize_t length, int base)

    Convert a sequence of Unicode digits to a Python long integer value. The first parameter, u, points to the first character of the Unicode string, length gives the number of characters, and base is the radix for the conversion. The radix must be in the range [2, 36]; if it is out of range, ValueError will be raised.

   New in version 1.6.

   Changed in version 2.5: This function used an int for length. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyLong_FromVoidPtr(void *p)

    Create a Python integer or long integer from the pointer p. The pointer value can be retrieved from the resulting value using PyLong_AsVoidPtr().

   New in version 1.5.2.

   Changed in version 2.5: If the integer is larger than LONG_MAX, a positive long integer is returned.

long PyLong_AsLong(PyObject *pylong)

   Return a C long representation of the contents of pylong. If pylong is greater than LONG_MAX, an OverflowError is raised and -1 will be returned.

long PyLong_AsLongAndOverflow(PyObject *pylong, int *overflow)
Return a C `long` representation of the contents of `pylong`. If `pylong` is greater than `LONG_MAX` or less than `LONG_MIN`, set `*overflow` to 1 or -1, respectively, and return -1; otherwise, set `*overflow` to 0. If any other exception occurs (for example a TypeError or MemoryError), then -1 will be returned and `*overflow` will be 0.

*New in version 2.7.*

**PY_LONG_LONG**

`PyLong_AsLongLongAndOverflow(PyObject *pylong, int *overflow)`

Return a C `long` representation of the contents of `pylong`. If `pylong` is greater than `PY_LLONG_MAX` or less than `PY_LLONG_MIN`, set `*overflow` to 1 or -1, respectively, and return -1; otherwise, set `*overflow` to 0. If any other exception occurs (for example a TypeError or MemoryError), then -1 will be returned and `*overflow` will be 0.

*New in version 2.7.*

`Py_ssize_t PyLong_AsSsize_t(PyObject *pylong)`

Return a C `Py_ssize_t` representation of the contents of `pylong`. If `pylong` is greater than `PY_SSIZE_T_MAX`, an `OverflowError` is raised and -1 will be returned.

*New in version 2.6.*

`unsigned long PyLong_AsUnsignedLong(PyObject *pylong)`

Return a C `unsigned long` representation of the contents of `pylong`. If `pylong` is greater than `ULONG_MAX`, an `OverflowError` is raised.

**PY_LONG_LONG**

`PyLong_AsLongLong(PyObject *pylong)`

Return a C `long long` from a Python long integer. If `pylong`
cannot be represented as a long long, an OverflowError is raised and -1 is returned.

*New in version 2.2.*

unsigned PY_LONG_LONG
PyLong_AsUnsignedLongLong(PyObject *pylong)
Return a C unsigned long long from a Python long integer. If pylong cannot be represented as an unsigned long long, an OverflowError is raised and (unsigned long long)-1 is returned.

*New in version 2.2.*

*Changed in version 2.7:* A negative pylong now raises OverflowError, not TypeError.

unsigned long PyLong_AsUnsignedLongMask(PyObject *io)
Return a C unsigned long from a Python long integer, without checking for overflow.

*New in version 2.3.*

unsigned PY_LONG_LONG
PyLong_AsUnsignedLongLongMask(PyObject *io)
Return a C unsigned long long from a Python long integer, without checking for overflow.

*New in version 2.3.*

double PyLong_AsDouble(PyObject *pylong)
Return a C double representation of the contents of pylong. If pylong cannot be approximately represented as a double, an OverflowError exception is raised and -1.0 will be returned.

void* PyLong_AsVoidPtr(PyObject *pylong)
Convert a Python integer or long integer \textit{pylong} to a C \texttt{void} pointer. If \textit{pylong} cannot be converted, an \texttt{OverflowError} will be raised. This is only assured to produce a usable \texttt{void} pointer for values created with \texttt{PyLong_FromVoidPtr()}.

\textit{New in version 1.5.2.}

\textit{Changed in version 2.5}: For values outside 0..\texttt{LONG_MAX}, both signed and unsigned integers are accepted.
Floating Point Objects

**PyFloatObject**
This subtype of **PyObject** represents a Python floating point object.

**PyTypeObject PyFloat_Type**
This instance of **PyTypeObject** represents the Python floating point type. This is the same object as `float` and `types.FloatType`.

`int PyFloat_Check(PyObject *p)`
Return true if its argument is a `PyFloatObject` or a subtype of `PyFloatObject`.

*Changed in version 2.2:* Allowed subtypes to be accepted.

`int PyFloat_CheckExact(PyObject *p)`
Return true if its argument is a `PyFloatObject`, but not a subtype of `PyFloatObject`.

*New in version 2.2.*

`PyObject* PyFloat_FromString(PyObject *str, char **pend)`
*Return value: New reference.*
Create a `PyFloatObject` object based on the string value in `str`, or `NULL` on failure. The `pend` argument is ignored. It remains only for backward compatibility.

`PyObject* PyFloat_FromDouble(double v)`
*Return value: New reference.*
Create a `PyFloatObject` object from `v`, or `NULL` on failure.

double `PyFloat_AsDouble(PyObject *pyfloat)`
Return a C `double` representation of the contents of `pyfloat`. If `pyfloat` is not a Python floating point object but has a `__float__()` method, this method will first be called to convert `pyfloat` into a float. This method returns `-1.0` upon failure, so one should call `PyErr_Occurred()` to check for errors.

```c
double PyFloat_AS_DOUBLE(PyObject *pyfloat)
```

Return a C `double` representation of the contents of `pyfloat`, but without error checking.

```c
PyObject* PyFloat_GetInfo(void)
```

Return a structseq instance which contains information about the precision, minimum and maximum values of a float. It's a thin wrapper around the header file `float.h`.

`New in version 2.6.`

```c
double PyFloat_GetMax()
```

Return the maximum representable finite float `DBL_MAX` as C `double`.

`New in version 2.6.`

```c
double PyFloat_GetMin()
```

Return the minimum normalized positive float `DBL_MIN` as C `double`.

`New in version 2.6.`

```c
int PyFloat_ClearFreeList()
```

Clear the float free list. Return the number of items that could not be freed.

`New in version 2.6.`
void `PyFloat_AsString`(char *`buf`, `PyFloatObject *v`)

Convert the argument `v` to a string, using the same rules as `str()`. The length of `buf` should be at least 100.

This function is unsafe to call because it writes to a buffer whose length it does not know.

*Deprecated since version 2.7:* Use `PyObject_Str()` or `PyOS_double_to_string()` instead.

void `PyFloat_AsReprString`(char *`buf`, `PyFloatObject *v`)

Same as `PyFloat_AsString`, except uses the same rules as `repr()`. The length of `buf` should be at least 100.

This function is unsafe to call because it writes to a buffer whose length it does not know.

*Deprecated since version 2.7:* Use `PyObject_Repr()` or `PyOS_double_to_string()` instead.
Complex Number Objects

Python's complex number objects are implemented as two distinct types when viewed from the C API: one is the Python object exposed to Python programs, and the other is a C structure which represents the actual complex number value. The API provides functions for working with both.
Complex Numbers as C Structures

Note that the functions which accept these structures as parameters and return them as results do so by value rather than dereferencing them through pointers. This is consistent throughout the API.

**Py_complex**
The C structure which corresponds to the value portion of a Python complex number object. Most of the functions for dealing with complex number objects use structures of this type as input or output values, as appropriate. It is defined as:

```c
typedef struct {
    double real;
    double imag;
} Py_complex;
```

**Py_complex _Py_c_sum(Py_complex left, Py_complex right)**
Return the sum of two complex numbers, using the C `Py_complex` representation.

**Py_complex _Py_c_diff(Py_complex left, Py_complex right)**
Return the difference between two complex numbers, using the C `Py_complex` representation.

**Py_complex _Py_c_neg(Py_complex complex)**
Return the negation of the complex number `complex`, using the C `Py_complex` representation.

**Py_complex _Py_c_prod(Py_complex left, Py_complex right)**
Return the product of two complex numbers, using the C `Py_complex` representation.

**Py_complex _Py_c_quot(Py_complex dividend, Py_complex divisor)**

Return the quotient of two complex numbers, using the C `Py_complex` representation.

If `divisor` is null, this method returns zero and sets `errno` to EDOM.

`Py_complex _Py_c_pow(Py_complex num, Py_complex exp)`

Return the exponentiation of `num` by `exp`, using the C `Py_complex` representation.

If `num` is null and `exp` is not a positive real number, this method returns zero and sets `errno` to EDOM.
Complex Numbers as Python Objects

**PyComplexObject**
This subtype of **PyObject** represents a Python complex number object.

**PyTypeObject PyComplex_Type**
This instance of **PyTypeObject** represents the Python complex number type. It is the same object as complex and types.ComplexType.

```c
int PyComplex_Check(PyObject *p)
```
Return true if its argument is a **PyComplexObject** or a subtype of **PyComplexObject**.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyComplex_CheckExact(PyObject *p)
```
Return true if its argument is a **PyComplexObject**, but not a subtype of **PyComplexObject**.

*New in version 2.2.*

**PyObject* PyComplex_FromCComplex(Py_complex v)**
Create a new Python complex number object from a C **Py_complex** value.

**PyObject* PyComplex_FromDoubles(double real, double imag)**
Return a new **PyComplexObject** object from *real* and *imag*.

```c
double PyComplex_RealAsDouble(PyObject *op)
```
Return the real part of \textit{op} as a C \texttt{double}.

\begin{verbatim}
double PyComplex_ImagAsDouble(PyObject \*op)
\end{verbatim}

Return the imaginary part of \textit{op} as a C \texttt{double}.

\begin{verbatim}
Py_complex PyComplex_AsCComplex(PyObject \*op)
\end{verbatim}

Return the \texttt{Py_complex} value of the complex number \textit{op}. Upon failure, this method returns \texttt{-1.0} as a real value.

\textit{Changed in version 2.6}: If \textit{op} is not a Python complex number object but has a \texttt{\_\_complex\_\()} method, this method will first be called to convert \textit{op} to a Python complex number object.
Byte Array Objects

*New in version 2.6.*

**PyByteArrayObject**
This subtype of *PyObject* represents a Python bytearray object.

**PyTypeObject PyByteArray_Type**
This instance of *PyTypeObject* represents the Python bytearray type; it is the same object as *bytearray* in the Python layer.
Type check macros

int PyByteArray_Check(PyObject *o)
    Return true if the object o is a bytearray object or an instance of a subtype of the bytearray type.

int PyByteArray_CheckExact(PyObject *o)
    Return true if the object o is a bytearray object, but not an instance of a subtype of the bytearray type.
### Direct API functions

**PyObject** PyByteArray_FromObject**(PyObject *o)**

Return a new bytearray object from any object, o, that implements the buffer protocol.

**PyObject** PyByteArray_FromStringAndSize**(const char *string, Py_ssize_t len)**

Create a new bytearray object from string and its length, len. On failure, NULL is returned.

**PyObject** PyByteArray_Concat**(PyObject *a, PyObject *b)**

Concat bytearrays a and b and return a new bytearray with the result.

**Py_ssize_t** PyByteArray_Size**(PyObject *bytearray)**

Return the size of bytearray after checking for a NULL pointer.

**char** PyByteArray_AsString**(PyObject *bytearray)**

Return the contents of bytearray as a char array after checking for a NULL pointer.

**int** PyByteArray_Resize**(PyObject *bytearray, Py_ssize_t len)**

Resize the internal buffer of bytearray to len.
Macros

These macros trade safety for speed and they don’t check pointers.

```c
char* PyByteArray_AS_STRING(PyObject *bytearray)
   Macro version of PyByteArray_AsString().
```

```c
Py_ssize_t PyByteArray_GET_SIZE(PyObject *bytearray)
   Macro version of PyByteArray_Size().
```
String/Bytes Objects

These functions raise **TypeError** when expecting a string parameter and are called with a non-string parameter.

**Note:** These functions have been renamed to PyBytes_* in Python 3.x. Unless otherwise noted, the PyBytes functions available in 3.x are aliased to their PyString_* equivalents to help porting.

**PyStringObject**

This subtype of **PyObject** represents a Python string object.

**PyTypeObject PyString_Type**

This instance of **PyTypeObject** represents the Python string type; it is the same object as **str** and **types.StringType** in the Python layer.

```c
int PyString_Check(PyObject *o)
```

Return true if the object o is a string object or an instance of a subtype of the string type.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyString_CheckExact(PyObject *o)
```

Return true if the object o is a string object, but not an instance of a subtype of the string type.

*New in version 2.2.*

```c
PyObject* PyString_FromString(const char *v)
```

*Return value: New reference.*

Return a new string object with a copy of the string v as value on success, and **NULL** on failure. The parameter v must not be
NULL; it will not be checked.

PyObject* PyString_FromStringAndSize(const char *v, Py_ssize_t len)

Return a new string object with a copy of the string v as value and length len on success, and NULL on failure. If v is NULL, the contents of the string are uninitialized.

Changed in version 2.5: This function used an int type for len. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyString_FromFormat(const char *format, ...)

Take a C printf()-style format string and a variable number of arguments, calculate the size of the resulting Python string and return a string with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the format string. The following format characters are allowed:

<table>
<thead>
<tr>
<th>Format Characters</th>
<th>Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>%n/a</td>
<td>n/a</td>
<td>The literal % character.</td>
</tr>
<tr>
<td>%c</td>
<td>int</td>
<td>A single character, represented as a C int.</td>
</tr>
<tr>
<td>%d</td>
<td>int</td>
<td>Exactly equivalent to printf(&quot;%d&quot;).</td>
</tr>
<tr>
<td>%u</td>
<td>unsigned int</td>
<td>Exactly equivalent to printf(&quot;%u&quot;).</td>
</tr>
<tr>
<td>%ld</td>
<td>long</td>
<td>Exactly equivalent to printf(&quot;%ld&quot;).</td>
</tr>
<tr>
<td>%lu</td>
<td>unsigned long</td>
<td>Exactly equivalent to printf(&quot;%lu&quot;).</td>
</tr>
<tr>
<td>Format Character</td>
<td>Data Type</td>
<td>Equivalent printf Function</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>%lld</td>
<td>long long</td>
<td>printf(&quot;%lld&quot;)</td>
</tr>
<tr>
<td>%llu</td>
<td>unsigned long long</td>
<td>printf(&quot;%llu&quot;)</td>
</tr>
<tr>
<td>%zd</td>
<td>Py_ssize_t</td>
<td>printf(&quot;%zd&quot;)</td>
</tr>
<tr>
<td>%zu</td>
<td>size_t</td>
<td>printf(&quot;%zu&quot;)</td>
</tr>
<tr>
<td>%i</td>
<td>int</td>
<td>printf(&quot;%i&quot;)</td>
</tr>
<tr>
<td>%x</td>
<td>int</td>
<td>printf(&quot;%x&quot;)</td>
</tr>
<tr>
<td>%s</td>
<td>char*</td>
<td>A null-terminated C character array.</td>
</tr>
<tr>
<td>%p</td>
<td>void*</td>
<td>The hex representation of a C pointer. Mostly equivalent to printf(&quot;%p&quot;) except that it is guaranteed to start with the literal 0x regardless of what the platform’s printf yields.</td>
</tr>
</tbody>
</table>

An unrecognized format character causes all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

**Note:** The “%lld” and “%llu” format specifiers are only available when `HAVE_LONG_LONG` is defined.

*Changed in version 2.7:* Support for “%lld” and “%llu” added.

**PyObject** `PyString_FromFormatV(const char *format, va_list vargs)`

*Return value:* New reference. Identical to `PyString_FromFormat()` except that it takes exactly two arguments.

**Py_ssize_t** `PyString_Size(PyObject *string)`
Return the length of the string in string object *string*.

*Changed in version 2.5:* This function returned an `int` type. This might require changes in your code for properly supporting 64-bit systems.

```c
Py_ssize_t PyString_GET_SIZE(PyObject *string)
```
Macro form of `PyString_Size()` but without error checking.

*Changed in version 2.5:* This macro returned an `int` type. This might require changes in your code for properly supporting 64-bit systems.

```c
char* PyString_AsString(PyObject *string)
```
Return a NUL-terminated representation of the contents of *string*. The pointer refers to the internal buffer of *string*, not a copy. The data must not be modified in any way, unless the string was just created using `PyString_FromStringAndSize(NULL, size)`. It must not be deallocated. If *string* is a Unicode object, this function computes the default encoding of *string* and operates on that. If *string* is not a string object at all, `PyString_AsString()` returns `NULL` and raises `TypeError`.

```c
char* PyString_AS_STRING(PyObject *string)
```
Macro form of `PyString_AsString()` but without error checking. Only string objects are supported; no Unicode objects should be passed.

```c
int PyString_AsStringAndSize(PyObject *obj, char **buffer, Py_ssize_t *length)
```
Return a NUL-terminated representation of the contents of the object *obj* through the output variables `buffer` and `length`.

The function accepts both string and Unicode objects as input. For Unicode objects it returns the default encoded version of the
object. If length is NULL, the resulting buffer may not contain NULL characters; if it does, the function returns -1 and a TypeError is raised.

The buffer refers to an internal string buffer of obj, not a copy. The data must not be modified in any way, unless the string was just created using PyObject_FromStringAndSize(NULL, size). It must not be deallocated. If string is a Unicode object, this function computes the default encoding of string and operates on that. If string is not a string object at all, PyObject_AsStringAndSize() returns -1 and raises TypeError.

Changed in version 2.5: This function used an int * type for length. This might require changes in your code for properly supporting 64-bit systems.

void PyObject_Concat(PyObject **string, PyObject *newpart)
Create a new string object in *string containing the contents of newpart appended to string; the caller will own the new reference. The reference to the old value of string will be stolen. If the new string cannot be created, the old reference to string will still be discarded and the value of *string will be set to NULL; the appropriate exception will be set.

void PyObject_ConcatAndDel(PyObject **string, PyObject *newpart)
Create a new string object in *string containing the contents of newpart appended to string. This version decrements the reference count of newpart.

int _PyObject_Resize(PyObject **string, Py_ssize_t newsize)
A way to resize a string object even though it is “immutable”. Only use this to build up a brand new string object; don’t use this if the string may already be known in other parts of the code. It is an error to call this function if the refcount on the input string object
is not one. Pass the address of an existing string object as an lvalue (it may be written into), and the new size desired. On success, *string holds the resized string object and 0 is returned; the address in *string may differ from its input value. If the reallocation fails, the original string object at *string is deallocated, *string is set to NULL, a memory exception is set, and -1 is returned.

*string* holds the resized string object and 0 is returned; the address in *string may differ from its input value. If the reallocation fails, the original string object at *string is deallocated, *string is set to NULL, a memory exception is set, and -1 is returned.

*string* may differ from its input value. If the reallocation fails, the original string object at *string is deallocated, *string is set to NULL, a memory exception is set, and -1 is returned.

Changed in version 2.5: This function used an int type for newsize. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** * PyString_Format**(PyObject *format, PyObject *args)**

*Return value: New reference.*

Return a new string object from format and args. Analogous to \texttt{format \% args}. The args argument must be a tuple or dict.

**void PyString_InternInPlace**(PyObject **string)**

Intern the argument *string in place. The argument must be the address of a pointer variable pointing to a Python string object. If there is an existing interned string that is the same as *string, it sets *string to it (decrementing the reference count of the old string object and incrementing the reference count of the interned string object), otherwise it leaves *string alone and interns it (incrementing its reference count). (Clarification: even though there is a lot of talk about reference counts, think of this function as reference-count-neutral; you own the object after the call if and only if you owned it before the call.)

**Note:** This function is not available in 3.x and does not have a PyBytes alias.

**PyObject** * PyString_InternFromString**(const char *v)**

*Return value: New reference.*
A combination of `PyString_FromString()` and `PyString_InternInPlace()`, returning either a new string object that has been interned, or a new (“owned”) reference to an earlier interned string object with the same value.

**Note:** This function is not available in 3.x and does not have a PyBytes alias.

```c
PyObject* PyString_Decode(const char *s, Py_ssize_t size, const char *encoding, const char *errors)
```

*Return value: New reference.*

Create an object by decoding size bytes of the encoded buffer `s` using the codec registered for `encoding`. `encoding` and `errors` have the same meaning as the parameters of the same name in the `unicode()` built-in function. The codec to be used is looked up using the Python codec registry. Return `NULL` if an exception was raised by the codec.

**Note:** This function is not available in 3.x and does not have a PyBytes alias.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

```c
PyObject* PyString_AsDecodedObject(PyObject *str, const char *encoding, const char *errors)
```

*Return value: New reference.*

Decode a string object by passing it to the codec registered for `encoding` and return the result as Python object. `encoding` and `errors` have the same meaning as the parameters of the same name in the string `encode()` method. The codec to be used is looked up using the Python codec registry. Return `NULL` if an exception was raised by the codec.
Note: This function is not available in 3.x and does not have a PyBytes alias.

PyObject* PyString_Encode(const char *s, Py_ssize_t size, const char *encoding, const char *errors)

Encode the char buffer of the given size by passing it to the codec registered for encoding and return a Python object. encoding and errors have the same meaning as the parameters of the same name in the string encode() method. The codec to be used is looked up using the Python codec registry. Return NULL if an exception was raised by the codec.

Note: This function is not available in 3.x and does not have a PyBytes alias.

Changed in version 2.5: This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyString_AsEncodedObject(PyObject *str, const char *encoding, const char *errors)

Encode a string object using the codec registered for encoding and return the result as Python object. encoding and errors have the same meaning as the parameters of the same name in the string encode() method. The codec to be used is looked up using the Python codec registry. Return NULL if an exception was raised by the codec.

Note: This function is not available in 3.x and does not have a PyBytes alias.
Unicode Objects

Unicode Type

These are the basic Unicode object types used for the Unicode implementation in Python:

**Py_UNICODE**
This type represents the storage type which is used by Python internally as basis for holding Unicode ordinals. Python’s default builds use a 16-bit type for **Py_UNICODE** and store Unicode values internally as UCS2. It is also possible to build a UCS4 version of Python (most recent Linux distributions come with UCS4 builds of Python). These builds then use a 32-bit type for **Py_UNICODE** and store Unicode data internally as UCS4. On platforms where wchar_t is available and compatible with the chosen Python Unicode build variant, **Py_UNICODE** is a typedef alias for wchar_t to enhance native platform compatibility. On all other platforms, **Py_UNICODE** is a typedef alias for either unsigned short (UCS2) or unsigned long (UCS4).

Note that UCS2 and UCS4 Python builds are not binary compatible. Please keep this in mind when writing extensions or interfaces.

**PyUnicodeObject**
This subtype of **PyObject** represents a Python Unicode object.

**PyTypeObject** **PyUnicode_Type**
This instance of **PyTypeObject** represents the Python Unicode type. It is exposed to Python code as **unicode** and **types.UnicodeType**.

The following APIs are really C macros and can be used to do fast
checks and to access internal read-only data of Unicode objects:

```python
int PyUnicode_Check(PyObject *o)
    Return true if the object o is a Unicode object or an instance of a Unicode subtype.

    Changed in version 2.2: Allowed subtypes to be accepted.
```

```python
int PyUnicode_CheckExact(PyObject *o)
    Return true if the object o is a Unicode object, but not an instance of a subtype.

    New in version 2.2.
```

```python
Py_ssize_t PyUnicode_GET_SIZE(PyObject *o)
    Return the size of the object. o has to be a PyUnicodeObject (not checked).

    Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.
```

```python
Py_ssize_t PyUnicode_GET_DATA_SIZE(PyObject *o)
    Return the size of the object's internal buffer in bytes. o has to be a PyUnicodeObject (not checked).

    Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.
```

```python
Py_UNICODE* PyUnicode_AS_UNICODE(PyObject *o)
    Return a pointer to the internal Py_UNICODE buffer of the object. o has to be a PyUnicodeObject (not checked).
```

```python
const char* PyUnicode_AS_DATA(PyObject *o)
    Return a pointer to the internal buffer of the object. o has to be a
PyUnicodeObject (not checked).

int PyUnicode_ClearFreeList()
    Clear the free list. Return the total number of freed items.

*New in version 2.6.*

### Unicode Character Properties

Unicode provides many different character properties. The most often needed ones are available through these macros which are mapped to C functions depending on the Python configuration.

int Py_UNICODE_ISSPACE(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a whitespace character.

int Py_UNICODE_ISLOWER(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a lowercase character.

int Py_UNICODE_ISUPPER(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an uppercase character.

int Py_UNICODE_ISTITLE(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a titlecase character.

int Py_UNICODE_ISLINEBREAK(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a linebreak character.

int Py_UNICODE_ISDECIMAL(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a decimal character.

int Py_UNICODE_ISDIGIT(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a digit character.
int Py_UNICODE_ISNUMERIC(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a numeric character.

int Py_UNICODE_ISALPHA(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an alphabetic character.

int Py_UNICODE_ISALNUM(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an alphanumeretic character.

These APIs can be used for fast direct character conversions:

Py_UNICODE Py_UNICODE_TOLOWER(Py_UNICODE ch)
    Return the character ch converted to lower case.

Py_UNICODE Py_UNICODE_TOUPPER(Py_UNICODE ch)
    Return the character ch converted to upper case.

Py_UNICODE Py_UNICODE_TOTITLE(Py_UNICODE ch)
    Return the character ch converted to title case.

int Py_UNICODE_TODECIMAL(Py_UNICODE ch)
    Return the character ch converted to a decimal positive integer. Return -1 if this is not possible. This macro does not raise exceptions.

int Py_UNICODE_TODIGIT(Py_UNICODE ch)
    Return the character ch converted to a single digit integer. Return -1 if this is not possible. This macro does not raise exceptions.

double Py_UNICODE_TONUMERIC(Py_UNICODE ch)
    Return the character ch converted to a double. Return -1.0 if this is not possible. This macro does not raise exceptions.
To create Unicode objects and access their basic sequence properties, use these APIs:

**PyObject** *PyUnicode_FromUnicode*(const Py_UNICODE *u, Py_ssize_t size)

*Return value: New reference.*
Create a Unicode object from the Py_UNICODE buffer `u` of the given size. `u` may be `NULL` which causes the contents to be undefined. It is the user’s responsibility to fill in the needed data. The buffer is copied into the new object. If the buffer is not `NULL`, the return value might be a shared object. Therefore, modification of the resulting Unicode object is only allowed when `u` is `NULL`.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** *PyUnicode_FromStringAndSize*(const char *u, Py_ssize_t size)

*Return value: New reference.*
Create a Unicode object from the char buffer `u`. The bytes will be interpreted as being UTF-8 encoded. `u` may also be `NULL` which causes the contents to be undefined. It is the user’s responsibility to fill in the needed data. The buffer is copied into the new object. If the buffer is not `NULL`, the return value might be a shared object. Therefore, modification of the resulting Unicode object is only allowed when `u` is `NULL`.

*New in version 2.6.*

**PyObject** *PyUnicode_FromString*(const char *u)

*Return value: New reference.*
Create a Unicode object from a UTF-8 encoded null-terminated
char buffer \textit{u}.

\textit{New in version 2.6.}

\textbf{PyObject* \texttt{PyUnicode_FromFormat}}(const char *\textit{format}, ...)

\textit{Return value: New reference.}

Take a C \texttt{printf()}-style \textit{format} string and a variable number of arguments, calculate the size of the resulting Python unicode string and return a string with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the \textit{format} string. The following format characters are allowed:

<table>
<thead>
<tr>
<th>Format Characters</th>
<th>Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>\textit{n/a}</td>
<td>The literal % character.</td>
</tr>
<tr>
<td>%c</td>
<td>\textit{int}</td>
<td>A single character, represented as a C int.</td>
</tr>
<tr>
<td>%d</td>
<td>\textit{int}</td>
<td>Exactly equivalent to printf(&quot;%d&quot;).</td>
</tr>
<tr>
<td>%u</td>
<td>unsigned \textit{int}</td>
<td>Exactly equivalent to printf(&quot;%u&quot;).</td>
</tr>
<tr>
<td>%ld</td>
<td>\textit{long}</td>
<td>Exactly equivalent to printf(&quot;%ld&quot;).</td>
</tr>
<tr>
<td>%lu</td>
<td>unsigned \textit{long}</td>
<td>Exactly equivalent to printf(&quot;%lu&quot;).</td>
</tr>
<tr>
<td>%zd</td>
<td>\textit{Py_ssize_t}</td>
<td>Exactly equivalent to printf(&quot;%zd&quot;).</td>
</tr>
<tr>
<td>%zu</td>
<td>\textit{size_t}</td>
<td>Exactly equivalent to printf(&quot;%zu&quot;).</td>
</tr>
<tr>
<td>%i</td>
<td>\textit{int}</td>
<td>Exactly equivalent to printf(&quot;%i&quot;).</td>
</tr>
<tr>
<td>%x</td>
<td>\textit{int}</td>
<td>Exactly equivalent to printf(&quot;%x&quot;).</td>
</tr>
</tbody>
</table>
| \%s                | char*          | A null-terminated C
<table>
<thead>
<tr>
<th>Character</th>
<th>Argument Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%p</code></td>
<td>void*</td>
<td>void*</td>
</tr>
<tr>
<td><code>%u</code></td>
<td>PyObject*</td>
<td>A unicode object.</td>
</tr>
<tr>
<td><code>%v</code></td>
<td>PyObject*, char *</td>
<td>A unicode object (which may be <code>NULL</code>) and a null-terminated C character array as a second parameter (which will be used, if the first parameter is <code>NULL</code>).</td>
</tr>
<tr>
<td><code>%S</code></td>
<td>PyObject*</td>
<td>The result of calling <code>PyObject_Unicode()</code>.</td>
</tr>
<tr>
<td><code>%R</code></td>
<td>PyObject*</td>
<td>The result of calling <code>PyObject_Repr()</code>.</td>
</tr>
</tbody>
</table>

An unrecognized format character causes all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

*New in version 2.6.*

```c
PyObject* PyUnicode_FromFormatV(const char *format, va_list vars)
```

*Return value: New reference.*

Identical to `PyUnicode_FromFormat()` except that it takes exactly two arguments.

*New in version 2.6.*

```c
Py_UNICODE* PyUnicode_AsUnicode(PyObject *unicode)
```

Return a read-only pointer to the Unicode object's internal
**Py_UNICODE** buffer, *NULL* if *unicode* is not a Unicode object. Note that the resulting **Py_UNICODE** string may contain embedded null characters, which would cause the string to be truncated when used in most C functions.

**Py_ssize_t** **PyUnicode_GetSize**(PyObject **unicode*)
Return the length of the Unicode object.

*Changed in version 2.5:* This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** *PyUnicode_FromEncodedObject**(PyObject *obj, const char *encoding, const char *errors)
*Return value: New reference.*
Coerce an encoded object *obj* to a Unicode object and return a reference with incremented refcount.

String and other char buffer compatible objects are decoded according to the given encoding and using the error handling defined by errors. Both can be *NULL* to have the interface use the default values (see the next section for details).

All other objects, including Unicode objects, cause a TypeError to be set.

The API returns *NULL* if there was an error. The caller is responsible for deallocating the returned objects.

**PyObject** *PyUnicode_FromObject**(PyObject *obj)
*Return value: New reference.*
Shortcut for PyUnicode_FromEncodedObject(*obj, NULL, "strict") which is used throughout the interpreter whenever coercion to Unicode is needed.
If the platform supports wchar_t and provides a header file wchar.h, Python can interface directly to this type using the following functions. Support is optimized if Python’s own Py_UNICODE type is identical to the system’s wchar_t.

## wchar_t Support

wchar_t support for platforms which support it:

**PyObject**\* PyUnicode_FromWideChar(const wchar_t *w, Py_ssize_t size)

*Return value: New reference.*
Create a Unicode object from the wchar_t buffer w of the given size. Return NULL on failure.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PyUnicode_AsWideChar(PyUnicodeObject *unicode, wchar_t *w, Py_ssize_t size)

Copy the Unicode object contents into the wchar_t buffer w. At most size wchar_t characters are copied (excluding a possibly trailing 0-termination character). Return the number of wchar_t characters copied or -1 in case of an error. Note that the resulting wchar_t string may or may not be 0-terminated. It is the responsibility of the caller to make sure that the wchar_t string is 0-terminated in case this is required by the application. Also, note that the wchar_t* string might contain null characters, which would cause the string to be truncated when used with most C functions.

*Changed in version 2.5:* This function returned an int type and
used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.
Built-in Codecs

Python provides a set of built-in codecs which are written in C for speed. All of these codecs are directly usable via the following functions.

Many of the following APIs take two arguments encoding and errors, and they have the same semantics as the ones of the built-in `unicode()` Unicode object constructor.

Setting encoding to `NULL` causes the default encoding to be used which is ASCII. The file system calls should use `Py_FileSystemDefaultEncoding` as the encoding for file names. This variable should be treated as read-only: on some systems, it will be a pointer to a static string, on others, it will change at run-time (such as when the application invokes `setlocale()`).

Error handling is set by errors which may also be set to `NULL` meaning to use the default handling defined for the codec. Default error handling for all built-in codecs is “strict” (`ValueError` is raised).

The codecs all use a similar interface. Only deviation from the following generic ones are documented for simplicity.

Generic Codecs

These are the generic codec APIs:

```c
PyObject* PyUnicode_Decode(const char *s, Py_ssize_t size, const char *encoding, const char *errors)
```

*Return value: New reference.*

Create a Unicode object by decoding `size` bytes of the encoded string `s`. `encoding` and `errors` have the same meaning as the parameters of the same name in the `unicode()` built-in function.
The codec to be used is looked up using the Python codec registry. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

`PyObject* PyUnicode_Encode(const Py_UNICODE *s, Py_ssize_t size, const char *encoding, const char *errors)`

*Return value: New reference.*

Encode the Py_UNICODE buffer s of the given size and return a Python string object. encoding and errors have the same meaning as the parameters of the same name in the Unicode encode() method. The codec to be used is looked up using the Python codec registry. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

`PyObject* PyUnicode_AsEncodedString(PyObject *unicode, const char *encoding, const char *errors)`

*Return value: New reference.*

Encode a Unicode object and return the result as Python string object. encoding and errors have the same meaning as the parameters of the same name in the Unicode encode() method. The codec to be used is looked up using the Python codec registry. Return NULL if an exception was raised by the codec.

### UTF-8 Codecs

These are the UTF-8 codec APIs:

`PyObject* PyUnicode_DecodeUTF8(const char *s, Py_ssize_t size,`
const char *errors)

Create a Unicode object by decoding size bytes of the UTF-8 encoded string s. Return NULL if an exception was raised by the codec.

Changed in version 2.5: This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyUnicode_DecodeUTF8Stateful(const char *s, Py_ssize_t size, const char *errors, Pysize_t *consumed)

If consumed is NULL, behave like PyUnicode_DecodeUTF8(). If consumed is not NULL, trailing incomplete UTF-8 byte sequences will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in consumed.

New in version 2.4.

Changed in version 2.5: This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyUnicode_EncodeUTF8(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

Encode the Py_UNICODE buffer s of the given size using UTF-8 and return a Python string object. Return NULL if an exception was raised by the codec.

Changed in version 2.5: This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.
PyObject* PyUnicode_AsUTF8String(PyObject *unicode)

Encode a Unicode object using UTF-8 and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

UTF-32 Codecs

These are the UTF-32 codec APIs:

PyObject* PyUnicode_DecodeUTF32(const char *s, Py_ssize_t size, const char *errors, int *byteorder)

Decide size bytes from a UTF-32 encoded buffer string and return the corresponding Unicode object. errors (if non-NULL) defines the error handling. It defaults to “strict”.

If byteorder is non-NULL, the decoder starts decoding using the given byte order:

*byteorder == -1: little endian
*byteorder == 0: native order
*byteorder == 1: big endian

If *byteorder is zero, and the first four bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If *byteorder is -1 or 1, any byte order mark is copied to the output.

After completion, *byteorder is set to the current byte order at the end of input data.

In a narrow build code points outside the BMP will be decoded as surrogate pairs.

If byteorder is NULL, the codec starts in native order mode.
Return *NULL* if an exception was raised by the codec.

*New in version 2.6.*

```c
PyObject* PyUnicode_DecodeUTF32Stateful(const char *s,
Py_ssize_t size, const char *errors, int *byteorder,
Py_ssize_t *consumed)
```

If `consumed` is *NULL*, behave like `PyUnicode_DecodeUTF32()`. If `consumed` is not *NULL*, `PyUnicode_DecodeUTF32Stateful()` will not treat trailing incomplete UTF-32 byte sequences (such as a number of bytes not divisible by four) as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in `consumed`.

*New in version 2.6.*

```c
PyObject* PyUnicode_EncodeUTF32(const Py_UNICODE *s,
Py_ssize_t size, const char *errors, int byteorder)
```

Return a Python bytes object holding the UTF-32 encoded value of the Unicode data in `s`. Output is written according to the following byte order:

<table>
<thead>
<tr>
<th>byteorder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>little endian</td>
</tr>
<tr>
<td>0</td>
<td>native byte order (writes a BOM mark)</td>
</tr>
<tr>
<td>1</td>
<td>big endian</td>
</tr>
</tbody>
</table>

If `byteorder` is 0, the output string will always start with the Unicode BOM mark (U+FEFF). In the other two modes, no BOM mark is prepended.

If `Py_UNICODE_WIDE` is not defined, surrogate pairs will be output as a single code point.

Return *NULL* if an exception was raised by the codec.

*New in version 2.6.*
PyObject* PyUnicode_AsUTF32String(PyObject *unicode)
Return a Python string using the UTF-32 encoding in native byte order. The string always starts with a BOM mark. Error handling is “strict”. Return NULL if an exception was raised by the codec.

New in version 2.6.

UTF-16 Codecs

These are the UTF-16 codec APIs:

PyObject* PyUnicode_DecodeUTF16(const char *s, Py_ssize_t size, const char *errors, int *byteorder)
Decode size bytes from a UTF-16 encoded buffer string and return the corresponding Unicode object. errors (if non-NULL) defines the error handling. It defaults to “strict”.

If byteorder is non-NULL, the decoder starts decoding using the given byte order:

*byteorder == -1: little endian
*byteorder == 0: native order
*byteorder == 1: big endian

If *byteorder is zero, and the first two bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If *byteorder is -1 or 1, any byte order mark is copied to the output (where it will result in either a \u00ef or a \ufffe character).

After completion, *byteorder is set to the current byte order at the end of input data.

If byteorder is NULL, the codec starts in native order mode.
Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

```
PyObject* PyUnicode_DecodeUTF16Stateful(const char *s,
Py_ssize_t size, const char *errors, int *byteorder,
Py_ssize_t *consumed)

If consumed is NULL, behave like PyUnicode_DecodeUTF16(). If consumed is not NULL, PyUnicode_DecodeUTF16Stateful() will not treat trailing incomplete UTF-16 byte sequences (such as an odd number of bytes or a split surrogate pair) as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in consumed.

New in version 2.4.

*Changed in version 2.5:* This function used an int type for size and an int * type for consumed. This might require changes in your code for properly supporting 64-bit systems.

```

```
PyObject* PyUnicode_EncodeUTF16(const Py_UNICODE *s,
Py_ssize_t size, const char *errors, int byteorder)

Return a Python string object holding the UTF-16 encoded value of the Unicode data in s. Output is written according to the following byte order:

<table>
<thead>
<tr>
<th>byteorder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>little endian</td>
</tr>
<tr>
<td>0</td>
<td>native byte order (writes a BOM mark)</td>
</tr>
<tr>
<td>1</td>
<td>big endian</td>
</tr>
</tbody>
</table>

If byteorder is 0, the output string will always start with the Unicode BOM mark (U+FEFF). In the other two modes, no BOM
mark is prepended.

If `Py_UNICODE_WIDE` is defined, a single `Py_UNICODE` value may get represented as a surrogate pair. If it is not defined, each `Py_UNICODE` values is interpreted as a UCS-2 character.

Return `NULL` if an exception was raised by the codec.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

```c
PyObject* PyUnicode_AsUTF16String(PyObject *unicode)

Return a Python string using the UTF-16 encoding in native byte order. The string always starts with a BOM mark. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.
```

### UTF-7 Codecs

These are the UTF-7 codec APIs:

```c
PyObject* PyUnicode_DecodeUTF7(const char *s, Py_ssize_t size, const char *errors)

Create a Unicode object by decoding `size` bytes of the UTF-7 encoded string `s`. Return `NULL` if an exception was raised by the codec.
```

```c
PyObject* PyUnicode_DecodeUTF7Stateful(const char *s, Py_ssize_t size, const char *errors, Py_ssize_t *consumed)

If `consumed` is `NULL`, behave like `PyUnicode_DecodeUTF7()`. If `consumed` is not `NULL`, trailing incomplete UTF-7 base-64 sections will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in `consumed`.
```
PyObject* PyUnicode_EncodeUTF7(const Py_UNICODE *s,
Py_ssize_t size, int base64SetO, int base64WhiteSpace, const char *errors)

Encode the Py_UNICODE buffer of the given size using UTF-7 and return a Python bytes object. Return NULL if an exception was raised by the codec.

If base64SetO is nonzero, “Set O” (punctuation that has no otherwise special meaning) will be encoded in base-64. If base64WhiteSpace is nonzero, whitespace will be encoded in base-64. Both are set to zero for the Python “utf-7” codec.

Unicode-Escape Codecs

These are the “Unicode Escape” codec APIs:

PyObject* PyUnicode_DecodeUnicodeEscape(const char *s,
Py_ssize_t size, const char *errors)

Create a Unicode object by decoding size bytes of the Unicode-Escape encoded string s. Return NULL if an exception was raised by the codec.

Changed in version 2.5: This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyUnicode_EncodeUnicodeEscape(const
Py_UNICODE *s, Py_ssize_t size)

Encode the Py_UNICODE buffer of the given size using Unicode-Escape and return a Python string object. Return NULL if an exception was raised by the codec.

Changed in version 2.5: This function used an int type for size.
This might require changes in your code for properly supporting 64-bit systems.

**PyObject* `PyUnicode_AsUnicodeEscapeString(PyObject *unicode)`**

*Return value: New reference.*

Encode a Unicode object using Unicode-Escape and return the result as Python string object. Error handling is “strict”. Return `NULL` if an exception was raised by the codec.

---

**Raw-Unicode-Escape Codecs**

These are the “Raw Unicode Escape” codec APIs:

**PyObject* `PyUnicode_DecodeRawUnicodeEscape(const char *s, Py_ssize_t size, const char *errors)`**

*Return value: New reference.*

Create a Unicode object by decoding size bytes of the Raw-Unicode-Escape encoded string s. Return `NULL` if an exception was raised by the codec.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

**PyObject* `PyUnicode_EncodeRawUnicodeEscape(const Py_UNICODE *s, Py_ssize_t size, const char *errors)`**

*Return value: New reference.*

Encode the `Py_UNICODE` buffer of the given `size` using Raw-Unicode-Escape and return a Python string object. Return `NULL` if an exception was raised by the codec.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.
PyObject*
PyUnicode_AsRawUnicodeEscapeString(PyObject *unicode)

*Return value: New reference.*

Encode a Unicode object using Raw-Unicode-Escape and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

## Latin-1 Codecs

These are the Latin-1 codec APIs: Latin-1 corresponds to the first 256 Unicode ordinals and only these are accepted by the codecs during encoding.

PyObject* PyUnicode_DecodeLatin1(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Create a Unicode object by decoding size bytes of the Latin-1 encoded string s. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyUnicode_EncodeLatin1(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Encode the Py_UNICODE buffer of the given size using Latin-1 and return a Python string object. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.
PyObject* **PyUnicode_AsLatin1String**(PyObject *unicode)

*Return value: New reference.*

Encode a Unicode object using Latin-1 and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

### ASCII Codecs

These are the ASCII codec APIs. Only 7-bit ASCII data is accepted. All other codes generate errors.

PyObject* **PyUnicode_DecodeASCII**(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Create a Unicode object by decoding size bytes of the ASCII encoded string s. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* **PyUnicode_EncodeASCII**(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Encode the Py_UNICODE buffer of the given size using ASCII and return a Python string object. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* **PyUnicode_AsASCIIString**(PyObject *unicode)

*Return value: New reference.*
Encode a Unicode object using ASCII and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

**Character Map Codecs**

This codec is special in that it can be used to implement many different codecs (and this is in fact what was done to obtain most of the standard codecs included in the `encodings` package). The codec uses mapping to encode and decode characters.

Decoding mappings must map single string characters to single Unicode characters, integers (which are then interpreted as Unicode ordinals) or None (meaning “undefined mapping” and causing an error).

Encoding mappings must map single Unicode characters to single string characters, integers (which are then interpreted as Latin-1 ordinals) or None (meaning “undefined mapping” and causing an error).

The mapping objects provided must only support the `__getitem__` mapping interface.

If a character lookup fails with a LookupError, the character is copied as-is meaning that its ordinal value will be interpreted as Unicode or Latin-1 ordinal resp. Because of this, mappings only need to contain those mappings which map characters to different code points.

These are the mapping codec APIs:

```c
PyObject* PyUnicode_DecodeCharmap(const char *s, Py_ssize_t size, PyObject *mapping, const char *errors)
```

*Return value: New reference.*

Create a Unicode object by decoding `size` bytes of the encoded
string s using the given \textit{mapping} object. Return \textit{NULL} if an exception was raised by the codec. If \textit{mapping} is \textit{NULL} latin-1 decoding will be done. Else it can be a dictionary mapping byte or a unicode string, which is treated as a lookup table. Byte values greater that the length of the string and U+FFFE “characters” are treated as “undefined mapping”.

\textit{Changed in version 2.4:} Allowed unicode string as mapping argument.

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \texttt{size}. This might require changes in your code for properly supporting 64-bit systems.

\texttt{PyObject* PyUnicode\_EncodeCharmap(const Py\_UNICODE *s, Py\_ssize\_t size, PyObject *mapping, const char *errors)}

\textit{Return value: New reference.}

Encode the \texttt{Py\_UNICODE} buffer of the given \texttt{size} using the given \textit{mapping} object and return a Python string object. Return \textit{NULL} if an exception was raised by the codec.

\textit{Changed in version 2.5:} This function used an \texttt{int} type for \texttt{size}. This might require changes in your code for properly supporting 64-bit systems.

\texttt{PyObject* PyUnicode\_AsCharmapString(PyObject *unicode, PyObject *mapping)}

\textit{Return value: New reference.}

Encode a Unicode object using the given \textit{mapping} object and return the result as Python string object. Error handling is “strict”. Return \textit{NULL} if an exception was raised by the codec.

The following codec API is special in that maps Unicode to Unicode.

\texttt{PyObject* PyUnicode\_TranslateCharmap(const Py\_UNICODE *s, Py\_ssize\_t size, PyObject *table, const char *errors)}
**Return value: New reference.**
Translate a `Py_UNICODE` buffer of the given `size` by applying a character mapping `table` to it and return the resulting Unicode object. Return `NULL` when an exception was raised by the codec.

The `mapping` table must map Unicode ordinal integers to Unicode ordinal integers or `None` (causing deletion of the character).

Mapping tables need only provide the `__getitem__()` interface; dictionaries and sequences work well. Unmapped character ordinals (ones which cause a `LookupError`) are left untouched and are copied as-is.

**Changed in version 2.5:** This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

---

**MBCS codecs for Windows**

These are the MBCS codec APIs. They are currently only available on Windows and use the Win32 MBCS converters to implement the conversions. Note that MBCS (or DBCS) is a class of encodings, not just one. The target encoding is defined by the user settings on the machine running the codec.

```c
PyObject* PyUnicode_DecodeMBCS(const char *s, Py_ssize_t size,
const char *errors)
```

**Return value: New reference.**
Create a Unicode object by decoding `size` bytes of the MBCS encoded string `s`. Return `NULL` if an exception was raised by the codec.

**Changed in version 2.5:** This function used an `int` type for `size`. This might require changes in your code for properly supporting
64-bit systems.

**PyObject** `PyUnicode_DecodeMBCSStateful` (const char *s, int size, const char *errors, int *consumed)

If consumed is NULL, behave like `PyUnicode_DecodeMBCS()`. If consumed is not NULL, `PyUnicode_DecodeMBCSStateful()` will not decode trailing lead byte and the number of bytes that have been decoded will be stored in consumed.

*New in version 2.5.*

**PyObject** `PyUnicode_EncodeMBCS` (const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Encode the Py_UNICODE buffer of the given size using MBCS and return a Python string object. Return NULL if an exception was raised by the codec.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

**PyObject** `PyUnicode_AsMBCSString` (PyObject *unicode)

*Return value: New reference.*

Encode a Unicode object using MBCS and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

---

**Methods & Slots**
Methods and Slot Functions

The following APIs are capable of handling Unicode objects and strings on input (we refer to them as strings in the descriptions) and return Unicode objects or integers as appropriate.

They all return *NULL* or -1 if an exception occurs.

**PyObject**\* **PyUnicode_Concat**\(\text{PyObject} *\text{left}, \text{PyObject} *\text{right}\)

*Return value: New reference.*

Concat two strings giving a new Unicode string.

**PyObject**\* **PyUnicode_Split**\(\text{PyObject} *\text{s}, \text{PyObject} *\text{sep},\)

\(\text{Py_ssize_t} \text{maxsplit}\)

*Return value: New reference.*

Split a string giving a list of Unicode strings. If \text{sep} is *NULL*, splitting will be done at all whitespace substrings. Otherwise, splits occur at the given separator. At most \text{maxsplit} splits will be done. If negative, no limit is set. Separators are not included in the resulting list.

*Changed in version 2.5:* This function used an int type for \text{maxsplit}. This might require changes in your code for properly supporting 64-bit systems.

**PyObject**\* **PyUnicode_Splitlines**\(\text{PyObject} *\text{s}, \text{int} \text{keepend}\)

*Return value: New reference.*

Split a Unicode string at line breaks, returning a list of Unicode strings. CRLF is considered to be one line break. If \text{keepend} is 0, the Line break characters are not included in the resulting strings.

**PyObject**\* **PyUnicode_Translate**\(\text{PyObject} *\text{str}, \text{PyObject} *\text{table},\)

\(\text{const} \text{char} *\text{errors}\)

*Return value: New reference.*
Translate a string by applying a character mapping table to it and return the resulting Unicode object.

The mapping table must map Unicode ordinal integers to Unicode ordinal integers or None (causing deletion of the character).

Mapping tables need only provide the __getitem__() interface; dictionaries and sequences work well. Unmapped character ordinals (ones which cause a LookupError) are left untouched and are copied as-is.

errors has the usual meaning for codecs. It may be NULL which indicates to use the default error handling.

PyObject* PyUnicode_Join(PyObject *separator, PyObject *seq)

Join a sequence of strings using the given separator and return the resulting Unicode string.

Py_ssize_t PyUnicode_Tailmatch(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end, int direction)

Return 1 if substr matches str[start:end] at the given tail end (direction == -1 means to do a prefix match, direction == 1 a suffix match), 0 otherwise. Return -1 if an error occurred.

Changed in version 2.5: This function used an int type for start and end. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PyUnicode_Find(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end, int direction)

Return the first position of substr in str[start:end] using the given direction (direction == 1 means to do a forward search, direction == -1 a backward search). The return value is the index
of the first match; a value of \(-1\) indicates that no match was found, and \(-2\) indicates that an error occurred and an exception has been set.

*Changed in version 2.5:* This function used an int type for \(\text{start}\) and \(\text{end}\). This might require changes in your code for properly supporting 64-bit systems.

```c
Py_ssize_t PyUnicode_Count(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end)
```

Return the number of non-overlapping occurrences of \(\text{substr}\) in \(\text{str}[\text{start}:\text{end}]\). Return \(-1\) if an error occurred.

*Changed in version 2.5:* This function returned an int type and used an int type for \(\text{start}\) and \(\text{end}\). This might require changes in your code for properly supporting 64-bit systems.

```c
PyObject* PyUnicode_REPLACE(PyObject *str, PyObject *substr, PyObject *replstr, Py_ssize_t maxcount)
```

*Return value: New reference.*

Replace at most \(\text{maxcount}\) occurrences of \(\text{substr}\) in \(\text{str}\) with \(\text{replstr}\) and return the resulting Unicode object. \(\text{maxcount} == -1\) means replace all occurrences.

*Changed in version 2.5:* This function used an int type for \(\text{maxcount}\). This might require changes in your code for properly supporting 64-bit systems.

```c
int PyUnicode_Compare(PyObject *left, PyObject *right)
```

Compare two strings and return \(-1\), \(0\), \(1\) for less than, equal, and greater than, respectively.

```c
int PyUnicode_RichCompare(PyObject *left, PyObject *right, int op)
```

Rich compare two unicode strings and return one of the following:
- **NULL** in case an exception was raised
- **Py_True** or **Py_False** for successful comparisons
- **Py_NotImplemented** in case the type combination is unknown

Note that **Py_EQ** and **Py_NE** comparisons can cause a `UnicodeWarning` in case the conversion of the arguments to Unicode fails with a `UnicodeDecodeError`.

Possible values for `op` are **Py_GT**, **Py_GE**, **Py_EQ**, **Py_NE**, **Py_LT**, and **Py_LE**.

**PyObject** * PyUnicode_Format (PyObject *format, PyObject *args) *

*Return value: New reference.*

Return a new string object from `format` and `args`; this is analogous to `format % args`.

**int** PyUnicode_Contains (PyObject *container, PyObject *element) *

Check whether `element` is contained in `container` and return true or false accordingly.

`element` has to coerce to a one element Unicode string. -1 is returned if there was an error.
Buffers and Memoryview Objects

Python objects implemented in C can export a group of functions called the “buffer interface.” These functions can be used by an object to expose its data in a raw, byte-oriented format. Clients of the object can use the buffer interface to access the object data directly, without needing to copy it first.

Two examples of objects that support the buffer interface are strings and arrays. The string object exposes the character contents in the buffer interface’s byte-oriented form. An array can only expose its contents via the old-style buffer interface. This limitation does not apply to Python 3, where memoryview objects can be constructed from arrays, too. Array elements may be multi-byte values.

An example user of the buffer interface is the file object's write() method. Any object that can export a series of bytes through the buffer interface can be written to a file. There are a number of format codes to PyArg_ParseTuple() that operate against an object's buffer interface, returning data from the target object.

Starting from version 1.6, Python has been providing Python-level buffer objects and a C-level buffer API so that any built-in or used-defined type can expose its characteristics. Both, however, have been deprecated because of various shortcomings, and have been officially removed in Python 3 in favour of a new C-level buffer API and a new Python-level object named memoryview.

The new buffer API has been backported to Python 2.6, and the memoryview object has been backported to Python 2.7. It is strongly advised to use them rather than the old APIs, unless you are blocked from doing so for compatibility reasons.
The new-style Py_buffer struct

Py_buffer
    void *buf
    A pointer to the start of the memory for the object.

Py_ssize_t len
    The total length of the memory in bytes.

int readonly
    An indicator of whether the buffer is read only.

const char *format
    A NULL terminated string in struct module style syntax giving the contents of the elements available through the buffer. If this is NULL, "B" (unsigned bytes) is assumed.

int ndim
    The number of dimensions the memory represents as a multi-dimensional array. If it is 0, strides and suboffsets must be NULL.

Py_ssize_t *shape
    An array of Py_ssize_t the length of ndim giving the shape of the memory as a multi-dimensional array. Note that ((*shape)[0] * ... * (*shape)[ndims-1])*itemsize should be equal to len.

Py_ssize_t *strides
    An array of Py_ssize_t the length of ndim giving the number of bytes to skip to get to a new element in each dimension.

Py_ssize_t *suboffsets
An array of `Py_ssize_t` the length of `ndim`. If these suboffset numbers are greater than or equal to 0, then the value stored along the indicated dimension is a pointer and the suboffset value dictates how many bytes to add to the pointer after de-referencing. A suboffset value that is negative indicates that no de-referencing should occur (striding in a contiguous memory block).

If all suboffsets are negative (i.e. no de-referencing is needed, then this field must be NULL (the default value).

Here is a function that returns a pointer to the element in an N-D array pointed to by an N-dimensional index when there are both non-NULL strides and suboffsets:

```c
void *get_item_pointer(int ndim, void *buf, Py_ssize_t *strides, Py_ssize_t *suboffsets, Py_ssize_t *indices) {
    char *pointer = (char*)buf;
    int i;
    for (i = 0; i < ndim; i++) {
        pointer += strides[i] * indices[i];
        if (suboffsets[i] >= 0) {
            pointer = *((char**)pointer) + suboffsets[i];
        }
    }
    return (void*)pointer;
}
```

**Py_ssize_t itemsize**

This is a storage for the itemsize (in bytes) of each element of the shared memory. It is technically un-necessary as it can be obtained using `PyBuffer_SizeFromFormat()`, however an exporter may know this information without parsing the format string and it is necessary to know the itemsize for proper interpretation of striding. Therefore, storing it is more convenient and faster.
void *internal

This is for use internally by the exporting object. For example, this might be re-cast as an integer by the exporter and used to store flags about whether or not the shape, strides, and suboffsets arrays must be freed when the buffer is released. The consumer should never alter this value.
Buffer related functions

int **buffer_check(PyObject *obj)**
Return 1 if *obj* supports the buffer interface otherwise 0.

int **buffer_get(PyObject *obj, Py_buffer *view, int flags)**
Export *obj* into a **buffer**, *view*. These arguments must never be NULL. The *flags* argument is a bit field indicating what kind of buffer the caller is prepared to deal with and therefore what kind of buffer the exporter is allowed to return. The buffer interface allows for complicated memory sharing possibilities, but some caller may not be able to handle all the complexity but may want to see if the exporter will let them take a simpler view to its memory.

Some exporters may not be able to share memory in every possible way and may need to raise errors to signal to some consumers that something is just not possible. These errors should be a **buffer_error** unless there is another error that is actually causing the problem. The exporter can use flags information to simplify how much of the **buffer** structure is filled in with non-default values and/or raise an error if the object can’t support a simpler view of its memory.

0 is returned on success and -1 on error.

The following table gives possible values to the *flags* arguments.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>buffer_simply</strong></td>
<td>This is the default flag state. The returned buffer may or may not have writable memory. The format of the data will be assumed to be unsigned bytes. This is a “stand-alone” flag</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PyBUF_WRITABLE</td>
<td>The returned buffer must be writable. If it is not writable, then raise an error.</td>
</tr>
<tr>
<td>PyBUF_STRIDES</td>
<td>This implies PyBUF_ND. The returned buffer must provide strides information (i.e. the strides cannot be NULL). This would be used when the consumer can handle strided, discontiguous arrays. Handling strides automatically assumes you can handle shape. The exporter can raise an error if a strided representation of the data is not possible (i.e. without the suboffsets).</td>
</tr>
<tr>
<td>PyBUF_ND</td>
<td>The returned buffer must provide shape information. The memory will be assumed C-style contiguous (last dimension varies the fastest). The exporter may raise an error if it cannot provide this kind of contiguous buffer. If this is not given then shape will be NULL.</td>
</tr>
<tr>
<td>PyBUF_C_CONTIGUOUS</td>
<td>These flags indicate that the contiguity returned buffer must be respectively, C-contiguous (last dimension varies the fastest), Fortran contiguous (first dimension varies the fastest) or either one. All of these flags imply PyBUF_STRIDES and guarantee that the strides buffer info structure will be filled in correctly.</td>
</tr>
<tr>
<td>PyBUF_F_CONTIGUOUS</td>
<td></td>
</tr>
<tr>
<td>PyBUF_ANY_CONTIGUOUS</td>
<td></td>
</tr>
<tr>
<td>PyBUF_INDIRECT</td>
<td>This flag indicates the returned buffer must have suboffsets information (which can be NULL if no suboffsets are needed). This can be used when the consumer can handle indirect array</td>
</tr>
</tbody>
</table>
referencing implied by these suboffsets. This implies **PyBUF_STRIDES**.

The returned buffer must have true format information if this flag is provided. This would be used when the consumer is going to be checking for what ‘kind’ of data is actually stored. An exporter should always be able to provide this information if requested. If format is not explicitly requested then the format must be returned as **NULL** (which means 'B', or unsigned bytes)

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyBUF_FORMAT</td>
<td>The returned buffer must have true format information if this flag is provided. An exporter should always be able to provide this information if requested. If format is not explicitly requested then the format must be returned as <strong>NULL</strong> (which means 'B', or unsigned bytes).</td>
</tr>
<tr>
<td>PyBUF_STRIDED</td>
<td>This is equivalent to ```(PyBUF_STRIDES</td>
</tr>
<tr>
<td>PyBUF_STRIDED_RO</td>
<td>This is equivalent to <code>(PyBUF_STRIDES)</code></td>
</tr>
<tr>
<td>PyBUF_RECORDS</td>
<td>This is equivalent to ```(PyBUF_STRIDES</td>
</tr>
<tr>
<td>PyBUF_RECORDS_RO</td>
<td>This is equivalent to ```(PyBUF_STRIDES</td>
</tr>
<tr>
<td>PyBUF_FULL</td>
<td>This is equivalent to ```(PyBUF_INDIRECT</td>
</tr>
<tr>
<td>PyBUF_FULL_RO</td>
<td>This is equivalent to ```(PyBUF_INDIRECT</td>
</tr>
<tr>
<td>PyBUF_CONTIG</td>
<td>This is equivalent to ```(PyBUF_ND</td>
</tr>
<tr>
<td>PyBUF_CONTIG_RO</td>
<td>This is equivalent to <code>(PyBUF_ND)</code></td>
</tr>
</tbody>
</table>

**void PyBuffer_Release(Py_buffer *view)**

Release the buffer *view*. This should be called when the buffer is no longer being used as it may free memory from it.

**Py_ssize_t PyBuffer_SizeFromFormat(const char *)**

Return the implied **itemsize** from the struct-stype **format**.

**int PyBuffer_IsContiguous(Py_buffer *view, char fortran)**
Return 1 if the memory defined by the view is C-style (\texttt{fortran} is 'C') or Fortran-style (\texttt{fortran} is 'F') contiguous or either one (\texttt{fortran} is 'A'). Return 0 otherwise.

\texttt{void PyBuffer\_FillContiguousStrides}(int \texttt{ndim},
Py\_ssize\_t \*\texttt{shape}, Py\_ssize\_t \*\texttt{strides}, Py\_ssize\_t \texttt{itemsize},
char \texttt{fortran})

Fill the \texttt{strides} array with byte-strides of a contiguous (C-style if \texttt{fortran} is 'C' or Fortran-style if \texttt{fortran} is 'F') array of the given shape with the given number of bytes per element.

\texttt{int PyBuffer\_FillInfo}(Py\_buffer \*\texttt{view}, PyObject \*\texttt{obj}, void \*\texttt{buf},
Py\_ssize\_t \texttt{len}, int \texttt{readonly}, int \texttt{infoflags})

Fill in a buffer-info structure, \texttt{view}, correctly for an exporter that can only share a contiguous chunk of memory of “unsigned bytes” of the given length. Return 0 on success and -1 (with raising an error) on error.
MemoryView objects

New in version 2.7.

A memoryview object exposes the new C level buffer interface as a Python object which can then be passed around like any other object.

PyObject *PyMemoryView_FromObject(PyObject *obj)
Create a memoryview object from an object that defines the new buffer interface.

PyObject *PyMemoryView_FromBuffer(Py_buffer *view)
Create a memoryview object wrapping the given buffer-info structure view. The memoryview object then owns the buffer, which means you shouldn’t try to release it yourself: it will be released on deallocation of the memoryview object.

PyObject *PyMemoryView_GetContiguous(PyObject *obj, int buffertype, char order)
Create a memoryview object to a contiguous chunk of memory (in either ‘C’ or ‘F’ortran order) from an object that defines the buffer interface. If memory is contiguous, the memoryview object points to the original memory. Otherwise copy is made and the memoryview points to a new bytes object.

int PyMemoryView_Check(PyObject *obj)
Return true if the object obj is a memoryview object. It is not currently allowed to create subclasses of memoryview.

Py_buffer *PyMemoryView_GET_BUFFER(PyObject *obj)
Return a pointer to the buffer-info structure wrapped by the given object. The object must be a memoryview instance; this macro doesn’t check its type, you must do it yourself or you will risk
crashes.
Old-style buffer objects

More information on the old buffer interface is provided in the section Buffer Object Structures, under the description for PyBufferProcs.

A “buffer object” is defined in the bufferobject.h header (included by Python.h). These objects look very similar to string objects at the Python programming level: they support slicing, indexing, concatenation, and some other standard string operations. However, their data can come from one of two sources: from a block of memory, or from another object which exports the buffer interface.

Buffer objects are useful as a way to expose the data from another object’s buffer interface to the Python programmer. They can also be used as a zero-copy slicing mechanism. Using their ability to reference a block of memory, it is possible to expose any data to the Python programmer quite easily. The memory could be a large, constant array in a C extension, it could be a raw block of memory for manipulation before passing to an operating system library, or it could be used to pass around structured data in its native, in-memory format.

PyBufferObject
This subtype of PyObject represents a buffer object.

PyTypeObject PyBuffer_Type
The instance of PyTypeObject which represents the Python buffer type; it is the same object as buffer and types.BufferType in the Python layer.

int Py_END_OF_BUFFER
This constant may be passed as the size parameter to PyBuffer_FromObject() or PyBuffer_FromReadWriteObject(). It
indicates that the new `PyBufferObject` should refer to `base` object from the specified `offset` to the end of its exported buffer. Using this enables the caller to avoid querying the `base` object for its length.

```c
int PyBuffer_Check(PyObject *p)
Return true if the argument has type `PyBuffer_Type`.
```

```c
PyObject* PyBuffer_FromObject(PyObject *base,
Py_ssize_t offset, Py_ssize_t size)
Return a new read-only buffer object. This raises `TypeError` if base doesn't support the read-only buffer protocol or doesn't provide exactly one buffer segment, or it raises `ValueError` if offset is less than zero. The buffer will hold a reference to the base object, and the buffer's contents will refer to the base object's buffer interface, starting as position offset and extending for size bytes. If size is `Py_END_OF_BUFFER`, then the new buffer's contents extend to the length of the base object's exported buffer data.

Changed in version 2.5: This function used an `int` type for offset and size. This might require changes in your code for properly supporting 64-bit systems.
```

```c
PyObject* PyBuffer_FromReadWriteObject(PyObject *base,
Py_ssize_t offset, Py_ssize_t size)
Return a new writable buffer object. Parameters and exceptions are similar to those for `PyBuffer_FromObject()`. If the base object does not export the writeable buffer protocol, then `TypeError` is raised.

Changed in version 2.5: This function used an `int` type for offset
and size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyBuffer_FromMemory(void *ptr, Py_ssize_t size)

*Return value: New reference.*
Return a new read-only buffer object that reads from a specified location in memory, with a specified size. The caller is responsible for ensuring that the memory buffer, passed in as ptr, is not deallocated while the returned buffer object exists. Raises ValueError if size is less than zero. Note that Py_END_OF_BUFFER may not be passed for the size parameter; ValueError will be raised in that case.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyBuffer_FromReadWriteMemory(void *ptr, Py_ssize_t size)

*Return value: New reference.*
Similar to PyBuffer_FromMemory(), but the returned buffer is writable.

*Changed in version 2.5:* This function used an int type for size. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyBuffer_New(Py_ssize_t size)

*Return value: New reference.*
Return a new writable buffer object that maintains its own memory buffer of size bytes. ValueError is returned if size is not zero or positive. Note that the memory buffer (as returned by PyObject_AsWriteBuffer()) is not specifically aligned.

*Changed in version 2.5:* This function used an int type for size.
This might require changes in your code for properly supporting 64-bit systems.
Tuple Objects

**PyTupleObject**
This subtype of **PyObject** represents a Python tuple object.

**PyTypeObject PyTuple_Type**
This instance of **PyTypeObject** represents the Python tuple type; it is the same object as `tuple` and `types.TupleType` in the Python layer.

```c
int PyTuple_Check(PyObject *p)
```
Return true if `p` is a tuple object or an instance of a subtype of the tuple type.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyTuple_CheckExact(PyObject *p)
```
Return true if `p` is a tuple object, but not an instance of a subtype of the tuple type.

*New in version 2.2.*

```c
PyObject* PyTuple_New(Py_ssize_t len)
```
*Return value: New reference.*
Return a new tuple object of size `len`, or `NULL` on failure.

*Changed in version 2.5:* This function used an `int` type for `len`. This might require changes in your code for properly supporting 64-bit systems.

```c
PyObject* PyTuple_Pack(Py_ssize_t n, ...)
```
*Return value: New reference.*
Return a new tuple object of size `n`, or `NULL` on failure. The tuple values are initialized to the subsequent `n` C arguments pointing to
Python objects.  PyTuple_Pack(2, a, b) is equivalent to Py_BuildValue("(OO)", a, b).

New in version 2.4.

Changed in version 2.5: This function used an int type for n. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PyTuple_Size(PyObject *p)

Take a pointer to a tuple object, and return the size of that tuple.

Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PyTuple_GET_SIZE(PyObject *p)

Return the size of the tuple p, which must be non-NULL and point to a tuple; no error checking is performed.

Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyTuple_GetItem(PyObject *p, Py_ssize_t pos)

Return value: Borrowed reference.

Return the object at position pos in the tuple pointed to by p. If pos is out of bounds, return NULL and sets an IndexError exception.

Changed in version 2.5: This function used an int type for pos. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyTuple_GET_ITEM(PyObject *p, Py_ssize_t pos)
Return value: Borrowed reference.
Like PyTuple_GetItem(), but does no checking of its arguments.

Changed in version 2.5: This function used an int type for pos. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyTuple_GetSlice(PyObject *p, Py_ssize_t low, Py_ssize_t high)
Take a slice of the tuple pointed to by p from low to high and return it as a new tuple.

Changed in version 2.5: This function used an int type for low and high. This might require changes in your code for properly supporting 64-bit systems.

int PyTuple_SetItem(PyObject *p, Py_ssize_t pos, PyObject *o)
Insert a reference to object o at position pos of the tuple pointed to by p. Return 0 on success.

Note: This function “steals” a reference to o.

Changed in version 2.5: This function used an int type for pos. This might require changes in your code for properly supporting 64-bit systems.

void PyTuple_SET_ITEM(PyObject *p, Py_ssize_t pos, PyObject *o)
Like PyTuple_SetItem(), but does no error checking, and should only be used to fill in brand new tuples.

Note: This function “steals” a reference to o.

Changed in version 2.5: This function used an int type for pos. This might require changes in your code for properly supporting
64-bit systems.

```c
int _PyTuple_Resize(PyObject **p, Py_ssize_t newsize)
```

Can be used to resize a tuple. `newsize` will be the new length of the tuple. Because tuples are supposed to be immutable, this should only be used if there is only one reference to the object. Do not use this if the tuple may already be known to some other part of the code. The tuple will always grow or shrink at the end. Think of this as destroying the old tuple and creating a new one, only more efficiently. Returns 0 on success. Client code should never assume that the resulting value of `p` will be the same as before calling this function. If the object referenced by `p` is replaced, the original `p` is destroyed. On failure, returns -1 and sets `p` to `NULL`, and raises `MemoryError` or `SystemError`.

*Changed in version 2.2:* Removed unused third parameter, `last_is_sticky`.

*Changed in version 2.5:* This function used an `int` type for `newsize`. This might require changes in your code for properly supporting 64-bit systems.

```c
int PyTuple_ClearFreeList()
```

Clear the free list. Return the total number of freed items.

*New in version 2.6.*
**List Objects**

**PyListObject**
This subtype of `PyObject` represents a Python list object.

**PyTypeObject PyList_Type**
This instance of `PyTypeObject` represents the Python list type. This is the same object as `list` in the Python layer.

```c
int PyList_Check(PyObject *p)
```

Return true if `p` is a list object or an instance of a subtype of the list type.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyList_CheckExact(PyObject *p)
```

Return true if `p` is a list object, but not an instance of a subtype of the list type.

*New in version 2.2.*

```c
PyObject* PyList_New(Py_ssize_t len)
```

*Return value: New reference.*

Return a new list of length `len` on success, or `NULL` on failure.

**Note:** If `len` is greater than zero, the returned list object’s items are set to `NULL`. Thus you cannot use abstract API functions such as `PySequence_SetItem()` or expose the object to Python code before setting all items to a real object with `PyList_SetItem()`.

*Changed in version 2.5:* This function used an `int` for `size`. This might require changes in your code for properly supporting 64-bit systems.
Py_ssize_t PyList_Size(PyObject *list)

Return the length of the list object in list; this is equivalent to len(list) on a list object.

Changed in version 2.5: This function returned an int. This might require changes in your code for properly supporting 64-bit systems.

Py_ssize_t PyList_GET_SIZE(PyObject *list)

Macro form of PyList_Size() without error checking.

Changed in version 2.5: This macro returned an int. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyList_GetItem(PyObject *list, Py_ssize_t index)

Return value: Borrowed reference.
Return the object at position index in the list pointed to by list. The position must be positive, indexing from the end of the list is not supported. If index is out of bounds, return NULL and set an IndexError exception.

Changed in version 2.5: This function used an int for index. This might require changes in your code for properly supporting 64-bit systems.

PyObject* PyList_GET_ITEM(PyObject *list, Py_ssize_t i)

Return value: Borrowed reference.
Macro form of PyList_GetItem() without error checking.

Changed in version 2.5: This macro used an int for i. This might require changes in your code for properly supporting 64-bit systems.

int PyList_SetItem(PyObject *list, Py_ssize_t index,
PyObject *item)

Set the item at index index in list to item. Return 0 on success or -1 on failure.

**Note:** This function “steals” a reference to item and discards a reference to an item already in the list at the affected position.

*Changed in version 2.5:* This function used an int for index. This might require changes in your code for properly supporting 64-bit systems.

```c
void PyList_SET_ITEM(PyObject *list, Py_ssize_t i, PyObject *o)
```

Macro form of PyList_SetItem() without error checking. This is normally only used to fill in new lists where there is no previous content.

**Note:** This macro “steals” a reference to item, and, unlike PyList_SetItem(), does not discard a reference to any item that it being replaced; any reference in list at position i will be leaked.

*Changed in version 2.5:* This macro used an int for i. This might require changes in your code for properly supporting 64-bit systems.

```c
int PyList_Insert(PyObject *list, Py_ssize_t index, PyObject *item)
```

Insert the item item into list list in front of index index. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to list.insert(index, item).

*Changed in version 2.5:* This function used an int for index. This might require changes in your code for properly supporting 64-bit systems.
int **PyList_Append** (**PyObject** *list, **PyObject** *item*)

Append the object *item* at the end of list *list*. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to `list.append(item)`.

**PyObject** *PyList_GetSlice** (**PyObject** *list, Py_ssize_t *low, Py_ssize_t *high*)

*Return value: New reference.*

Return a list of the objects in *list* containing the objects between *low* and *high*. Return NULL and set an exception if unsuccessful. Analogous to `list[low:high]`. Negative indices, as when slicing from Python, are not supported.

*Changed in version 2.5:* This function used an int for *low* and *high*. This might require changes in your code for properly supporting 64-bit systems.

int **PyList_SetSlice** (**PyObject** *list, Py_ssize_t *low, Py_ssize_t *high, **PyObject** *itemlist*)

Set the slice of *list* between *low* and *high* to the contents of *itemlist*. Analogous to `list[low:high] = itemlist`. The *itemlist* may be NULL, indicating the assignment of an empty list (slice deletion). Return 0 on success, -1 on failure. Negative indices, as when slicing from Python, are not supported.

*Changed in version 2.5:* This function used an int for *low* and *high*. This might require changes in your code for properly supporting 64-bit systems.

int **PyList_Sort** (**PyObject** *list*)

Sort the items of *list* in place. Return 0 on success, -1 on failure. This is equivalent to `list.sort()`.

int **PyList_Reverse** (**PyObject** *list*)
Reverse the items of list in place. Return 0 on success, -1 on failure. This is the equivalent of \texttt{list.reverse()}. 

\texttt{PyObject* PyList_AsTuple(PyObject *list)}

\textit{Return value: New reference.}

Return a new tuple object containing the contents of \texttt{list}; equivalent to \texttt{tuple(list)}.
Dictionary Objects

**PyDictObject**
This subtype of **PyObject** represents a Python dictionary object.

**PyTypeObject PyDict_Type**
This instance of **PyTypeObject** represents the Python dictionary type. This is exposed to Python programs as `dict` and `types.DictType`.

```c
int PyDict_Check(PyObject *p)
```
Return true if `p` is a dict object or an instance of a subtype of the dict type.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyDict_CheckExact(PyObject *p)
```
Return true if `p` is a dict object, but not an instance of a subtype of the dict type.

*New in version 2.4.*

```c
PyObject* PyDict_New()
```
*Return value: New reference.*
Return a new empty dictionary, or `NULL` on failure.

```c
PyObject* PyDictProxy_New(PyObject *dict)
```
*Return value: New reference.*
Return a proxy object for a mapping which enforces read-only behavior. This is normally used to create a proxy to prevent modification of the dictionary for non-dynamic class types.

*New in version 2.2.*

```c
void PyDict_Clear(PyObject *p)
```
Empty an existing dictionary of all key-value pairs.

int PyDict_Contains(PyObject *p, PyObject *key)
Determine if dictionary p contains key. If an item in p is matches key, return 1, otherwise return 0. On error, return -1. This is equivalent to the Python expression key in p.

New in version 2.4.

PyObject* PyDict_Copy(PyObject *p)
Return a new dictionary that contains the same key-value pairs as p.

New in version 1.6.

int PyDict_SetItem(PyObject *p, PyObject *key, PyObject *val)
Insert value into the dictionary p with a key of key. key must be hashable; if it isn’t, TypeError will be raised. Return 0 on success or -1 on failure.

int PyDict_SetItemString(PyObject *p, const char *key, PyObject *val)
Insert value into the dictionary p using key as a key. key should be a char*. The key object is created using PyString_FromString(key). Return 0 on success or -1 on failure.

int PyDict_DelItem(PyObject *p, PyObject *key)
Remove the entry in dictionary p with key key. key must be hashable; if it isn’t, TypeError is raised. Return 0 on success or -1 on failure.

int PyDict_DelItemString(PyObject *p, char *key)
Remove the entry in dictionary p which has a key specified by the string key. Return 0 on success or -1 on failure.
PyObject* PyDict_GetItem(PyObject *p, PyObject *key)

*Return value: Borrowed reference.*

Return the object from dictionary p which has a key key. Return NULL if the key key is not present, but without setting an exception.

PyObject* PyDict_GetItemString(PyObject *p, const char *key)

*Return value: Borrowed reference.*

This is the same as PyDict_GetItem(), but key is specified as a char*, rather than a PyObject*.

PyObject* PyDict_Items(PyObject *p)

*Return value: New reference.*

Return a PyListObject containing all the items from the dictionary, as in the dictionary method dict.items().

PyObject* PyDict_Keys(PyObject *p)

*Return value: New reference.*

Return a PyListObject containing all the keys from the dictionary, as in the dictionary method dict.keys().

PyObject* PyDict_Values(PyObject *p)

*Return value: New reference.*

Return a PyListObject containing all the values from the dictionary p, as in the dictionary method dict.values().

Py_ssize_t PyDict_Size(PyObject *p)

Return the number of items in the dictionary. This is equivalent to len(p) on a dictionary.

Changed in version 2.5: This function returned an int type. This might require changes in your code for properly supporting 64-bit systems.
int PyDict_Next(PyObject *p, Py_ssize_t *ppos, PyObject **pkey, PyObject **pvalue)

Iterate over all key-value pairs in the dictionary `p`. The `Py_ssize_t` referred to by `ppos` must be initialized to 0 prior to the first call to this function to start the iteration; the function returns true for each pair in the dictionary, and false once all pairs have been reported. The parameters `pkey` and `pvalue` should either point to `PyObject*` variables that will be filled in with each key and value, respectively, or may be `NULL`. Any references returned through them are borrowed. `ppos` should not be altered during iteration. Its value represents offsets within the internal dictionary structure, and since the structure is sparse, the offsets are not consecutive.

For example:

```c
PyObject *key, *value;
Py_ssize_t pos = 0;

while (PyDict_Next(self->dict, &pos, &key, &value)) {
    /* do something interesting with the values... */
    ...
}
```

The dictionary `p` should not be mutated during iteration. It is safe (since Python 2.1) to modify the values of the keys as you iterate over the dictionary, but only so long as the set of keys does not change. For example:

```c
PyObject *key, *value;
Py_ssize_t pos = 0;

while (PyDict_Next(self->dict, &pos, &key, &value)) {
    int i = PyInt_AS_LONG(value) + 1;
    PyObject *o = PyInt_FromLong(i);
    if (o == NULL)
        return -1;
    if (PyDict_SetItem(self->dict, key, o) < 0) {
        Py_DECREF(o);
        return -1;
    }
```
Changed in version 2.5: This function used an int * type for ppos. This might require changes in your code for properly supporting 64-bit systems.

int PyDict_Merge(PyObject *a, PyObject *b, int override)
Iterate over mapping object b adding key-value pairs to dictionary a. b may be a dictionary, or any object supporting PyMapping_Keys() and PyObject_GetItem(). If override is true, existing pairs in a will be replaced if a matching key is found in b, otherwise pairs will only be added if there is not a matching key in a. Return 0 on success or -1 if an exception was raised.

New in version 2.2.

int PyDict_Update(PyObject *a, PyObject *b)
This is the same as PyDict_Merge(a, b, 1) in C, and is similar to a.update(b) in Python except that PyDict_Update() doesn’t fall back to the iterating over a sequence of key value pairs if the second argument has no “keys” attribute. Return 0 on success or -1 if an exception was raised.

New in version 2.2.

int PyDict_MergeFromSeq2(PyObject *a, PyObject *seq2, int override)
Update or merge into dictionary a, from the key-value pairs in seq2. seq2 must be an iterable object producing iterable objects of length 2, viewed as key-value pairs. In case of duplicate keys, the last wins if override is true, else the first wins. Return 0 on success or -1 if an exception was raised. Equivalent Python (except for the return value):
def PyDict_MergeFromSeq2(a, seq2, override):
    for key, value in seq2:
        if override or key not in a:
            a[key] = value

New in version 2.2.
Class and Instance Objects

Note that the class objects described here represent old-style classes, which will go away in Python 3. When creating new types for extension modules, you will want to work with type objects (section Type Objects).

**PyClassObject**

The C structure of the objects used to describe built-in classes.

**PyObject**\* **PyClass_Type**

This is the type object for class objects; it is the same object as \texttt{types.ClassType} in the Python layer.

\begin{verbatim}
int PyClass_Check(PyObject \*o)
    Return true if the object \(o\) is a class object, including instances of types derived from the standard class object. Return false in all other cases.
\end{verbatim}

\begin{verbatim}
int PyClass_IsSubclass(PyObject \*klass, PyObject \*base)
    Return true if \(\texttt{klass}\) is a subclass of \(\texttt{base}\). Return false in all other cases.
\end{verbatim}

There are very few functions specific to instance objects.

**PyTypeObject** **PyInstance_Type**

Type object for class instances.

\begin{verbatim}
int PyInstance_Check(PyObject \*obj)
    Return true if \(\texttt{obj}\) is an instance.
\end{verbatim}

\begin{verbatim}
PyObject\* PyInstance_New(PyObject \*class, PyObject \*arg, PyObject \*kw)
    Create a new instance of a specific class. The parameters \texttt{arg}
and \( kw \) are used as the positional and keyword parameters to the object's constructor.

\[
\text{PyObject* } \text{PyInstance\_NewRaw}(\text{PyObject* class, PyObject* dict})
\]

*Return value: New reference.*

Create a new instance of a specific class without calling its constructor. `class` is the class of new object. The `dict` parameter will be used as the object's `__dict__`; if `NULL`, a new dictionary will be created for the instance.
Function Objects

There are a few functions specific to Python functions.

**PyFunctionObject**

The C structure used for functions.

**PyTypeObject PyFunction_Type**

This is an instance of PyTypeObject and represents the Python function type. It is exposed to Python programmers as types.FunctionType.

```c
int PyFunction_Check(PyObject *o)
```

Return true if o is a function object (has type PyFunction_Type). The parameter must not be NULL.

```c
PyObject* PyFunction_New(PyObject *code, PyObject *globals)
```

*Return value: New reference.*

Return a new function object associated with the code object code. globals must be a dictionary with the global variables accessible to the function.

The function's docstring, name and __module__ are retrieved from the code object, the argument defaults and closure are set to NULL.

```c
PyObject* PyFunction_GetCode(PyObject *op)
```

*Return value: Borrowed reference.*

Return the code object associated with the function object op.

```c
PyObject* PyFunction_GetGlobals(PyObject *op)
```

*Return value: Borrowed reference.*

Return the globals dictionary associated with the function object op.
PyObject* PyFunction_GetModule(PyObject *op)

Return value: Borrowed reference.
Return the __module__ attribute of the function object op. This is normally a string containing the module name, but can be set to any other object by Python code.

PyObject* PyFunction_GetDefaults(PyObject *op)

Return value: Borrowed reference.
Return the argument default values of the function object op. This can be a tuple of arguments or NULL.

int PyFunction_SetDefaults(PyObject *op, PyObject *defaults)

Set the argument default values for the function object op. defaults must be Py_None or a tuple.

Raises SystemError and returns -1 on failure.

PyObject* PyFunction_GetClosure(PyObject *op)

Return value: Borrowed reference.
Return the closure associated with the function object op. This can be NULL or a tuple of cell objects.

int PyFunction_SetClosure(PyObject *op, PyObject *closure)

Set the closure associated with the function object op. closure must be Py_None or a tuple of cell objects.

Raises SystemError and returns -1 on failure.
There are some useful functions that are useful for working with method objects.

**PyTypeObject PyMethod_Type**

This instance of PyTypeObject represents the Python method type. This is exposed to Python programs as types.MethodType.

`int PyMethod_Check(PyObject *o)`

Return true if `o` is a method object (has type PyMethod_Type). The parameter must not be NULL.

`PyObject* PyMethod_New(PyObject *func, PyObject *self, PyObject *class)`

*Return value: New reference.*

Return a new method object, with `func` being any callable object; this is the function that will be called when the method is called. If this method should be bound to an instance, `self` should be the instance and `class` should be the class of `self`, otherwise `self` should be NULL and `class` should be the class which provides the unbound method..

`PyObject* PyMethod_Class(PyObject *meth)`

*Return value: Borrowed reference.*

Return the class object from which the method `meth` was created; if this was created from an instance, it will be the class of the instance.

`PyObject* PyMethod_GET_CLASS(PyObject *meth)`

*Return value: Borrowed reference.*

Macro version of PyMethod_Class() which avoids error checking.

`PyObject* PyMethod_Function(PyObject *meth)`
Return value: Borrowed reference.
Return the function object associated with the method \texttt{meth}.

\texttt{PyObject* PyMethod\_GET\_FUNCTION(PyObject *meth)}

Return value: Borrowed reference.
Macro version of \texttt{PyMethod\_Function()} which avoids error checking.

\texttt{PyObject* PyMethod\_Self(PyObject *meth)}

Return value: Borrowed reference.
Return the instance associated with the method \texttt{meth} if it is bound, otherwise return \texttt{NULL}.

\texttt{PyObject* PyMethod\_GET\_SELF(PyObject *meth)}

Return value: Borrowed reference.
Macro version of \texttt{PyMethod\_Self()} which avoids error checking.

\texttt{int PyMethod\_Clear\_Free\_List()} 

Clear the free list. Return the total number of freed items.

New in version 2.6.
File Objects

Python's built-in file objects are implemented entirely on the FILE* support from the C standard library. This is an implementation detail and may change in future releases of Python.

**PyFileObject**

This subtype of PyObject represents a Python file object.

**PyTypeObject PyFile_Type**

This instance of PyTypeObject represents the Python file type. This is exposed to Python programs as file and types.FileType.

```c
int PyFile_Check(PyObject *p)
```

Return true if its argument is a PyFileObject or a subtype of PyFileObject.

*Changed in version 2.2:* Allowed subtypes to be accepted.

```c
int PyFile_CheckExact(PyObject *p)
```

Return true if its argument is a PyFileObject, but not a subtype of PyFileObject.

*New in version 2.2.*

```c
PyObject* PyFile_FromString(char *filename, char *mode)
```

*Return value: New reference.*

On success, return a new file object that is opened on the file given by filename, with a file mode given by mode, where mode has the same semantics as the standard C routine fopen(). On failure, return NULL.

```c
PyObject* PyFile_FromFile(FILE *fp, char *name, char *mode, int (*close)(FILE*))
```

**Return value: New reference.**
Create a new `PyFileObject` from the already-open standard C file pointer, `fp`. The function `close` will be called when the file should be closed. Return `NULL` and close the file using `close` on failure. `close` is optional and can be set to `NULL`.

```c
FILE* PyFile_AsFile(PyObject *p)
```
Return the file object associated with `p` as a `FILE*`.

If the caller will ever use the returned `FILE*` object while the GIL is released it must also call the `PyFile_IncUseCount()` and `PyFile_DecUseCount()` functions described below as appropriate.

```c
void PyFile_IncUseCount(PyFileObject *p)
```
Increments the PyFileObject’s internal use count to indicate that the underlying `FILE*` is being used. This prevents Python from calling `f_close()` on it from another thread. Callers of this must call `PyFile_DecUseCount()` when they are finished with the `FILE*`. Otherwise the file object will never be closed by Python.

The GIL must be held while calling this function.

The suggested use is to call this after `PyFile_AsFile()` and before you release the GIL:

```c
FILE *fp = PyFile_AsFile(p);
PyFile_IncUseCount(p);
/* ... */
Py_BEGIN_ALLOW_THREADS
do_something(fp);
Py_END_ALLOW_THREADS
/* ... */
PyFile_DecUseCount(p);
```

*New in version 2.6.*

```c
void PyFile_DecUseCount(PyFileObject *p)
```
Decrement the PyFileObject’s internal unlocked_count member to indicate that the caller is done with its own use of the FILE*. This may only be called to undo a prior call to PyFile_IncUseCount().

The GIL must be held while calling this function (see the example above).

New in version 2.6.

PyObject* PyFile_GetLine(PyObject *p, int n)

Equivalent to p.readline(n), this function reads one line from the object p. p may be a file object or any object with a readline() method. If n is 0, exactly one line is read, regardless of the length of the line. If n is greater than 0, no more than n bytes will be read from the file; a partial line can be returned. In both cases, an empty string is returned if the end of the file is reached immediately. If n is less than 0, however, one line is read regardless of length, but EOFError is raised if the end of the file is reached immediately.

PyObject* PyFile_Name(PyObject *p)

Return value: Borrowed reference.
Return the name of the file specified by p as a string object.

void PyFile_SetBufSize(PyFileObject *p, int n)
Available on systems with setvbuf() only. This should only be called immediately after file object creation.

int PyFile_SetEncoding(PyFileObject *p, const char *enc)
Set the file’s encoding for Unicode output to enc. Return 1 on success and 0 on failure.
New in version 2.3.

```c
int PyFile_SetEncodingAndErrors(PyFileObject *p, const char *enc, *errors)
```

Set the file’s encoding for Unicode output to `enc`, and its error mode to `err`. Return 1 on success and 0 on failure.

New in version 2.6.

```c
int PyFile_SoftSpace(PyObject *p, int newflag)
```

This function exists for internal use by the interpreter. Set the `softspace` attribute of `p` to `newflag` and return the previous value. `p` does not have to be a file object for this function to work properly; any object is supported (though its only interesting if the `softspace` attribute can be set). This function clears any errors, and will return 0 as the previous value if the attribute either does not exist or if there were errors in retrieving it. There is no way to detect errors from this function, but doing so should not be needed.

```c
int PyFile_WriteObject(PyObject *obj, PyObject *p, int flags)
```

Write object `obj` to file object `p`. The only supported flag for `flags` is `Py_PRINT_RAW`; if given, the `str()` of the object is written instead of the `repr()`. Return 0 on success or -1 on failure; the appropriate exception will be set.

```c
int PyFile_WriteString(const char *s, PyObject *p)
```

Write string `s` to file object `p`. Return 0 on success or -1 on failure; the appropriate exception will be set.
Module Objects

There are only a few functions special to module objects.

** PyTypeObject PyModule_Type
   This instance of PyTypeObject represents the Python module type. This is exposed to Python programs as types.ModuleType.

int PyModule_Check(PyObject *p)
   Return true if p is a module object, or a subtype of a module object.

   *Changed in version 2.2:* Allowed subtypes to be accepted.

int PyModule_CheckExact(PyObject *p)
   Return true if p is a module object, but not a subtype of PyModule_Type.

   *New in version 2.2.*

PyObject* PyModule_New(const char *name)
   *Return value: New reference.*
   Return a new module object with the __name__ attribute set to name. Only the module’s __doc__ and __name__ attributes are filled in; the caller is responsible for providing a __file__ attribute.

PyObject* PyModule_GetDict(PyObject *module)
   *Return value: Borrowed reference.*
   Return the dictionary object that implements module’s namespace; this object is the same as the __dict__ attribute of the module object. This function never fails. It is recommended extensions use other PyModule_*() and PyObject_*() functions rather than directly manipulate a module’s __dict__.
char* PyModule_GetName(PyObject *module)
    Return module's __name__ value. If the module does not provide one, or if it is not a string, SystemError is raised and NULL is returned.

cchar* PyModule_GetFilename(PyObject *module)
    Return the name of the file from which module was loaded using module's __file__ attribute. If this is not defined, or if it is not a string, raise SystemError and return NULL.

int PyModule_AddObject(PyObject *module, const char *name, PyObject *value)
    Add an object to module as name. This is a convenience function which can be used from the module's initialization function. This steals a reference to value. Return -1 on error, 0 on success.

    New in version 2.0.

int PyModule_AddIntConstant(PyObject *module, const char *name, long value)
    Add an integer constant to module as name. This convenience function can be used from the module's initialization function. Return -1 on error, 0 on success.

    New in version 2.0.

int PyModule_AddStringConstant(PyObject *module, const char *name, const char *value)
    Add a string constant to module as name. This convenience function can be used from the module's initialization function. The string value must be null-terminated. Return -1 on error, 0 on success.

    New in version 2.0.
**int PyModule_AddIntMacro(**PyObject *module, macro)**

Add an int constant to *module*. The name and the value are taken from *macro*. For example `PyModule_AddIntMacro(module, AF_INET)` adds the int constant `AF_INET` with the value of `AF_INET` to *module*. Return `-1` on error, `0` on success.

*New in version 2.6.*

**int PyModule_AddStringMacro(**PyObject *module, macro)**

Add a string constant to *module*.

*New in version 2.6.*
Python provides two general-purpose iterator objects. The first, a sequence iterator, works with an arbitrary sequence supporting the \_\_getitem\_\_() method. The second works with a callable object and a sentinel value, calling the callable for each item in the sequence, and ending the iteration when the sentinel value is returned.

**PyTypeObject** **PySeqIter\_Type**
Type object for iterator objects returned by **PySeqIter\_New()** and the one-argument form of the **iter()** built-in function for built-in sequence types.

*New in version 2.2.*

**int** **PySeqIter\_Check**(op)
Return true if the type of op is **PySeqIter\_Type**.

*New in version 2.2.*

**PyObject**\* **PySeqIter\_New**(PyObject \*seq)
*Return value: New reference.*
Return an iterator that works with a general sequence object, seq. The iteration ends when the sequence raises **IndexError** for the subscripting operation.

*New in version 2.2.*

**PyTypeObject** **PyCallIter\_Type**
Type object for iterator objects returned by **PyCallIter\_New()** and the two-argument form of the **iter()** built-in function.

*New in version 2.2.*
int **PyCallIter_Check**(op)

Return true if the type of op is **PyCallIter_Type**.

*New in version 2.2.*

**PyObject** * **PyCallIter_New**(PyObject **callable**, PyObject **sentinel**)

*Return value: New reference.*

Return a new iterator. The first parameter, **callable**, can be any Python callable object that can be called with no parameters; each call to it should return the next item in the iteration. When **callable** returns a value equal to **sentinel**, the iteration will be terminated.

*New in version 2.2.*
Descriptor Objects

“Descriptors” are objects that describe some attribute of an object. They are found in the dictionary of type objects.

**PyTypeObject** **PyProperty_Type**

The type object for the built-in descriptor types.

*New in version 2.2.*

**PyObject**

*PyDescr_NewGetSet*(PyTypeObject *type, struct PyGetSetDef *getset)

*Return value: New reference.*

*New in version 2.2.*

**PyObject**

*PyDescr_NewMember*(PyTypeObject *type, struct PyMemberDef *meth)

*Return value: New reference.*

*New in version 2.2.*

**PyObject**

*PyDescr_NewMethod*(PyTypeObject *type, struct PyMethodDef *meth)

*Return value: New reference.*

*New in version 2.2.*

**PyObject**

*PyDescr_NewWrapper*(PyTypeObject *type, struct wrapperbase *wrapper, void *wrapped)

*Return value: New reference.*

*New in version 2.2.*

**PyObject**

*PyDescr_NewClassMethod*(PyTypeObject *type, PyMethodDef *method)

*Return value: New reference.*

*New in version 2.3.*

**int** **PyDescr_IsData**(PyObject *descr)
Return true if the descriptor objects `descr` describes a data attribute, or false if it describes a method. `descr` must be a descriptor object; there is no error checking.

*New in version 2.2.*

```c
PyObject* PyWrapper_New(PyObject *, PyObject *)
```

*Return value: New reference.*

*New in version 2.2.*
Slice Objects

PyObject PySlice_Type
The type object for slice objects. This is the same as slice and types.SliceType.

int PySlice_Check(PyObject *ob)
Return true if ob is a slice object; ob must not be NULL.

PyObject* PySlice_New(PyObject *start, PyObject *stop, PyObject *step)
Return a new slice object with the given values. The start, stop, and step parameters are used as the values of the slice object attributes of the same names. Any of the values may be NULL, in which case the None will be used for the corresponding attribute. Return NULL if the new object could not be allocated.

int PySlice_GetIndices(PySliceObject *slice, Py_ssize_t length, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step)
Retrieve the start, stop and step indices from the slice object slice, assuming a sequence of length length. Treats indices greater than length as errors.

Returns 0 on success and -1 on error with no exception set (unless one of the indices was not None and failed to be converted to an integer, in which case -1 is returned with an exception set).

You probably do not want to use this function. If you want to use slice objects in versions of Python prior to 2.3, you would probably do well to incorporate the source of PySlice_GetIndicesEx(), suitably renamed, in the source of your extension.
Changed in version 2.5: This function used an `int` type for `length` and an `int *` type for `start`, `stop`, and `step`. This might require changes in your code for properly supporting 64-bit systems.

```c
int PySlice_GetIndicesEx(PySliceObject *slice, Py_ssize_t length, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step, Py_ssize_t *slicelength)
```

Usable replacement for `PySlice_GetIndices()`. Retrieve the start, stop, and step indices from the slice object `slice` assuming a sequence of length `length`, and store the length of the slice in `slicelength`. Out of bounds indices are clipped in a manner consistent with the handling of normal slices.

Returns 0 on success and -1 on error with exception set.

New in version 2.3.

Changed in version 2.5: This function used an `int` type for `length` and an `int *` type for `start`, `stop`, `step`, and `slicelength`. This might require changes in your code for properly supporting 64-bit systems.
Weak Reference Objects

Python supports *weak references* as first-class objects. There are two specific object types which directly implement weak references. The first is a simple reference object, and the second acts as a proxy for the original object as much as it can.

```c
int PyWeakref_Check(ob)
    Return true if *ob* is either a reference or proxy object.

    *New in version 2.2.*
```

```c
int PyWeakref_CheckRef(ob)
    Return true if *ob* is a reference object.

    *New in version 2.2.*
```

```c
int PyWeakref_CheckProxy(ob)
    Return true if *ob* is a proxy object.

    *New in version 2.2.*
```

```c
PyObject* PyWeakref_NewRef(PyObject *ob, PyObject *callback)

    *Return value: New reference.*
    Return a weak reference object for the object *ob*. This will always return a new reference, but is not guaranteed to create a new object; an existing reference object may be returned. The second parameter, *callback*, can be a callable object that receives notification when *ob* is garbage collected; it should accept a single parameter, which will be the weak reference object itself. *callback* may also be None or NULL. If *ob* is not a weakly-referencable object, or if *callback* is not callable, None, or NULL, this will return NULL and raise TypeError.

    *New in version 2.2.*
```
PyObject* PyWeakref_NewProxy(PyObject *ob, PyObject *callback)

*Return value: New reference.*

Return a weak reference proxy object for the object `ob`. This will always return a new reference, but is not guaranteed to create a new object; an existing proxy object may be returned. The second parameter, `callback`, can be a callable object that receives notification when `ob` is garbage collected; it should accept a single parameter, which will be the weak reference object itself. `callback` may also be `None` or `NULL`. If `ob` is not a weakly-referencable object, or if `callback` is not callable, `None`, or `NULL`, this will return `NULL` and raise `TypeError`.

*New in version 2.2.*

PyObject* PyWeakref_GetObject(PyObject *ref)

*Return value: Borrowed reference.*

Return the referenced object from a weak reference, `ref`. If the referent is no longer live, returns `Py_None`.

*New in version 2.2.*

**Warning:** This function returns a borrowed reference to the referenced object. This means that you should always call `Py_INCREF()` on the object except if you know that it cannot be destroyed while you are still using it.

PyObject* PyWeakref_GET_OBJECT(PyObject *ref)

*Return value: Borrowed reference.*

Similar to `PyWeakref_GetObject()`, but implemented as a macro that does no error checking.

*New in version 2.2.*
Capsules

Refer to Providing a C API for an Extension Module for more information on using these objects.

PyCapsule

This subtype of PyObject represents an opaque value, useful for C extension modules who need to pass an opaque value (as a void* pointer) through Python code to other C code. It is often used to make a C function pointer defined in one module available to other modules, so the regular import mechanism can be used to access C APIs defined in dynamically loaded modules.

PyCapsule_Destructor

The type of a destructor callback for a capsule. Defined as:

```c
typedef void (*PyCapsule_Destructor)(PyObject *);
```

See PyCapsule_New() for the semantics of PyCapsule_Destructor callbacks.

int PyCapsule_CheckExact(PyObject *p)

Return true if its argument is a PyCapsule.

PyObject* PyCapsule_New(void *pointer, const char *name, PyCapsule_Destructor destructor)

*Return value: New reference.*

Create a PyCapsule encapsulating the pointer. The pointer argument may not be NULL.

On failure, set an exception and return NULL.

The name string may either be NULL or a pointer to a valid C string. If non-NULL, this string must outlive the capsule. (Though
it is permitted to free it inside the destructor.

If the destructor argument is not NULL, it will be called with the capsule as its argument when it is destroyed.

If this capsule will be stored as an attribute of a module, the name should be specified as `modulename.attributename`. This will enable other modules to import the capsule using `PyCapsule.Import()`.

```c
void* PyCapsule_GetPointer(PyObject *capsule, const char *name)
```

Retrieve the pointer stored in the capsule. On failure, set an exception and return `NULL`.

The name parameter must compare exactly to the name stored in the capsule. If the name stored in the capsule is `NULL`, the name passed in must also be `NULL`. Python uses the C function `strcmp()` to compare capsule names.

```c
PyCapsule_Destructor
PyCapsule_GetDestructor(PyObject *capsule)
```

Return the current destructor stored in the capsule. On failure, set an exception and return `NULL`.

It is legal for a capsule to have a `NULL` destructor. This makes a `NULL` return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.

```c
void* PyCapsule_GetContext(PyObject *capsule)
```

Return the current context stored in the capsule. On failure, set an exception and return `NULL`.

It is legal for a capsule to have a `NULL` context. This makes a `NULL` return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.
const char* **PyCapsule_GetName**(*PyObject *capsule*)

Return the current name stored in the capsule. On failure, set an exception and return *NULL*.

It is legal for a capsule to have a *NULL* name. This makes a *NULL* return code somewhat ambiguous; use *PyCapsule_IsValid()* or *PyErr_Occurred()* to disambiguate.

**void** *PyCapsule_Import*(const char *name, int no_block)*

Import a pointer to a C object from a capsule attribute in a module. The *name* parameter should specify the full name to the attribute, as in *module.attribute*. The *name* stored in the capsule must match this string exactly. If *no_block* is true, import the module **without** blocking (using *PyImport_ImportModuleNoBlock()*). If *no_block* is false, import the module conventionally (using *PyImport_ImportModule()*).

Return the capsule’s internal **pointer** on success. On failure, set an exception and return *NULL*. However, if *PyCapsule_Import()* failed to import the module, and *no_block* was true, no exception is set.

**int** *PyCapsule_IsValid*(PyObject *capsule, const char *name)*

Determines whether or not *capsule* is a valid capsule. A valid capsule is non-*NULL*, passes *PyCapsule_CheckExact()*), has a non-*NULL* pointer stored in it, and its internal name matches the *name* parameter. (See *PyCapsule_GetPointer()* for information on how capsule names are compared.)

In other words, if *PyCapsule_IsValid()* returns a true value, calls to any of the accessors (any function starting with *PyCapsule_Get()*) are guaranteed to succeed.

Return a nonzero value if the object is valid and matches the
name passed in. Return 0 otherwise. This function will not fail.

int PyCapsule_SetContext(PyObject *capsule, void *context)
Set the context pointer inside capsule to context.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule_SetDestructor(PyObject *capsule, PyCapsule_Destructor destructor)
Set the destructor inside capsule to destructor.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule_SetName(PyObject *capsule, const char *name)
Set the name inside capsule to name. If non-NULL, the name must outlive the capsule. If the previous name stored in the capsule was not NULL, no attempt is made to free it.

Return 0 on success. Return nonzero and set an exception on failure.

int PyCapsule_SetPointer(PyObject *capsule, void *pointer)
Set the void pointer inside capsule to pointer. The pointer may not be NULL.

Return 0 on success. Return nonzero and set an exception on failure.
**CObjects**

**Warning:** The CObject API is deprecated as of Python 2.7. Please switch to the new Capsules API.

**PyCObject**

This subtype of `PyObject` represents an opaque value, useful for C extension modules who need to pass an opaque value (as a `void*` pointer) through Python code to other C code. It is often used to make a C function pointer defined in one module available to other modules, so the regular import mechanism can be used to access C APIs defined in dynamically loaded modules.

```c
int PyCObject_Check(PyObject *p)
    Return true if its argument is a PyCObject.

PyObject* PyCObject_FromVoidPtr(void* cobj, void (*destr)(void *))
    Create a PyCObject from the void * cobj. The destr function will be called when the object is reclaimed, unless it is NULL.

PyObject* PyCObject_FromVoidPtrAndDesc(void* cobj, void* desc, void (*destr)(void *, void *))
    Create a PyCObject from the void * cobj. The destr function will be called when the object is reclaimed. The desc argument can be used to pass extra callback data for the destructor function.

void* PyCObject_AsVoidPtr(PyObject* self)
    Return the object void * that the PyCObject self was created with.

void* PyCObject_GetDesc(PyObject* self)
    Return the description void * that the PyCObject self was created with.
```
with.

int **PyCObject_SetVoidPtr**(PyObject* self, void* cobj)

Set the void pointer inside self to cobj. The PyCObject must not have an associated destructor. Return true on success, false on failure.
Cell Objects

“Cell” objects are used to implement variables referenced by multiple scopes. For each such variable, a cell object is created to store the value; the local variables of each stack frame that references the value contains a reference to the cells from outer scopes which also use that variable. When the value is accessed, the value contained in the cell is used instead of the cell object itself. This de-referencing of the cell object requires support from the generated byte-code; these are not automatically de-referenced when accessed. Cell objects are not likely to be useful elsewhere.

**PyCellObject**

The C structure used for cell objects.

**PyTypeObject** **PyCell_Type**

The type object corresponding to cell objects.

```c
int PyCell_Check(ob)
    Return true if ob is a cell object; ob must not be NULL.
```

```c
PyObject* PyCell_New(PyObject *ob)
    Create and return a new cell object containing the value ob. The parameter may be NULL.
```

```c
PyObject* PyCell_Get(PyObject *cell)
    Return the contents of the cell cell.
```

```c
PyObject* PyCell_GET(PyObject *cell)
    Return value: Borrowed reference.
    Return the contents of the cell cell, but without checking that cell is non-NULL and a cell object.
```
int **cell_set** *(PyObject *cell, PyObject *value)*

Set the contents of the cell object *cell* to *value*. This releases the reference to any current content of the cell. *value* may be *NULL*. *cell* must be non-NULL; if it is not a cell object, `-1` will be returned. On success, `0` will be returned.

void **cell_set** *(PyObject *cell, PyObject *value)*

Sets the value of the cell object *cell* to *value*. No reference counts are adjusted, and no checks are made for safety; *cell* must be non-NULL and must be a cell object.
Generator Objects

Generator objects are what Python uses to implement generator iterators. They are normally created by iterating over a function that yields values, rather than explicitly calling `PyGen_New()`.

**PyGenObject**

The C structure used for generator objects.

**PyTypeObject** PyGen_Type

The type object corresponding to generator objects.

```c
int PyGen_Check(ob)
Return true if ob is a generator object; ob must not be NULL.
```

```c
int PyGen_CheckExact(ob)
Return true if ob's type is PyGen_Type is a generator object; ob must not be NULL.
```

```c
PyObject* PyGen_New(PyFrameObject *frame)
Create and return a new generator object based on the frame object. A reference to frame is stolen by this function. The parameter must not be NULL.
```
Various date and time objects are supplied by the `datetime` module. Before using any of these functions, the header file `datetime.h` must be included in your source (note that this is not included by `Python.h`), and the macro `PyDateTime_IMPORT` must be invoked, usually as part of the module initialisation function. The macro puts a pointer to a C structure into a static variable, `PyDateTimeAPI`, that is used by the following macros.

Type-check macros:

```c
int PyDate_Check(PyObject *ob)
    Return true if `ob` is of type `PyDateTime_DateType` or a subtype of `PyDateTime_DateType`. `ob` must not be `NULL`.

    *New in version 2.4.*

int PyDate_CheckExact(PyObject *ob)
    Return true if `ob` is of type `PyDateTime_DateType`. `ob` must not be `NULL`.

    *New in version 2.4.*

int PyDateTime_Check(PyObject *ob)
    Return true if `ob` is of type `PyDateTime_DateTimeType` or a subtype of `PyDateTime_DateTimeType`. `ob` must not be `NULL`.

    *New in version 2.4.*

int PyDateTime_CheckExact(PyObject *ob)
    Return true if `ob` is of type `PyDateTime_DateTimeType`. `ob` must not be `NULL`.
```
New in version 2.4.

int PyTime_Check(PyObject *ob)
Return true if ob is of type PyDateTime_TimeType or a subtype of PyDateTime_TimeType. ob must not be NULL.

New in version 2.4.

int PyTime_CheckExact(PyObject *ob)
Return true if ob is of type PyDateTime_TimeType. ob must not be NULL.

New in version 2.4.

int PyDelta_Check(PyObject *ob)
Return true if ob is of type PyDateTime_DeltaType or a subtype of PyDateTime_DeltaType. ob must not be NULL.

New in version 2.4.

int PyDelta_CheckExact(PyObject *ob)
Return true if ob is of type PyDateTime_DeltaType. ob must not be NULL.

New in version 2.4.

int PyTZInfo_Check(PyObject *ob)
Return true if ob is of type PyDateTime_TZInfoType or a subtype of PyDateTime_TZInfoType. ob must not be NULL.

New in version 2.4.

int PyTZInfo_CheckExact(PyObject *ob)
Return true if ob is of type PyDateTime_TZInfoType. ob must not be NULL.
New in version 2.4.

Macros to create objects:

**PyObject** `PyDate_FromDate`(int year, int month, int day)

*Return value: New reference.*

Return a `datetime.date` object with the specified year, month and day.

New in version 2.4.

**PyObject** `PyDateTime_FromDateAndTime`(int year, int month, int day, int hour, int minute, int second, int usecond)

*Return value: New reference.*

Return a `datetime.datetime` object with the specified year, month, day, hour, minute, second and microsecond.

New in version 2.4.

**PyObject** `PyTime_FromTime`(int hour, int minute, int second, int usecond)

*Return value: New reference.*

Return a `datetime.time` object with the specified hour, minute, second and microsecond.

New in version 2.4.

**PyObject** `PyDelta_FromDSU`(int days, int seconds, int useconds)

*Return value: New reference.*

Return a `datetime.timedelta` object representing the given number of days, seconds and microseconds. Normalization is performed so that the resulting number of microseconds and seconds lie in the ranges documented for `datetime.timedelta` objects.

New in version 2.4.
Macros to extract fields from date objects. The argument must be an instance of \texttt{PyDateTime\_Date}, including subclasses (such as \texttt{PyDateTime\_DateTime}). The argument must not be \texttt{NULL}, and the type is not checked:

\begin{verbatim}
int PyDateTime\_GET\_YEAR(PyDateTime\_Date *o)
    Return the year, as a positive int.

    \textit{New in version 2.4.}

int PyDateTime\_GET\_MONTH(PyDateTime\_Date *o)
    Return the month, as an int from 1 through 12.

    \textit{New in version 2.4.}

int PyDateTime\_GET\_DAY(PyDateTime\_Date *o)
    Return the day, as an int from 1 through 31.

    \textit{New in version 2.4.}
\end{verbatim}

Macros to extract fields from datetime objects. The argument must be an instance of \texttt{PyDateTime\_DateTime}, including subclasses. The argument must not be \texttt{NULL}, and the type is not checked:

\begin{verbatim}
int PyDateTime\_DATE\_GET\_HOUR(PyDateTime\_DateTime *o)
    Return the hour, as an int from 0 through 23.

    \textit{New in version 2.4.}

int PyDateTime\_DATE\_GET\_MINUTE(PyDateTime\_DateTime *o)
    Return the minute, as an int from 0 through 59.

    \textit{New in version 2.4.}

int PyDateTime\_DATE\_GET\_SECOND(PyDateTime\_DateTime *o)
    Return the second, as an int from 0 through 59.
\end{verbatim}
New in version 2.4.

int PyDateTime_DATE_GET_MICROSECOND(PyDateTime_DateTime *o)
    Return the microsecond, as an int from 0 through 999999.

New in version 2.4.

Macros to extract fields from time objects. The argument must be an instance of PyDateTime_Time, including subclasses. The argument must not be NULL, and the type is not checked:

int PyDateTime_TIME_GET_HOUR(PyDateTime_Time *o)
    Return the hour, as an int from 0 through 23.

New in version 2.4.

int PyDateTime_TIME_GET_MINUTE(PyDateTime_Time *o)
    Return the minute, as an int from 0 through 59.

New in version 2.4.

int PyDateTime_TIME_GET_SECOND(PyDateTime_Time *o)
    Return the second, as an int from 0 through 59.

New in version 2.4.

int PyDateTime_TIME_GET_MICROSECOND(PyDateTime_Time *o)
    Return the microsecond, as an int from 0 through 999999.

New in version 2.4.

Macros for the convenience of modules implementing the DB API:

PyObject* PyDateTime_FromTimestamp(PyObject *args)
    Create and return a new datetime.datetime object given an argument tuple suitable for passing to
datetime.datetime.fromtimestamp().

*New in version 2.4.*

**PyObject** *PyDate_FromTimestamp**(PyObject *args)**

*Return value: New reference.*

Create and return a new `datetime.date` object given an argument tuple suitable for passing to `datetime.date.fromtimestamp()`.

*New in version 2.4.*
Set Objects

New in version 2.5.

This section details the public API for `set` and `frozenset` objects. Any functionality not listed below is best accessed using the either the abstract object protocol (including `PyObject_CallMethod()`, `PyObject_RichCompareBool()`, `PyObject_Hash()`, `PyObject_Repr()`, `PyObject_IsTrue()`, `PyObject_Print()`, and `PyObject_GetIter()`) or the abstract number protocol (including `PyNumber_And()`, `PyNumber_Subtract()`, `PyNumber_Or()`, `PyNumber_Xor()`, `PyNumber_InPlaceAnd()`, `PyNumber_InPlaceSubtract()`, `PyNumber_InPlaceOr()`, and `PyNumber_InPlaceXor()`).

**PySetObject**

This subtype of `PyObject` is used to hold the internal data for both `set` and `frozenset` objects. It is like a `PyDictObject` in that it is a fixed size for small sets (much like tuple storage) and will point to a separate, variable sized block of memory for medium and large sized sets (much like list storage). None of the fields of this structure should be considered public and are subject to change. All access should be done through the documented API rather than by manipulating the values in the structure.

**PyTypeObject** **PySet_Type**

This is an instance of `PyTypeObject` representing the Python `set` type.

**PyTypeObject** **PyFrozenSet_Type**

This is an instance of `PyTypeObject` representing the Python `frozenset` type.

The following type check macros work on pointers to any Python
object. Likewise, the constructor functions work with any iterable Python object.

```c
int PySet_Check(PyObject *p)
```

Return true if `p` is a `set` object or an instance of a subtype.

*New in version 2.6.*

```c
int PyFrozenSet_Check(PyObject *p)
```

Return true if `p` is a `frozenset` object or an instance of a subtype.

*New in version 2.6.*

```c
int PyAnySet_Check(PyObject *p)
```

Return true if `p` is a `set` object, a `frozenset` object, or an instance of a subtype.

```c
int PyAnySet_CheckExact(PyObject *p)
```

Return true if `p` is a `set` object or a `frozenset` object but not an instance of a subtype.

```c
int PyFrozenSet_CheckExact(PyObject *p)
```

Return true if `p` is a `frozenset` object but not an instance of a subtype.

```c
PyObject* PySet_New(PyObject *iterable)
```

*Return value: New reference.*

Return a new `set` containing objects returned by the `iterable`. The `iterable` may be `NULL` to create a new empty set. Return the new set on success or `NULL` on failure. Raise `TypeError` if `iterable` is not actually iterable. The constructor is also useful for copying a set (`c=set(s)`).

```c
PyObject* PyFrozenSet_New(PyObject *iterable)
```

*Return value: New reference.*
Return a new `frozenset` containing objects returned by the `iterable`. The `iterable` may be `NULL` to create a new empty frozenset. Return the new set on success or `NULL` on failure. Raise `TypeError` if `iterable` is not actually iterable.

* Changed in version 2.6: * Now guaranteed to return a brand-new `frozenset`. Formerly, frozensets of zero-length were a singleton. This got in the way of building-up new frozensets with `PySet_Add()`.

The following functions and macros are available for instances of `set` or `frozenset` or instances of their subtypes.

- **Py_ssize_t PySet_Size(PyObject *anyset)**
  Return the length of a `set` or `frozenset` object. Equivalent to `len(anyset)`. Raises a `PyExc_SystemError` if `anyset` is not a `set`, `frozenset`, or an instance of a subtype.

  * Changed in version 2.5: * This function returned an `int`. This might require changes in your code for properly supporting 64-bit systems.

- **Py_ssize_t PySet_GET_SIZE(PyObject *anyset)**
  Macro form of `PySet_Size()` without error checking.

- **int PySet_Contains(PyObject *anyset, PyObject *key)**
  Return 1 if found, 0 if not found, and -1 if an error is encountered. Unlike the Python `__contains__()` method, this function does not automatically convert unhashable sets into temporary frozensets. Raise a `TypeError` if the `key` is unhashable. Raise `PyExc_SystemError` if `anyset` is not a `set`, `frozenset`, or an instance of a subtype.

- **int PySet_Add(PyObject *set, PyObject *key)**
Add key to a set instance. Does not apply to frozenset instances. Return 0 on success or -1 on failure. Raise a TypeError if the key is unhashable. Raise a MemoryError if there is no room to grow. Raise a SystemError if set is not an instance of set or its subtype.

*Changed in version 2.6:* Now works with instances of frozenset or its subtypes. Like PyTuple_SetItem() in that it can be used to fill-in the values of brand new frozensets before they are exposed to other code.

The following functions are available for instances of set or its subtypes but not for instances of frozenset or its subtypes.

```c
int PySet_Discard(PyObject *set, PyObject *key)
```

Return 1 if found and removed, 0 if not found (no action taken), and -1 if an error is encountered. Does not raise KeyError for missing keys. Raise a TypeError if the key is unhashable. Unlike the Python discard() method, this function does not automatically convert unhashable sets into temporary frozensets. Raise PyExc_SystemError if set is not an instance of set or its subtype.

```c
PyObject* PySet_Pop(PyObject *set)
```

Return a new reference to an arbitrary object in the set, and removes the object from the set. Return NULL on failure. Raise KeyError if the set is empty. Raise a SystemError if set is not an instance of set or its subtype.

```c
int PySet_Clear(PyObject *set)
```

Empty an existing set of all elements.
Code Objects

Code objects are a low-level detail of the CPython implementation. Each one represents a chunk of executable code that hasn't yet been bound into a function.

**PyCodeObject**

The C structure of the objects used to describe code objects. The fields of this type are subject to change at any time.

**PyTypeObject PyCode_Type**

This is an instance of `PyTypeObject` representing the Python code type.

```c
int PyCode_Check(PyObject *co)
Return true if co is a code object.
```

```c
int PyCode_GetNumFree(PyObject *co)
Return the number of free variables in co.
```

```c
PyCodeObject *PyCode_New(int argcount, int nlocals, int stacksize, int flags, PyObject *code, PyObject *consts, PyObject *names, PyObject *varnames, PyObject *freevars, PyObject *cellvars, PyObject *filename, PyObject *name, int firstlineno, PyCodeObject *lnotab)
Return a new code object. If you need a dummy code object to create a frame, use PyCode_NewEmpty() instead. Calling PyCode_New() directly can bind you to a precise Python version since the definition of the bytecode changes often.
```

```c
int PyCode_NewEmpty(const char *filename, const char *funcname, int firstlineno)
Return a new empty code object with the specified filename, function name, and first line number. It is illegal to exec or eval() the resulting code object.
```
Initialization, Finalization, and Threads
Initializing and finalizing the interpreter

void **Py_Initialize**

Initialize the Python interpreter. In an application embedding Python, this should be called before using any other Python/C API functions; with the exception of **Py_SetProgramName()**, **Py_SetPythonHome()**, **PyEval_InitThreads()**, **PyEval_ReleaseLock()**, and **PyEval_AcquireLock()**. This initializes the table of loaded modules (**sys.modules**), and creates the fundamental modules **__builtin__**, **__main__** and **sys**. It also initializes the module search path (**sys.path**). It does not set **sys.argv**; use **PySys_SetArgvEx()** for that. This is a no-op when called for a second time (without calling **Py_Finalize()** first). There is no return value; it is a fatal error if the initialization fails.

void **Py_InitializeEx**(int **initsigs**)

This function works like **Py_Initialize()** if **initsigs** is 1. If **initsigs** is 0, it skips initialization registration of signal handlers, which might be useful when Python is embedded.

*New in version 2.4.*

int **Py_IsInitialized**

Return true (nonzero) when the Python interpreter has been initialized, false (zero) if not. After **Py_Finalize()** is called, this returns false until **Py_Initialize()** is called again.

void **Py_Finalize**

Undo all initializations made by **Py_Initialize()** and subsequent use of Python/C API functions, and destroy all sub-interpreters (see **Py_NewInterpreter()** below) that were created and not yet destroyed since the last call to **Py_Initialize()**. Ideally, this frees
all memory allocated by the Python interpreter. This is a no-op when called for a second time (without calling `Py_Initialize()` again first). There is no return value; errors during finalization are ignored.

This function is provided for a number of reasons. An embedding application might want to restart Python without having to restart the application itself. An application that has loaded the Python interpreter from a dynamically loadable library (or DLL) might want to free all memory allocated by Python before unloading the DLL. During a hunt for memory leaks in an application a developer might want to free all memory allocated by Python before exiting from the application.

**Bugs and caveats:** The destruction of modules and objects in modules is done in random order; this may cause destructors (\_\_\_del\_\_\_() methods) to fail when they depend on other objects (even functions) or modules. Dynamically loaded extension modules loaded by Python are not unloaded. Small amounts of memory allocated by the Python interpreter may not be freed (if you find a leak, please report it). Memory tied up in circular references between objects is not freed. Some memory allocated by extension modules may not be freed. Some extensions may not work properly if their initialization routine is called more than once; this can happen if an application calls `Py_Initialize()` and `Py_Finalize()` more than once.
Process-wide parameters

void Py_SetProgramName(char *name)

This function should be called before Py_Initialize() is called for the first time, if it is called at all. It tells the interpreter the value of the argv[0] argument to the main() function of the program. This is used by Py_GetPath() and some other functions below to find the Python run-time libraries relative to the interpreter executable. The default value is 'python'. The argument should point to a zero-terminated character string in static storage whose contents will not change for the duration of the program's execution. No code in the Python interpreter will change the contents of this storage.

char* Py_GetProgramName()

Return the program name set with Py_SetProgramName(), or the default. The returned string points into static storage; the caller should not modify its value.

char* Py_GetPrefix()

Return the prefix for installed platform-independent files. This is derived through a number of complicated rules from the program name set with Py_SetProgramName() and some environment variables; for example, if the program name is '/usr/local/bin/python', the prefix is '/usr/local'. The returned string points into static storage; the caller should not modify its value. This corresponds to the prefix variable in the top-level Makefile and the --prefix argument to the configure script at build time. The value is available to Python code as sys.prefix. It is only useful on Unix. See also the next function.

char* Py_GetExecPrefix()
Return the `exec-prefix` for installed platform-dependent files. This is derived through a number of complicated rules from the program name set with `Py_SetProgramName()` and some environment variables; for example, if the program name is ‘/usr/local/bin/python’, the exec-prefix is ‘/usr/local’. The returned string points into static storage; the caller should not modify its value. This corresponds to the `exec_prefix` variable in the top-level Makefile and the `--exec-prefix` argument to the `configure` script at build time. The value is available to Python code as `sys.exec_prefix`. It is only useful on Unix.

Background: The exec-prefix differs from the prefix when platform dependent files (such as executables and shared libraries) are installed in a different directory tree. In a typical installation, platform dependent files may be installed in the `/usr/local/plat` subtree while platform independent may be installed in `/usr/local`.

Generally speaking, a platform is a combination of hardware and software families, e.g. Sparc machines running the Solaris 2.x operating system are considered the same platform, but Intel machines running Solaris 2.x are another platform, and Intel machines running Linux are yet another platform. Different major revisions of the same operating system generally also form different platforms. Non-Unix operating systems are a different story; the installation strategies on those systems are so different that the prefix and exec-prefix are meaningless, and set to the empty string. Note that compiled Python bytecode files are platform independent (but not independent from the Python version by which they were compiled!).

System administrators will know how to configure the `mount` or `automount` programs to share `/usr/local` between platforms while having `/usr/local/plat` be a different filesystem for each
platform.

char* Py_GetProgramFullPath()
Return the full program name of the Python executable; this is computed as a side-effect of deriving the default module search path from the program name (set by Py_SetProgramName() above). The returned string points into static storage; the caller should not modify its value. The value is available to Python code as sys.executable.

char* Py_GetPath()
Return the default module search path; this is computed from the program name (set by Py_SetProgramName() above) and some environment variables. The returned string consists of a series of directory names separated by a platform dependent delimiter character. The delimiter character is ':' on Unix and Mac OS X, ';' on Windows. The returned string points into static storage; the caller should not modify its value. The list sys.path is initialized with this value on interpreter startup; it can be (and usually is) modified later to change the search path for loading modules.

const char* Py_GetVersion()
Return the version of this Python interpreter. This is a string that looks something like

"1.5 (#67, Dec 31 1997, 22:34:28) [GCC 2.7.2.2]"

The first word (up to the first space character) is the current Python version; the first three characters are the major and minor version separated by a period. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as sys.version.

const char* Py_GetPlatform()
Return the platform identifier for the current platform. On Unix, this is formed from the “official” name of the operating system, converted to lower case, followed by the major revision number; e.g., for Solaris 2.x, which is also known as SunOS 5.x, the value is 'sunos5'. On Mac OS X, it is 'darwin'. On Windows, it is 'win'. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.platform`.

`const char* Py_GetCopyright()`
Return the official copyright string for the current Python version, for example

'Copyright 1991-1995 Stichting Mathematisch Centrum, Amsterdam'

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.copyright`.

`const char* Py_GetCompiler()`
Return an indication of the compiler used to build the current Python version, in square brackets, for example:

"[GCC 2.7.2.2]"

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

`const char* Py_GetBuildInfo()`
Return information about the sequence number and build date and time of the current Python interpreter instance, for example

"#67, Aug 1 1997, 22:34:28"
The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

```c
void PySys_SetArgvEx(int argc, char **argv, int updatepath)
```

Set `sys.argv` based on `argc` and `argv`. These parameters are similar to those passed to the program’s `main()` function with the difference that the first entry should refer to the script file to be executed rather than the executable hosting the Python interpreter. If there isn’t a script that will be run, the first entry in `argv` can be an empty string. If this function fails to initialize `sys.argv`, a fatal condition is signalled using `Py_FatalError()`.

If `updatepath` is zero, this is all the function does. If `updatepath` is non-zero, the function also modifies `sys.path` according to the following algorithm:

- If the name of an existing script is passed in `argv[0]`, the absolute path of the directory where the script is located is prepended to `sys.path`.
- Otherwise (that is, if `argc` is 0 or `argv[0]` doesn’t point to an existing file name), an empty string is prepended to `sys.path`, which is the same as prepending the current working directory `"."`.

**Note:** It is recommended that applications embedding the Python interpreter for purposes other than executing a single script pass 0 as `updatepath`, and update `sys.path` themselves if desired. See CVE-2008-5983.

On versions before 2.6.6, you can achieve the same effect by manually popping the first `sys.path` element after having called `PySys_SetArgv()`, for example using:

```python
PyRun_SimpleString("import sys; sys.path.pop(0)\n");
```
New in version 2.6.6.

void PySys_SetArgv(int argc, char **argv)
   This function works like PySys_SetArgvEx() with updatepath set to 1.

void Py_SetPythonHome(char *home)
   Set the default “home” directory, that is, the location of the standard Python libraries. See PYTHONHOME for the meaning of the argument string.

   The argument should point to a zero-terminated character string in static storage whose contents will not change for the duration of the program’s execution. No code in the Python interpreter will change the contents of this storage.

char* Py_GetPythonHome()
   Return the default “home”, that is, the value set by a previous call to Py_SetPythonHome(), or the value of the PYTHONHOME environment variable if it is set.
Thread State and the Global Interpreter Lock

The Python interpreter is not fully thread-safe. In order to support multi-threaded Python programs, there's a global lock, called the global interpreter lock or GIL, that must be held by the current thread before it can safely access Python objects. Without the lock, even the simplest operations could cause problems in a multi-threaded program: for example, when two threads simultaneously increment the reference count of the same object, the reference count could end up being incremented only once instead of twice.

Therefore, the rule exists that only the thread that has acquired the GIL may operate on Python objects or call Python/C API functions. In order to emulate concurrency of execution, the interpreter regularly tries to switch threads (see `sys.setcheckinterval()`). The lock is also released around potentially blocking I/O operations like reading or writing a file, so that other Python threads can run in the meantime.

The Python interpreter keeps some thread-specific bookkeeping information inside a data structure called `PyThreadState`. There's also one global variable pointing to the current `PyThreadState`: it can be retrieved using `PyThreadState_Get()`.

Releasing the GIL from extension code

Most extension code manipulating the GIL has the following simple structure:

Save the `thread` state in a local variable.
Release the global interpreter lock.
... Do some blocking I/O operation ...
Reacquire the global interpreter lock.
Restore the thread state from the local variable.

This is so common that a pair of macros exists to simplify it:

\[
\begin{array}{l}
\text{Py\_BEGIN\_ALLOW\_THREADS} \\
\ldots \text{Do some blocking I/O operation} \ldots \\
\text{Py\_END\_ALLOW\_THREADS}
\end{array}
\]

The \texttt{Py\_BEGIN\_ALLOW\_THREADS} macro opens a new block and declares a hidden local variable; the \texttt{Py\_END\_ALLOW\_THREADS} macro closes the block. These two macros are still available when Python is compiled without thread support (they simply have an empty expansion).

When thread support is enabled, the block above expands to the following code:

\[
\begin{array}{l}
\text{PyThreadState \_*\_save;} \\
\_save = \text{PyEval\_SaveThread();} \\
\ldots \text{Do some blocking I/O operation...} \\
\text{PyEval\_RestoreThread(_save);} \\
\end{array}
\]

Here is how these functions work: the global interpreter lock is used to protect the pointer to the current thread state. When releasing the lock and saving the thread state, the current thread state pointer must be retrieved before the lock is released (since another thread could immediately acquire the lock and store its own thread state in the global variable). Conversely, when acquiring the lock and restoring the thread state, the lock must be acquired before storing the thread state pointer.

\textbf{Note: } Calling system I/O functions is the most common use case for releasing the GIL, but it can also be useful before calling long-running computations which don’t need access to Python objects, such as compression or cryptographic functions operating over memory buffers. For example, the standard \texttt{zlib} and \texttt{hashlib}.
modules release the GIL when compressing or hashing data.

## Non-Python created threads

When threads are created using the dedicated Python APIs (such as the `threading` module), a thread state is automatically associated to them and the code showed above is therefore correct. However, when threads are created from C (for example by a third-party library with its own thread management), they don't hold the GIL, nor is there a thread state structure for them.

If you need to call Python code from these threads (often this will be part of a callback API provided by the aforementioned third-party library), you must first register these threads with the interpreter by creating a thread state data structure, then acquiring the GIL, and finally storing their thread state pointer, before you can start using the Python/C API. When you are done, you should reset the thread state pointer, release the GIL, and finally free the thread state data structure.

The `PyGILState_Ensure()` and `PyGILState_Release()` functions do all of the above automatically. The typical idiom for calling into Python from a C thread is:

```c
PyGILState_STATE gstate;
gstate = PyGILState_Ensure();

/* Perform Python actions here. */
result = CallSomeFunction();
/* evaluate result or handle exception */

/* Release the thread. No Python API allowed beyond this point. */
PyGILState_Release(gstate);
```

Note that the `PyGILState_*()` functions assume there is only one global interpreter (created automatically by `Py_Initialize()`). Python
supports the creation of additional interpreters (using `Py_NewInterpreter()`), but mixing multiple interpreters and the `PyGILState_*()` API is unsupported.

Another important thing to note about threads is their behaviour in the face of the C `fork()` call. On most systems with `fork()`, after a process forks only the thread that issued the fork will exist. That also means any locks held by other threads will never be released. Python solves this for `os.fork()` by acquiring the locks it uses internally before the fork, and releasing them afterwards. In addition, it resets any `Lock Objects` in the child. When extending or embedding Python, there is no way to inform Python of additional (non-Python) locks that need to be acquired before or reset after a fork. OS facilities such as `pthread_atfork()` would need to be used to accomplish the same thing. Additionally, when extending or embedding Python, calling `fork()` directly rather than through `os.fork()` (and returning to or calling into Python) may result in a deadlock by one of Python’s internal locks being held by a thread that is defunct after the fork. `PyOS_AfterFork()` tries to reset the necessary locks, but is not always able to.

### High-level API

These are the most commonly used types and functions when writing C extension code, or when embedding the Python interpreter:

**PyInterpreterState**

This data structure represents the state shared by a number of cooperating threads. Threads belonging to the same interpreter share their module administration and a few other internal items. There are no public members in this structure.

Threads belonging to different interpreters initially share nothing, except process state like available memory, open file descriptors
and such. The global interpreter lock is also shared by all threads, regardless of to which interpreter they belong.

**PyThreadState**

This data structure represents the state of a single thread. The only public data member is `PyInterpreterState *interp`, which points to this thread's interpreter state.

**void PyEval_InitThreads()**

Initialize and acquire the global interpreter lock. It should be called in the main thread before creating a second thread or engaging in any other thread operations such as `PyEval_ReleaseLock()` or `PyEval_ReleaseThread(tstate)`. It is not needed before calling `PyEval_SaveThread()` or `PyEval_RestoreThread()`.

This is a no-op when called for a second time. It is safe to call this function before calling `Py_Initialize()`.

**Note:** When only the main thread exists, no GIL operations are needed. This is a common situation (most Python programs do not use threads), and the lock operations slow the interpreter down a bit. Therefore, the lock is not created initially. This situation is equivalent to having acquired the lock: when there is only a single thread, all object accesses are safe. Therefore, when this function initializes the global interpreter lock, it also acquires it. Before the Python _thread module creates a new thread, knowing that either it has the lock or the lock hasn’t been created yet, it calls `PyEval_InitThreads()`. When this call returns, it is guaranteed that the lock has been created and that the calling thread has acquired it. It is **not** safe to call this function when it is unknown which thread (if any) currently has the global interpreter lock.

This function is not available when thread support is disabled at
int PyEval_ThreadsInitialized()

Returns a non-zero value if PyEval_InitThreads() has been called. This function can be called without holding the GIL, and therefore can be used to avoid calls to the locking API when running single-threaded. This function is not available when thread support is disabled at compile time.

New in version 2.4.

PyThreadState* PyEval_SaveThread()

Release the global interpreter lock (if it has been created and thread support is enabled) and reset the thread state to NULL, returning the previous thread state (which is not NULL). If the lock has been created, the current thread must have acquired it. (This function is available even when thread support is disabled at compile time.)

void PyEval_RestoreThread(PyThreadState *tstate)

Acquire the global interpreter lock (if it has been created and thread support is enabled) and set the thread state to tstate, which must not be NULL. If the lock has been created, the current thread must not have acquired it, otherwise deadlock ensues. (This function is available even when thread support is disabled at compile time.)

PyThreadState* PyThreadState_Get()

Return the current thread state. The global interpreter lock must be held. When the current thread state is NULL, this issues a fatal error (so that the caller needn’t check for NULL).

PyThreadState* PyThreadState_Swap(PyThreadState *tstate)

Swap the current thread state with the thread state given by the argument tstate, which may be NULL. The global interpreter lock
must be held and is not released.

void PyEval_ReInitThreads()
    This function is called from PyOS_AfterFork() to ensure that newly created child processes don't hold locks referring to threads which are not running in the child process.

The following functions use thread-local storage, and are not compatible with sub-interpreters:

PyGILState_STATE PyGILState_Ensure()
    Ensure that the current thread is ready to call the Python C API regardless of the current state of Python, or of the global interpreter lock. This may be called as many times as desired by a thread as long as each call is matched with a call to PyGILState_Release(). In general, other thread-related APIs may be used between PyGILState_Ensure() and PyGILState_Release() calls as long as the thread state is restored to its previous state before the Release(). For example, normal usage of the Py_BEGIN_ALLOW_THREADS and Py_END_ALLOW_THREADS macros is acceptable.

    The return value is an opaque “handle” to the thread state when PyGILState_Ensure() was called, and must be passed to PyGILState_Release() to ensure Python is left in the same state. Even though recursive calls are allowed, these handles cannot be shared - each unique call to PyGILState_Ensure() must save the handle for its call to PyGILState_Release().

    When the function returns, the current thread will hold the GIL and be able to call arbitrary Python code. Failure is a fatal error.

    New in version 2.3.

void PyGILState_Release(PyGILState_STATE)
Release any resources previously acquired. After this call, Python’s state will be the same as it was prior to the corresponding `PyGILState_Ensure()` call (but generally this state will be unknown to the caller, hence the use of the GILState API).

Every call to `PyGILState_Ensure()` must be matched by a call to `PyGILState_Release()` on the same thread.

*New in version 2.3.*

`PyThreadState* PyGILState_GetThisThreadState()`

Get the current thread state for this thread. May return `NULL` if no GILState API has been used on the current thread. Note that the main thread always has such a thread-state, even if no auto-thread-state call has been made on the main thread. This is mainly a helper/diagnostic function.

*New in version 2.3.*

The following macros are normally used without a trailing semicolon; look for example usage in the Python source distribution.

`Py_BEGIN_ALLOW_THREADS`

This macro expands to `{ PyThreadState *_save; _save = PyEval_SaveThread(); }`. Note that it contains an opening brace; it must be matched with a following `Py_END_ALLOW_THREADS` macro. See above for further discussion of this macro. It is a no-op when thread support is disabled at compile time.

`Py_END_ALLOW_THREADS`

This macro expands to `PyEval_RestoreThread(_save); }`. Note that it contains a closing brace; it must be matched with an earlier `Py_BEGIN_ALLOW_THREADS` macro. See above for further discussion of this macro. It is a no-op when thread support is disabled at compile time.
**Py_BLOCK_THREADS**

This macro expands to `PyEval_RestoreThread(_save);`: it is equivalent to `Py_END_ALLOW_THREADS` without the closing brace. It is a no-op when thread support is disabled at compile time.

**Py_UNBLOCK_THREADS**

This macro expands to `_save = PyEval_SaveThread();`: it is equivalent to `Py_BEGIN_ALLOW_THREADS` without the opening brace and variable declaration. It is a no-op when thread support is disabled at compile time.

### Low-level API

All of the following functions are only available when thread support is enabled at compile time, and must be called only when the global interpreter lock has been created.

**PyInterpreterState* PyInterpreterState_New()**

Create a new interpreter state object. The global interpreter lock need not be held, but may be held if it is necessary to serialize calls to this function.

**void PyInterpreterState_Clear(PyInterpreterState *interp)**

Reset all information in an interpreter state object. The global interpreter lock must be held.

**void PyInterpreterState_Delete(PyInterpreterState *interp)**

Destroy an interpreter state object. The global interpreter lock need not be held. The interpreter state must have been reset with a previous call to `PyInterpreterState_Clear()`.

**PyThreadState* PyThreadState_New(PyInterpreterState *interp)**

Create a new thread state object belonging to the given interpreter object. The global interpreter lock need not be held, but may be held if it is necessary to serialize calls to this function.
void PyThreadState_Clear(PyThreadState *tstate)
    Reset all information in a thread state object. The global interpreter lock must be held.

void PyThreadState_Delete(PyThreadState *tstate)
    Destroy a thread state object. The global interpreter lock need not be held. The thread state must have been reset with a previous call to PyThreadState_Clear().

PyObject* PyThreadState_GetDict()
    Return value: Borrowed reference.
    Return a dictionary in which extensions can store thread-specific state information. Each extension should use a unique key to use to store state in the dictionary. It is okay to call this function when no current thread state is available. If this function returns NULL, no exception has been raised and the caller should assume no current thread state is available.

    Changed in version 2.3: Previously this could only be called when a current thread is active, and NULL meant that an exception was raised.

int PyThreadState_SetAsyncExc(long id, PyObject *exc)
    Asynchronously raise an exception in a thread. The id argument is the thread id of the target thread; exc is the exception object to be raised. This function does not steal any references to exc. To prevent naive misuse, you must write your own C extension to call this. Must be called with the GIL held. Returns the number of thread states modified; this is normally one, but will be zero if the thread id isn’t found. If exc is NULL, the pending exception (if any) for the thread is cleared. This raises no exceptions.

    New in version 2.3.

void PyEval_AcquireThread(PyThreadState *tstate)
Acquire the global interpreter lock and set the current thread state to \textit{tstate}, which should not be \textit{NULL}. The lock must have been created earlier. If this thread already has the lock, deadlock ensues.

\textbf{PyEval_RestoreThread()} is a higher-level function which is always available (even when thread support isn’t enabled or when threads have not been initialized).

\textbf{void PyEval_ReleaseThread(PyThreadState \textit{tstate})}
Reset the current thread state to \textit{NULL} and release the global interpreter lock. The lock must have been created earlier and must be held by the current thread. The \textit{tstate} argument, which must not be \textit{NULL}, is only used to check that it represents the current thread state — if it isn’t, a fatal error is reported.

\textbf{PyEval_SaveThread()} is a higher-level function which is always available (even when thread support isn’t enabled or when threads have not been initialized).

\textbf{void PyEval_AcquireLock()}

Acquire the global interpreter lock. The lock must have been created earlier. If this thread already has the lock, a deadlock ensues.

\textbf{Warning:} This function does not change the current thread state. Please use \textbf{PyEval_RestoreThread()} or \textbf{PyEval_AcquireThread()} instead.

\textbf{void PyEval_ReleaseLock()}

Release the global interpreter lock. The lock must have been created earlier.

\textbf{Warning:} This function does not change the current thread
Please use `PyEval_SaveThread()` or `PyEval_ReleaseThread()` instead.
Sub-interpreter support

While in most uses, you will only embed a single Python interpreter, there are cases where you need to create several independent interpreters in the same process and perhaps even in the same thread. Sub-interpreters allow you to do that. You can switch between sub-interpreters using the `PyThreadState_Swap()` function. You can create and destroy them using the following functions:

**PyThreadState**\* `Py_NewInterpreter()`  
Create a new sub-interpreter. This is an (almost) totally separate environment for the execution of Python code. In particular, the new interpreter has separate, independent versions of all imported modules, including the fundamental modules `builtins`, `__main__` and `sys`. The table of loaded modules (`sys.modules`) and the module search path (`sys.path`) are also separate. The new environment has no `sys.argv` variable. It has new standard I/O stream file objects `sys.stdin`, `sys.stdout` and `sys.stderr` (however these refer to the same underlying file descriptors).

The return value points to the first thread state created in the new sub-interpreter. This thread state is made in the current thread state. Note that no actual thread is created; see the discussion of thread states below. If creation of the new interpreter is unsuccessful, `NULL` is returned; no exception is set since the exception state is stored in the current thread state and there may not be a current thread state. (Like all other Python/C API functions, the global interpreter lock must be held before calling this function and is still held when it returns; however, unlike most other Python/C API functions, there needn’t be a current thread state on entry.)

Extension modules are shared between (sub-)interpreters as
follows: the first time a particular extension is imported, it is initialized normally, and a (shallow) copy of its module’s dictionary is squirreled away. When the same extension is imported by another (sub-)interpreter, a new module is initialized and filled with the contents of this copy; the extension’s `init` function is not called. Note that this is different from what happens when an extension is imported after the interpreter has been completely re-initialized by calling `Py_Finalize()` and `Py_Initialize()`; in that case, the extension's `initmodule` function is called again.

```c
void Py_EndInterpreter(PyThreadState *tstate)
```

Destroy the (sub-)interpreter represented by the given thread state. The given thread state must be the current thread state. See the discussion of thread states below. When the call returns, the current thread state is `NULL`. All thread states associated with this interpreter are destroyed. (The global interpreter lock must be held before calling this function and is still held when it returns.) `Py_Finalize()` will destroy all sub-interpreters that haven’t been explicitly destroyed at that point.

## Bugs and caveats

Because sub-interpreters (and the main interpreter) are part of the same process, the insulation between them isn’t perfect — for example, using low-level file operations like `os.close()` they can (accidentally or maliciously) affect each other’s open files. Because of the way extensions are shared between (sub-)interpreters, some extensions may not work properly; this is especially likely when the extension makes use of (static) global variables, or when the extension manipulates its module’s dictionary after its initialization. It is possible to insert objects created in one sub-interpreter into a namespace of another sub-interpreter; this should be done with great care to avoid sharing user-defined functions, methods,
instances or classes between sub-interpreters, since import operations executed by such objects may affect the wrong (sub-)interpreter’s dictionary of loaded modules.

Also note that combining this functionality with `PyGILState_*()` APIs is delicate, because these APIs assume a bijection between Python thread states and OS-level threads, an assumption broken by the presence of sub-interpreters. It is highly recommended that you don’t switch sub-interpreters between a pair of matching `PyGILState_Engure()` and `PyGILState_Release()` calls. Furthermore, extensions (such as `ctypes`) using these APIs to allow calling of Python code from non-Python created threads will probably be broken when using sub-interpreters.
Asynchronous Notifications

A mechanism is provided to make asynchronous notifications to the main interpreter thread. These notifications take the form of a function pointer and a void pointer argument.

```c
int Py_AddPendingCall(int (*func)(void *), void *arg)
```

Schedule a function to be called from the main interpreter thread. On success, 0 is returned and `func` is queued for being called in the main thread. On failure, -1 is returned without setting any exception.

When successfully queued, `func` will be eventually called from the main interpreter thread with the argument `arg`. It will be called asynchronously with respect to normally running Python code, but with both these conditions met:

- on a bytecode boundary;
- with the main thread holding the global interpreter lock (`func` can therefore use the full C API).

`func` must return 0 on success, or -1 on failure with an exception set. `func` won’t be interrupted to perform another asynchronous notification recursively, but it can still be interrupted to switch threads if the global interpreter lock is released.

This function doesn’t need a current thread state to run, and it doesn’t need the global interpreter lock.

**Warning:** This is a low-level function, only useful for very special cases. There is no guarantee that `func` will be called as quick as possible. If the main thread is busy executing a system call, `func` won’t be called before the system call returns. This function is generally not suitable for calling Python code from
arbitrary C threads. Instead, use the PyGILState API.

New in version 2.7.
Profiling and Tracing

The Python interpreter provides some low-level support for attaching profiling and execution tracing facilities. These are used for profiling, debugging, and coverage analysis tools.

Starting with Python 2.2, the implementation of this facility was substantially revised, and an interface from C was added. This C interface allows the profiling or tracing code to avoid the overhead of calling through Python-level callable objects, making a direct C function call instead. The essential attributes of the facility have not changed; the interface allows trace functions to be installed per-thread, and the basic events reported to the trace function are the same as had been reported to the Python-level trace functions in previous versions.

```c
int (*Py_tracefunc)(PyObject *obj, PyFrameObject *frame, int what, PyObject *arg)
```

The type of the trace function registered using `PyEval_SetProfile()` and `PyEval_SetTrace()`. The first parameter is the object passed to the registration function as `obj`, `frame` is the frame object to which the event pertains, `what` is one of the constants `PyTrace_CALL`, `PyTrace_EXCEPTION`, `PyTrace_LINE`, `PyTrace_RETURN`, `PyTrace_C_CALL`, `PyTrace_C_EXCEPTION`, or `PyTrace_C_RETURN`, and `arg` depends on the value of `what`:

<table>
<thead>
<tr>
<th>Value of what</th>
<th>Meaning of arg</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>PyTrace_CALL</code></td>
<td>Always <code>NULL</code>.</td>
</tr>
<tr>
<td><code>PyTrace_EXCEPTION</code></td>
<td>Exception information as returned by <code>sys.exc_info()</code></td>
</tr>
<tr>
<td><code>PyTrace_LINE</code></td>
<td>Always <code>NULL</code>.</td>
</tr>
<tr>
<td><code>PyTrace_RETURN</code></td>
<td>Value being returned to the caller, or <code>NULL</code> if caused by an exception.</td>
</tr>
<tr>
<td>PyTrace_C_CALL</td>
<td>Function object being called.</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>PyTrace_C_EXCEPTION</td>
<td>Function object being called.</td>
</tr>
<tr>
<td>PyTrace_C_RETURN</td>
<td>Function object being called.</td>
</tr>
</tbody>
</table>

**int PyTrace_CALL**
The value of the *what* parameter to a `Py_tracefunc` function when a new call to a function or method is being reported, or a new entry into a generator. Note that the creation of the iterator for a generator function is not reported as there is no control transfer to the Python bytecode in the corresponding frame.

**int PyTrace_EXCEPTION**
The value of the *what* parameter to a `Py_tracefunc` function when an exception has been raised. The callback function is called with this value for *what* when after any bytecode is processed after which the exception becomes set within the frame being executed. The effect of this is that as exception propagation causes the Python stack to unwind, the callback is called upon return to each frame as the exception propagates. Only trace functions receives these events; they are not needed by the profiler.

**int PyTrace_LINE**
The value passed as the *what* parameter to a trace function (but not a profiling function) when a line-number event is being reported.

**int PyTrace_RETURN**
The value for the *what* parameter to `Py_tracefunc` functions when a call is returning without propagating an exception.

**int PyTrace_C_CALL**
The value for the *what* parameter to `Py_tracefunc` functions when a C function is about to be called.
int PyTrace_C_EXCEPTION
The value for the what parameter to Py_tracefunc functions when a C function has raised an exception.

int PyTrace_C_RETURN
The value for the what parameter to Py_tracefunc functions when a C function has returned.

void PyEval_SetProfile(Py_tracefunc func, PyObject *obj)
Set the profiler function to func. The obj parameter is passed to the function as its first parameter, and may be any Python object, or NULL. If the profile function needs to maintain state, using a different value for obj for each thread provides a convenient and thread-safe place to store it. The profile function is called for all monitored events except the line-number events.

void PyEval_SetTrace(Py_tracefunc func, PyObject *obj)
Set the tracing function to func. This is similar to PyEval_SetProfile(), except the tracing function does receive line-number events.

PyObject* PyEval_GetCallStats(PyObject *self)
Return a tuple of function call counts. There are constants defined for the positions within the tuple:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCALL_ALL</td>
<td>0</td>
</tr>
<tr>
<td>PCALL_FUNCTION</td>
<td>1</td>
</tr>
<tr>
<td>PCALL_FAST_FUNCTION</td>
<td>2</td>
</tr>
<tr>
<td>PCALL_FASTER_FUNCTION</td>
<td>3</td>
</tr>
<tr>
<td>PCALL_METHOD</td>
<td>4</td>
</tr>
<tr>
<td>PCALL_BOUND_METHOD</td>
<td>5</td>
</tr>
<tr>
<td>PCALL_CFUNCTION</td>
<td>6</td>
</tr>
<tr>
<td>PCALL_TYPE</td>
<td>7</td>
</tr>
<tr>
<td>PCALL_GENERATOR</td>
<td>8</td>
</tr>
<tr>
<td>-----------------</td>
<td>---</td>
</tr>
<tr>
<td>PCALL_OTHER</td>
<td>9</td>
</tr>
<tr>
<td>PCALL_POP</td>
<td>10</td>
</tr>
</tbody>
</table>

**PCALL_FAST_FUNCTION** means no argument tuple needs to be created. **PCALL_FASTER_FUNCTION** means that the fast-path frame setup code is used.

If there is a method call where the call can be optimized by changing the argument tuple and calling the function directly, it gets recorded twice.

This function is only present if Python is compiled with **CALL_PROFILE** defined.
Advanced Debugger Support

These functions are only intended to be used by advanced debugging tools.

**PyInterpreterState**

*PyInterpreterState* Head()

Return the interpreter state object at the head of the list of all such objects.

*New in version 2.2.*

**PyInterpreterState**

*PyInterpreterState* Next(PyInterpreterState *interp)

Return the next interpreter state object after *interp* from the list of all such objects.

*New in version 2.2.*

**PyThreadState**

*PyInterpreterState* ThreadHead(PyInterpreterState *interp)

Return the pointer to the first PyThreadState object in the list of threads associated with the interpreter *interp*.

*New in version 2.2.*

**PyThreadState**

*PyThreadState* Next(PyThreadState *tstate)

Return the next thread state object after *tstate* from the list of all such objects belonging to the same PyInterpreterState object.

*New in version 2.2.*
Memory Management
Overview

Memory management in Python involves a private heap containing all Python objects and data structures. The management of this private heap is ensured internally by the Python memory manager. The Python memory manager has different components which deal with various dynamic storage management aspects, like sharing, segmentation, preallocation or caching.

At the lowest level, a raw memory allocator ensures that there is enough room in the private heap for storing all Python-related data by interacting with the memory manager of the operating system. On top of the raw memory allocator, several object-specific allocators operate on the same heap and implement distinct memory management policies adapted to the peculiarities of every object type. For example, integer objects are managed differently within the heap than strings, tuples or dictionaries because integers imply different storage requirements and speed/space tradeoffs. The Python memory manager thus delegates some of the work to the object-specific allocators, but ensures that the latter operate within the bounds of the private heap.

It is important to understand that the management of the Python heap is performed by the interpreter itself and that the user has no control over it, even if she regularly manipulates object pointers to memory blocks inside that heap. The allocation of heap space for Python objects and other internal buffers is performed on demand by the Python memory manager through the Python/C API functions listed in this document.

To avoid memory corruption, extension writers should never try to operate on Python objects with the functions exported by the C library: malloc(), calloc(), realloc() and free(). This will result in
mixed calls between the C allocator and the Python memory manager with fatal consequences, because they implement different algorithms and operate on different heaps. However, one may safely allocate and release memory blocks with the C library allocator for individual purposes, as shown in the following example:

```c
PyObject *res;
char *buf = (char *) malloc(BUFSIZ); /* for I/O */

if (buf == NULL)
    return PyErr_NoMemory();
...Do some I/O operation involving buf...
res = PyString_FromString(buf);
free(buf); /* malloc'ed */
return res;
```

In this example, the memory request for the I/O buffer is handled by the C library allocator. The Python memory manager is involved only in the allocation of the string object returned as a result.

In most situations, however, it is recommended to allocate memory from the Python heap specifically because the latter is under control of the Python memory manager. For example, this is required when the interpreter is extended with new object types written in C. Another reason for using the Python heap is the desire to *inform* the Python memory manager about the memory needs of the extension module. Even when the requested memory is used exclusively for internal, highly-specific purposes, delegating all memory requests to the Python memory manager causes the interpreter to have a more accurate image of its memory footprint as a whole. Consequently, under certain circumstances, the Python memory manager may or may not trigger appropriate actions, like garbage collection, memory compaction or other preventive procedures. Note that by using the C library allocator as shown in the previous example, the allocated memory for the I/O buffer escapes completely the Python memory manager.
Memory Interface

The following function sets, modeled after the ANSI C standard, but specifying behavior when requesting zero bytes, are available for allocating and releasing memory from the Python heap:

void* **PyMem_Malloc** (size_t \(n\))

Allocates \(n\) bytes and returns a pointer of type void* to the allocated memory, or NULL if the request fails. Requesting zero bytes returns a distinct non-NULL pointer if possible, as if PyMem_Malloc(1) had been called instead. The memory will not have been initialized in any way.

void* **PyMem_Realloc** (void* \(p\), size_t \(n\))

Resizes the memory block pointed to by \(p\) to \(n\) bytes. The contents will be unchanged to the minimum of the old and the new sizes. If \(p\) is NULL, the call is equivalent to PyMem_Malloc(\(n\)); else if \(n\) is equal to zero, the memory block is resized but is not freed, and the returned pointer is non-NULL. Unless \(p\) is NULL, it must have been returned by a previous call to PyMem_Malloc() or PyMem_Realloc(). If the request fails, PyMem_Realloc() returns NULL and \(p\) remains a valid pointer to the previous memory area.

void **PyMem_Free** (void* \(p\))

Frees the memory block pointed to by \(p\), which must have been returned by a previous call to PyMem_Malloc() or PyMem_Realloc(). Otherwise, or if PyMem_Free(\(p\)) has been called before, undefined behavior occurs. If \(p\) is NULL, no operation is performed.

The following type-oriented macros are provided for convenience. Note that TYPE refers to any C type.

**TYPE*** PyMem_New**(TYPE, size_t \(n\))
Same as \texttt{PyMem\_Malloc()}, but allocates \((n \times \text{sizeof}(\text{TYPE}))\) bytes of memory. Returns a pointer cast to \texttt{TYPE*}. The memory will not have been initialized in any way.

\texttt{TYPE* PyMem\_Resize}(\texttt{void *p, TYPE, size_t n})

Same as \texttt{PyMem\_Realloc()}, but the memory block is resized to \((n \times \text{sizeof}(\text{TYPE}))\) bytes. Returns a pointer cast to \texttt{TYPE*}. On return, \(p\) will be a pointer to the new memory area, or \texttt{NULL} in the event of failure. This is a C preprocessor macro; \(p\) is always reassigned. Save the original value of \(p\) to avoid losing memory when handling errors.

\texttt{void PyMem\_Del}(\texttt{void *p})

Same as \texttt{PyMem\_Free()}.

In addition, the following macro sets are provided for calling the Python memory allocator directly, without involving the C API functions listed above. However, note that their use does not preserve binary compatibility across Python versions and is therefore deprecated in extension modules.

\texttt{PyMem\_MALLOC()}, \texttt{PyMem\_REALLOC()}, \texttt{PyMem\_FREE()}.

\texttt{PyMem\_NEW()}, \texttt{PyMem\_RESIZE()}, \texttt{PyMem\_DEL()}. 
Examples

Here is the example from section Overview, rewritten so that the I/O buffer is allocated from the Python heap by using the first function set:

```c
PyObject *res;
char *buf = (char *) PyMem_Malloc(BUFSIZ); /* for I/O */

if (buf == NULL)
    return PyErr_NoMemory();
/* ...Do some I/O operation involving buf... */
res = PyString_FromString(buf);
PyMem_Free(buf); /* allocated with PyMem_Malloc */
return res;
```

The same code using the type-oriented function set:

```c
PyObject *res;
char *buf = PyMem_New(char, BUFSIZ); /* for I/O */

if (buf == NULL)
    return PyErr_NoMemory();
/* ...Do some I/O operation involving buf... */
res = PyString_FromString(buf);
PyMem_Del(buf); /* allocated with PyMem_Malloc */
return res;
```

Note that in the two examples above, the buffer is always manipulated via functions belonging to the same set. Indeed, it is required to use the same memory API family for a given memory block, so that the risk of mixing different allocators is reduced to a minimum. The following code sequence contains two errors, one of which is labeled as fatal because it mixes two different allocators operating on different heaps.

```c
char *buf1 = PyMem_New(char, BUFSIZ);
char *buf2 = (char *) malloc(BUFSIZ);
```
In addition to the functions aimed at handling raw memory blocks from the Python heap, objects in Python are allocated and released with `PyObject_New()`, `PyObject_NewVar()` and `PyObject_Del()`. These will be explained in the next chapter on defining and implementing new object types in C.
This chapter describes the functions, types, and macros used when defining new object types.

- Buffer Object Structures
- Supporting Cyclic Garbage Collection
Allocating Objects on the Heap

PyObject* _PyObject_New(PyTypeObject *type)

*Return value: New reference.*

PyVarObject* _PyObject_NewVar(PyTypeObject *type, Py_ssize_t size)

*Return value: New reference.*

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

void _PyObject_Del(PyObject *op)

PyObject* PyObject_Init(PyObject *op, PyTypeObject *type)

*Return value: Borrowed reference.*

Initialize a newly-allocated object `op` with its type and initial reference. Returns the initialized object. If `type` indicates that the object participates in the cyclic garbage detector, it is added to the detector’s set of observed objects. Other fields of the object are not affected.

PyVarObject* PyObject_InitVar(PyVarObject *op, PyTypeObject *type, Py_ssize_t size)

*Return value: Borrowed reference.*

This does everything `PyObject_Init()` does, and also initializes the length information for a variable-size object.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

TYPE* PyObject_New(TYPE, PyTypeObject *type)

*Return value: New reference.*
Allocate a new Python object using the C structure type `TYPE` and the Python type object `type`. Fields not defined by the Python object header are not initialized; the object's reference count will be one. The size of the memory allocation is determined from the `tp_basicsize` field of the type object.

```c
TYPE* PyObject_NewVar(TYPE, PyTypeObject *type, Py_ssize_t size)
```

*Return value: New reference.*

Allocate a new Python object using the C structure type `TYPE` and the Python type object `type`. Fields not defined by the Python object header are not initialized. The allocated memory allows for the `TYPE` structure plus `size` fields of the size given by the `tp_itemsize` field of `type`. This is useful for implementing objects like tuples, which are able to determine their size at construction time. Embedding the array of fields into the same allocation decreases the number of allocations, improving the memory management efficiency.

*Changed in version 2.5:* This function used an `int` type for `size`. This might require changes in your code for properly supporting 64-bit systems.

```c
void PyObject_Del(PyObject *op)
```

Releases memory allocated to an object using `PyObject_New()` or `PyObject_NewVar()`. This is normally called from the `tp_dealloc` handler specified in the object's type. The fields of the object should not be accessed after this call as the memory is no longer a valid Python object.

```c
PyObject* Py_InitModule(char *name, PyMethodDef *methods)
```

*Return value: Borrowed reference.*

Create a new module object based on a name and table of functions, returning the new module object.
Changed in version 2.3: Older versions of Python did not support NULL as the value for the methods argument.

PyObject* Py_InitModule3(char *name, PyMethodDef *methods, char *doc)

Return value: Borrowed reference.
Create a new module object based on a name and table of functions, returning the new module object. If doc is non-NULL, it will be used to define the docstring for the module.

Changed in version 2.3: Older versions of Python did not support NULL as the value for the methods argument.

PyObject* Py_InitModule4(char *name, PyMethodDef *methods, char *doc, PyObject *self, int apiver)

Return value: Borrowed reference.
Create a new module object based on a name and table of functions, returning the new module object. If doc is non-NULL, it will be used to define the docstring for the module. If self is non-NULL, it will be passed to the functions of the module as their (otherwise NULL) first parameter. (This was added as an experimental feature, and there are no known uses in the current version of Python.) For apiver, the only value which should be passed is defined by the constant PYTHON_API_VERSION.

Note: Most uses of this function should probably be using the Py_InitModule3() instead; only use this if you are sure you need it.

Changed in version 2.3: Older versions of Python did not support NULL as the value for the methods argument.

PyObject _Py_NoneStruct
Object which is visible in Python as None. This should only be accessed using the Py_None macro, which evaluates to a pointer
to this object.
Common Object Structures

There are a large number of structures which are used in the definition of object types for Python. This section describes these structures and how they are used.

All Python objects ultimately share a small number of fields at the beginning of the object’s representation in memory. These are represented by the `PyObject` and `PyVarObject` types, which are defined, in turn, by the expansions of some macros also used, whether directly or indirectly, in the definition of all other Python objects.

**PyObject**

All object types are extensions of this type. This is a type which contains the information Python needs to treat a pointer to an object as an object. In a normal “release” build, it contains only the object’s reference count and a pointer to the corresponding type object. It corresponds to the fields defined by the expansion of the `PyObject_HEAD` macro.

**PyVarObject**

This is an extension of `PyObject` that adds the `ob_size` field. This is only used for objects that have some notion of `length`. This type does not often appear in the Python/C API. It corresponds to the fields defined by the expansion of the `PyObject_VAR_HEAD` macro.

These macros are used in the definition of `PyObject` and `PyVarObject`:

**PyObject_HEAD**

This is a macro which expands to the declarations of the fields of the `PyObject` type; it is used when declaring new types which represent objects without a varying length. The specific fields it
expands to depend on the definition of `Py_TRACE_REFS`. By default, that macro is not defined, and `PyObject_HEAD` expands to:

```c
Py_ssize_t ob_refcnt;
PyTypeObject *ob_type;
```

When `Py_TRACE_REFS` is defined, it expands to:

```c
PyObject *ob_next, *ob_prev;
Py_ssize_t ob_refcnt;
PyTypeObject *ob_type;
```

**PyObject_VAR_HEAD**

This is a macro which expands to the declarations of the fields of the `PyVarObject` type; it is used when declaring new types which represent objects with a length that varies from instance to instance. This macro always expands to:

```c
PyObject_HEAD
Py_ssize_t ob_size;
```

Note that `PyObject_HEAD` is part of the expansion, and that its own expansion varies depending on the definition of `Py_TRACE_REFS`.

**Py_TYPE(o)**

This macro is used to access the `ob_type` member of a Python object. It expands to:

```c
(((PyObject*)(o))->ob_type)
```

*New in version 2.6.*

**Py_REFCNT(o)**

This macro is used to access the `ob_refcnt` member of a Python object. It expands to:

```c
(((PyObject*)(o))->ob_refcnt)
```
New in version 2.6.

Py_SIZE(o)
This macro is used to access the ob_size member of a Python object. It expands to:

```c
(((PyVarObject*)(o))->ob_size)
```

New in version 2.6.

PyObject_HEAD_INIT(type)
This is a macro which expands to initialization values for a new PyObject type. This macro expands to:

```c
_PyObject_EXTRA_INIT 1, type,
```

PyVarObject_HEAD_INIT(type, size)
This is a macro which expands to initialization values for a new PyVarObject type, including the ob_size field. This macro expands to:

```c
_PyObject_EXTRA_INIT 1, type, size,
```

PyCFunction
Type of the functions used to implement most Python callables in C. Functions of this type take two PyObject* parameters and return one such value. If the return value is NULL, an exception shall have been set. If not NULL, the return value is interpreted as the return value of the function as exposed in Python. The function must return a new reference.

PyMethodDef
Structure used to describe a method of an extension type. This
structure has four fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_name</td>
<td>char *</td>
<td>name of the method</td>
</tr>
<tr>
<td>ml_meth</td>
<td>PyCFunction</td>
<td>pointer to the C implementation</td>
</tr>
<tr>
<td>ml_flags</td>
<td>int</td>
<td>flag bits indicating how the call should be constructed</td>
</tr>
<tr>
<td>ml_doc</td>
<td>char *</td>
<td>points to the contents of the docstring</td>
</tr>
</tbody>
</table>

The `ml_meth` is a C function pointer. The functions may be of different types, but they always return `PyObject*`. If the function is not of the `PyCFunction`, the compiler will require a cast in the method table. Even though `PyCFunction` defines the first parameter as `PyObject*`, it is common that the method implementation uses the specific C type of the `self` object.

The `ml_flags` field is a bitfield which can include the following flags. The individual flags indicate either a calling convention or a binding convention. Of the calling convention flags, only `METH_VARARGS` and `METH_KEYWORDS` can be combined. Any of the calling convention flags can be combined with a binding flag.

**METH_VARARGS**

This is the typical calling convention, where the methods have the type `PyCFunction`. The function expects two `PyObject*` values. The first one is the `self` object for methods; for module functions, it is the module object. The second parameter (often called `args`) is a tuple object representing all arguments. This parameter is typically processed using `PyArg_ParseTuple()` or `PyArg_UnpackTuple()`.

**METH_KEYWORDS**
Methods with these flags must be of type `PyCFunctionWithKeywords`. The function expects three parameters: `self`, `args`, and a dictionary of all the keyword arguments. The flag is typically combined with `METH_VARARGS`, and the parameters are typically processed using `PyArg_ParseTupleAndKeywords()`.

**METH_NOARGS**
Methods without parameters don’t need to check whether arguments are given if they are listed with the `METH_NOARGS` flag. They need to be of type `PyCFunction`. The first parameter is typically named `self` and will hold a reference to the module or object instance. In all cases the second parameter will be `NULL`.

**METH_O**
Methods with a single object argument can be listed with the `METH_O` flag, instead of invoking `PyArg_ParseTuple()` with a "0" argument. They have the type `PyCFunction`, with the `self` parameter, and a `PyObject*` parameter representing the single argument.

**METH_OLDARGS**
This calling convention is deprecated. The method must be of type `PyCFunction`. The second argument is `NULL` if no arguments are given, a single object if exactly one argument is given, and a tuple of objects if more than one argument is given. There is no way for a function using this convention to distinguish between a call with multiple arguments and a call with a tuple as the only argument.

These two constants are not used to indicate the calling convention but the binding when use with methods of classes. These may not be used for functions defined for modules. At most one of these flags may be set for any given method.
**METH_CLASS**

The method will be passed the type object as the first parameter rather than an instance of the type. This is used to create *class methods*, similar to what is created when using the `classmethod()` built-in function.

*New in version 2.3.*

**METH_STATIC**

The method will be passed `NULL` as the first parameter rather than an instance of the type. This is used to create *static methods*, similar to what is created when using the `staticmethod()` built-in function.

*New in version 2.3.*

One other constant controls whether a method is loaded in place of another definition with the same method name.

**METH_COEXIST**

The method will be loaded in place of existing definitions. Without `METH_COEXIST`, the default is to skip repeated definitions. Since slot wrappers are loaded before the method table, the existence of a `sq_contains` slot, for example, would generate a wrapped method named `__contains__()` and preclude the loading of a corresponding PyCFunction with the same name. With the flag defined, the PyCFunction will be loaded in place of the wrapper object and will co-exist with the slot. This is helpful because calls to PyCFunctions are optimized more than wrapper object calls.

*New in version 2.4.*

**PyMemberDef**

Structure which describes an attribute of a type which corresponds to a C struct member. Its fields are:
<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>char *</td>
<td>name of the member</td>
</tr>
<tr>
<td>type</td>
<td>int</td>
<td>the type of the member in the C struct</td>
</tr>
<tr>
<td>offset</td>
<td>Py_ssize_t</td>
<td>the offset in bytes that the member is located on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the type’s object struct</td>
</tr>
<tr>
<td>flags</td>
<td>int</td>
<td>flag bits indicating if the field should be read-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>only or writable</td>
</tr>
<tr>
<td>doc</td>
<td>char *</td>
<td>points to the contents of the docstring</td>
</tr>
</tbody>
</table>

The `type` can be one of many `T_` macros corresponding to various C types. When the member is accessed in Python, it will be converted to the equivalent Python type.

T_PYSSIZET | Py_ssize_t

T_OBJECT and T_OBJECT_EX differ in that T_OBJECT returns None if the member is NULL and T_OBJECT_EX raises an AttributeError. Try to use T_OBJECT_EX over T_OBJECT because T_OBJECT_EX handles use of the `del` statement on that attribute more correctly than T_OBJECT.

flags can be 0 for write and read access or READONLY for read-only access. Using T_STRING for type implies READONLY. Only T_OBJECT and T_OBJECT_EX members can be deleted. (They are set to NULL).

```
PyObject* Py_FindMethod(PyMethodDef table[], PyObject *ob, char *name)
```

Return a bound method object for an extension type implemented in C. This can be useful in the implementation of a `tp_getattro` or `tp_getattr` handler that does not use the `PyObject_GenericGetAttr()` function.
Type Objects

Perhaps one of the most important structures of the Python object system is the structure that defines a new type: the `PyTypeObject` structure. Type objects can be handled using any of the `PyObject_*()` or `PyType_*()` functions, but do not offer much that’s interesting to most Python applications. These objects are fundamental to how objects behave, so they are very important to the interpreter itself and to any extension module that implements new types.

Type objects are fairly large compared to most of the standard types. The reason for the size is that each type object stores a large number of values, mostly C function pointers, each of which implements a small part of the type’s functionality. The fields of the type object are examined in detail in this section. The fields will be described in the order in which they occur in the structure.

Typedefs: `unaryfunc`, `binaryfunc`, `ternaryfunc`, `inquiry`, `coercion`, `intargfunc`, `intintargfunc`, `intobjargproc`, `intintobjargproc`, `objobjargproc`, `destructor`, `freefunc`, `printfunc`, `getattrfunc`, `getattrofunc`, `setattrfunc`, `setattrofunc`, `cmpfunc`, `reprfunc`, `hashfunc`

The structure definition for `PyTypeObject` can be found in `Include/object.h`. For convenience of reference, this repeats the definition found there:

```c
typedef struct _typeobject {
    PyObject_VAR_HEAD
    char *tp_name; /* For printing, in format "<module>.<name>" */
    int tp_basicsize, tp_itemsize; /* For allocation */

    /* Methods to implement standard operations */

    destructor tp_dealloc;
    printfunc tp_print;
    getattrfunc tp_getattr;
}
```
setattrfunc tp_setattr;
cmpfunc tp_compare;
reprfunc tp_repr;

/* Method suites for standard classes */
PyNumberMethods *tp_as_number;
PySequenceMethods *tp_as_sequence;
PyMappingMethods *tp_as_mapping;

/* More standard operations (here for binary compatibility) */
hashfunc tp_hash;
ternaryfunc tp_call;
reprfunc tp_str;
getattrofunc tp_getattro;
setattrofunc tp_setattro;

/* Functions to access object as input/output buffer */
PyBufferProcs *tp_as_buffer;

/* Flags to define presence of optional/expanded features */
long tp_flags;

char *tp_doc; /* Documentation string */

/* Assigned meaning in release 2.0 */
/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* Assigned meaning in release 2.1 */
/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
long tp_weaklistoffset;

/* Added in release 2.2 */
/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
The type object structure extends the `PyVarObject` structure. The `ob_size` field is used for dynamic types (created by `type_new()`, usually called from a class statement). Note that `PyType_Type` (the metatype) initializes `tp_itemsize`, which means that its instances (i.e. type objects) must have the `ob_size` field.

`PyObject* PyObject._ob_next`  
`PyObject* PyObject._ob_prev`  
These fields are only present when the macro `PY_TRACE_REFS` is defined. Their initialization to `NULL` is taken care of by the `PyObject_HEAD_INIT` macro. For statically allocated objects, these fields always remain `NULL`. For dynamically allocated objects, these two fields are used to link the object into a doubly-linked list of all live objects on the heap. This could be used for various debugging purposes; currently the only use is to print the objects that are still alive at the end of a run when the environment variable `PYTHONDUMPREFS` is set.
These fields are not inherited by subtypes.

Py_ssize_t **PyObject**.ob_refcnt
This is the type object's reference count, initialized to 1 by the **PyObject**.HEAD_INIT macro. Note that for statically allocated type objects, the type's instances (objects whose **ob_type** points back to the type) do not count as references. But for dynamically allocated type objects, the instances do count as references.

This field is not inherited by subtypes.

*Changed in version 2.5:* This field used to be an **int** type. This might require changes in your code for properly supporting 64-bit systems.

PyTypeObject* **PyObject**.ob_type
This is the type's type, in other words its metatype. It is initialized by the argument to the **PyObject**.HEAD_INIT macro, and its value should normally be &PyType_Type. However, for dynamically loadable extension modules that must be usable on Windows (at least), the compiler complains that this is not a valid initializer. Therefore, the convention is to pass **NULL** to the **PyObject**.HEAD_INIT macro and to initialize this field explicitly at the start of the module's initialization function, before doing anything else. This is typically done like this:

```c
Foo_Type.ob_type = &PyType_Type;
```

This should be done before any instances of the type are created. **PyType_Ready()** checks if **ob_type** is **NULL**, and if so, initializes it: in Python 2.2, it is set to &PyType_Type; in Python 2.2.1 and later it is initialized to the **ob_type** field of the base class. **PyType_Ready()** will not change this field if it is non-zero.
In Python 2.2, this field is not inherited by subtypes. In 2.2.1, and in 2.3 and beyond, it is inherited by subtypes.

Py_ssize_t PyVarObject.ob_size
For statically allocated type objects, this should be initialized to zero. For dynamically allocated type objects, this field has a special internal meaning.

This field is not inherited by subtypes.

char* PyTypeObject.tp_name
Pointer to a NUL-terminated string containing the name of the type. For types that are accessible as module globals, the string should be the full module name, followed by a dot, followed by the type name; for built-in types, it should be just the type name. If the module is a submodule of a package, the full package name is part of the full module name. For example, a type named T defined in module M in subpackage Q in package P should have the tp_name initializer "P.Q.M.T".

For dynamically allocated type objects, this should just be the type name, and the module name explicitly stored in the type dict as the value for key '__module__'.

For statically allocated type objects, the tp_name field should contain a dot. Everything before the last dot is made accessible as the __module__ attribute, and everything after the last dot is made accessible as the __name__ attribute.

If no dot is present, the entire tp_name field is made accessible as the __name__ attribute, and the __module__ attribute is undefined (unless explicitly set in the dictionary, as explained above). This means your type will be impossible to pickle. Additionally, it will not be listed in module documentations created with pydoc.
This field is not inherited by subtypes.

Py_ssize_t PyTypeObject.tp_basicsize
Py_ssize_t PyTypeObject.tp_itemsize

These fields allow calculating the size in bytes of instances of the type.

There are two kinds of types: types with fixed-length instances have a zero \texttt{tp\_itemsize} field, types with variable-length instances have a non-zero \texttt{tp\_itemsize} field. For a type with fixed-length instances, all instances have the same size, given in \texttt{tp\_basicsize}.

For a type with variable-length instances, the instances must have an \texttt{ob\_size} field, and the instance size is \texttt{tp\_basicsize} plus \( N \) times \texttt{tp\_itemsize}, where \( N \) is the “length” of the object. The value of \( N \) is typically stored in the instance’s \texttt{ob\_size} field. There are exceptions: for example, long ints use a negative \texttt{ob\_size} to indicate a negative number, and \( N \) is \texttt{abs(ob\_size)} there. Also, the presence of an \texttt{ob\_size} field in the instance layout doesn’t mean that the instance structure is variable-length (for example, the structure for the list type has fixed-length instances, yet those instances have a meaningful \texttt{ob\_size} field).

The basic size includes the fields in the instance declared by the macro \texttt{PyObject\_HEAD} or \texttt{PyObject\_VAR\_HEAD} (whichever is used to declare the instance struct) and this in turn includes the \_ob\_prev and \_ob\_next fields if they are present. This means that the only correct way to get an initializer for the \texttt{tp\_basicsize} is to use the \texttt{sizeof} operator on the struct used to declare the instance layout. The basic size does not include the GC header size (this is new in Python 2.2; in 2.1 and 2.0, the GC header size was included in \texttt{tp\_basicsize}).
These fields are inherited separately by subtypes. If the base type has a non-zero \texttt{tp_itemsize}, it is generally not safe to set \texttt{tp_itemsize} to a different non-zero value in a subtype (though this depends on the implementation of the base type).

A note about alignment: if the variable items require a particular alignment, this should be taken care of by the value of \texttt{tp_basicsize}. Example: suppose a type implements an array of \texttt{double}. \texttt{tp_itemsize} is \texttt{sizeof(double)}. It is the programmer's responsibility that \texttt{tp_basicsize} is a multiple of \texttt{sizeof(double)} (assuming this is the alignment requirement for \texttt{double}).

\textbf{destructor \texttt{PyTypeObject.tp_dealloc}}

A pointer to the instance destructor function. This function must be defined unless the type guarantees that its instances will never be deallocated (as is the case for the singletons \texttt{None} and \texttt{Ellipsis}).

The destructor function is called by the \texttt{Py\_DECREF()} and \texttt{Py\_XDECREF()} macros when the new reference count is zero. At this point, the instance is still in existence, but there are no references to it. The destructor function should free all references which the instance owns, free all memory buffers owned by the instance (using the freeing function corresponding to the allocation function used to allocate the buffer), and finally (as its last action) call the type's \texttt{tp\_free} function. If the type is not subtypable (doesn't have the \texttt{Py\_TPFLAGS\_BASETYPE} flag bit set), it is permissible to call the object deallocator directly instead of via \texttt{tp\_free}. The object deallocator should be the one used to allocate the instance; this is normally \texttt{PyObject\_Del()} if the instance was allocated using \texttt{PyObject\_New()} or \texttt{PyObject\_VarNew()}, or \texttt{PyObject\_GC\_Del()} if the instance was allocated using \texttt{PyObject\_GC\_New()} or \texttt{PyObject\_GC\_NewVar()}. 
This field is inherited by subtypes.

printfunc PyTypeObject.tp_print

An optional pointer to the instance print function.

The print function is only called when the instance is printed to a real file; when it is printed to a pseudo-file (like a StringIO instance), the instance's tp_repr or tp_str function is called to convert it to a string. These are also called when the type's tp_print field is NULL. A type should never implement tp_print in a way that produces different output than tp_repr or tp_str would.

The print function is called with the same signature as PyObject_Print(): int tp_print(PyObject *self, FILE *file, int flags). The self argument is the instance to be printed. The file argument is the stdio file to which it is to be printed. The flags argument is composed of flag bits. The only flag bit currently defined is Py_PRINT_RAW. When the Py_PRINT_RAW flag bit is set, the instance should be printed the same way as tp_str would format it; when the Py_PRINT_RAW flag bit is clear, the instance should be printed the same was as tp_repr would format it. It should return -1 and set an exception condition when an error occurred during the comparison.

It is possible that the tp_print field will be deprecated. In any case, it is recommended not to define tp_print, but instead to rely on tp_repr and tp_str for printing.

This field is inherited by subtypes.

getattrfunc PyTypeObject.tp_getattr

An optional pointer to the get-attribute-string function.
This field is deprecated. When it is defined, it should point to a function that acts the same as the `tp_getattro` function, but taking a C string instead of a Python string object to give the attribute name. The signature is

```
PyObject * tp_getattr(PyObject *o, char *attr_name);
```

This field is inherited by subtypes together with `tp_getattro`: a subtype inherits both `tp_getattr` and `tp_getattro` from its base type when the subtype’s `tp_getattr` and `tp_getattro` are both `NULL`.

`setattrfunc PyTypeObject.tp_setattr`

An optional pointer to the function for setting and deleting attributes.

This field is deprecated. When it is defined, it should point to a function that acts the same as the `tp_setattro` function, but taking a C string instead of a Python string object to give the attribute name. The signature is

```
PyObject * tp_setattr(PyObject *o, char *attr_name, PyObject *v);
```

The `v` argument is set to `NULL` to delete the attribute. This field is inherited by subtypes together with `tp_setattro`: a subtype inherits both `tp_setattr` and `tp_setattro` from its base type when the subtype’s `tp_setattr` and `tp_setattro` are both `NULL`.

`cmpfunc PyTypeObject.tp_compare`

An optional pointer to the three-way comparison function.

The signature is the same as for `PyObject_Compare()`. The function should return `1` if `self` greater than `other`, `0` if `self` is equal to `other`, and `-1` if `self` less than `other`. It should return `-1` and set
an exception condition when an error occurred during the comparison.

This field is inherited by subtypes together with \texttt{tp\_richcompare} and \texttt{tp\_hash}: a subtypes inherits all three of \texttt{tp\_compare}, \texttt{tp\_richcompare}, and \texttt{tp\_hash} when the subtype’s \texttt{tp\_compare}, \texttt{tp\_richcompare}, and \texttt{tp\_hash} are all \texttt{NULL}.

\textbf{reprfunc} \texttt{PyTypeObject.tp\_repr}

An optional pointer to a function that implements the built-in function \texttt{repr()}. The signature is the same as for \texttt{PyObject\_Repr()}; it must return a string or a Unicode object. Ideally, this function should return a string that, when passed to \texttt{eval()}, given a suitable environment, returns an object with the same value. If this is not feasible, it should return a string starting with \texttt{'<'} and ending with \texttt{'>'} from which both the type and the value of the object can be deduced.

When this field is not set, a string of the form \texttt{<\texttt{\%s} object at \texttt{\%p}>} is returned, where \texttt{\%s} is replaced by the type name, and \texttt{\%p} by the object’s memory address.

This field is inherited by subtypes.

\textbf{PyNumberMethods* tp\_as\_number}

Pointer to an additional structure that contains fields relevant only to objects which implement the number protocol. These fields are documented in \texttt{Number Object Structures}.

The \texttt{tp\_as\_number} field is not inherited, but the contained fields are inherited individually.

\textbf{PySequenceMethods* tp\_as\_sequence}

Pointer to an additional structure that contains fields relevant only
to objects which implement the sequence protocol. These fields are documented in \textit{Sequence Object Structures}.

The \texttt{tp\_as\_sequence} field is not inherited, but the contained fields are inherited individually.

\textbf{PyMappingMethods* \texttt{tp\_as\_mapping}}

Pointer to an additional structure that contains fields relevant only to objects which implement the mapping protocol. These fields are documented in \textit{Mapping Object Structures}.

The \texttt{tp\_as\_mapping} field is not inherited, but the contained fields are inherited individually.

\textbf{hashfunc \texttt{PyTypeObject\_tp\_hash}}

An optional pointer to a function that implements the built-in function \texttt{hash()}.

The signature is the same as for \texttt{PyObject\_Hash()}; it must return a C long. The value \texttt{-1} should not be returned as a normal return value; when an error occurs during the computation of the hash value, the function should set an exception and return \texttt{-1}.

This field can be set explicitly to \texttt{PyObject\_HashNotImplemented()} to block inheritance of the hash method from a parent type. This is interpreted as the equivalent of \texttt{\_\_hash\_\_ = None} at the Python level, causing \texttt{isinstance(o, collections.Hashable)} to correctly return \texttt{False}. Note that the converse is also true - setting \texttt{\_\_hash\_\_ = None} on a class at the Python level will result in the \texttt{tp\_hash} slot being set to \texttt{PyObject\_HashNotImplemented()}.

When this field is not set, two possibilities exist: if the \texttt{tp\_compare} and \texttt{tp\_richcompare} fields are both \texttt{NULL}, a default hash value based on the object's address is returned; otherwise, a \texttt{TypeError}
is raised.

This field is inherited by subtypes together with `tp richcompare` and `tp compare`: a subtypes inherits all three of `tp compare`, `tp richcompare`, and `tp hash`, when the subtype's `tp compare`, `tp richcompare` and `tp hash` are all `NULL`.

**ternaryfunc** `PyTypeObject.tp_call`

An optional pointer to a function that implements calling the object. This should be `NULL` if the object is not callable. The signature is the same as for `PyObject_Call()`.

This field is inherited by subtypes.

**reprfunc** `PyTypeObject.tp_str`

An optional pointer to a function that implements the built-in operation `str()`. (Note that `str` is a type now, and `str()` calls the constructor for that type. This constructor calls `PyObject_Str()` to do the actual work, and `PyObject_Str()` will call this handler.)

The signature is the same as for `PyObject_Str()`; it must return a string or a Unicode object. This function should return a “friendly” string representation of the object, as this is the representation that will be used by the print statement.

When this field is not set, `PyObject_Repr()` is called to return a string representation.

This field is inherited by subtypes.

**getattrofunc** `PyTypeObject.tp_getattro`

An optional pointer to the get-attribute function.

The signature is the same as for `PyObject_GetAttr()`. It is usually convenient to set this field to `PyObject_GenericGetAttr()`, which
implements the normal way of looking for object attributes.

This field is inherited by subtypes together with `tp_getattr`: a subtype inherits both `tp_getattr` and `tp_getattro` from its base type when the subtype's `tp_getattr` and `tp_getattro` are both `NULL`.

`setattrofunc PyTypeObject.tp_setattro`

An optional pointer to the function for setting and deleting attributes.

The signature is the same as for `PyObject_SetAttr()`, but setting `v` to `NULL` to delete an attribute must be supported. It is usually convenient to set this field to `PyObject_GenericSetAttr()`, which implements the normal way of setting object attributes.

This field is inherited by subtypes together with `tp_setattr`: a subtype inherits both `tp_setattr` and `tp_setattro` from its base type when the subtype's `tp_setattr` and `tp_setattro` are both `NULL`.

`PyBufferProcs* PyTypeObject.tp_as_buffer`

Pointer to an additional structure that contains fields relevant only to objects which implement the buffer interface. These fields are documented in Buffer Object Structures.

The `tp_as_buffer` field is not inherited, but the contained fields are inherited individually.

`long PyTypeObject.tp_flags`

This field is a bit mask of various flags. Some flags indicate variant semantics for certain situations; others are used to indicate that certain fields in the type object (or in the extension structures referenced via `tp_as_number`, `tp_as_sequence`,
tp_as_mapping, and tp_as_buffer) that were historically not always present are valid; if such a flag bit is clear, the type fields it guards must not be accessed and must be considered to have a zero or NULL value instead.

Inheritance of this field is complicated. Most flag bits are inherited individually, i.e. if the base type has a flag bit set, the subtype inherits this flag bit. The flag bits that pertain to extension structures are strictly inherited if the extension structure is inherited, i.e. the base type's value of the flag bit is copied into the subtype together with a pointer to the extension structure. The Py_TPFLAGS_HAVE_GC flag bit is inherited together with the tp_traverse and tp_clear fields, i.e. if the Py_TPFLAGS_HAVE_GC flag bit is clear in the subtype and the tp_traverse and tp_clear fields in the subtype exist (as indicated by the Py_TPFLAGS_HAVE_RICHCOMPARE flag bit) and have NULL values.

The following bit masks are currently defined; these can be ORed together using the | operator to form the value of the tp_flags field. The macro PyType_HasFeature() takes a type and a flags value, tp and f, and checks whether tp->tp_flags & f is non-zero.

**Py_TPFLAGS_HAVE_GETCHARBUFFER**
If this bit is set, the PyBufferProcs struct referenced by tp_as_buffer has the bf_getcharbuffer field.

**Py_TPFLAGS_HAVE_SEQUENCE_IN**
If this bit is set, the PySequenceMethods struct referenced by tp_as_sequence has the sq_contains field.

**Py_TPFLAGS_GC**
This bit is obsolete. The bit it used to name is no longer in use. The symbol is now defined as zero.
Py_TPFLAGS_HAVE_INPLACEOPS
If this bit is set, the PySequenceMethods struct referenced by tp_as_sequence and the PyNumberMethods structure referenced by tp_as_number contain the fields for in-place operators. In particular, this means that the PyNumberMethods structure has the fields nb_inplace_add, nb_inplace_subtract, nb_inplace_multiply, nb_inplace_divide, nb_inplace_remainder, nb_inplace_power, nb_inplace_lshift, nb_inplace_rshift, nb_inplace_and, nb_inplace_xor, and nb_inplace_or; and the PySequenceMethods struct has the fields sq_inplace_concat and sq_inplace_repeat.

Py_TPFLAGS_CHECKTYPES
If this bit is set, the binary and ternary operations in the PyNumberMethods structure referenced by tp_as_number accept arguments of arbitrary object types, and do their own type conversions if needed. If this bit is clear, those operations require that all arguments have the current type as their type, and the caller is supposed to perform a coercion operation first. This applies to nb_add, nb_subtract, nb_multiply, nb_divide, nb_remainder, nb_divmod, nb_power, nb_lshift, nb_rshift, nb_and, nb_xor, and nb_or.

Py_TPFLAGS_HAVE_RICHCOMPARE
If this bit is set, the type object has the tp_richcompare field, as well as the tp_traverse and the tp_clear fields.

Py_TPFLAGS_HAVE_WEAKREFS
If this bit is set, the tp_weaklistoffset field is defined. Instances of a type are weakly referenceable if the type's tp_weaklistoffset field has a value greater than zero.

Py_TPFLAGS_HAVE_ITER
If this bit is set, the type object has the \texttt{tp_iter} and \texttt{tp_iternext} fields.

\textbf{Py\_TPFLAGS\_HAVE\_CLASS}

If this bit is set, the type object has several new fields defined starting in Python 2.2: \texttt{tp\_methods, tp\_members, tp\_getset, tp\_base, tp\_dict, tp\_descr\_get, tp\_descr\_set, tp\_dictoffset, tp\_init, tp\_alloc, tp\_new, tp\_free, tp\_is\_gc, tp\_bases, tp\_mro, tp\_cache, tp\_subclasses, and tp\_weaklist}.

\textbf{Py\_TPFLAGS\_HEAPTYPE}

This bit is set when the type object itself is allocated on the heap. In this case, the \texttt{ob\_type} field of its instances is considered a reference to the type, and the type object is INCREF’ed when a new instance is created, and DECREF’ed when an instance is destroyed (this does not apply to instances of subtypes; only the type referenced by the instance’s \texttt{ob\_type} gets INCREF’ed or DECREF’ed).

\textbf{Py\_TPFLAGS\_BASETYPE}

This bit is set when the type can be used as the base type of another type. If this bit is clear, the type cannot be subtyped (similar to a “final” class in Java).

\textbf{Py\_TPFLAGS\_READY}

This bit is set when the type object has been fully initialized by \texttt{ PyTuple\_Ready()}.

\textbf{Py\_TPFLAGS\_REAMDYING}

This bit is set while \texttt{ PyTuple\_Ready()} is in the process of initializing the type object.

\textbf{Py\_TPFLAGS\_HAVE\_GC}

This bit is set when the object supports garbage collection. If this bit is set, instances must be created using
PyObject_GC_New() and destroyed using PyObject_GC_Del(). More information in section Supporting Cyclic Garbage Collection. This bit also implies that the GC-related fields tp_traverse and tp_clear are present in the type object; but those fields also exist when Py_TPFLAGS_HAVE_GC is clear but Py_TPFLAGS_HAVE_RICHCOMPARE is set.

Py_TPFLAGS_DEFAULT
This is a bitmask of all the bits that pertain to the existence of certain fields in the type object and its extension structures. Currently, it includes the following bits: Py_TPFLAGS_HAVE_GETCHARBUFFER, Py_TPFLAGS_HAVE_SEQUENCE_IN, Py_TPFLAGS_HAVE_INPLACEOPS, Py_TPFLAGS_HAVE_RICHCOMPARE, Py_TPFLAGS_HAVE_WEAKREFS, Py_TPFLAGS_HAVE_ITER, and Py_TPFLAGS_HAVE_CLASS.

char* PyTypeObject.tp_doc
An optional pointer to a NUL-terminated C string giving the docstring for this type object. This is exposed as the __doc__ attribute on the type and instances of the type.

This field is not inherited by subtypes.

The following three fields only exist if the Py_TPFLAGS_HAVE_RICHCOMPARE flag bit is set.

traverseproc PyTypeObject.tp_traverse
An optional pointer to a traversal function for the garbage collector. This is only used if the Py_TPFLAGS_HAVE_GC flag bit is set. More information about Python’s garbage collection scheme can be found in section Supporting Cyclic Garbage Collection.

The tp_traverse pointer is used by the garbage collector to detect reference cycles. A typical implementation of a
tp_traverse function simply calls Py_VISIT() on each of the instance's members that are Python objects. For example, this is function local_traverse() from the thread extension module:

```c
static int
local_traverse(localobject *self, visitproc visit, void *arg
{
    Py_VISIT(self->args);
    Py_VISIT(self->kw);
    Py_VISIT(self->dict);
    return 0;
}
```

Note that Py_VISIT() is called only on those members that can participate in reference cycles. Although there is also a self->key member, it can only be NULL or a Python string and therefore cannot be part of a reference cycle.

On the other hand, even if you know a member can never be part of a cycle, as a debugging aid you may want to visit it anyway just so the gc module's get_referents() function will include it.

Note that Py_VISIT() requires the visit and arg parameters to local_traverse() to have these specific names; don't name them just anything.

This field is inherited by subtypes together with tp_clear and the Py_TPFLAGS_HAVE_GC flag bit: the flag bit, tp_traverse, and tp_clear are all inherited from the base type if they are all zero in the subtype and the subtype has the Py_TPFLAGS_HAVE_RICHCOMPARE flag bit set.

inquiry PyTypeObject.tp_clear

An optional pointer to a clear function for the garbage collector. This is only used if the Py_TPFLAGS_HAVE_GC flag bit is set.
The `tp_clear` member function is used to break reference cycles in cyclic garbage detected by the garbage collector. Taken together, all `tp_clear` functions in the system must combine to break all reference cycles. This is subtle, and if in any doubt supply a `tp_clear` function. For example, the tuple type does not implement a `tp_clear` function, because it's possible to prove that no reference cycle can be composed entirely of tuples. Therefore the `tp_clear` functions of other types must be sufficient to break any cycle containing a tuple. This isn't immediately obvious, and there's rarely a good reason to avoid implementing `tp_clear`.

Implementations of `tp_clear` should drop the instance's references to those of its members that may be Python objects, and set its pointers to those members to `NULL`, as in the following example:

```c
static int
local_clear(localobject *self)
{
    Py_CLEAR(self->key);
    Py_CLEAR(self->args);
    Py_CLEAR(self->kw);
    Py_CLEAR(self->dict);
    return 0;
}
```

The `Py_CLEAR()` macro should be used, because clearing references is delicate: the reference to the contained object must not be decremented until after the pointer to the contained object is set to `NULL`. This is because decrementing the reference count may cause the contained object to become trash, triggering a chain of reclamation activity that may include invoking arbitrary Python code (due to finalizers, or weakref callbacks, associated with the contained object). If it's possible for such code to reference `self` again, it's important that the pointer to the
contained object be \textit{NULL} at that time, so that \textit{self} knows the contained object can no longer be used. The \texttt{Py\_CLEAR()} macro performs the operations in a safe order.

Because the goal of \texttt{tp\_clear} functions is to break reference cycles, it's not necessary to clear contained objects like Python strings or Python integers, which can't participate in reference cycles. On the other hand, it may be convenient to clear all contained Python objects, and write the type's \texttt{tp\_dealloc} function to invoke \texttt{tp\_clear}.

More information about Python's garbage collection scheme can be found in section \textit{Supporting Cyclic Garbage Collection}.

This field is inherited by subtypes together with \texttt{tp\_traverse} and the \texttt{Py\_TPFLAGS\_HAVE\_GC} flag bit: the flag bit, \texttt{tp\_traverse}, and \texttt{tp\_clear} are all inherited from the base type if they are all zero in the subtype \textit{and} the subtype has the \texttt{Py\_TPFLAGS\_HAVE\_RICHCOMPARE} flag bit set.

\texttt{richcmpfunc} \texttt{PyTypeObject.tp\_richcompare}

An optional pointer to the rich comparison function, whose signature is \texttt{PyObject *tp\_richcompare(PyObject *a, PyObject *b, int op)}.

The function should return the result of the comparison (usually \texttt{Py\_True} or \texttt{Py\_False}). If the comparison is undefined, it must return \texttt{Py\_NotImplemented}, if another error occurred it must return \texttt{NULL} and set an exception condition.

\textbf{Note:} If you want to implement a type for which only a limited set of comparisons makes sense (e.g. \texttt{==} and \texttt{!=}, but not \texttt{<} and friends), directly raise \texttt{TypeError} in the rich comparison
This field is inherited by subtypes together with `tp_compare` and `tp_hash`: a subtype inherits all three of `tp_compare`, `tp_richcompare`, and `tp_hash`, when the subtype’s `tp_compare`, `tp_richcompare`, and `tp_hash` are all `NULL`.

The following constants are defined to be used as the third argument for `tp_richcompare` and for `PyObject_RichCompare()`:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Comparison</th>
</tr>
</thead>
<tbody>
<tr>
<td>Py_LT</td>
<td>&lt;</td>
</tr>
<tr>
<td>Py_LE</td>
<td>&lt;=</td>
</tr>
<tr>
<td>Py_EQ</td>
<td>==</td>
</tr>
<tr>
<td>Py_NE</td>
<td>!=</td>
</tr>
<tr>
<td>Py_GT</td>
<td>&gt;</td>
</tr>
<tr>
<td>Py_GE</td>
<td>&gt;=</td>
</tr>
</tbody>
</table>

The next field only exists if the `Py_TPFLAGS_HAVE_WEAKREFS` flag bit is set.

`long PyTypeObject.tp_weaklistoffset`

If the instances of this type are weakly referenceable, this field is greater than zero and contains the offset in the instance structure of the weak reference list head (ignoring the GC header, if present); this offset is used by `PyObject_ClearWeakRefs()` and the `PyWeakref_*()` functions. The instance structure needs to include a field of type `PyObject*` which is initialized to `NULL`.

Do not confuse this field with `tp_weaklist`; that is the list head for weak references to the type object itself.

This field is inherited by subtypes, but see the rules listed below. A subtype may override this offset; this means that the subtype uses a different weak reference list head than the base type.
Since the list head is always found via `tp_weaklistoffset`, this should not be a problem.

When a type defined by a class statement has no `__slots__` declaration, and none of its base types are weakly referenceable, the type is made weakly referenceable by adding a weak reference list head slot to the instance layout and setting the `tp_weaklistoffset` of that slot's offset.

When a type's `__slots__` declaration contains a slot named `__weakref__`, that slot becomes the weak reference list head for instances of the type, and the slot's offset is stored in the type's `tp_weaklistoffset`.

When a type's `__slots__` declaration does not contain a slot named `__weakref__`, the type inherits its `tp_weaklistoffset` from its base type.

The next two fields only exist if the `Py_TPFLAGS_HAVE_ITER` flag bit is set.

**getiterfunc** `PyTypeObject.tp_iter`

An optional pointer to a function that returns an iterator for the object. Its presence normally signals that the instances of this type are iterable (although sequences may be iterable without this function, and classic instances always have this function, even if they don't define an `__iter__()` method).

This function has the same signature as `PyObject_GetIter()`.

This field is inherited by subtypes.

**iternextfunc** `PyTypeObject.tp_iternext`

An optional pointer to a function that returns the next item in an iterator. When the iterator is exhausted, it must return `NULL`; a
StopIteration exception may or may not be set. When another error occurs, it must return NULL too. Its presence normally signals that the instances of this type are iterators (although classic instances always have this function, even if they don’t define a next() method).

Iterator types should also define the tp_iter function, and that function should return the iterator instance itself (not a new iterator instance).

This function has the same signature as PyIter_Next().

This field is inherited by subtypes.

The next fields, up to and including tp_weaklist, only exist if the Py_TPFLAGS_HAVE_CLASS flag bit is set.

struct PyMethodDef* PyTypeObject.tp_methods
An optional pointer to a static NULL-terminated array of PyMethodDef structures, declaring regular methods of this type.

For each entry in the array, an entry is added to the type's dictionary (see tp_dict below) containing a method descriptor.

This field is not inherited by subtypes (methods are inherited through a different mechanism).

struct PyMemberDef* PyTypeObject.tp_members
An optional pointer to a static NULL-terminated array of PyMemberDef structures, declaring regular data members (fields or slots) of instances of this type.

For each entry in the array, an entry is added to the type's dictionary (see tp_dict below) containing a member descriptor.
This field is not inherited by subtypes (members are inherited through a different mechanism).

**struct PyGetSetDef** *PyTypeObject.tp_getset*

An optional pointer to a static NULL-terminated array of *PyGetSetDef* structures, declaring computed attributes of instances of this type.

For each entry in the array, an entry is added to the type's dictionary (see *tp_dict* below) containing a getset descriptor.

This field is not inherited by subtypes (computed attributes are inherited through a different mechanism).

Docs for *PyGetSetDef*:

```c
typedef PyObject *(getter)(PyObject *, void *);
typedef int *(setter)(PyObject *, PyObject *, void *);
typedef struct PyGetSetDef {
    char *name;       /* attribute name */
    getter get;      /* C function to get the attribute */
    setter set;      /* C function to set or delete the attribute */
    char *doc;       /* optional doc string */
    void *closure;   /* optional additional data for getter and setter */
} PyGetSetDef;
```

**PyTypeObject** *PyTypeObject.tp_base*

An optional pointer to a base type from which type properties are inherited. At this level, only single inheritance is supported; multiple inheritance require dynamically creating a type object by calling the metatype.

This field is not inherited by subtypes (obviously), but it defaults to &PyBaseObject_Type (which to Python programmers is known as the type *object*).
PyObject* `PyTypeObject.tp_dict`

The type’s dictionary is stored here by `PyType_Ready()`.

This field should normally be initialized to NULL before `PyType_Ready` is called; it may also be initialized to a dictionary containing initial attributes for the type. Once `PyType_Ready()` has initialized the type, extra attributes for the type may be added to this dictionary only if they don’t correspond to overloaded operations (like `__add__()`).

This field is not inherited by subtypes (though the attributes defined in here are inherited through a different mechanism).

descrgetfunc `PyTypeObject.tp_descr_get`

An optional pointer to a “descriptor get” function.

The function signature is

```c
PyObject * tp_descr_get(PyObject *self, PyObject *obj, PyObj
```

This field is inherited by subtypes.

descrsetfunc `PyTypeObject.tp_descr_set`

An optional pointer to a function for setting and deleting a descriptor’s value.

The function signature is

```c
int tp_descr_set(PyObject *self, PyObject *obj, PyObject *va
```

The `value` argument is set to NULL to delete the value. This field is inherited by subtypes.

long `PyTypeObject.tp_dictoffset`

If the instances of this type have a dictionary containing instance
variables, this field is non-zero and contains the offset in the instances of the type of the instance variable dictionary; this offset is used by `PyObject_GenericGetAttr()`.

Do not confuse this field with `tp_dict`; that is the dictionary for attributes of the type object itself.

If the value of this field is greater than zero, it specifies the offset from the start of the instance structure. If the value is less than zero, it specifies the offset from the end of the instance structure. A negative offset is more expensive to use, and should only be used when the instance structure contains a variable-length part. This is used for example to add an instance variable dictionary to subtypes of `str` or `tuple`. Note that the `tp_basicsize` field should account for the dictionary added to the end in that case, even though the dictionary is not included in the basic object layout. On a system with a pointer size of 4 bytes, `tp_dictoffset` should be set to -4 to indicate that the dictionary is at the very end of the structure.

The real dictionary offset in an instance can be computed from a negative `tp_dictoffset` as follows:

```python
dictoffset = tp_basicsize + abs(ob_size)*tp_itemsize + tp_dictoffset
if dictoffset is not aligned on sizeof(void*):
    round up to sizeof(void*)
```

where `tp_basicsize`, `tp_itemsize` and `tp_dictoffset` are taken from the type object, and `ob_size` is taken from the instance. The absolute value is taken because long ints use the sign of `ob_size` to store the sign of the number. (There's never a need to do this calculation yourself; it is done for you by `_PyObject_GetDictPtr()`.)
This field is inherited by subtypes, but see the rules listed below. A subtype may override this offset; this means that the subtype instances store the dictionary at a difference offset than the base type. Since the dictionary is always found via tp_dictoffset, this should not be a problem.

When a type defined by a class statement has no __slots__ declaration, and none of its base types has an instance variable dictionary, a dictionary slot is added to the instance layout and the tp_dictoffset is set to that slot’s offset.

When a type defined by a class statement has a __slots__ declaration, the type inherits its tp_dictoffset from its base type.

(Adding a slot named __dict__ to the __slots__ declaration does not have the expected effect, it just causes confusion. Maybe this should be added as a feature just like __weakref__ though.)

initproc PyTypeObject.tp_init

An optional pointer to an instance initialization function.

This function corresponds to the __init__() method of classes. Like __init__(), it is possible to create an instance without calling __init__(), and it is possible to reinitialize an instance by calling its __init__() method again.

The function signature is

```c
int tp_init(PyObject *self, PyObject *args, PyObject *kwds)
```

The self argument is the instance to be initialized; the args and kwds arguments represent positional and keyword arguments of the call to __init__().

The tp_init function, if not NULL, is called when an instance is
created normally by calling its type, after the type's \texttt{tp\_new} function has returned an instance of the type. If the \texttt{tp\_new} function returns an instance of some other type that is not a subtype of the original type, no \texttt{tp\_init} function is called; if \texttt{tp\_new} returns an instance of a subtype of the original type, the subtype's \texttt{tp\_init} is called. (VERSION NOTE: described here is what is implemented in Python 2.2.1 and later. In Python 2.2, the \texttt{tp\_init} of the type of the object returned by \texttt{tp\_new} was always called, if not \texttt{NULL}.)

This field is inherited by subtypes.

\textbf{allocfunc} \texttt{PyTypeObject}.'\texttt{tp\_alloc}

An optional pointer to an instance allocation function.

The function signature is

\begin{verbatim}
PyObject *tp_alloc(PyTypeObject *self, Py_ssize_t nitems)
\end{verbatim}

The purpose of this function is to separate memory allocation from memory initialization. It should return a pointer to a block of memory of adequate length for the instance, suitably aligned, and initialized to zeros, but with \texttt{ob\_refcnt} set to 1 and \texttt{ob\_type} set to the type argument. If the type's \texttt{tp\_itemsize} is non-zero, the object's \texttt{ob\_size} field should be initialized to \texttt{nitems} and the length of the allocated memory block should be \texttt{tp\_basicsize + nitems*tp\_itemsize}, rounded up to a multiple of \texttt{sizeof(void*)}; otherwise, \texttt{nitems} is not used and the length of the block should be \texttt{tp\_basicsize}.

Do not use this function to do any other instance initialization, not even to allocate additional memory; that should be done by \texttt{tp\_new}. 

This field is inherited by static subtypes, but not by dynamic subtypes (subtypes created by a class statement); in the latter, this field is always set to `PyType_GenericAlloc()`, to force a standard heap allocation strategy. That is also the recommended value for statically defined types.

newfunc `PyTypeObject.tp_new`

An optional pointer to an instance creation function.

If this function is `NULL` for a particular type, that type cannot be called to create new instances; presumably there is some other way to create instances, like a factory function.

The function signature is

```
PyObject *tp_new(PyTypeObject *subtype, PyObject *args, PyObject *kwds)
```

The subtype argument is the type of the object being created; the `args` and `kwds` arguments represent positional and keyword arguments of the call to the type. Note that subtype doesn't have to equal the type whose `tp_new` function is called; it may be a subtype of that type (but not an unrelated type).

The `tp_new` function should call `subtype->tp_alloc(subtype, nitems)` to allocate space for the object, and then do only as much further initialization as is absolutely necessary. Initialization that can safely be ignored or repeated should be placed in the `tp_init` handler. A good rule of thumb is that for immutable types, all initialization should take place in `tp_new`, while for mutable types, most initialization should be deferred to `tp_init`.

This field is inherited by subtypes, except it is not inherited by static types whose `tp_base` is `NULL` or `&PyBaseObject_Type`. The latter exception is a precaution so that old extension types don't
become callable simply by being linked with Python 2.2.

destructor **PyTypeObject.tp_free**

An optional pointer to an instance deallocation function.

The signature of this function has changed slightly: in Python 2.2 and 2.2.1, its signature is *destructor*:

```c
void tp_free(PyObject *)
```

In Python 2.3 and beyond, its signature is *freefunc*:

```c
void tp_free(void *)
```

The only initializer that is compatible with both versions is \_PyObject\_Del, whose definition has suitably adapted in Python 2.3.

This field is inherited by static subtypes, but not by dynamic subtypes (subtypes created by a class statement); in the latter, this field is set to a deallocator suitable to match *PyType\_GenericAlloc()* and the value of the *Py\_TPFLAGS\_HAVE\_GC* flag bit.

**inquiry** **PyTypeObject.tp_is_gc**

An optional pointer to a function called by the garbage collector.

The garbage collector needs to know whether a particular object is collectible or not. Normally, it is sufficient to look at the object's type's *tp_flags* field, and check the *Py\_TPFLAGS\_HAVE\_GC* flag bit. But some types have a mixture of statically and dynamically allocated instances, and the statically allocated instances are not collectible. Such types should define this function; it should return 1 for a collectible instance, and 0 for a non-collectible instance. The signature is
int tp_is_gc(PyObject *self)

(The only example of this are types themselves. The metatype, `PyType_Type`, defines this function to distinguish between statically and dynamically allocated types.)

This field is inherited by subtypes. (VERSION NOTE: in Python 2.2, it was not inherited. It is inherited in 2.2.1 and later versions.)

**PyObject** `PyTypeObject.tp_bases`  
Tuple of base types.

This is set for types created by a class statement. It should be `NULL` for statically defined types.

This field is not inherited.

**PyObject** `PyTypeObject.tp_mro`  
Tuple containing the expanded set of base types, starting with the type itself and ending with `object`, in Method Resolution Order.

This field is not inherited; it is calculated fresh by `PyType_Ready()`.

**PyObject** `PyTypeObject.tp_cache`  
Unused. Not inherited. Internal use only.

**PyObject** `PyTypeObject.tp_subclasses`  
List of weak references to subclasses. Not inherited. Internal use only.

**PyObject** `PyTypeObject.tp_weaklist`  
Weak reference list head, for weak references to this type object. Not inherited. Internal use only.

The remaining fields are only defined if the feature test macro
**COUNT_ALLOCS** is defined, and are for internal use only. They are documented here for completeness. None of these fields are inherited by subtypes.

`Py_ssize_t PyTypeObject.tp_allocs`

Number of allocations.

`Py_ssize_t PyTypeObject.tp_frees`

Number of frees.

`Py_ssize_t PyTypeObject.tp_maxalloc`

Maximum simultaneously allocated objects.

`PyTypeObject* PyTypeObject.tp_next`

Pointer to the next type object with a non-zero `tp_allocs` field.

Also, note that, in a garbage collected Python, `tp_dealloc` may be called from any Python thread, not just the thread which created the object (if the object becomes part of a refcount cycle, that cycle might be collected by a garbage collection on any thread). This is not a problem for Python API calls, since the thread on which `tp_dealloc` is called will own the Global Interpreter Lock (GIL). However, if the object being destroyed in turn destroys objects from some other C or C++ library, care should be taken to ensure that destroying those objects on the thread which called `tp_dealloc` will not violate any assumptions of the library.
Number Object Structures

PyNumberMethods

This structure holds pointers to the functions which an object uses to implement the number protocol. Almost every function below is used by the function of similar name documented in the Number Protocol section.

Here is the structure definition:

typedef struct {
    binaryfunc nb_add;
    binaryfunc nb_subtract;
    binaryfunc nb_multiply;
    binaryfunc nb_divide;
    binaryfunc nb_remainder;
    binaryfunc nb_divmod;
    ternaryfunc nb_power;
    unaryfunc nb_negative;
    unaryfunc nb_positive;
    unaryfunc nb_absolute;
    inquiry nb_nonzero; /* Used by PyObject_IsTrue */
    unaryfunc nb_invert;
    binaryfunc nb_lshift;
    binaryfunc nb_rshift;
    binaryfunc nb_and;
    binaryfunc nb_xor;
    binaryfunc nb_or;
    coercion nb_coerce; /* Used by the coerce() function */
    unaryfunc nb_int;
    unaryfunc nb_long;
    unaryfunc nb_float;
    unaryfunc nb_oct;
    unaryfunc nb_hex;

    /* Added in release 2.0 */
    binaryfunc nb_inplace_add;
    binaryfunc nb_inplace_subtract;
    binaryfunc nb_inplace_multiply;
    binaryfunc nb_inplace_divide;
    binaryfunc nb_inplace_remainder;
    ternaryfunc nb_inplace_power;
}
Binary and ternary functions may receive different kinds of arguments, depending on the flag bit `Py_TPFLAGS_CHECKTYPES`:

- If `Py_TPFLAGS_CHECKTYPES` is not set, the function arguments are guaranteed to be of the object’s type; the caller is responsible for calling the coercion method specified by the `nb_coerce` member to convert the arguments:

  coercion `PyNumberMethods.nb_coerce`

  This function is used by `PyNumber_CoerceEx()` and has the same signature. The first argument is always a pointer to an object of the defined type. If the conversion to a common “larger” type is possible, the function replaces the pointers with new references to the converted objects and returns 0. If the conversion is not possible, the function returns 1. If an error condition is set, it will return -1.

- If the `Py_TPFLAGS_CHECKTYPES` flag is set, binary and ternary functions must check the type of all their operands, and implement the necessary conversions (at least one of the operands is an instance of the defined type). This is the
recommended way; with Python 3 coercion will disappear completely.

If the operation is not defined for the given operands, binary and ternary functions must return `Py_NotImplemented`, if another error occurred they must return `NULL` and set an exception.
Mapping Object Structures

**PyMappingMethods**
This structure holds pointers to the functions which an object uses to implement the mapping protocol. It has three members:

lenfunc **PyMappingMethods.mp_length**
This function is used by `PyMapping_Length()` and `PyObject_Size()`, and has the same signature. This slot may be set to `NULL` if the object has no defined length.

binaryfunc **PyMappingMethods.mp_subscript**
This function is used by `PyObject_GetItem()` and has the same signature. This slot must be filled for the `PyMapping_Check()` function to return 1, it can be `NULL` otherwise.

objobjargproc **PyMappingMethods.mp_ass_subscript**
This function is used by `PyObject_SetItem()` and `PyObject_DelItem()`. It has the same signature as `PyObject_SetItem()`, but `v` can also be set to `NULL` to delete an item. If this slot is `NULL`, the object does not support item assignment and deletion.
**Sequence Object Structures**

**PySequenceMethods**

This structure holds pointers to the functions which an object uses to implement the sequence protocol.

**lenfunc PySequenceMethods.sq_length**

This function is used by `PySequence_Size()` and `PyObject_Size()`, and has the same signature.

**binaryfunc PySequenceMethods.sq_concat**

This function is used by `PySequence_Concat()` and has the same signature. It is also used by the `+` operator, after trying the numeric addition via the `nb_add` slot.

**ssizeargfunc PySequenceMethods.sq_repeat**

This function is used by `PySequence_Repeat()` and has the same signature. It is also used by the `*` operator, after trying numeric multiplication via the `nb_multiply` slot.

**ssizeargfunc PySequenceMethods.sq_item**

This function is used by `PySequence_GetItem()` and has the same signature. This slot must be filled for the `PySequence_Check()` function to return 1, it can be `NULL` otherwise.

Negative indexes are handled as follows: if the `sq_length` slot is filled, it is called and the sequence length is used to compute a positive index which is passed to `sq_item`. If `sq_length` is `NULL`, the index is passed as is to the function.

**ssizeobjargproc PySequenceMethods.sq_ass_item**

This function is used by `PySequence_SetItem()` and has the same signature. This slot may be left to `NULL` if the object does not
support item assignment and deletion.

**objobjproc** `PySequenceMethods.sq_contains`

This function may be used by `PySequence_Contains()` and has the same signature. This slot may be left to `NULL`, in this case `PySequence_Contains()` simply traverses the sequence until it finds a match.

**binaryfunc** `PySequenceMethods.sq_inplace_concat`

This function is used by `PySequence_InPlaceConcat()` and has the same signature. It should modify its first operand, and return it.

**ssizeargfunc** `PySequenceMethods.sq_inplace_repeat`

This function is used by `PySequence_InPlaceRepeat()` and has the same signature. It should modify its first operand, and return it.
Buffer Object Structures

The buffer interface exports a model where an object can expose its internal data as a set of chunks of data, where each chunk is specified as a pointer/length pair. These chunks are called *segments* and are presumed to be non-contiguous in memory.

If an object does not export the buffer interface, then its `tp_as_buffer` member in the `PyTypeObject` structure should be `NULL`. Otherwise, the `tp_as_buffer` will point to a `PyBufferProcs` structure.

**Note:** It is very important that your `PyTypeObject` structure uses `Py_TPFLAGS_DEFAULT` for the value of the `tp_flags` member rather than 0. This tells the Python runtime that your `PyBufferProcs` structure contains the `bf_getcharbuffer` slot. Older versions of Python did not have this member, so a new Python interpreter using an old extension needs to be able to test for its presence before using it.

**PyBufferProcs**

Structure used to hold the function pointers which define an implementation of the buffer protocol.

The first slot is `bf_getreadbuffer`, of type `getreadbufferproc`. If this slot is `NULL`, then the object does not support reading from the internal data. This is non-sensical, so implementors should fill this in, but callers should test that the slot contains a non-`NULL` value.

The next slot is `bf_getwritebuffer` having type `getwritebufferproc`. This slot may be `NULL` if the object does not allow writing into its returned buffers.
The third slot is `bf_getsegcount`, with type `getsegcountproc`. This slot must not be `NULL` and is used to inform the caller how many segments the object contains. Simple objects such as `PyString_Type` and `PyBuffer_Type` objects contain a single segment.

The last slot is `bf_getcharbuffer`, of type `getcharbufferproc`. This slot will only be present if the `Py_TPFLAGS_HAVE_GETCHARBUFFER` flag is present in the `tp_flags` field of the object’s `PyTypeObject`. Before using this slot, the caller should test whether it is present by using the `PyType_HasFeature()` function. If the flag is present, `bf_getcharbuffer` may be `NULL`, indicating that the object’s contents cannot be used as 8-bit characters. The slot function may also raise an error if the object’s contents cannot be interpreted as 8-bit characters. For example, if the object is an array which is configured to hold floating point values, an exception may be raised if a caller attempts to use `bf_getcharbuffer` to fetch a sequence of 8-bit characters. This notion of exporting the internal buffers as “text” is used to distinguish between objects that are binary in nature, and those which have character-based content.

**Note:** The current policy seems to state that these characters may be multi-byte characters. This implies that a buffer size of `N` does not mean there are `N` characters present.

```c
Py_TPFLAGS_HAVE_GETCHARBUFFER
Flag bit set in the type structure to indicate that the `bf_getcharbuffer` slot is known. This being set does not indicate that the object supports the buffer interface or that the `bf_getcharbuffer` slot is non-NULL.

Py_ssize_t (*readbufferproc)(PyObject *self,
Py_ssize_t segment, void **ptrptr)
```
Return a pointer to a readable segment of the buffer in *ptrptr. This function is allowed to raise an exception, in which case it must return -1. The segment which is specified must be zero or positive, and strictly less than the number of segments returned by the bf_getsegcount slot function. On success, it returns the length of the segment, and sets *ptrptr to a pointer to that memory.

Py_ssize_t (*writebufferproc)(PyObject *self, Py_ssize_t segment, void **ptrptr)

Return a pointer to a writable memory buffer in *ptrptr, and the length of that segment as the function return value. The memory buffer must correspond to buffer segment segment. Must return -1 and set an exception on error. TypeError should be raised if the object only supports read-only buffers, and SystemError should be raised when segment specifies a segment that doesn't exist.

Py_ssize_t (*segcountproc)(PyObject *self, Py_ssize_t *lenp)

Return the number of memory segments which comprise the buffer. If lenp is not NULL, the implementation must report the sum of the sizes (in bytes) of all segments in *lenp. The function cannot fail.

Py_ssize_t (*charbufferproc)(PyObject *self, Py_ssize_t segment, char **ptrptr)

Return the size of the segment segment that ptrptr is set to. *ptrptr is set to the memory buffer. Returns -1 on error.
Supporting Cyclic Garbage Collection

Python's support for detecting and collecting garbage which involves circular references requires support from object types which are “containers” for other objects which may also be containers. Types which do not store references to other objects, or which only store references to atomic types (such as numbers or strings), do not need to provide any explicit support for garbage collection.

To create a container type, the `tp_flags` field of the type object must include the `Py_TPFLAGS_HAVE_GC` and provide an implementation of the `tp_traverse` handler. If instances of the type are mutable, a `tp_clear` implementation must also be provided.

`Py_TPFLAGS_HAVE_GC`

Objects with a type with this flag set must conform with the rules documented here. For convenience these objects will be referred to as container objects.

Constructors for container types must conform to two rules:

1. The memory for the object must be allocated using `PyObject_GC_New()` or `PyObject_GC_NewVar()`.
2. Once all the fields which may contain references to other containers are initialized, it must call `PyObject_GC_Track()`.

`TYPE* PyObject_GC_New(TYPE, PyTypeObject *type)`

Analogous to `PyObject_New()` but for container objects with the `Py_TPFLAGS_HAVE_GC` flag set.

`TYPE* PyObject_GC_NewVar(TYPE, PyTypeObject *type, Py_ssize_t size)`
Analogous to `PyObject_NewVar()` but for container objects with the `Py_TPFLAGS_HAVE_GC` flag set.

Changed in version 2.5: This function used an `int` type for size. This might require changes in your code for properly supporting 64-bit systems.

```c
TYPE* PyObject_GC_Resize(TYPE, PyVarObject *op, Py_ssize_t newsize)
```
Resize an object allocated by `PyObject_NewVar()`. Returns the resized object or `NULL` on failure.

Changed in version 2.5: This function used an `int` type for `newsize`. This might require changes in your code for properly supporting 64-bit systems.

```c
void PyObject_GC_Track(PyObject *op)
```
Adds the object `op` to the set of container objects tracked by the collector. The collector can run at unexpected times so objects must be valid while being tracked. This should be called once all the fields followed by the `tp_traverse` handler become valid, usually near the end of the constructor.

```c
void _PyObject_GC_TRACK(PyObject *op)
```
A macro version of `PyObject_GC_Track()`. It should not be used for extension modules.

Similarly, the deallocator for the object must conform to a similar pair of rules:

1. Before fields which refer to other containers are invalidated, `PyObject_GC_UnTrack()` must be called.
2. The object’s memory must be deallocated using `PyObject_GC_Del()`. 
void **PyObject**_**GC**_**Del**(void *op)

 Releepse memory allocated to an object using **PyObject**_**GC**_**New**(())
or **PyObject**_**GC**_**NewVar**(()).

void **PyObject**_**GC**_**UnTrack**(void *op)

 Remove the object op from the set of container objects tracked by the collector. Note that **PyObject**_**GC**_**Track**(()) can be called again on this object to add it back to the set of tracked objects. The deallocator (**tp**_**dealloc** handler) should call this for the object before any of the fields used by the **tp**_**traverse** handler become invalid.

void **PyObject**_**GC**_**UNTRACK**(PyObject *op)

 A macro version of **PyObject**_**GC**_**UnTrack**(()). It should not be used for extension modules.

The **tp**_**traverse** handler accepts a function parameter of this type:

int (*visitproc)(PyObject *object, void *arg)

 Type of the visitor function passed to the **tp**_**traverse** handler. The function should be called with an object to traverse as object and the third parameter to the **tp**_**traverse** handler as arg. The Python core uses several visitor functions to implement cyclic garbage detection; it's not expected that users will need to write their own visitor functions.

The **tp**_**traverse** handler must have the following type:

int (*traverseproc)(PyObject *self, visitproc visit, void *arg)

 Traversal function for a container object. Implementations must call the visit function for each object directly contained by self, with the parameters to visit being the contained object and the arg value passed to the handler. The visit function must not be called with a **NULL** object argument. If visit returns a non-zero
value that value should be returned immediately.

To simplify writing `tp_traverse` handlers, a `Py_VISIT()` macro is provided. In order to use this macro, the `tp_traverse` implementation must name its arguments exactly `visit` and `arg`:

```c
void Py_VISIT(PyObject *o)
    If o is not NULL, call the visit callback, with arguments o and arg. If visit returns a non-zero value, then return it. Using this macro, `tp_traverse` handlers look like:

```c
static int
my_traverse(Noddy *self, visitproc visit, void *arg)
{
    Py_VISIT(self->foo);
    Py_VISIT(self->bar);
    return 0;
}
```

New in version 2.4.

The `tp_clear` handler must be of the `inquiry` type, or `NULL` if the object is immutable.

```c
int (*inquiry)(PyObject *self)
    Drop references that may have created reference cycles. Immutable objects do not have to define this method since they can never directly create reference cycles. Note that the object must still be valid after calling this method (don’t just call `Py_DECREF()` on a reference). The collector will call this method if it detects that this object is involved in a reference cycle.
```
Porting Python 2 Code to Python 3

author: Brett Cannon

Abstract

With Python 3 being the future of Python while Python 2 is still in active use, it is good to have your project available for both major releases of Python. This guide is meant to help you figure out how best to support both Python 2 & 3 simultaneously.

If you are looking to port an extension module instead of pure Python code, please see Porting Extension Modules to Python 3.

If you would like to read one core Python developer’s take on why Python 3 came into existence, you can read Nick Coghlan's Python 3 Q & A.

For help with porting, you can email the python-porting mailing list with questions.
The Short Explanation

To make your project be single-source Python 2/3 compatible, the basic steps are:

1. Update your code to drop support for Python 2.5 or older (supporting only Python 2.7 is ideal)
2. Make sure you have good test coverage (coverage.py can help; pip install coverage)
3. Learn the differences between Python 2 & 3
4. Use Modernize or Futurize to update your code (pip install modernize or pip install future, respectively)
5. Use Pylint to help make sure you don’t regress on your Python 3 support (if only supporting Python 2.7/3.4 or newer; pip install pylint)
6. Use caniusepython3 to find out which of your dependencies are blocking your use of Python 3 (pip install caniusepython3)
7. Once your dependencies are no longer blocking you, use continuous integration to make sure you stay compatible with Python 2 & 3 (tox can help test against multiple versions of Python; pip install tox)

If you are dropping support for Python 2 entirely, then after you learn the differences between Python 2 & 3 you can run 2to3 over your code and skip the rest of the steps outlined above.
A key point about supporting Python 2 & 3 simultaneously is that you can start **today**! Even if your dependencies are not supporting Python 3 yet that does not mean you can’t modernize your code now to support Python 3. Most changes required to support Python 3 lead to cleaner code using newer practices even in Python 2.

Another key point is that modernizing your Python 2 code to also support Python 3 is largely automated for you. While you might have to make some API decisions thanks to Python 3 clarifying text data versus binary data, the lower-level work is now mostly done for you and thus can at least benefit from the automated changes immediately.

Keep those key points in mind while you read on about the details of porting your code to support Python 2 & 3 simultaneously.

**Drop support for Python 2.5 and older (at least)**

While you can make Python 2.5 work with Python 3, it is much easier if you only have to work with Python 2.6 or newer (and easier still if you only have to work with Python 2.7). If dropping Python 2.5 is not an option then the six project can help you support Python 2.5 & 3 simultaneously (`pip install six`). Do realize, though, that nearly all the projects listed in this HOWTO will not be available to you.

If you are able to only support Python 2.6 or newer, then the required changes to your code should continue to look and feel like idiomatic Python code. At worst you will have to use a function instead of a method in some instances or have to import a function instead of using a built-in one, but otherwise the overall transformation should
not feel foreign to you.

But please aim for Python 2.7. Bugfixes for that version of Python will continue until 2020 while Python 2.6 is no longer supported. There are also some tools mentioned in this HOWTO which do not support Python 2.6 (e.g., Pylint), and this will become more commonplace as time goes on.

Make sure you specify the proper version support in your setup.py file

In your setup.py file you should have the proper trove classifier specifying what versions of Python you support. As your project does not support Python 3 yet you should at least have Programming Language :: Python :: 2 :: Only specified. Ideally you should also specify each major/minor version of Python that you do support, e.g. Programming Language :: Python :: 2.7.

Have good test coverage

Once you have your code supporting the oldest version of Python 2 you want it to, you will want to make sure your test suite has good coverage. A good rule of thumb is that if you want to be confident enough in your test suite that any failures that appear after having tools rewrite your code are actual bugs in the tools and not in your code. If you want a number to aim for, try to get over 80% coverage (and don't feel bad if you can't easily get past 90%). If you don't already have a tool to measure test coverage then coverage.py is recommended.

Learn the differences between Python 2 & 3

Once you have your code well-tested you are ready to begin porting
your code to Python 3! But to fully understand how your code is going to change and what you want to look out for while you code, you will want to learn what changes Python 3 makes in terms of Python 2. Typically the two best ways of doing that is reading the “What’s New” doc for each release of Python 3 and the Porting to Python 3 book (which is free online). There is also a handy cheat sheet from the Python-Future project.

**Update your code**

Once you feel like you know what is different in Python 3 compared to Python 2, it’s time to update your code! You have a choice between two tools in porting your code automatically: Modernize and Futurize. Which tool you choose will depend on how much like Python 3 you want your code to be. Futurize does its best to make Python 3 idioms and practices exist in Python 2, e.g. backporting the bytes type from Python 3 so that you have semantic parity between the major versions of Python. Modernize, on the other hand, is more conservative and targets a Python 2/3 subset of Python, relying on six to help provide compatibility.

Regardless of which tool you choose, they will update your code to run under Python 3 while staying compatible with the version of Python 2 you started with. Depending on how conservative you want to be, you may want to run the tool over your test suite first and visually inspect the diff to make sure the transformation is accurate. After you have transformed your test suite and verified that all the tests still pass as expected, then you can transform your application code knowing that any tests which fail is a translation failure.

Unfortunately the tools can’t automate everything to make your code work under Python 3 and so there are a handful of things you will need to update manually to get full Python 3 support (which of these steps are necessary vary between the tools). Read the
documentation for the tool you choose to use to see what it fixes by default and what it can do optionally to know what will (not) be fixed for you and what you may have to fix on your own (e.g. using `io.open()` over the built-in `open()` function is off by default in Modernize). Luckily, though, there are only a couple of things to watch out for which can be considered large issues that may be hard to debug if not watched for.

**Division**

In Python 3, `5 / 2 == 2.5` and not 2; all division between `int` values result in a `float`. This change has actually been planned since Python 2.2 which was released in 2002. Since then users have been encouraged to add `from __future__ import division` to any and all files which use the `/` and `//` operators or to be running the interpreter with the `-Q` flag. If you have not been doing this then you will need to go through your code and do two things:

1. Add `from __future__ import division` to your files
2. Update any division operator as necessary to either use `//` to use floor division or continue using `/` and expect a float

The reason that `/` isn’t simply translated to `//` automatically is that if an object defines its own `__div__` method but not `__floordiv__` then your code would begin to fail.

**Text versus binary data**

In Python 2 you could use the `str` type for both text and binary data. Unfortunately this confluence of two different concepts could lead to brittle code which sometimes worked for either kind of data, sometimes not. It also could lead to confusing APIs if people didn’t explicitly state that something that accepted `str` accepted either text
or binary data instead of one specific type. This complicated the situation especially for anyone supporting multiple languages as APIs wouldn’t bother explicitly supporting `unicode` when they claimed text data support.

To make the distinction between text and binary data clearer and more pronounced, Python 3 did what most languages created in the age of the internet have done and made text and binary data distinct types that cannot blindly be mixed together (Python predates widespread access to the internet). For any code that only deals with text or only binary data, this separation doesn’t pose an issue. But for code that has to deal with both, it does mean you might have to now care about when you are using text compared to binary data, which is why this cannot be entirely automated.

To start, you will need to decide which APIs take text and which take binary (it is highly recommended you don’t design APIs that can take both due to the difficulty of keeping the code working; as stated earlier it is difficult to do well). In Python 2 this means making sure the APIs that take text can work with `unicode` in Python 2 and those that work with binary data work with the `bytes` type from Python 3 and thus a subset of `str` in Python 2 (which the `bytes` type in Python 2 is an alias for). Usually the biggest issue is realizing which methods exist for which types in Python 2 & 3 simultaneously (for text that’s `unicode` in Python 2 and `str` in Python 3, for binary that’s `str`/`bytes` in Python 2 and `bytes` in Python 3). The following table lists the unique methods of each data type across Python 2 & 3 (e.g., the `decode()` method is usable on the equivalent binary data type in either Python 2 or 3, but it can’t be used by the text data type consistently between Python 2 and 3 because `str` in Python 3 doesn’t have the method).

<table>
<thead>
<tr>
<th>Text data</th>
<th>Binary data</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__mod__</code> (% operator)</td>
<td></td>
</tr>
</tbody>
</table>
Making the distinction easier to handle can be accomplished by encoding and decoding between binary data and text at the edge of your code. This means that when you receive text in binary data, you should immediately decode it. And if your code needs to send text as binary data then encode it as late as possible. This allows your code to work with only text internally and thus eliminates having to keep track of what type of data you are working with.

The next issue is making sure you know whether the string literals in your code represent text or binary data. At minimum you should add a `b` prefix to any literal that presents binary data. For text you should either use the `from __future__ import unicode_literals` statement or add a `u` prefix to the text literal.

As part of this dichotomy you also need to be careful about opening files. Unless you have been working on Windows, there is a chance you have not always bothered to add the `b` mode when opening a binary file (e.g., `rb` for binary reading). Under Python 3, binary files and text files are clearly distinct and mutually incompatible; see the `io` module for details. Therefore, you must make a decision of whether a file will be used for binary access (allowing binary data to be read and/or written) or text access (allowing text data to be read and/or written). You should also use `io.open()` for opening files instead of the built-in `open()` function as the `io` module is consistent from Python 2 to 3 while the built-in `open()` function is not (in Python 3 it’s actually `io.open()`).
The constructors of both `str` and `bytes` have different semantics for the same arguments between Python 2 & 3. Passing an integer to `bytes` in Python 2 will give you the string representation of the integer: `bytes(3) == '3'`. But in Python 3, an integer argument to `bytes` will give you a bytes object as long as the integer specified, filled with null bytes: `bytes(3) == b'\x00\x00\x00'`. A similar worry is necessary when passing a bytes object to `str`. In Python 2 you just get the bytes object back: `str(b'3') == b'3'`. But in Python 3 you get the string representation of the bytes object: `str(b'3') == "b'3'"`.

Finally, the indexing of binary data requires careful handling (slicing does not require any special handling). In Python 2, `b'123'[1] == b'2'` while in Python 3 `b'123'[1] == 50`. Because binary data is simply a collection of binary numbers, Python 3 returns the integer value for the byte you index on. But in Python 2 because `bytes == str`, indexing returns a one-item slice of bytes. The six project has a function named `six.indexbytes()` which will return an integer like in Python 3: `six.indexbytes(b'123', 1)`.

To summarize:

1. Decide which of your APIs take text and which take binary data
2. Make sure that your code that works with text also works with `unicode` and code for binary data works with `bytes` in Python 2 (see the table above for what methods you cannot use for each type)
3. Mark all binary literals with a `b` prefix, use a `u` prefix or `__future__` import statement for text literals
4. Decode binary data to text as soon as possible, encode text as binary data as late as possible
5. Open files using `io.open()` and make sure to specify the `b` mode when appropriate
6. Be careful when indexing binary data

Prevent compatibility regressions

Once you have fully translated your code to be compatible with Python 3, you will want to make sure your code doesn't regress and stop working under Python 3. This is especially true if you have a dependency which is blocking you from actually running under Python 3 at the moment.

To help with staying compatible, any new modules you create should have at least the following block of code at the top of it:

```python
from __future__ import absolute_import
from __future__ import division
from __future__ import print_function
from __future__ import unicode_literals
```

You can also run Python 2 with the `-3` flag to be warned about various compatibility issues your code triggers during execution. If you turn warnings into errors with `-Werror` then you can make sure that you don’t accidentally miss a warning.

You can also use the Pylint project and its `--py3k` flag to lint your code to receive warnings when your code begins to deviate from Python 3 compatibility. This also prevents you from having to run Modernize or Futurize over your code regularly to catch compatibility regressions. This does require you only support Python 2.7 and Python 3.4 or newer as that is Pylint’s minimum Python version support.

Check which dependencies block your transition

After you have made your code compatible with Python 3 you should begin to care about whether your dependencies have also
been ported. The caniusepython3 project was created to help you determine which projects – directly or indirectly – are blocking you from supporting Python 3. There is both a command-line tool as well as a web interface at https://caniusepython3.com.

The project also provides code which you can integrate into your test suite so that you will have a failing test when you no longer have dependencies blocking you from using Python 3. This allows you to avoid having to manually check your dependencies and to be notified quickly when you can start running on Python 3.

**Update your setup.py file to denote Python 3 compatibility**

Once your code works under Python 3, you should update the classifiers in your `setup.py` to contain `Programming Language :: Python :: 3` and to not specify sole Python 2 support. This will tell anyone using your code that you support Python 2 and 3. Ideally you will also want to add classifiers for each major/minor version of Python you now support.

**Use continuous integration to stay compatible**

Once you are able to fully run under Python 3 you will want to make sure your code always works under both Python 2 & 3. Probably the best tool for running your tests under multiple Python interpreters is `tox`. You can then integrate tox with your continuous integration system so that you never accidentally break Python 2 or 3 support.

You may also want to use the `-bb` flag with the Python 3 interpreter to trigger an exception when you are comparing bytes to strings. Usually it's simply `False`, but if you made a mistake in your separation of text/binary data handling you may be accidentally comparing text and binary data. This flag will raise an exception
when that occurs to help track down such cases.

And that’s mostly it! At this point your code base is compatible with both Python 2 and 3 simultaneously. Your testing will also be set up so that you don’t accidentally break Python 2 or 3 compatibility regardless of which version you typically run your tests under while developing.
Dropping Python 2 support completely

If you are able to fully drop support for Python 2, then the steps required to transition to Python 3 simplify greatly.

1. Update your code to only support Python 2.7
2. Make sure you have good test coverage (*coverage.py* can help)
3. Learn the differences between Python 2 & 3
4. Use *2to3* to rewrite your code to run only under Python 3

After this your code will be fully Python 3 compliant but in a way that is not supported by Python 2. You should also update the classifiers in your *setup.py* to contain `Programming Language :: Python :: 3 :: Only`. 
Porting Extension Modules to Python 3

author: Benjamin Peterson

Abstract

Although changing the C-API was not one of Python 3's objectives, the many Python-level changes made leaving Python 2's API intact impossible. In fact, some changes such as `int()` and `long()` unification are more obvious on the C level. This document endeavors to document incompatibilities and how they can be worked around.
Conditional compilation

The easiest way to compile only some code for Python 3 is to check if `PY_MAJOR_VERSION` is greater than or equal to 3.

```c
#if PY_MAJOR_VERSION >= 3
#define IS_PY3K
#endif
```

API functions that are not present can be aliased to their equivalents within conditional blocks.
Changes to Object APIs

Python 3 merged together some types with similar functions while cleanly separating others.

str/unicode Unification

Python 3’s `str()` type is equivalent to Python 2’s `unicode()`; the C functions are called `PyUnicode_*` for both. The old 8-bit string type has become `bytes()`, with C functions called `PyBytes_*`. Python 2.6 and later provide a compatibility header, `bytesobject.h`, mapping `PyBytes` names to `PyString` ones. For best compatibility with Python 3, `PyUnicode` should be used for textual data and `PyBytes` for binary data. It’s also important to remember that `PyBytes` and `PyUnicode` in Python 3 are not interchangeable like `PyString` and `PyUnicode` are in Python 2. The following example shows best practices with regards to `PyUnicode`, `PyString`, and `PyBytes`.

```c
#include "stdlib.h"
#include "Python.h"
#include "bytesobject.h"

/* text example */
static PyObject *
say_hello(PyObject *self, PyObject *args) {
    PyObject *name, *result;

    if (!PyArg_ParseTuple(args, "U:say_hello", &name))
        return NULL;

    result = PyUnicode_FromFormat("Hello, %S!", name);
    return result;
}

/* just a forward */
static char *
do_encode(PyObject *);
```
/* bytes example */
static PyObject *
encode_object(PyObject *self, PyObject *args) {
    char *encoded;
    PyObject *result, *myobj;

    if (!PyArg_ParseTuple(args, "O:encode_object", &myobj))
        return NULL;

    encoded = do_encode(myobj);
    if (encoded == NULL)
        return NULL;
    result = PyBytes_FromString(encoded);
    free(encoded);
    return result;
}

long/int Unification

Python 3 has only one integer type, \texttt{int()}. But it actually corresponds to Python 2’s \texttt{long()} type—the \texttt{int()} type used in Python 2 was removed. In the C-API, \texttt{PyInt_*} functions are replaced by their \texttt{PyLong_*} equivalents.
Module initialization and state

Python 3 has a revamped extension module initialization system. (See PEP 3121.) Instead of storing module state in globals, they should be stored in an interpreter specific structure. Creating modules that act correctly in both Python 2 and Python 3 is tricky. The following simple example demonstrates how.

```c
#include "Python.h"

struct module_state {
    PyObject *error;
};

#if PY_MAJOR_VERSION >= 3
#define GETSTATE(m) ((struct module_state*)PyModule_GetState(m))
#else
#define GETSTATE(m) (&_state)
#endif

static struct module_state _state;

static PyObject *
error_out(PyObject *m) {
    struct module_state *st = GETSTATE(m);
    PyErr_SetString(st->error, "something bad happened");
    return NULL;
}

static PyMethodDef myextension_methods[] = {
    {"error_out", (PyCFunction)error_out, METH_NOARGS, NULL},
    {NULL, NULL}
};

#if PY_MAJOR_VERSION >= 3
static int myextension_traverse(PyObject *m, visitproc visit, void *v) {
    Py_VISIT(GETSTATE(m)->error);
    return 0;
}
#else
static int myextension_traverse(PyObject *m, visitproc visit, void *v) {
    Py_VISIT(GETSTATE(m)->error);
    return 0;
}
#endif

static int myextension_clear(PyObject *m) {
    Py_CLEAR(GETSTATE(m)->error);
}
```
return 0;
}

static struct PyModuleDef moduledef = {
  PyModuleDef_HEAD_INIT,
  "myextension",
  NULL,
  sizeof(struct module_state),
  myextension_methods,
  NULL,
  myextension_traverse,
  myextension_clear,
  NULL
};

#define INITERROR return NULL

PyMODINIT_FUNC
PyInit_myextension(void)
{
  #if PY_MAJOR_VERSION >= 3
    PyObject *module = PyModule_Create(&moduledef);
  #else
    PyObject *module = Py_InitModule("myextension",
  #endif

    if (module == NULL)
      INITERROR;

    struct module_state *st = GETSTATE(module);

    st->error = PyErr_NewException("myextension.Error", NULL, NULL);
    if (st->error == NULL) {
      Py_DECREF(module);
      INITERROR;
    }

  #if PY_MAJOR_VERSION >= 3
    return module;
  #endif
}

#include "readline/readline.h"
The `capsule` object was introduced in Python 3.1 and 2.7 to replace `CObject`. CObjects were useful, but the `CObject` API was problematic: it didn't permit distinguishing between valid CObjects, which allowed mismatched CObjects to crash the interpreter, and some of its APIs relied on undefined behavior in C. (For further reading on the rationale behind Capsules, please see issue 5630.)

If you're currently using CObjects, and you want to migrate to 3.1 or newer, you'll need to switch to Capsules. `CObject` was deprecated in 3.1 and 2.7 and completely removed in Python 3.2. If you only support 2.7, or 3.1 and above, you can simply switch to `Capsule`. If you need to support Python 3.0, or versions of Python earlier than 2.7, you'll have to support both CObjects and Capsules. (Note that Python 3.0 is no longer supported, and it is not recommended for production use.)

The following example header file `capsulethunk.h` may solve the problem for you. Simply write your code against the `Capsule` API and include this header file after `Python.h`. Your code will automatically use Capsules in versions of Python with Capsules, and switch to CObjects when Capsules are unavailable.

`capsulethunk.h` simulates Capsules using CObjects. However, `CObject` provides no place to store the capsule's “name”. As a result the simulated `Capsule` objects created by `capsulethunk.h` behave slightly differently from real Capsules. Specifically:

- The name parameter passed in to `PyCapsule_New()` is ignored.
- The name parameter passed in to `PyCapsule_IsValid()` and
**PyCapsule_GetPointer()** is ignored, and no error checking of the name is performed.

- **PyCapsule_GetName()** always returns NULL.
- **PyCapsule_SetName()** always raises an exception and returns failure. (Since there's no way to store a name in a CObject, noisy failure of **PyCapsule_SetName()** was deemed preferable to silent failure here. If this is inconvenient, feel free to modify your local copy as you see fit.)

You can find **capsulethunk.h** in the Python source distribution as **Doc/includes/capsulethunk.h**. We also include it here for your convenience:

```c
#ifndef __CAPSULETHUNK_H
#define __CAPSULETHUNK_H

#if (  (PY_VERSION_HEX < 0x02070000)   
  ||  ((PY_VERSION_HEX >= 0x03000000)   
        && (PY_VERSION_HEX < 0x03010000)) )

#define __PyCapsule_GetField(capsule, field, default_value)  
  (PyCapsule_CheckExact(capsule)  
        ? (((PyCObject *)capsule)->field)  
          : (default_value)  
  )

#define __PyCapsule_SetField(capsule, field, value)  
  (PyCapsule_CheckExact(capsule)  
        ? (((PyCObject *)capsule)->field = value), 1  
          : 0  
  )

#define PyCapsule_Type PyCObject_Type

#define PyCapsule_CheckExact(capsule) (PyCObject_Check(capsule)
#define PyCapsule_IsValid(capsule, name) (PyCObject_Check(capsule)

#define PyCapsule_New(pointer, name, destructor)  
  (PyCObject_FromVoidPtr(pointer, destructor))
```

#define PyCapsule_GetPointer(capsule, name) \  (PyObject_AsVoidPtr(capsule))

/* Don't call PyCObject_SetPointer here, it fails if there's a */
#define PyCapsule_SetPointer(capsule, pointer) \  __PyCapsule_SetField(capsule, cobject, pointer)

#define PyCapsule_GetDestructor(capsule) \  __PyCapsule_GetField(capsule, destructor)
#define PyCapsule_SetDestructor(capsule, dtor) \  __PyCapsule_SetField(capsule, destructor, dtor)

/*
 * Sorry, there's simply no place
 * to store a Capsule "name" in a CObject.
 */
#define PyCapsuleGetName(capsule) NULL

    return return_value;
}
#endif /* #if PY_VERSION_HEX < 0x02070000 */
#endif /* __CAPSULETHUNK_H */
Other options

If you are writing a new extension module, you might consider Cython. It translates a Python-like language to C. The extension modules it creates are compatible with Python 3 and Python 2.
Abstract

This document describes how to write text-mode programs with Python 2.x, using the `curses` extension module to control the display.
What is curses?

The curses library supplies a terminal-independent screen-painting and keyboard-handling facility for text-based terminals; such terminals include VT100s, the Linux console, and the simulated terminal provided by X11 programs such as xterm and rxvt. Display terminals support various control codes to perform common operations such as moving the cursor, scrolling the screen, and erasing areas. Different terminals use widely differing codes, and often have their own minor quirks.

In a world of X displays, one might ask “why bother”? It's true that character-cell display terminals are an obsolete technology, but there are niches in which being able to do fancy things with them are still valuable. One is on small-footprint or embedded Unixes that don’t carry an X server. Another is for tools like OS installers and kernel configurators that may have to run before X is available.

The curses library hides all the details of different terminals, and provides the programmer with an abstraction of a display, containing multiple non-overlapping windows. The contents of a window can be changed in various ways—adding text, erasing it, changing its appearance—and the curses library will automagically figure out what control codes need to be sent to the terminal to produce the right output.

The curses library was originally written for BSD Unix; the later System V versions of Unix from AT&T added many enhancements and new functions. BSD curses is no longer maintained, having been replaced by ncurses, which is an open-source implementation of the AT&T interface. If you're using an open-source Unix such as Linux or FreeBSD, your system almost certainly uses ncurses. Since most current commercial Unix versions are based on System V code, all the functions described here will probably be available. The older
versions of curses carried by some proprietary Unixes may not support everything, though.

No one has made a Windows port of the curses module. On a Windows platform, try the Console module written by Fredrik Lundh. The Console module provides cursor-addressable text output, plus full support for mouse and keyboard input, and is available from http://effbot.org/zone/console-index.htm.

The Python curses module

Thy Python module is a fairly simple wrapper over the C functions provided by curses; if you're already familiar with curses programming in C, it's really easy to transfer that knowledge to Python. The biggest difference is that the Python interface makes things simpler, by merging different C functions such as `addstr()`, `mvaddstr()`, `mvwaddstr()`, into a single `addstr()` method. You'll see this covered in more detail later.

This HOWTO is simply an introduction to writing text-mode programs with curses and Python. It doesn't attempt to be a complete guide to the curses API; for that, see the Python library guide’s section on ncurses, and the C manual pages for ncurses. It will, however, give you the basic ideas.
Starting and ending a curses application

Before doing anything, curses must be initialized. This is done by calling the `initscr()` function, which will determine the terminal type, send any required setup codes to the terminal, and create various internal data structures. If successful, `initscr()` returns a window object representing the entire screen; this is usually called `stdscr`, after the name of the corresponding C variable.

```python
import curses
stdscr = curses.initscr()
```

Usually curses applications turn off automatic echoing of keys to the screen, in order to be able to read keys and only display them under certain circumstances. This requires calling the `noecho()` function.

```python
curses.noecho()
```

Applications will also commonly need to react to keys instantly, without requiring the Enter key to be pressed; this is called `cbreak` mode, as opposed to the usual buffered input mode.

```python
curses.cbreak()
```

Terminals usually return special keys, such as the cursor keys or navigation keys such as Page Up and Home, as a multibyte escape sequence. While you could write your application to expect such sequences and process them accordingly, curses can do it for you, returning a special value such as `curses.KEY_LEFT`. To get curses to do the job, you’ll have to enable keypad mode.

```python
stdscr.keypad(1)
```

Terminating a curses application is much easier than starting one.
You'll need to call

```python
curses.nocbreak(); stdscr.keypad(0); curses.echo()
```

to reverse the curses-friendly terminal settings. Then call the `endwin()` function to restore the terminal to its original operating mode.

```python
curses.endwin()
```

A common problem when debugging a curses application is to get your terminal messed up when the application dies without restoring the terminal to its previous state. In Python this commonly happens when your code is buggy and raises an uncaught exception. Keys are no longer echoed to the screen when you type them, for example, which makes using the shell difficult.

In Python you can avoid these complications and make debugging much easier by importing the `curses.wrapper()` function. It takes a callable and does the initializations described above, also initializing colors if color support is present. It then runs your provided callable and finally deinitializes appropriately. The callable is called inside a try-catch clause which catches exceptions, performs curses deinitialization, and then passes the exception upwards. Thus, your terminal won’t be left in a funny state on exception.
Windows and Pads

Windows are the basic abstraction in curses. A window object represents a rectangular area of the screen, and supports various methods to display text, erase it, allow the user to input strings, and so forth.

The `stdscr` object returned by the `initscr()` function is a window object that covers the entire screen. Many programs may need only this single window, but you might wish to divide the screen into smaller windows, in order to redraw or clear them separately. The `newwin()` function creates a new window of a given size, returning the new window object.

```c
begin_x = 20; begin_y = 7
height = 5; width = 40
win = curses.newwin(height, width, begin_y, begin_x)
```

A word about the coordinate system used in curses: coordinates are always passed in the order y,x, and the top-left corner of a window is coordinate (0,0). This breaks a common convention for handling coordinates, where the x coordinate usually comes first. This is an unfortunate difference from most other computer applications, but it's been part of curses since it was first written, and it's too late to change things now.

When you call a method to display or erase text, the effect doesn't immediately show up on the display. This is because curses was originally written with slow 300-baud terminal connections in mind; with these terminals, minimizing the time required to redraw the screen is very important. This lets curses accumulate changes to the screen, and display them in the most efficient manner. For example, if your program displays some characters in a window, and then clears the window, there's no need to send the original characters
because they'd never be visible.

Accordingly, curses requires that you explicitly tell it to redraw windows, using the `refresh()` method of window objects. In practice, this doesn't really complicate programming with curses much. Most programs go into a flurry of activity, and then pause waiting for a keypress or some other action on the part of the user. All you have to do is to be sure that the screen has been redrawn before pausing to wait for user input, by simply calling `stdscr.refresh()` or the `refresh()` method of some other relevant window.

A pad is a special case of a window; it can be larger than the actual display screen, and only a portion of it displayed at a time. Creating a pad simply requires the pad's height and width, while refreshing a pad requires giving the coordinates of the on-screen area where a subsection of the pad will be displayed.

```python
pad = curses.newpad(100, 100)
# These loops fill the pad with letters; this is
# explained in the next section
for y in range(0, 100):
    for x in range(0, 100):
        try:
            pad.addch(y,x, ord('a') + (x*x+y*y) % 26)
        except curses.error:
            pass

# Displays a section of the pad in the middle of the screen
pad.refresh(0, 0, 5, 5, 20, 75)
```

The `refresh()` call displays a section of the pad in the rectangle extending from coordinate (5,5) to coordinate (20,75) on the screen; the upper left corner of the displayed section is coordinate (0,0) on the pad. Beyond that difference, pads are exactly like ordinary windows and support the same methods.

If you have multiple windows and pads on screen there is a more efficient way to go, which will prevent annoying screen flicker at
refresh time. Use the `noutrefresh()` method of each window to update the data structure representing the desired state of the screen; then change the physical screen to match the desired state in one go with the function `doupdate()`. The normal `refresh()` method calls `doupdate()` as its last act.
Displaying Text

From a C programmer’s point of view, curses may sometimes look like a twisty maze of functions, all subtly different. For example, addstr() displays a string at the current cursor location in the stdscr window, while mvaddstr() moves to a given y,x coordinate first before displaying the string. waddstr() is just like addstr(), but allows specifying a window to use, instead of using stdscr by default. mvwaddstr() follows similarly.

Fortunately the Python interface hides all these details; stdscr is a window object like any other, and methods like addstr() accept multiple argument forms. Usually there are four different forms.

<table>
<thead>
<tr>
<th>Form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>str or ch</td>
<td>Display the string str or character ch at the current position</td>
</tr>
<tr>
<td>str or ch, attr</td>
<td>Display the string str or character ch, using attribute attr at the current position</td>
</tr>
<tr>
<td>y, x, str or ch</td>
<td>Move to position y,x within the window, and display str or ch</td>
</tr>
<tr>
<td>y, x, str or ch, attr</td>
<td>Move to position y,x within the window, and display str or ch, using attribute attr</td>
</tr>
</tbody>
</table>

Attributes allow displaying text in highlighted forms, such as in boldface, underline, reverse code, or in color. They’ll be explained in more detail in the next subsection.

The addstr() function takes a Python string as the value to be displayed, while the addch() functions take a character, which can be either a Python string of length 1 or an integer. If it's a string, you’re
limited to displaying characters between 0 and 255. SVr4 curses provides constants for extension characters; these constants are integers greater than 255. For example, `ACS_PLMINUS` is a +/- symbol, and `ACS_ULCORNER` is the upper left corner of a box (handy for drawing borders).

Windows remember where the cursor was left after the last operation, so if you leave out the y,x coordinates, the string or character will be displayed wherever the last operation left off. You can also move the cursor with the `move(y, x)` method. Because some terminals always display a flashing cursor, you may want to ensure that the cursor is positioned in some location where it won’t be distracting; it can be confusing to have the cursor blinking at some apparently random location.

If your application doesn’t need a blinking cursor at all, you can call `curs_set(0)` to make it invisible. Equivalently, and for compatibility with older curses versions, there’s a `leaveok(bool)` function. When `bool` is true, the curses library will attempt to suppress the flashing cursor, and you won’t need to worry about leaving it in odd locations.

## Attributes and Color

Characters can be displayed in different ways. Status lines in a text-based application are commonly shown in reverse video; a text viewer may need to highlight certain words. curses supports this by allowing you to specify an attribute for each cell on the screen.

An attribute is an integer, each bit representing a different attribute. You can try to display text with multiple attribute bits set, but curses doesn’t guarantee that all the possible combinations are available, or that they’re all visually distinct. That depends on the ability of the terminal being used, so it’s safest to stick to the most commonly available attributes, listed here.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A_BLINK</td>
<td>Blinking text</td>
</tr>
<tr>
<td>A_BOLD</td>
<td>Extra bright or bold text</td>
</tr>
<tr>
<td>A_DIM</td>
<td>Half bright text</td>
</tr>
<tr>
<td>A_REVERSE</td>
<td>Reverse-video text</td>
</tr>
<tr>
<td>A_STANDOUT</td>
<td>The best highlighting mode available</td>
</tr>
<tr>
<td>A_UNDERLINE</td>
<td>Underlined text</td>
</tr>
</tbody>
</table>

So, to display a reverse-video status line on the top line of the screen, you could code:

```python
stdscr.addstr(0, 0, "Current mode: Typing mode", curses.A_REVERSE)
stdscr.refresh()
```

The curses library also supports color on those terminals that provide it. The most common such terminal is probably the Linux console, followed by color xterms.

To use color, you must call the `start_color()` function soon after calling `initscr()`, to initialize the default color set (the `curses.wrapper.wrapper()` function does this automatically). Once that's done, the `has_colors()` function returns TRUE if the terminal in use can actually display color. (Note: curses uses the American spelling ‘color’, instead of the Canadian/British spelling ‘colour’. If you’re used to the British spelling, you’ll have to resign yourself to misspelling it for the sake of these functions.)

The curses library maintains a finite number of color pairs, containing a foreground (or text) color and a background color. You can get the attribute value corresponding to a color pair with the `color_pair()` function; this can be bitwise-OR’ed with other attributes such as `A_REVERSE`, but again, such combinations are not guaranteed to work.
on all terminals.

An example, which displays a line of text using color pair 1:

```c
stdscr.addstr("Pretty text", curses.color_pair(1))
stdscr.refresh()
```

As I said before, a color pair consists of a foreground and background color. `start_color()` initializes 8 basic colors when it activates color mode. They are: 0:black, 1:red, 2:green, 3:yellow, 4:blue, 5:magenta, 6:cyan, and 7:white. The curses module defines named constants for each of these colors: `curses.COLOR_BLACK`, `curses.COLOR_RED`, and so forth.

The `init_pair(n, f, b)` function changes the definition of color pair `n`, to foreground color `f` and background color `b`. Color pair 0 is hard-wired to white on black, and cannot be changed.

Let's put all this together. To change color 1 to red text on a white background, you would call:

```c
 curses.init_pair(1, curses.COLOR_RED, curses.COLOR_WHITE)
```

When you change a color pair, any text already displayed using that color pair will change to the new colors. You can also display new text in this color with:

```c
stdscr.addstr(0,0, "RED ALERT!", curses.color_pair(1))
```

Very fancy terminals can change the definitions of the actual colors to a given RGB value. This lets you change color 1, which is usually red, to purple or blue or any other color you like. Unfortunately, the Linux console doesn’t support this, so I’m unable to try it out, and can’t provide any examples. You can check if your terminal can do this by calling `can_change_color()`, which returns TRUE if the
capability is there. If you're lucky enough to have such a talented terminal, consult your system's man pages for more information.
The curses library itself offers only very simple input mechanisms. Python’s support adds a text-input widget that makes up some of the lack.

The most common way to get input to a window is to use its `getch()` method. `getch()` pauses and waits for the user to hit a key, displaying it if `echo()` has been called earlier. You can optionally specify a coordinate to which the cursor should be moved before pausing.

It’s possible to change this behavior with the method `nodelay()`. After `nodelay(1), getch()` for the window becomes non-blocking and returns `curses.ERR` (a value of -1) when no input is ready. There’s also a `halfdelay()` function, which can be used to (in effect) set a timer on each `getch();` if no input becomes available within a specified delay (measured in tenths of a second), curses raises an exception.

The `getch()` method returns an integer; if it’s between 0 and 255, it represents the ASCII code of the key pressed. Values greater than 255 are special keys such as Page Up, Home, or the cursor keys. You can compare the value returned to constants such as `curses.KEY_PPAge, curses.KEY_HOME,` or `curses.KEY_LEFT`. Usually the main loop of your program will look something like this:

```python
while 1:
    c = stdscr.getch()
    if c == ord('p'):
        PrintDocument()
    elif c == ord('q'):
        break  # Exit the while()
    elif c == curses.KEY_HOME:
        x = y = 0
```
The `curses.ascii` module supplies ASCII class membership functions that take either integer or 1-character-string arguments; these may be useful in writing more readable tests for your command interpreters. It also supplies conversion functions that take either integer or 1-character-string arguments and return the same type. For example, `curses.ascii.ctrl()` returns the control character corresponding to its argument.

There's also a method to retrieve an entire string, `getstr()`. It isn't used very often, because its functionality is quite limited; the only editing keys available are the backspace key and the Enter key, which terminates the string. It can optionally be limited to a fixed number of characters.

```python
curses.echo()  # Enable echoing of characters

# Get a 15-character string, with the cursor on the top line
s = stdscr.getstr(0, 0, 15)
```

The Python `curses.textpad` module supplies something better. With it, you can turn a window into a text box that supports an Emacs-like set of keybindings. Various methods of `Textbox` class support editing with input validation and gathering the edit results either with or without trailing spaces. See the library documentation on `curses.textpad` for the details.
This HOWTO didn’t cover some advanced topics, such as screen-scraping or capturing mouse events from an xterm instance. But the Python library page for the curses modules is now pretty complete. You should browse it next.

If you’re in doubt about the detailed behavior of any of the ncurses entry points, consult the manual pages for your curses implementation, whether it's ncurses or a proprietary Unix vendor’s. The manual pages will document any quirks, and provide complete lists of all the functions, attributes, and \texttt{acs\_} characters available to you.

Because the curses API is so large, some functions aren't supported in the Python interface, not because they’re difficult to implement, but because no one has needed them yet. Feel free to add them and then submit a patch. Also, we don't yet have support for the menu library associated with ncurses; feel free to add that.

If you write an interesting little program, feel free to contribute it as another demo. We can always use more of them!

Abstract

Defines descriptors, summarizes the protocol, and shows how descriptors are called. Examines a custom descriptor and several built-in python descriptors including functions, properties, static methods, and class methods. Shows how each works by giving a pure Python equivalent and a sample application.

Learning about descriptors not only provides access to a larger toolset, it creates a deeper understanding of how Python works and an appreciation for the elegance of its design.
Definition and Introduction

In general, a descriptor is an object attribute with “binding behavior”, one whose attribute access has been overridden by methods in the descriptor protocol. Those methods are `__get__()`, `__set__()`, and `__delete__()`. If any of those methods are defined for an object, it is said to be a descriptor.

The default behavior for attribute access is to get, set, or delete the attribute from an object’s dictionary. For instance, `a.x` has a lookup chain starting with `a.__dict__['x']`, then `type(a).__dict__['x']`, and continuing through the base classes of `type(a)` excluding metaclasses. If the looked-up value is an object defining one of the descriptor methods, then Python may override the default behavior and invoke the descriptor method instead. Where this occurs in the precedence chain depends on which descriptor methods were defined. Note that descriptors are only invoked for new style objects or classes (a class is new style if it inherits from `object` or `type`).

Descriptors are a powerful, general purpose protocol. They are the mechanism behind properties, methods, static methods, class methods, and `super()`. They are used throughout Python itself to implement the new style classes introduced in version 2.2. Descriptors simplify the underlying C-code and offer a flexible set of new tools for everyday Python programs.
Descriptor Protocol

```python
descr.__get__(self, obj, type=None) --> value

descr.__set__(self, obj, value) --> None

descr.__delete__(self, obj) --> None
```

That is all there is to it. Define any of these methods and an object is considered a descriptor and can override default behavior upon being looked up as an attribute.

If an object defines both `__get__()` and `__set__()`, it is considered a data descriptor. Descriptors that only define `__get__()` are called non-data descriptors (they are typically used for methods but other uses are possible).

Data and non-data descriptors differ in how overrides are calculated with respect to entries in an instance's dictionary. If an instance's dictionary has an entry with the same name as a data descriptor, the data descriptor takes precedence. If an instance's dictionary has an entry with the same name as a non-data descriptor, the dictionary entry takes precedence.

To make a read-only data descriptor, define both `__get__()` and `__set__()` with the `__set__()` raising an `AttributeError` when called. Defining the `__set__()` method with an exception raising placeholder is enough to make it a data descriptor.
Invoking Descriptors

A descriptor can be called directly by its method name. For example, `d.__get__(obj)`.

Alternatively, it is more common for a descriptor to be invoked automatically upon attribute access. For example, `obj.d` looks up `d` in the dictionary of `obj`. If `d` defines the method `__get__()`, then `d.__get__(obj)` is invoked according to the precedence rules listed below.

The details of invocation depend on whether `obj` is an object or a class. Either way, descriptors only work for new style objects and classes. A class is new style if it is a subclass of `object`.

For objects, the machinery is in `object.__getattribute__()` which transforms `b.x` into `type(b).__dict__['x'].__get__(b, type(b))`. The implementation works through a precedence chain that gives data descriptors priority over instance variables, instance variables priority over non-data descriptors, and assigns lowest priority to `__getattr__()` if provided. The full C implementation can be found in `PyObject_GenericGetAttr()` in `Objects/object.c`.

For classes, the machinery is in `type.__getattribute__()` which transforms `B.x` into `B.__dict__['x'].__get__(None, B)`. In pure Python, it looks like:

```python
def __getattribute__(self, key):
    "Emulate type_getattro() in Objects/typeobject.c"
    v = object.__getattribute__(self, key)
    if hasattr(v, '__get__'):
        return v.__get__(None, self)
    return v
```
The important points to remember are:

- descriptors are invoked by the `__getattribute__()` method
- overriding `__getattribute__()` prevents automatic descriptor calls
- `__getattribute__()` is only available with new style classes and objects
- `object.__getattribute__()` and `type.__getattribute__()` make different calls to `__get__()`. 
- data descriptors always override instance dictionaries.
- non-data descriptors may be overridden by instance dictionaries.

The object returned by `super()` also has a custom `__getattribute__()` method for invoking descriptors. The call `super(B, obj).m()` searches `obj.__class__.__mro__` for the base class `A` immediately following `B` and then returns `A.__dict__['m'].__get__(obj, B)`. If not a descriptor, `m` is returned unchanged. If not in the dictionary, `m` reverts to a search using `object.__getattribute__()`.

Note, in Python 2.2, `super(B, obj).m()` would only invoke `__get__()` if `m` was a data descriptor. In Python 2.3, non-data descriptors also get invoked unless an old-style class is involved. The implementation details are in `super_getattro()` in `Objects/typeobject.c`.

The details above show that the mechanism for descriptors is embedded in the `__getattribute__()` methods for `object`, `type`, and `super()`. Classes inherit this machinery when they derive from `object` or if they have a meta-class providing similar functionality. Likewise, classes can turn-off descriptor invocation by overriding `__getattribute__()`.
### Descriptor Example

The following code creates a class whose objects are data descriptors which print a message for each get or set. Overriding `__getattribute__()` is alternate approach that could do this for every attribute. However, this descriptor is useful for monitoring just a few chosen attributes:

```python
class RevealAccess(object):
    """A data descriptor that sets and returns values normally and prints a message logging their access. """
    def __init__(self, initval=None, name='var'):
        self.val = initval
        self.name = name
    def __get__(self, obj, objtype):
        print 'Retrieving', self.name
        return self.val
    def __set__(self, obj, val):
        print 'Updating', self.name
        self.val = val
```

```python
>>> class MyClass(object):
...     x = RevealAccess(10, 'var "x"')
...     y = 5
... >>> m = MyClass()
... >>> m.x
Retrieving var "x"
10
>>> m.x = 20
Updating var "x"
>>> m.x
Retrieving var "x"
20
>>> m.y
5
```
The protocol is simple and offers exciting possibilities. Several use cases are so common that they have been packaged into individual function calls. Properties, bound and unbound methods, static methods, and class methods are all based on the descriptor protocol.
Properties

Calling `property()` is a succinct way of building a data descriptor that triggers function calls upon access to an attribute. Its signature is:

```python
property(fget=None, fset=None, fdel=None, doc=None) -> property
```

The documentation shows a typical use to define a managed attribute `x`:

```python
class C(object):
    def getx(self): return self.__x
    def setx(self, value): self.__x = value
    def delx(self): del self.__x
    x = property(getx, setx, delx, "I'm the 'x' property.")
```

To see how `property()` is implemented in terms of the descriptor protocol, here is a pure Python equivalent:

```python
class Property(object):
    "Emulate PyProperty_Type() in Objects/descrobject.c"

    def __init__(self, fget=None, fset=None, fdel=None, doc=None):
        self.fget = fget
        self.fset = fset
        self.fdel = fdel
        if doc is None and fget is not None:
            doc = fget.__doc__
        self.__doc__ = doc

    def __get__(self, obj, objtype=None):
        if obj is None:
            return self
        if self.fget is None:
            raise AttributeError("unreadable attribute")
        return self.fget(obj)

    def __set__(self, obj, value):
        if self.fset is None:
The *property()* builtin helps whenever a user interface has granted attribute access and then subsequent changes require the intervention of a method.

For instance, a spreadsheet class may grant access to a cell value through `Cell('b10').value`. Subsequent improvements to the program require the cell to be recalculated on every access; however, the programmer does not want to affect existing client code accessing the attribute directly. The solution is to wrap access to the value attribute in a property data descriptor:

```python
class Cell(object):
    
    def _fget__(self, fget):
        return type(self)(fget, self.fset, self.fdel, self.__doc__)
    
    def _fset__(self, obj, value):
        self.fset(obj, value)
        
    def __delete__(self, obj):
        if self.fdel is None:
            raise AttributeError("can't delete attribute")
        self.fdel(obj)
        
    def getter(self, fget):
        return type(self)(fget, self.fset, self.fdel, self.__doc__)
    
    def setter(self, fset):
        return type(self)(self.fget, fset, self.fdel, self.__doc__)
    
    def deleter(self, fdel):
        return type(self)(self.fget, self.fset, fdel, self.__doc__)
```
Functions and Methods

Python’s object oriented features are built upon a function based environment. Using non-data descriptors, the two are merged seamlessly.

Class dictionaries store methods as functions. In a class definition, methods are written using `def` and `lambda`, the usual tools for creating functions. The only difference from regular functions is that the first argument is reserved for the object instance. By Python convention, the instance reference is called `self` but may be called `this` or any other variable name.

To support method calls, functions include the `__get__()` method for binding methods during attribute access. This means that all functions are non-data descriptors which return bound or unbound methods depending whether they are invoked from an object or a class. In pure python, it works like this:

```python
class Function(object):
    ...
    def __get__(self, obj, objtype=None):
        "Simulate func_descr_get() in Objects/funcobject.c"
        return types.MethodType(self, obj, objtype)
```

Running the interpreter shows how the function descriptor works in practice:

```python
>>> class D(object):
...    def f(self, x):
...        return x
...    ...
>>> d = D()
>>> D.__dict__['f']    # Stored internally as a function
<function f at 0x00C45070>
>>> D.f                # Get from a class becomes an unbound meth
<unbound method D.f>
```
The output suggests that bound and unbound methods are two different types. While they could have been implemented that way, the actual C implementation of `PyMethod_Type` in `Objects/classobject.c` is a single object with two different representations depending on whether the `im_self` field is set or is `NULL` (the C equivalent of `None`).

Likewise, the effects of calling a method object depend on the `im_self` field. If set (meaning bound), the original function (stored in the `im_func` field) is called as expected with the first argument set to the instance. If unbound, all of the arguments are passed unchanged to the original function. The actual C implementation of `instancemethod_call()` is only slightly more complex in that it includes some type checking.
Non-data descriptors provide a simple mechanism for variations on the usual patterns of binding functions into methods.

To recap, functions have a `__get__()` method so that they can be converted to a method when accessed as attributes. The non-data descriptor transforms an `obj.f(*args)` call into `f(obj, *args)`. Calling `klass.f(*args)` becomes `f(*args)`.

This chart summarizes the binding and its two most useful variants:

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Called from an Object</th>
<th>Called from a Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td><code>f(obj, *args)</code></td>
<td><code>f(*args)</code></td>
</tr>
<tr>
<td>staticmethod</td>
<td><code>f(*args)</code></td>
<td><code>f(*args)</code></td>
</tr>
<tr>
<td>classmethod</td>
<td><code>f(type(obj), *args)</code></td>
<td><code>f(klass, *args)</code></td>
</tr>
</tbody>
</table>

Static methods return the underlying function without changes. Calling either `c.f` or `C.f` is the equivalent of a direct lookup into `object.__getattribute__(c, "f")` or `object.__getattribute__(C, "f")`. As a result, the function becomes identically accessible from either an object or a class.

Good candidates for static methods are methods that do not reference the `self` variable.

For instance, a statistics package may include a container class for experimental data. The class provides normal methods for computing the average, mean, median, and other descriptive statistics that depend on the data. However, there may be useful functions which are conceptually related but do not depend on the data. For instance, `erf(x)` is handy conversion routine that comes
up in statistical work but does not directly depend on a particular dataset. It can be called either from an object or the class: 

\[ \text{s.erf}(1.5) \rightarrow .9332 \text{ or } \text{Sample.erf}(1.5) \rightarrow .9332. \]

Since staticmethods return the underlying function with no changes, the example calls are unexciting:

```python
>>> class E(object):
...     def f(x):
...         print x
...     f = staticmethod(f)
...
>>> print E.f(3)
3
>>> print E().f(3)
3
```

Using the non-data descriptor protocol, a pure Python version of `staticmethod()` would look like this:

```python
class StaticMethod(object):
    "Emulate PyStaticMethod_Type() in Objects/funcobject.c"

    def __init__(self, f):
        self.f = f

    def __get__(self, obj, objtype=None):
        return self.f
```

Unlike static methods, class methods prepend the class reference to the argument list before calling the function. This format is the same for whether the caller is an object or a class:

```python
>>> class E(object):
...     def f(klass, x):
...         return klass.__name__, x
...     f = classmethod(f)
...
>>> print E.f(3)
('E', 3)
>>> print E().f(3)
```
This behavior is useful whenever the function only needs to have a class reference and does not care about any underlying data. One use for classmethods is to create alternate class constructors. In Python 2.3, the classmethod `dict.fromkeys()` creates a new dictionary from a list of keys. The pure Python equivalent is:

```python
class Dict(object):
    ...
    def fromkeys(klass, iterable, value=None):
        """Emulate dict_fromkeys() in Objects/dictobject.c"
        d = klass()
        for key in iterable:
            d[key] = value
        return d
fromkeys = classmethod(fromkeys)
```

Now a new dictionary of unique keys can be constructed like this:

```python
>>> Dict.fromkeys('abracadabra')
{'a': None, 'r': None, 'b': None, 'c': None, 'd': None}
```

Using the non-data descriptor protocol, a pure Python version of `classmethod()` would look like this:

```python
class ClassMethod(object):
    """Emulate PyClassMethod_Type() in Objects/funcobject.c"
    
    def __init__(self, f):
        self.f = f

    def __get__(self, obj, klass=None):
        if klass is None:
            klass = type(obj)
        def newfunc(*args):
            return self.f(klass, *args)
        return newfunc
```
Idioms and Anti-Idioms in Python

Abstract

This document can be considered a companion to the tutorial. It shows how to use Python, and even more importantly, how not to use Python.
## Language Constructs You Should Not Use

While Python has relatively few gotchas compared to other languages, it still has some constructs which are only useful in corner cases, or are plain dangerous.

### from module import *

#### Inside Function Definitions

*from module import * is invalid* inside function definitions. While many versions of Python do not check for the invalidity, it does not make it more valid, no more than having a smart lawyer makes a man innocent. Do not use it like that ever. Even in versions where it was accepted, it made the function execution slower, because the compiler could not be certain which names were local and which were global. In Python 2.1 this construct causes warnings, and sometimes even errors.

#### At Module Level

While it is valid to use *from module import * at module level* it is usually a bad idea. For one, this loses an important property Python otherwise has — you can know where each toplevel name is defined by a simple “search” function in your favourite editor. You also open yourself to trouble in the future, if some module grows additional functions or classes.

One of the most awful questions asked on the newsgroup is why this code:

```python
f = open("www")
f.read()
```
does not work. Of course, it works just fine (assuming you have a file called “www”.) But it does not work if somewhere in the module, the statement from os import * is present. The os module has a function called open() which returns an integer. While it is very useful, shadowing a builtin is one of its least useful properties.

Remember, you can never know for sure what names a module exports, so either take what you need — from module import name1, name2, or keep them in the module and access on a per-need basis — import module; print module.name.

When It Is Just Fine

There are situations in which from module import * is just fine:

- The interactive prompt. For example, from math import * makes Python an amazing scientific calculator.
- When extending a module in C with a module in Python.
- When the module advertises itself as from import * safe.

Unadorned exec, execfile() and friends

The word “unadorned” refers to the use without an explicit dictionary, in which case those constructs evaluate code in the current environment. This is dangerous for the same reasons from import * is dangerous — it might step over variables you are counting on and mess up things for the rest of your code. Simply do not do that.

Bad examples:

```python
g>>> for name in sys.argv[1:]:
  ...   exec "%s=1" % name
>>> def func(s, **kw):
  ...   for var, val in kw.items():
  ...     exec "s.%s=val" % var  # invalid!
```
Good examples:

```python
>>> d = {}
>>> for name in sys.argv[1:]:
...     d[name] = 1
>>> def func(s, **kw):
...     for var, val in kw.items():
...         setattr(s, var, val)
>>> d = {}
>>> execfile("handler.py", d, d)
>>> handle = d['handle']
>>> handle()
```

```python
from module import name1, name2
```

This is a “don’t” which is much weaker than the previous “don’t”s but is still something you should not do if you don’t have good reasons to do that. The reason it is usually a bad idea is because you suddenly have an object which lives in two separate namespaces. When the binding in one namespace changes, the binding in the other will not, so there will be a discrepancy between them. This happens when, for example, one module is reloaded, or changes the definition of a function at runtime.

Bad example:

```python
# foo.py
da = 1

# bar.py
from foo import a
if something():
    a = 2 # danger: foo.a != a
```

Good example:
Python has the `except:` clause, which catches all exceptions. Since every error in Python raises an exception, using `except:` can make many programming errors look like runtime problems, which hinders the debugging process.

The following code shows a great example of why this is bad:

```python
try:
    foo = opne("file")  # misspelled "open"
except:
    sys.exit("could not open file!")
```

The second line triggers a `NameError`, which is caught by the `except` clause. The program will exit, and the error message the program prints will make you think the problem is the readability of "file" when in fact the real error has nothing to do with "file".

A better way to write the above is

```python
try:
    foo = opne("file")
except IOError:
    sys.exit("could not open file")
```

When this is run, Python will produce a traceback showing the `NameError`, and it will be immediately apparent what needs to be fixed.
Because `except:` catches *all* exceptions, including `SystemExit`, `KeyboardInterrupt`, and `GeneratorExit` (which is not an error and should not normally be caught by user code), using a bare `except:` is almost never a good idea. In situations where you need to catch all “normal” errors, such as in a framework that runs callbacks, you can catch the base class for all normal exceptions, `Exception`. Unfortunately in Python 2.x it is possible for third-party code to raise exceptions that do not inherit from `Exception`, so in Python 2.x there are some cases where you may have to use a bare `except:` and manually re-raise the exceptions you don’t want to catch.
Exceptions

Exceptions are a useful feature of Python. You should learn to raise them whenever something unexpected occurs, and catch them only where you can do something about them.

The following is a very popular anti-idiom

```python
def get_status(file):
    if not os.path.exists(file):
        print "file not found"
        sys.exit(1)
    return open(file).readline()
```

Consider the case where the file gets deleted between the time the call to `os.path.exists()` is made and the time `open()` is called. In that case the last line will raise an `IOError`. The same thing would happen if `file` exists but has no read permission. Since testing this on a normal machine on existent and non-existent files makes it seem bugless, the test results will seem fine, and the code will get shipped. Later an unhandled `IOError` (or perhaps some other `EnvironmentError`) escapes to the user, who gets to watch the ugly traceback.

Here is a somewhat better way to do it.

```python
def get_status(file):
    try:
        return open(file).readline()
    except EnvironmentError as err:
        print "Unable to open file: {}".format(err)
        sys.exit(1)
```

In this version, *either* the file gets opened and the line is read (so it works even on flaky NFS or SMB connections), or an error message is printed that provides all the available information on why the open
failed, and the application is aborted.

However, even this version of `get_status()` makes too many assumptions — that it will only be used in a short running script, and not, say, in a long running server. Sure, the caller could do something like

```python
try:
    status = get_status(log)
except SystemExit:
    status = None
```

But there is a better way. You should try to use as few `except` clauses in your code as you can — the ones you do use will usually be inside calls which should always succeed, or a catch-all in a main function.

So, an even better version of `get_status()` is probably

```python
def get_status(file):
    return open(file).readline()
```

The caller can deal with the exception if it wants (for example, if it tries several files in a loop), or just let the exception filter upwards to its caller.

But the last version still has a serious problem — due to implementation details in CPython, the file would not be closed when an exception is raised until the exception handler finishes; and, worse, in other implementations (e.g., Jython) it might not be closed at all regardless of whether or not an exception is raised.

The best version of this function uses the `open()` call as a context manager, which will ensure that the file gets closed as soon as the function returns:
def get_status(file):
    with open(file) as fp:
        return fp.readline()
Using the Batteries

Every so often, people seem to be writing stuff in the Python library again, usually poorly. While the occasional module has a poor interface, it is usually much better to use the rich standard library and data types that come with Python than inventing your own.

A useful module very few people know about is `os.path`. It always has the correct path arithmetic for your operating system, and will usually be much better than whatever you come up with yourself.

Compare:

```python
# ugh!
return dir+"/"+file
# better
return os.path.join(dir, file)
```

More useful functions in `os.path`: `basename()`, `dirname()` and `splitext()`.

There are also many useful built-in functions people seem not to be aware of for some reason: `min()` and `max()` can find the minimum/maximum of any sequence with comparable semantics, for example, yet many people write their own `max()/min()`. Another highly useful function is `reduce()` which can be used to repeatedly apply a binary operation to a sequence, reducing it to a single value. For example, compute a factorial with a series of multiply operations:

```python
>>> n = 4
>>> import operator
>>> reduce(operator.mul, range(1, n+1))
24
```

When it comes to parsing numbers, note that `float()`, `int()` and
`long()` all accept string arguments and will reject ill-formed strings by raising an `ValueError`. 
Using Backslash to Continue Statements

Since Python treats a newline as a statement terminator, and since statements are often more than is comfortable to put in one line, many people do:

```python
if foo.bar()['first'][0] == baz.quux(1, 2)[5:9] and \
calculate_number(10, 20) != forbulate(500, 360):
    pass
```

You should realize that this is dangerous: a stray space after the \ would make this line wrong, and stray spaces are notoriously hard to see in editors. In this case, at least it would be a syntax error, but if the code was:

```python
value = foo.bar()['first'][0]*baz.quux(1, 2)[5:9] \
      + calculate_number(10, 20)*forbulate(500, 360)
```

then it would just be subtly wrong.

It is usually much better to use the implicit continuation inside parenthesis:

This version is bulletproof:

```python
value = (foo.bar()['first'][0]*baz.quux(1, 2)[5:9] \
    + calculate_number(10, 20)*forbulate(500, 360))
```
In this document, we'll take a tour of Python’s features suitable for implementing programs in a functional style. After an introduction to the concepts of functional programming, we'll look at language features such as iterators and generators and relevant library modules such as itertools and functools.
This section explains the basic concept of functional programming; if you’re just interested in learning about Python language features, skip to the next section.

Programming languages support decomposing problems in several different ways:

- Most programming languages are **procedural**: programs are lists of instructions that tell the computer what to do with the program’s input. C, Pascal, and even Unix shells are procedural languages.
- In **declarative** languages, you write a specification that describes the problem to be solved, and the language implementation figures out how to perform the computation efficiently. SQL is the declarative language you’re most likely to be familiar with; a SQL query describes the data set you want to retrieve, and the SQL engine decides whether to scan tables or use indexes, which subclauses should be performed first, etc.
- **Object-oriented** programs manipulate collections of objects. Objects have internal state and support methods that query or modify this internal state in some way. Smalltalk and Java are object-oriented languages. C++ and Python are languages that support object-oriented programming, but don’t force the use of object-oriented features.
- **Functional** programming decomposes a problem into a set of functions. Ideally, functions only take inputs and produce outputs, and don’t have any internal state that affects the output produced for a given input. Well-known functional languages include the ML family (Standard ML, OCaml, and other variants) and Haskell.

The designers of some computer languages choose to emphasize
one particular approach to programming. This often makes it difficult to write programs that use a different approach. Other languages are multi-paradigm languages that support several different approaches. Lisp, C++, and Python are multi-paradigm; you can write programs or libraries that are largely procedural, object-oriented, or functional in all of these languages. In a large program, different sections might be written using different approaches; the GUI might be object-oriented while the processing logic is procedural or functional, for example.

In a functional program, input flows through a set of functions. Each function operates on its input and produces some output. Functional style discourages functions with side effects that modify internal state or make other changes that aren’t visible in the function’s return value. Functions that have no side effects at all are called purely functional. Avoiding side effects means not using data structures that get updated as a program runs; every function’s output must only depend on its input.

Some languages are very strict about purity and don’t even have assignment statements such as a=3 or c = a + b, but it’s difficult to avoid all side effects. Printing to the screen or writing to a disk file are side effects, for example. For example, in Python a print statement or a time.sleep(1) both return no useful value; they’re only called for their side effects of sending some text to the screen or pausing execution for a second.

Python programs written in functional style usually won’t go to the extreme of avoiding all I/O or all assignments; instead, they’ll provide a functional-appearing interface but will use non-functional features internally. For example, the implementation of a function will still use assignments to local variables, but won’t modify global variables or have other side effects.

Functional programming can be considered the opposite of object-
oriented programming. Objects are little capsules containing some internal state along with a collection of method calls that let you modify this state, and programs consist of making the right set of state changes. Functional programming wants to avoid state changes as much as possible and works with data flowing between functions. In Python you might combine the two approaches by writing functions that take and return instances representing objects in your application (e-mail messages, transactions, etc.).

Functional design may seem like an odd constraint to work under. Why should you avoid objects and side effects? There are theoretical and practical advantages to the functional style:

- Formal proviability.
- Modularity.
- Composability.
- Ease of debugging and testing.

**Formal proviability**

A theoretical benefit is that it's easier to construct a mathematical proof that a functional program is correct.

For a long time researchers have been interested in finding ways to mathematically prove programs correct. This is different from testing a program on numerous inputs and concluding that its output is usually correct, or reading a program’s source code and concluding that the code looks right; the goal is instead a rigorous proof that a program produces the right result for all possible inputs.

The technique used to prove programs correct is to write down invariants, properties of the input data and of the program’s variables that are always true. For each line of code, you then show that if invariants X and Y are true before the line is executed, the slightly different invariants X’ and Y’ are true after the line is
executed. This continues until you reach the end of the program, at which point the invariants should match the desired conditions on the program's output.

Functional programming's avoidance of assignments arose because assignments are difficult to handle with this technique; assignments can break invariants that were true before the assignment without producing any new invariants that can be propagated onward.

Unfortunately, proving programs correct is largely impractical and not relevant to Python software. Even trivial programs require proofs that are several pages long; the proof of correctness for a moderately complicated program would be enormous, and few or none of the programs you use daily (the Python interpreter, your XML parser, your web browser) could be proven correct. Even if you wrote down or generated a proof, there would then be the question of verifying the proof; maybe there's an error in it, and you wrongly believe you've proved the program correct.

Modularity

A more practical benefit of functional programming is that it forces you to break apart your problem into small pieces. Programs are more modular as a result. It's easier to specify and write a small function that does one thing than a large function that performs a complicated transformation. Small functions are also easier to read and to check for errors.

Ease of debugging and testing

Testing and debugging a functional-style program is easier.

Debugging is simplified because functions are generally small and clearly specified. When a program doesn't work, each function is an interface point where you can check that the data are correct. You
can look at the intermediate inputs and outputs to quickly isolate the function that’s responsible for a bug.

Testing is easier because each function is a potential subject for a unit test. Functions don’t depend on system state that needs to be replicated before running a test; instead you only have to synthesize the right input and then check that the output matches expectations.

Composability

As you work on a functional-style program, you’ll write a number of functions with varying inputs and outputs. Some of these functions will be unavoidably specialized to a particular application, but others will be useful in a wide variety of programs. For example, a function that takes a directory path and returns all the XML files in the directory, or a function that takes a filename and returns its contents, can be applied to many different situations.

Over time you'll form a personal library of utilities. Often you'll assemble new programs by arranging existing functions in a new configuration and writing a few functions specialized for the current task.
I’ll start by looking at a Python language feature that’s an important foundation for writing functional-style programs: iterators.

An iterator is an object representing a stream of data; this object returns the data one element at a time. A Python iterator must support a method called `next()` that takes no arguments and always returns the next element of the stream. If there are no more elements in the stream, `next()` must raise the `StopIteration` exception. Iterators don’t have to be finite, though; it’s perfectly reasonable to write an iterator that produces an infinite stream of data.

The built-in `iter()` function takes an arbitrary object and tries to return an iterator that will return the object’s contents or elements, raising `TypeError` if the object doesn’t support iteration. Several of Python’s built-in data types support iteration, the most common being lists and dictionaries. An object is called an `iterable` object if you can get an iterator for it.

You can experiment with the iteration interface manually:

```python
>>> L = [1,2,3]
>>> it = iter(L)
>>> print it
<...iterator object at ...>
>>> it.next()
1
>>> it.next()
2
>>> it.next()
3
>>> it.next()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
StopIteration
```
Python expects iterable objects in several different contexts, the most important being the `for` statement. In the statement `for X in Y`, Y must be an iterator or some object for which `iter()` can create an iterator. These two statements are equivalent:

```python
for i in iter(obj):
    print i
for i in obj:
    print i
```

Iterators can be materialized as lists or tuples by using the `list()` or `tuple()` constructor functions:

```python
>>> L = [1,2,3]
>>> iterator = iter(L)
>>> t = tuple(iterator)
>>> t
(1, 2, 3)
```

Sequence unpacking also supports iterators: if you know an iterator will return N elements, you can unpack them into an N-tuple:

```python
>>> L = [1,2,3]
>>> iterator = iter(L)
>>> a,b,c = iterator
>>> a,b,c
(1, 2, 3)
```

Built-in functions such as `max()` and `min()` can take a single iterator argument and will return the largest or smallest element. The "in" and "not in" operators also support iterators: `X in iterator` is true if X is found in the stream returned by the iterator. You'll run into obvious problems if the iterator is infinite; `max()`, `min()` will never return, and if the element X never appears in the stream, the "in"
and "not in" operators won’t return either.

Note that you can only go forward in an iterator; there’s no way to get the previous element, reset the iterator, or make a copy of it. Iterator objects can optionally provide these additional capabilities, but the iterator protocol only specifies the `next()` method. Functions may therefore consume all of the iterator’s output, and if you need to do something different with the same stream, you’ll have to create a new iterator.

**Data Types That Support Iterators**

We’ve already seen how lists and tuples support iterators. In fact, any Python sequence type, such as strings, will automatically support creation of an iterator.

Calling `iter()` on a dictionary returns an iterator that will loop over the dictionary’s keys:

```python
c
>>> m = {'Jan': 1, 'Feb': 2, 'Mar': 3, 'Apr': 4, 'May': 5, 'Jun...
...     'Jul': 7, 'Aug': 8, 'Sep': 9, 'Oct': 10, 'Nov': 11, 'D
>>> for key in m:
...     print key, m[key]
Mar 3
Feb 2
Aug 8
Sep 9
Apr 4
Jun 6
Jul 7
Jan 1
May 5
Nov 11
Dec 12
Oct 10
```

Note that the order is essentially random, because it’s based on the hash ordering of the objects in the dictionary.
Applying `iter()` to a dictionary always loops over the keys, but dictionaries have methods that return other iterators. If you want to iterate over keys, values, or key/value pairs, you can explicitly call the `iterkeys()`, `itervalues()`, or `iteritems()` methods to get an appropriate iterator.

The `dict()` constructor can accept an iterator that returns a finite stream of (key, value) tuples:

```python
>>> L = [('Italy', 'Rome'), ('France', 'Paris'), ('US', 'Washington DC'), ('France', 'Paris')]
>>> dict(iter(L))
{'Italy': 'Rome', 'US': 'Washington DC', 'France': 'Paris'}
```

Files also support iteration by calling the `readline()` method until there are no more lines in the file. This means you can read each line of a file like this:

```python
for line in file:
    # do something for each line
...
```

Sets can take their contents from an iterable and let you iterate over the set's elements:

```python
S = set((2, 3, 5, 7, 11, 13))
for i in S:
    print i
```
Generator expressions and list comprehensions

Two common operations on an iterator’s output are 1) performing some operation for every element, 2) selecting a subset of elements that meet some condition. For example, given a list of strings, you might want to strip off trailing whitespace from each line or extract all the strings containing a given substring.

List comprehensions and generator expressions (short form: “listcomps” and “genexps”) are a concise notation for such operations, borrowed from the functional programming language Haskell (https://www.haskell.org/). You can strip all the whitespace from a stream of strings with the following code:

```python
line_list = [' line 1
', 'line 2 
', '...' ]

# Generator expression -- returns iterator
stripped_iter = (line.strip() for line in line_list)

# List comprehension -- returns list
stripped_list = [line.strip() for line in line_list]
```

You can select only certain elements by adding an "if" condition:

```python
stripped_list = [line.strip() for line in line_list
if line != '']
```

With a list comprehension, you get back a Python list; stripped_list is a list containing the resulting lines, not an iterator. Generator expressions return an iterator that computes the values as necessary, not needing to materialize all the values at once. This means that list comprehensions aren’t useful if you’re working with iterators that return an infinite stream or a very large amount of data. Generator expressions are preferable in these situations.
Generator expressions are surrounded by parentheses (“()”) and list comprehensions are surrounded by square brackets (“[]”). Generator expressions have the form:

```
(expression for expr in sequence1
    if condition1
    for expr2 in sequence2
    if condition2
    for expr3 in sequence3 ...
    if condition3
    for exprN in sequenceN
    if conditionN)
```

Again, for a list comprehension only the outside brackets are different (square brackets instead of parentheses).

The elements of the generated output will be the successive values of `expression`. The `if` clauses are all optional; if present, `expression` is only evaluated and added to the result when `condition` is true.

Generator expressions always have to be written inside parentheses, but the parentheses signalling a function call also count. If you want to create an iterator that will be immediately passed to a function you can write:

```
obj_total = sum(obj.count for obj in list_all_objects())
```

The `for...in` clauses contain the sequences to be iterated over. The sequences do not have to be the same length, because they are iterated over from left to right, **not** in parallel. For each element in `sequence1`, `sequence2` is looped over from the beginning. `sequence3` is then looped over for each resulting pair of elements from `sequence1` and `sequence2`.

To put it another way, a list comprehension or generator expression is equivalent to the following Python code:
for expr1 in sequence1:
    if not (condition1):
        continue  # Skip this element
for expr2 in sequence2:
    if not (condition2):
        continue  # Skip this element
...
for exprN in sequenceN:
    if not (conditionN):
        continue  # Skip this element

# Output the value of
# the expression.

This means that when there are multiple for...in clauses but no if clauses, the length of the resulting output will be equal to the product of the lengths of all the sequences. If you have two lists of length 3, the output list is 9 elements long:

```python
>>> seq1 = 'abc'
>>> seq2 = (1,2,3)
>>> [(x,y) for x in seq1 for y in seq2]
[('a', 1), ('a', 2), ('a', 3),
 ('b', 1), ('b', 2), ('b', 3),
 ('c', 1), ('c', 2), ('c', 3)]
```

To avoid introducing an ambiguity into Python’s grammar, if expression is creating a tuple, it must be surrounded with parentheses. The first list comprehension below is a syntax error, while the second one is correct:

```python
# Syntax error
[ x,y for x in seq1 for y in seq2]
# Correct
[ (x,y) for x in seq1 for y in seq2]
```
Generators

Generators are a special class of functions that simplify the task of writing iterators. Regular functions compute a value and return it, but generators return an iterator that returns a stream of values.

You’re doubtless familiar with how regular function calls work in Python or C. When you call a function, it gets a private namespace where its local variables are created. When the function reaches a `return` statement, the local variables are destroyed and the value is returned to the caller. A later call to the same function creates a new private namespace and a fresh set of local variables. But, what if the local variables weren’t thrown away on exiting a function? What if you could later resume the function where it left off? This is what generators provide; they can be thought of as resumable functions.

Here’s the simplest example of a generator function:

```python
def generate_ints(N):
    for i in range(N):
        yield i
```

Any function containing a `yield` keyword is a generator function; this is detected by Python’s `bytecode` compiler which compiles the function specially as a result.

When you call a generator function, it doesn’t return a single value; instead it returns a generator object that supports the iterator protocol. On executing the `yield` expression, the generator outputs the value of `i`, similar to a `return` statement. The big difference between `yield` and a `return` statement is that on reaching a `yield` the generator’s state of execution is suspended and local variables are preserved. On the next call to the generator’s `.next()` method, the function will resume executing.
Here's a sample usage of the `generate_ints()` generator:

```python
>>> gen = generate_ints(3)
>>> gen
<generator object generate_ints at ...>
>>> gen.next()
0
>>> gen.next()
1
>>> gen.next()
2
>>> gen.next()
Traceback (most recent call last):
  File "stdin", line 1, in ?
  File "stdin", line 2, in generate_ints
StopIteration
```

You could equally write `for i in generate_ints(5)`, or `a, b, c = generate_ints(3)`.

Inside a generator function, the `return` statement can only be used without a value, and signals the end of the procession of values; after executing a `return` the generator cannot return any further values. `return` with a value, such as `return 5`, is a syntax error inside a generator function. The end of the generator's results can also be indicated by raising `StopIteration` manually, or by just letting the flow of execution fall off the bottom of the function.

You could achieve the effect of generators manually by writing your own class and storing all the local variables of the generator as instance variables. For example, returning a list of integers could be done by setting `self.count` to 0, and having the `next()` method increment `self.count` and return it. However, for a moderately complicated generator, writing a corresponding class can be much messier.

The test suite included with Python's library, `test_generators.py`,
contains a number of more interesting examples. Here's one generator that implements an in-order traversal of a tree using generators recursively.

```python
# A recursive generator that generates Tree leaves in in-order.
def inorder(t):
    if t:
        for x in inorder(t.left):
            yield x

        yield t.label

        for x in inorder(t.right):
            yield x
```

Two other examples in `test_generators.py` produce solutions for the N-Queens problem (placing N queens on an NxN chess board so that no queen threatens another) and the Knight's Tour (finding a route that takes a knight to every square of an NxN chessboard without visiting any square twice).

### Passing values into a generator

In Python 2.4 and earlier, generators only produced output. Once a generator's code was invoked to create an iterator, there was no way to pass any new information into the function when its execution is resumed. You could hack together this ability by making the generator look at a global variable or by passing in some mutable object that callers then modify, but these approaches are messy.

In Python 2.5 there's a simple way to pass values into a generator. `yield` became an expression, returning a value that can be assigned to a variable or otherwise operated on:

```python
val = (yield i)
```
I recommend that you **always** put parentheses around a `yield` expression when you’re doing something with the returned value, as in the above example. The parentheses aren’t always necessary, but it’s easier to always add them instead of having to remember when they’re needed.

(PEP 342 explains the exact rules, which are that a `yield`-expression must always be parenthesized except when it occurs at the top-level expression on the right-hand side of an assignment. This means you can write `val = yield i` but have to use parentheses when there’s an operation, as in `val = (yield i) + 12`.)

Values are sent into a generator by calling its `send(value)` method. This method resumes the generator’s code and the `yield` expression returns the specified value. If the regular `next()` method is called, the `yield` returns `None`.

Here’s a simple counter that increments by 1 and allows changing the value of the internal counter.

```python
def counter (maximum):
    i = 0
    while i < maximum:
        val = (yield i)
        # If value provided, change counter
        if val is not None:
            i = val
        else:
            i += 1
```

And here’s an example of changing the counter:

```python
>>> it = counter(10)
>>> print it.next()
0
>>> print it.next()
1
>>> print it.send(8)
```
Because `yield` will often be returning `None`, you should always check for this case. Don’t just use its value in expressions unless you’re sure that the `send()` method will be the only method used to resume your generator function.

In addition to `send()`, there are two other new methods on generators:

- `throw(type, value=None, traceback=None)` is used to raise an exception inside the generator; the exception is raised by the `yield` expression where the generator’s execution is paused.

- `close()` raises a `GeneratorExit` exception inside the generator to terminate the iteration. On receiving this exception, the generator’s code must either raise `GeneratorExit` or `StopIteration`; catching the exception and doing anything else is illegal and will trigger a `RuntimeError`. `close()` will also be called by Python’s garbage collector when the generator is garbage-collected.

  If you need to run cleanup code when a `GeneratorExit` occurs, I suggest using a `try: ... finally:` suite instead of catching `GeneratorExit`.

The cumulative effect of these changes is to turn generators from one-way producers of information into both producers and consumers.
Generators also become **coroutines**, a more generalized form of subroutines. Subroutines are entered at one point and exited at another point (the top of the function, and a `return` statement), but coroutines can be entered, exited, and resumed at many different points (the `yield` statements).
Let's look in more detail at built-in functions often used with iterators.

Two of Python's built-in functions, `map()` and `filter()`, are somewhat obsolete; they duplicate the features of list comprehensions but return actual lists instead of iterators.

```
map(f, iterA, iterB, ...) returns a list containing f(iterA[0], iterB[0]), f(iterA[1], iterB[1]), f(iterA[2], iterB[2]), ...
```

```sh
>>> def upper(s):
...     return s.upper()

>>> map(upper, ['sentence', 'fragment'])
['SENTENCE', 'FRAGMENT']

>>> [upper(s) for s in ['sentence', 'fragment']]
['SENTENCE', 'FRAGMENT']
```

As shown above, you can achieve the same effect with a list comprehension. The `itertools.imap()` function does the same thing but can handle infinite iterators; it'll be discussed later, in the section on the `itertools` module.

```
filter(predicate, iter) returns a list that contains all the sequence elements that meet a certain condition, and is similarly duplicated by list comprehensions. A `predicate` is a function that returns the truth value of some condition; for use with `filter()`, the predicate must take a single value.
```

```
>>> def is_even(x):
...     return (x % 2) == 0

>>> filter(is_even, range(10))
```
This can also be written as a list comprehension:

```python
>>> [x for x in range(10) if is_even(x)]
[0, 2, 4, 6, 8]
```

`filter()` also has a counterpart in the `itertools` module, `itertools.ifilter()`, that returns an iterator and can therefore handle infinite sequences just as `itertools.imap()` can.

`reduce(func, iter, [initial_value])` doesn’t have a counterpart in the `itertools` module because it cumulatively performs an operation on all the iterable’s elements and therefore can’t be applied to infinite iterables. `func` must be a function that takes two elements and returns a single value. `reduce()` takes the first two elements A and B returned by the iterator and calculates `func(A, B)`. It then requests the third element, C, calculates `func(func(A, B), C)`, combines this result with the fourth element returned, and continues until the iterable is exhausted. If the iterable returns no values at all, a `TypeError` exception is raised. If the initial value is supplied, it’s used as a starting point and `func(initial_value, A)` is the first calculation.

```python
>>> import operator
>>> reduce(operator.concat, ['A', 'BB', 'C'])
'ABBC'
>>> reduce(operator.concat, [])
Traceback (most recent call last):
  ...TypeError: reduce() of empty sequence with no initial value
```

If you use `operator.add()` with `reduce()`, you’ll add up all the
elements of the iterable. This case is so common that there's a special built-in called `sum()` to compute it:

```python
>>> reduce(operator.add, [1,2,3,4], 0)
10
>>> sum([1,2,3,4])
10
>>> sum([])
0
```

For many uses of `reduce()`, though, it can be clearer to just write the obvious `for` loop:

```python
# Instead of:
product = reduce(operator.mul, [1,2,3], 1)

# You can write:
product = 1
for i in [1,2,3]:
    product *= i
```

`enumerate(iter)` counts off the elements in the iterable, returning 2-tuples containing the count and each element.

```python
>>> for item in enumerate(['subject', 'verb', 'object']):
...     print item
(0, 'subject')
(1, 'verb')
(2, 'object')
```

`enumerate()` is often used when looping through a list and recording the indexes at which certain conditions are met:

```python
f = open('data.txt', 'r')
for i, line in enumerate(f):
    if line.strip() == '':
        print 'Blank line at line #%i' % i
```

```python
sorted(iterable, [cmp=None], [key=None], [reverse=False])
```
collects all the elements of the iterable into a list, sorts the list, and returns the sorted result. The \texttt{cmp}, \texttt{key}, and \texttt{reverse} arguments are passed through to the constructed list’s \texttt{.sort()} method.

```python
>>> import random
>>> # Generate 8 random numbers between [0, 10000)
>>> rand_list = random.sample(range(10000), 8)
>>> rand_list
[769, 7953, 9828, 6431, 8442, 9878, 6213, 2207]
>>> sorted(rand_list)
[769, 2207, 6213, 6431, 7953, 8442, 9828, 9878]
>>> sorted(rand_list, reverse=True)
[9878, 9828, 8442, 7953, 6431, 6213, 2207, 769]
```

(For a more detailed discussion of sorting, see the Sorting mini-HOWTO in the Python wiki at https://wiki.python.org/moin/HowTo/Sorting.)

The \texttt{any(iter)} and \texttt{all(iter)} built-ins look at the truth values of an iterable's contents. \texttt{any()} returns \texttt{True} if any element in the iterable is a true value, and \texttt{all()} returns \texttt{True} if all of the elements are true values:

```python
>>> any([0,1,0])
True
>>> any([0,0,0])
False
>>> any([1,1,1])
True
>>> all([0,1,0])
False
>>> all([0,0,0])
False
>>> all([1,1,1])
True
```
Small functions and the lambda expression

When writing functional-style programs, you'll often need little functions that act as predicates or that combine elements in some way.

If there's a Python built-in or a module function that's suitable, you don't need to define a new function at all:

```python
stripped_lines = [line.strip() for line in lines]
existing_files = filter(os.path.exists, file_list)
```

If the function you need doesn't exist, you need to write it. One way to write small functions is to use the `lambda` statement. `lambda` takes a number of parameters and an expression combining these parameters, and creates a small function that returns the value of the expression:

```python
lowercase = lambda x: x.lower()
print_assign = lambda name, value: name + '=' + str(value)
adder = lambda x, y: x+y
```

An alternative is to just use the `def` statement and define a function in the usual way:

```python
def lowercase(x):
    return x.lower()

def print_assign(name, value):
    return name + '=' + str(value)

def adder(x,y):
    return x + y
```

Which alternative is preferable? That's a style question; my usual
course is to avoid using \texttt{lambda}.

One reason for my preference is that \texttt{lambda} is quite limited in the functions it can define. The result has to be computable as a single expression, which means you can’t have multiway if... elif... else comparisons or try... except statements. If you try to do too much in a \texttt{lambda} statement, you’ll end up with an overly complicated expression that’s hard to read. Quick, what’s the following code doing?

\begin{verbatim}
total = reduce(lambda a, b: (0, a[1] + b[1]), items)[1]
\end{verbatim}

You can figure it out, but it takes time to disentangle the expression to figure out what’s going on. Using a short nested \texttt{def} statements makes things a little bit better:

\begin{verbatim}
def combine (a, b):
    return (0, a[1] + b[1])
total = reduce(combine, items)[1]
\end{verbatim}

But it would be best of all if I had simply used a \texttt{for} loop:

\begin{verbatim}
total = 0
for a, b in items:
    total += b
\end{verbatim}

Or the \texttt{sum()} built-in and a generator expression:

\begin{verbatim}
total = sum(b for a,b in items)
\end{verbatim}

Many uses of \texttt{reduce()} are clearer when written as \texttt{for} loops.

Fredrik Lundh once suggested the following set of rules for refactoring uses of \texttt{lambda}:
1. Write a lambda function.
2. Write a comment explaining what the heck that lambda does.
3. Study the comment for a while, and think of a name that captures the essence of the comment.
4. Convert the lambda to a def statement, using that name.
5. Remove the comment.

I really like these rules, but you’re free to disagree about whether this lambda-free style is better.
The *itertools* module contains a number of commonly-used iterators as well as functions for combining several iterators. This section will introduce the module's contents by showing small examples.

The module's functions fall into a few broad classes:

- Functions that create a new iterator based on an existing iterator.
- Functions for treating an iterator’s elements as function arguments.
- Functions for selecting portions of an iterator’s output.
- A function for grouping an iterator’s output.

**Creating new iterators**

*itertools.count(n)* returns an infinite stream of integers, increasing by 1 each time. You can optionally supply the starting number, which defaults to 0:

```python
itertools.count() =>
  0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

tools.count(10) =>
  10, 11, 12, 13, 14, 15, 16, 17, 18, 19, ...
```

*itertools.cycle(iter)* saves a copy of the contents of a provided iterable and returns a new iterator that returns its elements from first to last. The new iterator will repeat these elements infinitely.

```python
itertools.cycle([1,2,3,4,5]) =>
  1, 2, 3, 4, 5, 1, 2, 3, 4, 5, ...
```
`itertools.repeat(elem, [n])` returns the provided element \( n \) times, or returns the element endlessly if \( n \) is not provided.

```python
itertools.repeat('abc') =>
  abc, abc, abc, abc, abc, abc, abc, abc, abc, ...
itertools.repeat('abc', 5) =>
  abc, abc, abc, abc, abc
```

`itertools.chain(iterA, iterB, ...)` takes an arbitrary number of iterables as input, and returns all the elements of the first iterator, then all the elements of the second, and so on, until all of the iterables have been exhausted.

```python
itertools.chain(["a", "b", "c"], (1, 2, 3)) =>
  a, b, c, 1, 2, 3
```

`itertools.izip(iterA, iterB, ...)` takes one element from each iterable and returns them in a tuple:

```python
itertools.izip(["a", "b", "c"], (1, 2, 3)) =>
  ("a", 1), ("b", 2), ("c", 3)
```

It's similar to the built-in `zip()` function, but doesn't construct an in-memory list and exhaust all the input iterators before returning; instead tuples are constructed and returned only if they're requested. (The technical term for this behaviour is lazy evaluation.)

This iterator is intended to be used with iterables that are all of the same length. If the iterables are of different lengths, the resulting stream will be the same length as the shortest iterable.

```python
itertools.izip(["a", "b"], (1, 2, 3)) =>
  ("a", 1), ("b", 2)
```

You should avoid doing this, though, because an element may be taken from the longer iterators and discarded. This means you can't
go on to use the iterators further because you risk skipping a discarded element.

```
import itertools

# itertools.islice(iter, [start], stop, [step]) returns a stream that's a slice of the iterator. With a single stop argument, it will return the first stop elements. If you supply a starting index, you'll get stop-start elements, and if you supply a value for step, elements will be skipped accordingly. Unlike Python's string and list slicing, you can't use negative values for start, stop, or step.

itertools.islice(range(10), 8) =>
  0, 1, 2, 3, 4, 5, 6, 7
itertools.islice(range(10), 2, 8) =>
  2, 3, 4, 5, 6, 7
itertools.islice(range(10), 2, 8, 2) =>
  2, 4, 6
```

```
# itertools.tee(iter, [n]) replicates an iterator; it returns n independent iterators that will all return the contents of the source iterator. If you don't supply a value for n, the default is 2. Replicating iterators requires saving some of the contents of the source iterator, so this can consume significant memory if the iterator is large and one of the new iterators is consumed more than the others.

itertools.tee(itertools.count()) =>
  iterA, iterB
where iterA ->
  0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
and iterB ->
  0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```

Calling functions on elements

Two functions are used for calling other functions on the contents of an iterable.
itertools.imap(f, iterA, iterB, ...) returns a stream containing
f(iterA[0], iterB[0]), f(iterA[1], iterB[1]), f(iterA[2], iterB[2]), ...:

```
import operator

itertools.imap(operator.add, [5, 6, 5], [1, 2, 3]) =>
6, 8, 8
```

The `operator` module contains a set of functions corresponding to
Python's operators. Some examples are `operator.add(a, b)` (adds
two values), `operator.ne(a, b)` (same as `a!=b`), and
`operator.attrgetter('id')` (returns a callable that fetches the "id"
attribute).

```
def is_even(x):
    return (x % 2) == 0

itertools.ifilter(is_even, itertools.count()) =>
0, 2, 4, 6, 8, 10, 12, 14, ...
```
**itertools.ifilterfalse(predicate, iter)** is the opposite, returning all elements for which the predicate returns false:

```python
itertools.ifilterfalse(is_even, itertools.count()) =>
    1, 3, 5, 7, 9, 11, 13, 15, ...
```

**itertools.takewhile(predicate, iter)** returns elements for as long as the predicate returns true. Once the predicate returns false, the iterator will signal the end of its results.

```python
def less_than_10(x):
    return (x < 10)

itertools.takewhile(less_than_10, itertools.count()) =>
    0, 1, 2, 3, 4, 5, 6, 7, 8, 9

itertools.takewhile(is_even, itertools.count()) =>
    0
```

**itertools.dropwhile(predicate, iter)** discards elements while the predicate returns true, and then returns the rest of the iterable’s results.

```python
itertools.dropwhile(less_than_10, itertools.count()) =>
    10, 11, 12, 13, 14, 15, 16, 17, 18, 19, ...

itertools.dropwhile(is_even, itertools.count()) =>
    1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
```

### Grouping elements

The last function I’ll discuss, **itertools.groupby(iter, key_func=None)**, is the most complicated. **key_func(elem)** is a function that can compute a key value for each element returned by the iterable. If you don’t supply a key function, the key is simply each element itself.
`groupby()` collects all the consecutive elements from the underlying iterable that have the same key value, and returns a stream of 2-tuples containing a key value and an iterator for the elements with that key.

```python
city_list = [('Decatur', 'AL'), ('Huntsville', 'AL'), ('Selma', 'AL'), ('Anchorage', 'AK'), ('Nome', 'AK'), ('Flagstaff', 'AZ'), ('Phoenix', 'AZ'), ('Tucson', 'AZ'), ...
```

def get_state((city, state)):
    return state

itertools.groupby(city_list, get_state) =>
    ('AL', iterator-1),
    ('AK', iterator-2),
    ('AZ', iterator-3), ...

where
iterator-1 =>
    ('Decatur', 'AL'), ('Huntsville', 'AL'), ('Selma', 'AL')
iterator-2 =>
    ('Anchorage', 'AK'), ('Nome', 'AK')
iterator-3 =>
    ('Flagstaff', 'AZ'), ('Phoenix', 'AZ'), ('Tucson', 'AZ')
```

`groupby()` assumes that the underlying iterable’s contents will already be sorted based on the key. Note that the returned iterators also use the underlying iterable, so you have to consume the results of iterator-1 before requesting iterator-2 and its corresponding key.
The **functools** module in Python 2.5 contains some higher-order functions. A **higher-order function** takes one or more functions as input and returns a new function. The most useful tool in this module is the **functools.partial()** function.

For programs written in a functional style, you'll sometimes want to construct variants of existing functions that have some of the parameters filled in. Consider a Python function `f(a, b, c);` you may wish to create a new function `g(b, c)` that's equivalent to `f(1, b, c);` you're filling in a value for one of `f()`'s parameters. This is called "partial function application".

The constructor for **partial** takes the arguments `(function, arg1, arg2, ... kwarg1=value1, kwarg2=value2)`. The resulting object is callable, so you can just call it to invoke `function` with the filled-in arguments.

Here's a small but realistic example:

```python
import functools

def log (message, subsystem):
    "Write the contents of 'message' to the specified subsystem"
    print '%s: %s' % (subsystem, message)
...

server_log = functools.partial(log, subsystem='server')
server_log('Unable to open socket')
```

The **operator** module was mentioned earlier. It contains a set of
functions corresponding to Python’s operators. These functions are often useful in functional-style code because they save you from writing trivial functions that perform a single operation.

Some of the functions in this module are:

- Math operations: `add()`, `sub()`, `mul()`, `div()`, `floordiv()`, `abs()`, ...
- Logical operations: `not()``, `truth()`.
- Bitwise operations: `and()`, `or()`, `invert()`.
- Comparisons: `eq()`, `ne()`, `lt()`, `le()`, `gt()`, and `ge()`.
- Object identity: `is()``, `is_not()`.

Consult the operator module’s documentation for a complete list.
Revision History and Acknowledgements

The author would like to thank the following people for offering suggestions, corrections and assistance with various drafts of this article: Ian Bicking, Nick Coghlan, Nick Efford, Raymond Hettinger, Jim Jewett, Mike Krell, Leandro Lameiro, Jussi Salmela, Collin Winter, Blake Winton.

Version 0.1: posted June 30 2006.

Version 0.11: posted July 1 2006. Typo fixes.

Version 0.2: posted July 10 2006. Merged genexp and listcomp sections into one. Typo fixes.

Version 0.21: Added more references suggested on the tutor mailing list.

Version 0.30: Adds a section on the functional module written by Collin Winter; adds short section on the operator module; a few other edits.
**General**

**Structure and Interpretation of Computer Programs**, by Harold Abelson and Gerald Jay Sussman with Julie Sussman. Full text at [https://mitpress.mit.edu/sicp/](https://mitpress.mit.edu/sicp/). In this classic textbook of computer science, chapters 2 and 3 discuss the use of sequences and streams to organize the data flow inside a program. The book uses Scheme for its examples, but many of the design approaches described in these chapters are applicable to functional-style Python code.

[http://www.defmacro.org/ramblings/fp.html](http://www.defmacro.org/ramblings/fp.html): A general introduction to functional programming that uses Java examples and has a lengthy historical introduction.

**Python-specific**

Mertz also wrote a 3-part series of articles on functional programming for IBM’s DeveloperWorks site; see

**PEP 342**: “Coroutines via Enhanced Generators” describes the new generator features in Python 2.5.
Basic Logging Tutorial

Logging is a means of tracking events that happen when some software runs. The software's developer adds logging calls to their code to indicate that certain events have occurred. An event is described by a descriptive message which can optionally contain variable data (i.e. data that is potentially different for each occurrence of the event). Events also have an importance which the developer ascribes to the event; the importance can also be called the level or severity.

When to use logging

Logging provides a set of convenience functions for simple logging usage. These are `debug()`, `info()`, `warning()`, `error()` and `critical()`. To determine when to use logging, see the table below, which states, for each of a set of common tasks, the best tool to use for it.

<table>
<thead>
<tr>
<th>Task you want to perform</th>
<th>The best tool for the task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display console output for ordinary usage of a command line script or program</td>
<td><code>print()</code></td>
</tr>
<tr>
<td>Report events that occur during normal operation of a program (e.g. for status monitoring or fault investigation)</td>
<td><code>logging.info()</code> (or <code>logging.debug()</code> for very detailed output for diagnostic purposes)</td>
</tr>
<tr>
<td>Issue a warning regarding a particular runtime event</td>
<td><code>warnings.warn()</code> in library code if the issue is avoidable and the client application should be modified to eliminate the warning</td>
</tr>
<tr>
<td></td>
<td><code>logging.warning()</code> if there is</td>
</tr>
</tbody>
</table>
nothing the client application can do about the situation, but the event should still be noted

<table>
<thead>
<tr>
<th>Report an error regarding a particular runtime event</th>
<th>Raise an exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report suppression of an error without raising an exception (e.g. error handler in a long-running server process)</td>
<td><code>logging.error()</code>, <code>logging.exception()</code> or <code>logging.critical()</code> as appropriate for the specific error and application domain</td>
</tr>
</tbody>
</table>

The logging functions are named after the level or severity of the events they are used to track. The standard levels and their applicability are described below (in increasing order of severity):

<table>
<thead>
<tr>
<th>Level</th>
<th>When it’s used</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG</td>
<td>Detailed information, typically of interest only when diagnosing problems.</td>
</tr>
<tr>
<td>INFO</td>
<td>Confirmation that things are working as expected.</td>
</tr>
<tr>
<td>WARNING</td>
<td>An indication that something unexpected happened, or indicative of some problem in the near future (e.g. ‘disk space low’). The software is still working as expected.</td>
</tr>
<tr>
<td>ERROR</td>
<td>Due to a more serious problem, the software has not been able to perform some function.</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>A serious error, indicating that the program itself may be unable to continue running.</td>
</tr>
</tbody>
</table>

The default level is **WARNING**, which means that only events of this level and above will be tracked, unless the logging package is configured to do otherwise.

Events that are tracked can be handled in different ways. The simplest way of handling tracked events is to print them to the console. Another common way is to write them to a disk file.
**A simple example**

A very simple example is:

```python
import logging
logging.warning('Watch out!')  # will print a message to the console
logging.info('I told you so')  # will not print anything
```

If you type these lines into a script and run it, you'll see:

```
WARNING:root:Watch out!
```

printed out on the console. The `INFO` message doesn’t appear because the default level is `WARNING`. The printed message includes the indication of the level and the description of the event provided in the logging call, i.e. ‘Watch out!’. Don’t worry about the ‘root’ part for now: it will be explained later. The actual output can be formatted quite flexibly if you need that; formatting options will also be explained later.

**Logging to a file**

A very common situation is that of recording logging events in a file, so let’s look at that next. Be sure to try the following in a newly-started Python interpreter, and don’t just continue from the session described above:

```python
import logging
logging.basicConfig(filename='example.log', level=logging.DEBUG)
logging.debug('This message should go to the log file')
logging.info('So should this')
logging.warning('And this, too')
```

And now if we open the file and look at what we have, we should find the log messages:
This example also shows how you can set the logging level which acts as the threshold for tracking. In this case, because we set the threshold to DEBUG, all of the messages were printed.

If you want to set the logging level from a command-line option such as:

```bash
--log=INFO
```

and you have the value of the parameter passed for `--log` in some variable `loglevel`, you can use:

```python
getattr(logging, loglevel.upper())
```

to get the value which you’ll pass to `basicConfig()` via the `level` argument. You may want to error check any user input value, perhaps as in the following example:

```python
# assuming loglevel is bound to the string value obtained from # command line argument. Convert to upper case to allow the use # specify --log=DEBUG or --log=debug numeric_level = getattr(logging, loglevel.upper(), None) if not isinstance(numeric_level, int):
    raise ValueError('Invalid log level: %s' % loglevel) logging.basicConfig(level=numeric_level, ...)
```

The call to `basicConfig()` should come before any calls to `debug()`, `info()` etc. As it’s intended as a one-off simple configuration facility, only the first call will actually do anything: subsequent calls are effectively no-ops.

If you run the above script several times, the messages from
successive runs are appended to the file *example.log*. If you want each run to start afresh, not remembering the messages from earlier runs, you can specify the *filemode* argument, by changing the call in the above example to:

```
logging.basicConfig(filename='example.log', filemode='w', level=logging.INFO)
```

The output will be the same as before, but the log file is no longer appended to, so the messages from earlier runs are lost.

## Logging from multiple modules

If your program consists of multiple modules, here’s an example of how you could organize logging in it:

```
# myapp.py
import logging
import mylib

def main():
    logging.basicConfig(filename='myapp.log', level=logging.INFO)
    logging.info('Started')
    mylib.do_something()
    logging.info('Finished')

if __name__ == '__main__':
    main()
```

```
# mylib.py
import logging

def do_something():
    logging.info('Doing something')
```

If you run *myapp.py*, you should see this in *myapp.log*:

```
INFO:root:Started
INFO:root:Doing something
```
which is hopefully what you were expecting to see. You can
generalize this to multiple modules, using the pattern in mylib.py.
Note that for this simple usage pattern, you won't know, by looking in
the log file, where in your application your messages came from, 
apart from looking at the event description. If you want to track the
location of your messages, you'll need to refer to the documentation
beyond the tutorial level – see Advanced Logging Tutorial.

Logging variable data

To log variable data, use a format string for the event description
message and append the variable data as arguments. For example:

```python
import logging
logging.warning('%s before you %s', 'Look', 'leap!')
```

will display:

```
WARNING:root:Look before you leap!
```

As you can see, merging of variable data into the event description
message uses the old, %-style of string formatting. This is for
backwards compatibility: the logging package pre-dates newer
formatting options such as `str.format()` and `string.Template`.
These newer formatting options are supported, but exploring them is
outside the scope of this tutorial.

Changing the format of displayed messages

To change the format which is used to display messages, you need
to specify the format you want to use:

```python
import logging
```
logging.basicConfig(format='%(levelname)s:%(message)s', level=logging.DEBUG)
logging.debug('This message should appear on the console')
logging.info('So should this')
logging.warning('And this, too')

which would print:

DEBUG:This message should appear on the console
INFO:So should this
WARNING:And this, too

Notice that the ‘root’ which appeared in earlier examples has disappeared. For a full set of things that can appear in format strings, you can refer to the documentation for LogRecord attributes, but for simple usage, you just need thelevelname(severity), message(event description, including variable data) and perhaps to display when the event occurred. This is described in the next section.

Displaying the date/time in messages

To display the date and time of an event, you would place ‘% (asctime)s’ in your format string:

import logging
logging.basicConfig(format='%s %s', datefmt='%Y-%m-%d %H:%M:%S')
logging.warning('is when this event was logged.')

which should print something like this:

2010-12-12 11:41:42,612 is when this event was logged.

The default format for date/time display (shown above) is ISO8601. If you need more control over the formatting of the date/time, provide a datefmt argument to basicConfig, as in this example:
logging.warning('is when this event was logged.')

which would display something like this:

12/12/2010 11:46:36 AM is when this event was logged.

The format of the datefmt argument is the same as supported by time.strftime().

Next Steps

That concludes the basic tutorial. It should be enough to get you up and running with logging. There’s a lot more that the logging package offers, but to get the best out of it, you’ll need to invest a little more of your time in reading the following sections. If you’re ready for that, grab some of your favourite beverage and carry on.

If your logging needs are simple, then use the above examples to incorporate logging into your own scripts, and if you run into problems or don’t understand something, please post a question on the comp.lang.python Usenet group (available at https://groups.google.com/group/comp.lang.python) and you should receive help before too long.

Still here? You can carry on reading the next few sections, which provide a slightly more advanced/in-depth tutorial than the basic one above. After that, you can take a look at the Logging Cookbook.
Advanced Logging Tutorial

The logging library takes a modular approach and offers several categories of components: loggers, handlers, filters, and formatters.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

Log event information is passed between loggers, handlers, filters and formatters in a `LogRecord` instance.

Logging is performed by calling methods on instances of the `Logger` class (hereafter called `loggers`). Each instance has a name, and they are conceptually arranged in a namespace hierarchy using dots (periods) as separators. For example, a logger named ‘scan’ is the parent of loggers ‘scan.text’, ‘scan.html’ and ‘scan.pdf’. Logger names can be anything you want, and indicate the area of an application in which a logged message originates.

A good convention to use when naming loggers is to use a module-level logger, in each module which uses logging, named as follows:

```python
logger = logging.getLogger(__name__)
```

This means that logger names track the package/module hierarchy, and it’s intuitively obvious where events are logged just from the logger name.

The root of the hierarchy of loggers is called the root logger. That’s the logger used by the functions `debug()`, `info()`, `warning()`, `error()`
and **critical()**, which just call the same-named method of the root logger. The functions and the methods have the same signatures. The root logger’s name is printed as ‘root’ in the logged output.

It is, of course, possible to log messages to different destinations. Support is included in the package for writing log messages to files, HTTP GET/POST locations, email via SMTP, generic sockets, or OS-specific logging mechanisms such as syslog or the Windows NT event log. Destinations are served by *handler* classes. You can create your own log destination class if you have special requirements not met by any of the built-in handler classes.

By default, no destination is set for any logging messages. You can specify a destination (such as console or file) by using `basicConfig()` as in the tutorial examples. If you call the functions `debug()`, `info()`, `warning()`, `error()` and `critical()`, they will check to see if no destination is set; and if one is not set, they will set a destination of the console (`sys.stderr`) and a default format for the displayed message before delegating to the root logger to do the actual message output.

The default format set by `basicConfig()` for messages is:

```
severity:logger name:message
```

You can change this by passing a format string to `basicConfig()` with the *format* keyword argument. For all options regarding how a format string is constructed, see [Formatter Objects](#).

---

**Logging Flow**

The flow of log event information in loggers and handlers is illustrated in the following diagram.
Loggers

Logger objects have a threelfold job. First, they expose several methods to application code so that applications can log messages at runtime. Second, logger objects determine which log messages to act upon based upon severity (the default filtering facility) or filter objects. Third, logger objects pass along relevant log messages to all interested log handlers.

The most widely used methods on logger objects fall into two categories: configuration and message sending.

These are the most common configuration methods:
• **Logger.setLevel()** specifies the lowest-severity log message a logger will handle, where debug is the lowest built-in severity level and critical is the highest built-in severity. For example, if the severity level is INFO, the logger will handle only INFO, WARNING, ERROR, and CRITICAL messages and will ignore DEBUG messages.

• **Logger.addHandler()** and **Logger.removeHandler()** add and remove handler objects from the logger object. Handlers are covered in more detail in [Handlers](#).

• **Logger.addFilter()** and **Logger.removeFilter()** add and remove filter objects from the logger object. Filters are covered in more detail in [Filter Objects](#).

You don’t need to always call these methods on every logger you create. See the last two paragraphs in this section.

With the logger object configured, the following methods create log messages:

• **Logger.debug(), Logger.info(), Logger.warning(), Logger.error(), and Logger.critical()** all create log records with a message and a level that corresponds to their respective method names. The message is actually a format string, which may contain the standard string substitution syntax of %s, %d, %f, and so on. The rest of their arguments is a list of objects that correspond with the substitution fields in the message. With regard to **kwargs, the logging methods care only about a keyword of exc_info and use it to determine whether to log exception information.

• **Logger.exception()** creates a log message similar to **Logger.error()**. The difference is that **Logger.exception()** dumps a stack trace along with it. Call this method only from an exception handler.

• **Logger.log()** takes a log level as an explicit argument. This is a
little more verbose for logging messages than using the log level convenience methods listed above, but this is how to log at custom log levels.

`getLogger()` returns a reference to a logger instance with the specified name if it is provided, or `root` if not. The names are period-separated hierarchical structures. Multiple calls to `getLogger()` with the same name will return a reference to the same logger object. Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`.

Loggers have a concept of *effective level*. If a level is not explicitly set on a logger, the level of its parent is used instead as its effective level. If the parent has no explicit level set, its parent is examined, and so on - all ancestors are searched until an explicitly set level is found. The root logger always has an explicit level set (`WARNING` by default). When deciding whether to process an event, the effective level of the logger is used to determine whether the event is passed to the logger’s handlers.

Child loggers propagate messages up to the handlers associated with their ancestor loggers. Because of this, it is unnecessary to define and configure handlers for all the loggers an application uses. It is sufficient to configure handlers for a top-level logger and create child loggers as needed. (You can, however, turn off propagation by setting the `propagate` attribute of a logger to `False`.)

**Handlers**

Handler objects are responsible for dispatching the appropriate log messages (based on the log messages’ severity) to the handler’s specified destination. Logger objects can add zero or more handler
objects to themselves with an `addHandler()` method. As an example scenario, an application may want to send all log messages to a log file, all log messages of error or higher to stdout, and all messages of critical to an email address. This scenario requires three individual handlers where each handler is responsible for sending messages of a specific severity to a specific location.

The standard library includes quite a few handler types (see Useful Handlers); the tutorials use mainly `StreamHandler` and `FileHandler` in its examples.

There are very few methods in a handler for application developers to concern themselves with. The only handler methods that seem relevant for application developers who are using the built-in handler objects (that is, not creating custom handlers) are the following configuration methods:

- The `setLevel()` method, just as in logger objects, specifies the lowest severity that will be dispatched to the appropriate destination. Why are there two `setLevel()` methods? The level set in the logger determines which severity of messages it will pass to its handlers. The level set in each handler determines which messages that handler will send on.
- `setFormatter()` selects a Formatter object for this handler to use.
- `addFilter()` and `removeFilter()` respectively configure and deconfigure filter objects on handlers.

Application code should not directly instantiate and use instances of `Handler`. Instead, the `Handler` class is a base class that defines the interface that all handlers should have and establishes some default behavior that child classes can use (or override).

---

**Formatters**
Formatter objects configure the final order, structure, and contents of the log message. Unlike the base `logging.Handler` class, application code may instantiate formatter classes, although you could likely subclass the formatter if your application needs special behavior. The constructor takes two optional arguments – a message format string and a date format string.

```
logging.Formatter.__init__(fmt=None, datefmt=None)
```

If there is no message format string, the default is to use the raw message. If there is no date format string, the default date format is:

```
%Y-%m-%d %H:%M:%S
```

with the milliseconds tacked on at the end.

The message format string uses `%(<dictionary key>)s` styled string substitution; the possible keys are documented in `LogRecord attributes`.

The following message format string will log the time in a human-readable format, the severity of the message, and the contents of the message, in that order:

```
'%(asctime)s - %(levelname)s - %(message)s'
```

Formatters use a user-configurable function to convert the creation time of a record to a tuple. By default, `time.localtime()` is used; to change this for a particular formatter instance, set the `converter` attribute of the instance to a function with the same signature as `time.localtime()` or `time.gmtime()`. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the Formatter class (to `time.gmtime` for GMT display).
Configuring Logging

Programmers can configure logging in three ways:

1. Creating loggers, handlers, and formatters explicitly using Python code that calls the configuration methods listed above.
2. Creating a logging config file and reading it using the `fileConfig()` function.
3. Creating a dictionary of configuration information and passing it to the `dictConfig()` function.

For the reference documentation on the last two options, see `Configuration functions`. The following example configures a very simple logger, a console handler, and a simple formatter using Python code:

```python
import logging

# create logger
logger = logging.getLogger('simple_example')
logger.setLevel(logging.DEBUG)

# create console handler and set level to debug
ch = logging.StreamHandler()
ch.setLevel(logging.DEBUG)

# create formatter
formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s - %(message)s')

# add formatter to ch
ch.setFormatter(formatter)

# add ch to logger
logger.addHandler(ch)

# 'application' code
logger.debug('debug message')
logger.info('info message')
logger.warn('warn message')
logger.error('error message')
logger.critical('critical message')
```
Running this module from the command line produces the following output:

$ python simple_logging_module.py
2005-03-19 15:10:26,618 - simple_example - DEBUG - debug message
2005-03-19 15:10:26,620 - simple_example - INFO - info message
2005-03-19 15:10:26,695 - simple_example - WARNING - warn message
2005-03-19 15:10:26,697 - simple_example - ERROR - error message
2005-03-19 15:10:26,773 - simple_example - CRITICAL - critical message

The following Python module creates a logger, handler, and formatter nearly identical to those in the example listed above, with the only difference being the names of the objects:

```python
ing
import logging
import logging.config

logging.config.fileConfig('logging.conf')

# create logger
logger = logging.getLogger('simpleExample')

# 'application' code
logger.debug('debug message')
logger.info('info message')
logger.warn('warn message')
logger.error('error message')
logger.critical('critical message')
```

Here is the logging.conf file:

```
[loggers]
keys=root,simpleExample

[handlers]
keys=consoleHandler

[formatters]
keys=simpleFormatter
```
The output is nearly identical to that of the non-config-file-based example:

```
$ python simple_logging_config.py
2005-03-19 15:38:55,977 - simpleExample - DEBUG - debug message
2005-03-19 15:38:55,979 - simpleExample - INFO - info message
2005-03-19 15:38:56,054 - simpleExample - WARNING - warn message
2005-03-19 15:38:56,055 - simpleExample - ERROR - error message
2005-03-19 15:38:56,130 - simpleExample - CRITICAL - critical message
```

You can see that the config file approach has a few advantages over the Python code approach, mainly separation of configuration and code and the ability of noncoders to easily modify the logging properties.

**Warning:** The `fileConfig()` function takes a default parameter, `disable_existing_loggers`, which defaults to `True` for reasons of backward compatibility. This may or may not be what you want, since it will cause any loggers existing before the `fileConfig()` call to be disabled unless they (or an ancestor) are explicitly named in
the configuration. Please refer to the reference documentation for more information, and specify False for this parameter if you wish.

The dictionary passed to dictConfig() can also specify a Boolean value with key disable_existing_loggers, which if not specified explicitly in the dictionary also defaults to being interpreted as True. This leads to the logger-disabling behaviour described above, which may not be what you want - in which case, provide the key explicitly with a value of False.

Note that the class names referenced in config files need to be either relative to the logging module, or absolute values which can be resolved using normal import mechanisms. Thus, you could use either WatchedFileHandler (relative to the logging module) or mypackage.mymodule.MyHandler (for a class defined in package mypackage and module mymodule, where mypackage is available on the Python import path).

In Python 2.7, a new means of configuring logging has been introduced, using dictionaries to hold configuration information. This provides a superset of the functionality of the config-file-based approach outlined above, and is the recommended configuration method for new applications and deployments. Because a Python dictionary is used to hold configuration information, and since you can populate that dictionary using different means, you have more options for configuration. For example, you can use a configuration file in JSON format, or, if you have access to YAML processing functionality, a file in YAML format, to populate the configuration dictionary. Or, of course, you can construct the dictionary in Python code, receive it in pickled form over a socket, or use whatever approach makes sense for your application.

Here's an example of the same configuration as above, in YAML format for the new dictionary-based approach:
For more information about logging using a dictionary, see Configuration functions.

**What happens if no configuration is provided**

If no logging configuration is provided, it is possible to have a situation where a logging event needs to be output, but no handlers can be found to output the event. The behaviour of the logging package in these circumstances is dependent on the Python version.

For Python 2.x, the behaviour is as follows:

- If `logging.raiseExceptions` is `False` (production mode), the event is silently dropped.
- If `logging.raiseExceptions` is `True` (development mode), a message ‘No handlers could be found for logger X.Y.Z’ is printed once.

**Configuring Logging for a Library**
When developing a library which uses logging, you should take care to document how the library uses logging - for example, the names of loggers used. Some consideration also needs to be given to its logging configuration. If the using application does not configure logging, and library code makes logging calls, then (as described in the previous section) an error message will be printed to \texttt{sys.stderr}.

If for some reason you \textit{don't} want this message printed in the absence of any logging configuration, you can attach a do-nothing handler to the top-level logger for your library. This avoids the message being printed, since a handler will be always be found for the library's events: it just doesn't produce any output. If the library user configures logging for application use, presumably that configuration will add some handlers, and if levels are suitably configured then logging calls made in library code will send output to those handlers, as normal.

A do-nothing handler is included in the logging package: \texttt{NullHandler} (since Python 2.7). An instance of this handler could be added to the top-level logger of the logging namespace used by the library \textit{(if you want to prevent an error message being output to \texttt{sys.stderr} in the absence of logging configuration)}. If all logging by a library \texttt{foo} is done using loggers with names matching `foo.x', `foo.x.y', etc. then the code:

```python
import logging
logging.getLogger('foo').addHandler(logging.NullHandler())
```

should have the desired effect. If an organisation produces a number of libraries, then the logger name specified can be `orgname.foo' rather than just `foo'.

\textbf{Note:} It is strongly advised that you \textit{do not add any handlers other than NullHandler} to your library's loggers. This is because the configuration of handlers is the prerogative of the application.
developer who uses your library. The application developer knows their target audience and what handlers are most appropriate for their application: if you add handlers ‘under the hood’, you might well interfere with their ability to carry out unit tests and deliver logs which suit their requirements.
Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

<table>
<thead>
<tr>
<th>Level</th>
<th>Numeric value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRITICAL</td>
<td>50</td>
</tr>
<tr>
<td>ERROR</td>
<td>40</td>
</tr>
<tr>
<td>WARNING</td>
<td>30</td>
</tr>
<tr>
<td>INFO</td>
<td>20</td>
</tr>
<tr>
<td>DEBUG</td>
<td>10</td>
</tr>
<tr>
<td>NOTSET</td>
<td>0</td>
</tr>
</tbody>
</table>

Levels can also be associated with loggers, being set either by the developer or through loading a saved logging configuration. When a logging method is called on a logger, the logger compares its own level with the level associated with the method call. If the logger's level is higher than the method call's, no logging message is actually generated. This is the basic mechanism controlling the verbosity of logging output.

Logging messages are encoded as instances of the LogRecord class. When a logger decides to actually log an event, a LogRecord instance is created from the logging message.

Logging messages are subjected to a dispatch mechanism through the use of handlers, which are instances of subclasses of the Handler class. Handlers are responsible for ensuring that a logged message (in the form of a LogRecord) ends up in a particular location.
(or set of locations) which is useful for the target audience for that message (such as end users, support desk staff, system administrators, developers). Handlers are passed LogRecord instances intended for particular destinations. Each logger can have zero, one or more handlers associated with it (via the addHandler() method of Logger). In addition to any handlers directly associated with a logger, all handlers associated with all ancestors of the logger are called to dispatch the message (unless the propagate flag for a logger is set to a false value, at which point the passing to ancestor handlers stops).

Just as for loggers, handlers can have levels associated with them. A handler's level acts as a filter in the same way as a logger's level does. If a handler decides to actually dispatch an event, the emit() method is used to send the message to its destination. Most user-defined subclasses of Handler will need to override this emit().

### Custom Levels

Defining your own levels is possible, but should not be necessary, as the existing levels have been chosen on the basis of practical experience. However, if you are convinced that you need custom levels, great care should be exercised when doing this, and it is possibly a very bad idea to define custom levels if you are developing a library. That's because if multiple library authors all define their own custom levels, there is a chance that the logging output from such multiple libraries used together will be difficult for the using developer to control and/or interpret, because a given numeric value might mean different things for different libraries.
Useful Handlers

In addition to the base Handler class, many useful subclasses are provided:

1. **StreamHandler** instances send messages to streams (file-like objects).
2. **FileHandler** instances send messages to disk files.
3. **BaseRotatingHandler** is the base class for handlers that rotate log files at a certain point. It is not meant to be instantiated directly. Instead, use **RotatingFileHandler** or **TimedRotatingFileHandler**.
4. **RotatingFileHandler** instances send messages to disk files, with support for maximum log file sizes and log file rotation.
5. **TimedRotatingFileHandler** instances send messages to disk files, rotating the log file at certain timed intervals.
6. **SocketHandler** instances send messages to TCP/IP sockets.
7. **DatagramHandler** instances send messages to UDP sockets.
8. **SMTPHandler** instances send messages to a designated email address.
9. **SysLogHandler** instances send messages to a Unix syslog daemon, possibly on a remote machine.
10. **NTEventLogHandler** instances send messages to a Windows NT/2000/XP event log.
11. **MemoryHandler** instances send messages to a buffer in memory, which is flushed whenever specific criteria are met.
12. **HTTPHandler** instances send messages to an HTTP server using either GET or POST semantics.
13. **WatchedFileHandler** instances watch the file they are logging to. If the file changes, it is closed and reopened using the file name. This handler is only useful on Unix-like systems; Windows does
not support the underlying mechanism used.

14. **NullHandler** instances do nothing with error messages. They are used by library developers who want to use logging, but want to avoid the ‘No handlers could be found for logger XXX’ message which can be displayed if the library user has not configured logging. See Configuring Logging for a Library for more information.

*New in version 2.7:* The **NullHandler** class.

The **NullHandler**, **StreamHandler** and **FileHandler** classes are defined in the core logging package. The other handlers are defined in a sub-module, **logging.handlers**. (There is also another sub-module, **logging.config**, for configuration functionality.)

Logged messages are formatted for presentation through instances of the **Formatter** class. They are initialized with a format string suitable for use with the % operator and a dictionary.

For formatting multiple messages in a batch, instances of **BufferingFormatter** can be used. In addition to the format string (which is applied to each message in the batch), there is provision for header and trailer format strings.

When filtering based on logger level and/or handler level is not enough, instances of **Filter** can be added to both **Logger** and **Handler** instances (through their **addFilter()** method). Before deciding to process a message further, both loggers and handlers consult all their filters for permission. If any filter returns a false value, the message is not processed further.

The basic **Filter** functionality allows filtering by specific logger name. If this feature is used, messages sent to the named logger and its children are allowed through the filter, and all others dropped.
Exceptions raised during logging

The logging package is designed to swallow exceptions which occur while logging in production. This is so that errors which occur while handling logging events - such as logging misconfiguration, network or other similar errors - do not cause the application using logging to terminate prematurely.

SystemExit and KeyboardInterrupt exceptions are never swallowed. Other exceptions which occur during the emit() method of a Handler subclass are passed to its handleError() method.

The default implementation of handleError() in Handler checks to see if a module-level variable, raiseExceptions, is set. If set, a traceback is printed to sys.stderr. If not set, the exception is swallowed.

**Note:** The default value of raiseExceptions is True. This is because during development, you typically want to be notified of any exceptions that occur. It’s advised that you set raiseExceptions to False for production usage.
Using arbitrary objects as messages

In the preceding sections and examples, it has been assumed that the message passed when logging the event is a string. However, this is not the only possibility. You can pass an arbitrary object as a message, and its `__str__()` method will be called when the logging system needs to convert it to a string representation. In fact, if you want to, you can avoid computing a string representation altogether - for example, the `SocketHandler` emits an event by pickling it and sending it over the wire.
Optimization

Formatting of message arguments is deferred until it cannot be avoided. However, computing the arguments passed to the logging method can also be expensive, and you may want to avoid doing it if the logger will just throw away your event. To decide what to do, you can call the `isEnabledFor()` method which takes a level argument and returns true if the event would be created by the Logger for that level of call. You can write code like this:

```python
if logger.isEnabledFor(logging.DEBUG):
    logger.debug('Message with %s, %s', expensive_func1(), expensive_func2())
```

so that if the logger's threshold is set above `DEBUG`, the calls to `expensive_func1()` and `expensive_func2()` are never made.

**Note:** In some cases, `isEnabledFor()` can itself be more expensive than you’d like (e.g. for deeply nested loggers where an explicit level is only set high up in the logger hierarchy). In such cases (or if you want to avoid calling a method in tight loops), you can cache the result of a call to `isEnabledFor()` in a local or instance variable, and use that instead of calling the method each time. Such a cached value would only need to be recomputed when the logging configuration changes dynamically while the application is running (which is not all that common).

There are other optimizations which can be made for specific applications which need more precise control over what logging information is collected. Here's a list of things you can do to avoid processing during logging which you don’t need:

<table>
<thead>
<tr>
<th>What you don’t want to collect</th>
<th>How to avoid collecting it</th>
</tr>
</thead>
</table>

Information about where calls were made from.

Set `logging._srcfile` to `None`. This avoids calling `sys._getframe()`, which may help to speed up your code in environments like PyPy (which can’t speed up code that uses `sys._getframe()`).

Threading information.

Set `logging.logThreads` to `0`.

Process information.

Set `logging.logProcesses` to `0`.

Also note that the core logging module only includes the basic handlers. If you don’t import `logging.handlers` and `logging.config`, they won’t take up any memory.

A logging cookbook
Logging Cookbook

Author: Vinay Sajip <vinay_sajip at red-dove dot com>

This page contains a number of recipes related to logging, which have been found useful in the past.
Using logging in multiple modules

Multiple calls to `logging.getLogger('someLogger')` return a reference to the same logger object. This is true not only within the same module, but also across modules as long as it is in the same Python interpreter process. It is true for references to the same object; additionally, application code can define and configure a parent logger in one module and create (but not configure) a child logger in a separate module, and all logger calls to the child will pass up to the parent. Here is a main module:

```python
import logging
import auxiliary_module

# create logger with 'spam_application'
logger = logging.getLogger('spam_application')
logger.setLevel(logging.DEBUG)
# create file handler which logs even debug messages
fh = logging.FileHandler('spam.log')
fh.setLevel(logging.DEBUG)
# create console handler with a higher log level
ch = logging.StreamHandler()
ch.setLevel(logging.ERROR)
# create formatter and add it to the handlers
formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s - %(message)s')
fh.setFormatter(formatter)
ch.setFormatter(formatter)
# add the handlers to the logger
logger.addHandler(fh)
logger.addHandler(ch)

logger.info('creating an instance of auxiliary_module.Auxiliary')
a = auxiliary_module.Auxiliary()
logger.info('created an instance of auxiliary_module.Auxiliary')
logger.info('calling auxiliary_module.Auxiliary.do_something')
a.do_something()
logger.info('finished auxiliary_module.Auxiliary.do_something')
logger.info('calling auxiliary_module.some_function()')
auxiliary_module.some_function()
logger.info('done with auxiliary_module.some_function()')
```
Here is the auxiliary module:

```python
import logging

# create logger
module_logger = logging.getLogger('spam_application.auxiliary')

class Auxiliary:
    def __init__(self):
        self.logger = logging.getLogger('spam_application.auxiliary.Auxiliary')
        self.logger.info('creating an instance of Auxiliary')

    def do_something(self):
        self.logger.info('doing something')
        a = 1 + 1
        self.logger.info('done doing something')

def some_function():
    module_logger.info('received a call to "some_function"')
```

The output looks like this:

```
2005-03-23 23:47:11,671 - spam_application - INFO - calling auxiliary_module.some_function()
2005-03-23 23:47:11,672 - spam_application.auxiliary - INFO - received a call to 'some_function'
2005-03-23 23:47:11,673 - spam_application - INFO - done with auxiliary_module.some_function()
```
Logging from multiple threads

Logging from multiple threads requires no special effort. The following example shows logging from the main (initial) thread and another thread:

```python
import logging
import threading
import time

def worker(arg):
    while not arg['stop']:
        logging.debug('Hi from myfunc')
        time.sleep(0.5)

def main():
    logging.basicConfig(level=logging.DEBUG, format='%({relativeCreated}6d info = {'stop': False}
    thread = threading.Thread(target=worker, args=(info,))
    thread.start()
    while True:
        try:
            logging.debug('Hello from main')
            time.sleep(0.75)
        except KeyboardInterrupt:
            info['stop'] = True
            break
    thread.join()

if __name__ == '__main__':
    main()
```

When run, the script should print something like the following:

```
0 Thread-1 Hi from myfunc
3 MainThread Hello from main
505 Thread-1 Hi from myfunc
755 MainThread Hello from main
1007 Thread-1 Hi from myfunc
1597 MainThread Hello from main
1508 Thread-1 Hi from myfunc
```
This shows the logging output interspersed as one might expect. This approach works for more threads than shown here, of course.
Multiple handlers and formatters

Loggers are plain Python objects. The `addHandler()` method has no minimum or maximum quota for the number of handlers you may add. Sometimes it will be beneficial for an application to log all messages of all severities to a text file while simultaneously logging errors or above to the console. To set this up, simply configure the appropriate handlers. The logging calls in the application code will remain unchanged. Here is a slight modification to the previous simple module-based configuration example:

```python
import logging

logger = logging.getLogger('simple_example')
logger.setLevel(logging.DEBUG)
# create file handler which logs even debug messages
fh = logging.FileHandler('spam.log')
fh.setLevel(logging.DEBUG)
# create console handler with a higher log level
ch = logging.StreamHandler()
ch.setLevel(logging.ERROR)
# create formatter and add it to the handlers
formatter = logging.Formatter('%(asctime)s - %(name)s - %(levelname)s - %(message)s')
ch.setFormatter(formatter)
fh.setFormatter(formatter)
# add the handlers to logger
logger.addHandler(ch)
logger.addHandler(fh)

# 'application' code
logger.debug('debug message')
logger.info('info message')
logger.warn('warn message')
logger.error('error message')
logger.critical('critical message')
```

Notice that the ‘application’ code does not care about multiple handlers. All that changed was the addition and configuration of a new handler named `fh`. 
The ability to create new handlers with higher- or lower-severity filters can be very helpful when writing and testing an application. Instead of using many `print` statements for debugging, use `logger.debug`: Unlike the print statements, which you will have to delete or comment out later, the logger.debug statements can remain intact in the source code and remain dormant until you need them again. At that time, the only change that needs to happen is to modify the severity level of the logger and/or handler to debug.
# Logging to multiple destinations

Let’s say you want to log to console and file with different message formats and in differing circumstances. Say you want to log messages with levels of DEBUG and higher to file, and those messages at level INFO and higher to the console. Let’s also assume that the file should contain timestamps, but the console messages should not. Here’s how you can achieve this:

```python
import logging

# set up logging to file - see previous section for more detail
logging.basicConfig(level=logging.DEBUG,
    format='%(asctime)s %(name)-12s %(levelname)-8s
    datefmt='%m-%d %H:%M',
    filename='/temp/myapp.log',
    filemode='w')

# define a Handler which writes INFO messages or higher to the
console = logging.StreamHandler()
console.setLevel(logging.INFO)

# set a format which is simpler for console use
formatter = logging.Formatter('%(name)-12s: %(levelname)-8s

# tell the handler to use this format
console.setFormatter(formatter)

# add the handler to the root logger
logging.getLogger('').addHandler(console)

# Now, we can log to the root logger, or any other logger. First
logging.info('Jackdaws love my big sphinx of quartz.

# Now, define a couple of other loggers which might represent an application:

logger1 = logging.getLogger('myapp.area1')
logger2 = logging.getLogger('myapp.area2')

logger1.debug('Quick zephyrs blow, vexing daft Jim.
logger1.info('How quickly daft jumping zebras vex.
logger2.warning('Jail zesty vixen who grabbed pay from quack.
logger2.error('The five boxing wizards jump quickly.
```
When you run this, on the console you will see

```
root : INFO      Jackdaws love my big sphinx of quartz.
myapp.area1 : INFO   How quickly daft jumping zebras vex.
myapp.area2 : WARNING Jail zesty vixen who grabbed pay from quack.
myapp.area2 : ERROR    The five boxing wizards jump quickly.
```

and in the file you will see something like

```
10-22 22:19 root INFO     Jackdaws love my big sphinx of quartz.
10-22 22:19 myapp.area1 DEBUG Quick zephyrs blow, vexing daft
dafthopping zebras.
10-22 22:19 myapp.area1 INFO How quickly daft jumping zebras vex.
10-22 22:19 myapp.area2 WARNING Jail zesty vixen who grabbed
pay from quack.
10-22 22:19 myapp.area2 ERROR    The five boxing wizards jump
quickly.
```

As you can see, the DEBUG message only shows up in the file. The other messages are sent to both destinations.

This example uses console and file handlers, but you can use any number and combination of handlers you choose.
Here is an example of a module using the logging configuration server:

```python
import logging
import logging.config
import time
import os

# read initial config file
logging.config.fileConfig('logging.conf')

# create and start listener on port 9999
t = logging.config.listen(9999)
t.start()

logger = logging.getLogger('simpleExample')

try:
    # loop through logging calls to see the difference
    # new configurations make, until Ctrl+C is pressed
    while True:
        logger.debug('debug message')
        logger.info('info message')
        logger.warn('warn message')
        logger.error('error message')
        logger.critical('critical message')
        time.sleep(5)
except KeyboardInterrupt:
    # cleanup
    logging.config.stopListening()
t.join()
```

And here is a script that takes a filename and sends that file to the server, properly preceded with the binary-encoded length, as the new logging configuration:

```bash
#!/usr/bin/env python
import socket, sys, struct
```
with open(sys.argv[1], 'rb') as f:
    data_to_send = f.read()

HOST = 'localhost'
PORT = 9999
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
print('connecting...')
s.connect((HOST, PORT))
print('sending config...')
s.send(struct.pack('>L', len(data_to_send)))
s.send(data_to_send)
s.close()
print('complete')
Sending and receiving logging events across a network

Let’s say you want to send logging events across a network, and handle them at the receiving end. A simple way of doing this is attaching a `SocketHandler` instance to the root logger at the sending end:

```python
import logging, logging.handlers

rootLogger = logging.getLogger('')
rootLogger.setLevel(logging.DEBUG)
socketHandler = logging.handlers.SocketHandler('localhost',
                                               logging.handlers.DEFAULT_TCP_LOGGING_PORT)
# don't bother with a formatter, since a socket handler sends to
# an unformatted pickle
rootLogger.addHandler(socketHandler)

# Now, we can log to the root logger, or any other logger. First
# logging.info('Jackdaws love my big sphinx of quartz.')

# Now, define a couple of other loggers which might represent a
# application:

logger1 = logging.getLogger('myapp.area1')
logger2 = logging.getLogger('myapp.area2')

logger1.debug('Quick zephyrs blow, vexing daft Jim.')
logger1.info('How quickly daft jumping zebras vex.')
logger2.warning('Jail zesty vixen who grabbed pay from quack.')
logger2.error('The five boxing wizards jump quickly.')
```

At the receiving end, you can set up a receiver using the `SocketServer` module. Here is a basic working example:

```python
import pickle
import logging
import logging.handlers
import SocketServer
```
import struct

class LogRecordStreamHandler(SocketServer.StreamRequestHandler):
    """Handler for a streaming logging request.

    This basically logs the record using whatever logging policy is configured locally.
    """

def handle(self):
    """Handle multiple requests - each expected to be a 4-byte length,
    followed by the LogRecord in pickle format. Logs the record
    according to whatever policy is configured locally.
    """
    while True:
        chunk = self.connection.recv(4)
        if len(chunk) < 4:
            break
        slen = struct.unpack('>L', chunk)[0]
        chunk = self.connection.recv(slen)
        obj = self.unPickle(chunk)
        record = logging.makeLogRecord(obj)
        self.handleLogRecord(record)

def unPickle(self, data):
    return pickle.loads(data)

def handleLogRecord(self, record):
    # if a name is specified, we use the named logger rather than
    # implied by the record.
    if self.server.logname is not None:
        name = self.server.logname
    else:
        name = record.name
    logger = logging.getLogger(name)
    # N.B. EVERY record gets logged. This is because Logger
    # is normally called AFTER logger-level filtering. If you
    # to do filtering, do it at the client end to save wast
    # cycles and network bandwidth!
    logger.handle(record)

class LogRecordSocketReceiver(SocketServer.ThreadingTCPServer):
    """
Simple TCP socket-based logging receiver suitable for testing

```
allow_reuse_address = 1

def __init__(self, host='localhost',
             port=logging.handlers.DEFAULT_TCP_LOGGING_PORT,
             handler=LogRecordStreamHandler):
    SocketServer.ThreadingTCPServer.__init__(
        self, (host, p
    self.abort = 0
    self.timeout = 1
    self.logname = None

def serve_until_stopped(self):
    import select
    abort = 0
    while not abort:
        rd, wr, ex = select.select([self.socket.fileno()],
                                   [], [],
                                   self.timeout)

        if rd:
            self.handle_request()
        abort = self.abort

def main():
    logging.basicConfig(
        format='%(%relativeCreated)5d %(%name)-15s %(%levelname)-8s
    tcpserver = LogRecordSocketReceiver()
    print('About to start TCP server...')
    tcpserver.serve_until_stopped()

if __name__ == '__main__':
    main()
```

First run the server, and then the client. On the client side, nothing is printed on the console; on the server side, you should see something like:

```
About to start TCP server...
  59  root INFO    Jackdaws love my big sphinx of quartz
  59 myapp.area1 DEBUG Quick zephyrs blow, vexing daft
  69 myapp.area1 INFO    How quickly daft jumping zebras
  69 myapp.area2 WARNING Jail zesty vixen who grabbed pay
  69 myapp.area2 ERROR    The five boxing wizards jump qui
```
Note that there are some security issues with pickle in some scenarios. If these affect you, you can use an alternative serialization scheme by overriding the `makePickle()` method and implementing your alternative there, as well as adapting the above script to use your alternative serialization.
Adding contextual information to your logging output

Sometimes you want logging output to contain contextual information in addition to the parameters passed to the logging call. For example, in a networked application, it may be desirable to log client-specific information in the log (e.g. remote client's username, or IP address). Although you could use the extra parameter to achieve this, it's not always convenient to pass the information in this way. While it might be tempting to create Logger instances on a per-connection basis, this is not a good idea because these instances are not garbage collected. While this is not a problem in practice, when the number of Logger instances is dependent on the level of granularity you want to use in logging an application, it could be hard to manage if the number of Logger instances becomes effectively unbounded.

Using LoggerAdapters to impart contextual information

An easy way in which you can pass contextual information to be output along with logging event information is to use the LoggerAdapter class. This class is designed to look like a Logger, so that you can call debug(), info(), warning(), error(), exception(), critical() and log(). These methods have the same signatures as their counterparts in Logger, so you can use the two types of instances interchangeably.

When you create an instance of LoggerAdapter, you pass it a Logger instance and a dict-like object which contains your contextual information. When you call one of the logging methods on an
instance of `LoggerAdapter`, it delegates the call to the underlying instance of `Logger` passed to its constructor, and arranges to pass the contextual information in the delegated call. Here's a snippet from the code of `LoggerAdapter`:

```python
def debug(self, msg, *args, **kwargs):
    
    Delegate a debug call to the underlying logger, after adding contextual information from this adapter instance.
    
    msg, kwargs = self.process(msg, kwargs)
    self.logger.debug(msg, *args, **kwargs)
```

The `process()` method of `LoggerAdapter` is where the contextual information is added to the logging output. It's passed the message and keyword arguments of the logging call, and it passes back (potentially) modified versions of these to use in the call to the underlying logger. The default implementation of this method leaves the message alone, but inserts an ‘extra’ key in the keyword argument whose value is the dict-like object passed to the constructor. Of course, if you had passed an ‘extra’ keyword argument in the call to the adapter, it will be silently overwritten.

The advantage of using ‘extra’ is that the values in the dict-like object are merged into the `LogRecord` instance's `__dict__`, allowing you to use customized strings with your `Formatter` instances which know about the keys of the dict-like object. If you need a different method, e.g. if you want to prepend or append the contextual information to the message string, you just need to subclass `LoggerAdapter` and override `process()` to do what you need. Here is a simple example:

```python
class CustomAdapter(logging.LoggerAdapter):
    
    This example adapter expects the passed in dict-like object 'connid' key, whose value in brackets is prepended to the log message.
```

def process(self, msg, kwargs):
    return ' [%s] %s' % (self.extra['connid'], msg), kwargs

which you can use like this:

logger = logging.getLogger(__name__)
adapters = CustomAdapter(logger, {'connid': some_conn_id})

Then any events that you log to the adapter will have the value of 
some_conn_id prepended to the log messages.

Using objects other than dicts to pass contextual information

You don’t need to pass an actual dict to a LoggerAdapter - you could 
pass an instance of a class which implements __getitem__ and  
__iter__ so that it looks like a dict to logging. This would be useful if  
you want to generate values dynamically (whereas the values in a  
dict would be constant).

Using Filters to impart contextual information

You can also add contextual information to log output using a user-defined Filter. Filter instances are allowed to modify the LogRecords passed to them, including adding additional attributes which can then be output using a suitable format string, or if needed a custom Formatter.

For example in a web application, the request being processed (or at  
least, the interesting parts of it) can be stored in a threadlocal  
(threading.local) variable, and then accessed from a Filter to add,  
say, information from the request - say, the remote IP address and remote user’s username - to the LogRecord, using the attribute names ‘ip’ and ‘user’ as in the LoggerAdapter example above. In that  
case, the same format string can be used to get similar output to that
shown above. Here’s an example script:

```python
import logging
from random import choice

class ContextFilter(logging.Filter):
    """
    This is a filter which injects contextual information into
    Rather than use actual contextual information, we just use
data in this demo.
    """

    USERS = ['jim', 'fred', 'sheila']
    IPS = ['123.231.231.123', '127.0.0.1', '192.168.0.1']

def filter(self, record):
    record.ip = choice(ContextFilter.IPS)
    record.user = choice(ContextFilter.USERS)
    return True

if __name__ == '__main__':
    levels = (logging.DEBUG, logging.INFO, logging.WARNING, log
    logging.basicConfig(level=logging.DEBUG,
    format='%(asctime)-15s %(name)-5s %(levelname)-8s
    a1 = logging.getLogger('a.b.c')
a2 = logging.getLogger('d.e.f')

    f = ContextFilter()
a1.addFilter(f)
a2.addFilter(f)
a1.debug('A debug message')
a1.info('An info message with %s', 'some parameters')
    for x in range(10):
        lvl = choice(levels)
        lvlname = logging.getLoggerName(lvl)
        a2.log(lvl, 'A message at %s level with %d %s', lvlname,
```

which, when run, produces something like:

```
2010-09-06 22:38:15,292 a.b.c DEBUG      IP: 123.231.231.123 User
2010-09-06 22:38:15,300 a.b.c INFO       IP: 192.168.0.1    User

Logging to a single file from multiple processes

Although logging is thread-safe, and logging to a single file from multiple threads in a single process is supported, logging to a single file from *multiple processes* is *not* supported, because there is no standard way to serialize access to a single file across multiple processes in Python. If you need to log to a single file from multiple processes, one way of doing this is to have all the processes log to a `SocketHandler`, and have a separate process which implements a socket server which reads from the socket and logs to file. (If you prefer, you can dedicate one thread in one of the existing processes to perform this function.) This section documents this approach in more detail and includes a working socket receiver which can be used as a starting point for you to adapt in your own applications.

If you are using a recent version of Python which includes the `multiprocessing` module, you could write your own handler which uses the `Lock` class from this module to serialize access to the file from your processes. The existing `FileHandler` and subclasses do not make use of `multiprocessing` at present, though they may do so in the future. Note that at present, the `multiprocessing` module does not provide working lock functionality on all platforms (see https://bugs.python.org/issue3770).
Using file rotation

Sometimes you want to let a log file grow to a certain size, then open a new file and log to that. You may want to keep a certain number of these files, and when that many files have been created, rotate the files so that the number of files and the size of the files both remain bounded. For this usage pattern, the logging package provides a `RotatingFileHandler`:

```python
import glob
import logging
import logging.handlers

LOG_FILENAME = 'logging_rotatingfile_example.out'

# Set up a specific logger with our desired output level
my_logger = logging.getLogger('MyLogger')
my_logger.setLevel(logging.DEBUG)

# Add the log message handler to the logger
handler = logging.handlers.RotatingFileHandler(
    LOG_FILENAME, maxBytes=20, backupCount=5)

my_logger.addHandler(handler)

# Log some messages
for i in range(20):
    my_logger.debug('i = %d' % i)

# See what files are created
logfiles = glob.glob('%s*' % LOG_FILENAME)

for filename in logfiles:
    print(filename)
```

The result should be 6 separate files, each with part of the log history for the application:
The most current file is always `logging_rotatingfile_example.out`, and each time it reaches the size limit it is renamed with the suffix `.1`. Each of the existing backup files is renamed to increment the suffix (.1 becomes .2, etc.) and the .6 file is erased.

Obviously this example sets the log length much too small as an extreme example. You would want to set `maxBytes` to an appropriate value.
An example dictionary-based configuration

Below is an example of a logging configuration dictionary - it’s taken from the documentation on the Django project. This dictionary is passed to `dictConfig()` to put the configuration into effect:

```python
LOGGING = {
    'version': 1,
    'disable_existing_loggers': True,
    'formatters': {
        'verbose': {
            'format': '%(levelname)s %(asctime)s %(module)s %(process)d
        },
        'simple': {
            'format': '%(levelname)s %(message)s'
        },
    },
    'filters': {
        'special': {
            '()': 'project.logging.SpecialFilter',
            'foo': 'bar',
        },
    },
    'handlers': {
        'null': {
            'level': 'DEBUG',
            'class': 'django.utils.log.NullHandler',
        },
        'console':{
            'level': 'DEBUG',
            'class': 'logging.StreamHandler',
            'formatter': 'simple'
        },
        'mail_admins': {  
            'level': 'ERROR',
            'class': 'django.utils.log.AdminEmailHandler',
            'filters': ['special']
        },
    },
    'loggers': {
        'django': {
            'handlers': ['null'],
            'propagate': True,
        };
```
For more information about this configuration, you can see the relevant section of the Django documentation.
Inserting a BOM into messages sent to a SysLogHandler

RFC 5424 requires that a Unicode message be sent to a syslog daemon as a set of bytes which have the following structure: an optional pure-ASCII component, followed by a UTF-8 Byte Order Mark (BOM), followed by Unicode encoded using UTF-8. (See the relevant section of the specification.)

In Python 2.6 and 2.7, code was added to `SysLogHandler` to insert a BOM into the message, but unfortunately, it was implemented incorrectly, with the BOM appearing at the beginning of the message and hence not allowing any pure-ASCII component to appear before it.

As this behaviour is broken, the incorrect BOM insertion code is being removed from Python 2.7.4 and later. However, it is not being replaced, and if you want to produce RFC 5424-compliant messages which include a BOM, an optional pure-ASCII sequence before it and arbitrary Unicode after it, encoded using UTF-8, then you need to do the following:

1. Attach a `Formatter` instance to your `SysLogHandler` instance, with a format string such as:

   ```
   u'ASCII section\u0000Unicode section'
   ```

   The Unicode code point `u'\u0000'`, when encoded using UTF-8, will be encoded as a UTF-8 BOM – the byte-string `\xef\xbb\xbf`.

2. Replace the ASCII section with whatever placeholders you like, but make sure that the data that appears in there after
substitution is always ASCII (that way, it will remain unchanged after UTF-8 encoding).

3. Replace the Unicode section with whatever placeholders you like; if the data which appears there after substitution contains characters outside the ASCII range, that's fine – it will be encoded using UTF-8.

If the formatted message is Unicode, it will be encoded using UTF-8 encoding by `SysLogHandler`. If you follow the above rules, you should be able to produce RFC 5424-compliant messages. If you don't, logging may not complain, but your messages will not be RFC 5424-compliant, and your syslog daemon may complain.
Implementing structured logging

Although most logging messages are intended for reading by humans, and thus not readily machine-parseable, there might be circumstances where you want to output messages in a structured format which is capable of being parsed by a program (without needing complex regular expressions to parse the log message). This is straightforward to achieve using the logging package. There are a number of ways in which this could be achieved, but the following is a simple approach which uses JSON to serialise the event in a machine-parseable manner:

```python
import json
import logging

class StructuredMessage(object):
    def __init__(self, message, **kwargs):
        self.message = message
        self.kwars = kwargs

    def __str__(self):
        return '%s >>> %s' % (self.message, json.dumps(self.kwars))

_logging = StructuredMessage  # optional, to improve readability

logging.basicConfig(level=logging.INFO, format='%(message)s')
logging.info(_('message 1', foo='bar', bar='baz', num=123, fnum=123.456))
```

If the above script is run, it prints:

```
message 1 >>> {"fnum": 123.456, "num": 123, "bar": "baz", "foo"
```

Note that the order of items might be different according to the version of Python used.

If you need more specialised processing, you can use a custom
JSON encoder, as in the following complete example:

```python
from __future__ import unicode_literals

import json
import logging

# This next bit is to ensure the script runs unchanged on 2.x and 3.x
try:
    unicode
except NameError:
    unicode = str

class Encoder(json.JSONEncoder):
    def default(self, o):
        if isinstance(o, set):
            return tuple(o)
        elif isinstance(o, unicode):
            return o.encode('unicode_escape').decode('ascii')
        return super(Encoder, self).default(o)

class StructuredMessage(object):
    def __init__(self, message, **kwargs):
        self.message = message
        self.kwargs = kwargs

    def __str__(self):
        s = Encoder().encode(self.kwargs)
        return '%s >>> %s' % (self.message, s)

_ = StructuredMessage  # optional, to improve readability

def main():
    logging.basicConfig(level=logging.INFO, format='%(message)s')
    logging.info(_('message 1', set_value=set([1, 2, 3]), snowman)

if __name__ == '__main__':
    main()
```

When the above script is run, it prints:

```
message 1 >>> {"snowman": "\u2603", "set_value": [1, 2, 3]}
```
Note that the order of items might be different according to the version of Python used.
Customizing handlers with \texttt{dictConfig()}

There are times when you want to customize logging handlers in particular ways, and if you use \texttt{dictConfig()} you may be able to do this without subclassing. As an example, consider that you may want to set the ownership of a log file. On POSIX, this is easily done using \texttt{os.chown()}, but the file handlers in the stdlib don’t offer built-in support. You can customize handler creation using a plain function such as:

\begin{verbatim}
def owned_file_handler(filename, mode='a', encoding=None, owner=None):
    if owner:
        import os, pwd, grp
        # convert user and group names to uid and gid
        uid = pwd.getpwnam(owner[0]).pw_uid
        gid = grp.getgrnam(owner[1]).gr_gid
        owner = (uid, gid)
        if not os.path.exists(filename):
            open(filename, 'a').close()
        os.chown(filename, *owner)
    return logging.FileHandler(filename, mode, encoding)
\end{verbatim}

You can then specify, in a logging configuration passed to \texttt{dictConfig()}, that a logging handler be created by calling this function:

\begin{verbatim}
LOGGING = {
    'version': 1,
    'disable_existing_loggers': False,
    'formatters': {
        'default': {
            'format': '%(asctime)s %(levelname)s %(name)s %(message)s
        },
    },
    'handlers': {
        'file':{
            # The values below are popped from this dictionary, # used to create the handler, set the handler's level

\end{verbatim}
In this example I am setting the ownership using the `pulse` user and group, just for the purposes of illustration. Putting it together into a working script, `chowntest.py`:

```python
import logging, logging.config, os, shutil

def owned_file_handler(filename, mode='a', encoding=None, owner=None):
    if owner:
        if not os.path.exists(filename):
            open(filename, 'a').close()
            shutil.chown(filename, *owner)
        return logging.FileHandler(filename, mode, encoding)

LOGGING = {
    'version': 1,
    'disable_existing_loggers': False,
    'formatters': {
        'default': {
            'format': '%(asctime)s %(levelname)s %(name)s %(message)s
        },
    },
    'handlers': {
        'file':{
            '# The values below are popped from this dictionary and
            # used to create the handler, set the handler's level and
            '# its formatter.
        }
    },
    'root':{
        'handlers': ['file'],
        'level': 'DEBUG',
    },
}
```

In this example I am setting the ownership using the `pulse` user and group, just for the purposes of illustration. Putting it together into a working script, `chowntest.py`:

```python
import logging, logging.config, os, shutil

def owned_file_handler(filename, mode='a', encoding=None, owner=None):
    if owner:
        if not os.path.exists(filename):
            open(filename, 'a').close()
            shutil.chown(filename, *owner)
        return logging.FileHandler(filename, mode, encoding)

LOGGING = {
    'version': 1,
    'disable_existing_loggers': False,
    'formatters': {
        'default': {
            'format': '%(asctime)s %(levelname)s %(name)s %(message)s
        },
    },
    'handlers': {
        'file':{
            '# The values below are popped from this dictionary and
            # used to create the handler, set the handler's level and
            '# its formatter.
        }
    },
    'root':{
        'handlers': ['file'],
        'level': 'DEBUG',
    },
}
```
'()': owned_file_handler,
'level': 'DEBUG',
'formatter': 'default',
# The values below are passed to the handler creator callable
# as keyword arguments.
'owner': ['pulse', 'pulse'],
'filename': 'chowntest.log',
'mode': 'w',
'encoding': 'utf-8',
},
},
'root': {
  'handlers': ['file'],
  'level': 'DEBUG',
},
}

logging.config.dictConfig(LOGGING)
logger = logging.getLogger('mylogger')
logger.debug('A debug message')

To run this, you will probably need to run as root:

$ sudo python3.3 chowntest.py
$ cat chowntest.log
2013-11-05 09:34:51,128 DEBUG mylogger A debug message
$ ls -l chowntest.log
-rw-r--r-- 1 pulse pulse 55 2013-11-05 09:34 chowntest.log

Note that this example uses Python 3.3 because that's where shutil.chown() makes an appearance. This approach should work with any Python version that supports dictConfig() - namely, Python 2.7, 3.2 or later. With pre-3.3 versions, you would need to implement the actual ownership change using e.g. os.chown().

In practice, the handler-creating function may be in a utility module somewhere in your project. Instead of the line in the configuration:

'()': owned_file_handler,
you could use e.g.:

```python
'()': 'ext://project.util.owned_file_handler',
```

where `project.util` can be replaced with the actual name of the package where the function resides. In the above working script, using `ext://__main__.owned_file_handler` should work. Here, the actual callable is resolved by `dictConfig()` from the `ext://` specification.

This example hopefully also points the way to how you could implement other types of file change - e.g. setting specific POSIX permission bits - in the same way, using `os.chmod()`.

Of course, the approach could also be extended to types of handler other than a `FileHandler` - for example, one of the rotating file handlers, or a different type of handler altogether.
You can configure filters using `dictConfig()`, though it might not be obvious at first glance how to do it (hence this recipe). Since `Filter` is the only filter class included in the standard library, and it is unlikely to cater to many requirements (it’s only there as a base class), you will typically need to define your own `Filter` subclass with an overridden `filter()` method. To do this, specify the `()` key in the configuration dictionary for the filter, specifying a callable which will be used to create the filter (a class is the most obvious, but you can provide any callable which returns a `Filter` instance). Here is a complete example:

```python
import logging
import logging.config
import sys

class MyFilter(logging.Filter):
    def __init__(self, param=None):
        self.param = param

    def filter(self, record):
        if self.param is None:
            allow = True
        else:
            allow = self.param not in record.msg
        if allow:
            record.msg = 'changed: ' + record.msg
        return allow

LOGGING = {
    'version': 1,
    'filters': {
        'myfilter': {
            '()': MyFilter,
            'param': 'noshow',
        }
    },
    'handlers': {
        'console': {
```
{'class': 'logging.StreamHandler',
'filters': ['myfilter']
},
},
'root': {
    'level': 'DEBUG',
    'handlers': ['console']
},
}

if __name__ == '__main__':
    logging.config.dictConfig(LOGGING)
    logging.debug('hello')
    logging.debug('hello - noshow')

This example shows how you can pass configuration data to the callable which constructs the instance, in the form of keyword parameters. When run, the above script will print:

changed: hello

which shows that the filter is working as configured.

A couple of extra points to note:

- If you can't refer to the callable directly in the configuration (e.g. if it lives in a different module, and you can't import it directly where the configuration dictionary is), you can use the form `ext://...` as described in Access to external objects. For example, you could have used the text `ext://__main__.MyFilter` instead of `MyFilter` in the above example.
- As well as for filters, this technique can also be used to configure custom handlers and formatters. See User-defined objects for more information on how logging supports using user-defined objects in its configuration, and see the other cookbook recipe Customizing handlers with dictConfig() above.
Customized exception formatting

There might be times when you want to do customized exception formatting - for argument’s sake, let’s say you want exactly one line per logged event, even when exception information is present. You can do this with a custom formatter class, as shown in the following example:

```python
import logging

class OneLineExceptionFormatter(logging.Formatter):
    def formatException(self, exc_info):
        """
        Format an exception so that it prints on a single line.
        """
        result = super(OneLineExceptionFormatter, self).formatException(exc_info)
        return repr(result)  # or format into one line however you
        def format(self, self, record):
            s = super(OneLineExceptionFormatter, self).format(record)
            if record.exc_text:
                s = s.replace('
', '') + '|
            return s

def configure_logging():
    fh = logging.FileHandler('output.txt', 'w')
    f = OneLineExceptionFormatter('%(asctime)s|%(levelname)s|%(message)s',
                                  '%d/%m/%Y %H:%M:%S')
    fh.setFormatter(f)
    root = logging.getLogger()
    root.setLevel(logging.DEBUG)
    root.addHandler(fh)

def main():
    configure_logging()
    logging.info('Sample message')
    try:
        x = 1 / 0
    except ZeroDivisionError as e:
        logging.exception('ZeroDivisionError: %s', e)

if __name__ == '__main__':
```
When run, this produces a file with exactly two lines:

<table>
<thead>
<tr>
<th>Date</th>
<th>Time</th>
<th>Level</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>28/01/2015 07:21:23</td>
<td>INFO</td>
<td></td>
<td>Sample message</td>
</tr>
<tr>
<td>28/01/2015 07:21:23</td>
<td>ERROR</td>
<td></td>
<td>ZeroDivisionError: integer division o</td>
</tr>
</tbody>
</table>

While the above treatment is simplistic, it points the way to how exception information can be formatted to your liking. The `traceback` module may be helpful for more specialized needs.
Speaking logging messages

There might be situations when it is desirable to have logging messages rendered in an audible rather than a visible format. This is easy to do if you have text- to-speech (TTS) functionality available in your system, even if it doesn't have a Python binding. Most TTS systems have a command line program you can run, and this can be invoked from a handler using subprocess. It's assumed here that TTS command line programs won't expect to interact with users or take a long time to complete, and that the frequency of logged messages will be not so high as to swamp the user with messages, and that it's acceptable to have the messages spoken one at a time rather than concurrently. The example implementation below waits for one message to be spoken before the next is processed, and this might cause other handlers to be kept waiting. Here is a short example showing the approach, which assumes that the espeak TTS package is available:

```python
import logging
import subprocess
import sys

class TTSHandler(logging.Handler):
    def emit(self, record):
        msg = self.format(record)
        # Speak slowly in a female English voice
        cmd = ['espeak', '-s150', '-ven+f3', msg]
        p = subprocess.Popen(cmd, stdout=subprocess.PIPE,
                             stderr=subprocess.STDOUT)
        # wait for the program to finish
        p.communicate()

def configure_logging():
    h = TTSHandler()
    root = logging.getLogger()
    root.addHandler(h)
    # the default formatter just returns the message
    root.setLevel(logging.DEBUG)
```
def main():
    logging.info('Hello')
    logging.debug('Goodbye')

if __name__ == '__main__':
    configure_logging()
    sys.exit(main())

When run, this script should say “Hello” and then “Goodbye” in a female voice.

The above approach can, of course, be adapted to other TTS systems and even other systems altogether which can process messages via external programs run from a command line.
Buffering logging messages and outputting them conditionally

There might be situations where you want to log messages in a temporary area and only output them if a certain condition occurs. For example, you may want to start logging debug events in a function, and if the function completes without errors, you don’t want to clutter the log with the collected debug information, but if there is an error, you want all the debug information to be output as well as the error.

Here is an example which shows how you could do this using a decorator for your functions where you want logging to behave this way. It makes use of the `logging.handlers.MemoryHandler`, which allows buffering of logged events until some condition occurs, at which point the buffered events are flushed - passed to another handler (the target handler) for processing. By default, the `MemoryHandler` flushed when its buffer gets filled up or an event whose level is greater than or equal to a specified threshold is seen. You can use this recipe with a more specialised subclass of `MemoryHandler` if you want custom flushing behavior.

The example script has a simple function, `foo`, which just cycles through all the logging levels, writing to `sys.stderr` to say what level it’s about to log at, and then actually logging a message at that level. You can pass a parameter to `foo` which, if true, will log at ERROR and CRITICAL levels - otherwise, it only logs at DEBUG, INFO and WARNING levels.

The script just arranges to decorate `foo` with a decorator which will do the conditional logging that’s required. The decorator takes a logger as a parameter and attaches a memory handler for the
duration of the call to the decorated function. The decorator can be additionally parameterised using a target handler, a level at which flushing should occur, and a capacity for the buffer. These default to a `StreamHandler` which writes to `sys.stderr`, `logging.ERROR` and 100 respectively.

Here's the script:

```python
import logging
from logging.handlers import MemoryHandler
import sys

logger = logging.getLogger(__name__)
logger.addHandler(logging.NullHandler())

def log_if_errors(logger, target_handler=None, flush_level=None):
    if target_handler is None:
        target_handler = logging.StreamHandler()
    if flush_level is None:
        flush_level = logging.ERROR
    if capacity is None:
        capacity = 100
    handler = MemoryHandler(capacity, flushLevel=flush_level, t

def decorator(fn):
    def wrapper(*args, **kwargs):
        logger.addHandler(handler)
        try:
            return fn(*args, **kwargs)
        except Exception:
            logger.exception('call failed')
        raise
    finally:
        super(MemoryHandler, handler).flush()
        logger.removeHandler(handler)
    return wrapper

def write_line(s):
    sys.stderr.write('%s
' % s)

def foo(fail=False):
    write_line('about to log at DEBUG ...')
```
logger.debug('Actually logged at DEBUG')
write_line('about to log at INFO ...')
logger.info('Actually logged at INFO')
write_line('about to log at WARNING ...')
logger.warning('Actually logged at WARNING')

if fail:
    write_line('about to log at ERROR ...')
    logger.error('Actually logged at ERROR')
    write_line('about to log at CRITICAL ...')
    logger.critical('Actually logged at CRITICAL')

return fail

decorated_foo = log_if_errors(logger)(foo)

if __name__ == '__main__':
    logger.setLevel(logging.DEBUG)
    write_line('Calling undecorated foo with False')
    assert not foo(False)
    write_line('Calling undecorated foo with True')
    assert foo(True)
    write_line('Calling decorated foo with False')
    assert not decorated_foo(False)
    write_line('Calling decorated foo with True')
    assert decorated_foo(True)

When this script is run, the following output should be observed:

Calling undecorated foo with False
about to log at DEBUG ...
about to log at INFO ...
about to log at WARNING ...
Calling undecorated foo with True
about to log at DEBUG ...
about to log at INFO ...
about to log at WARNING ...
about to log at ERROR ...
about to log at CRITICAL ...
Calling decorated foo with False
about to log at DEBUG ...
about to log at INFO ...
about to log at WARNING ...
Calling decorated foo with True
about to log at DEBUG ...
about to log at INFO ...
about to log at WARNING ...
About to log at ERROR ... Actually logged at DEBUG
Actually logged at INFO
Actually logged at WARNING
Actually logged at ERROR
About to log at CRITICAL ...
Actually logged at CRITICAL

As you can see, actual logging output only occurs when an event is logged whose severity is ERROR or greater, but in that case, any previous events at lower severities are also logged.

You can of course use the conventional means of decoration:

```python
@log_if_errors(logger)
def foo(fail=False):
    ...
```
Sometimes you want to format times using UTC, which can be done using a class such as `UTCFormatter`, shown below:

```python
import logging
import time
class UTCFormatter(logging.Formatter):
    converter = time.gmtime
```

and you can then use the `UTCFormatter` in your code instead of `Formatter`. If you want to do that via configuration, you can use the `dictConfig()` API with an approach illustrated by the following complete example:

```python
import logging
import logging.config
import time
class UTCFormatter(logging.Formatter):
    converter = time.gmtime

LOGGING = {
    'version': 1,
    'disable_existing_loggers': False,
    'formatters': {
        'utc': {
            '()': UTCFormatter,
            'format': '%(asctime)s %(message)s',
        },
        'local': {
            'format': '%(asctime)s %(message)s',
        },
    },
    'handlers': {
        'console1': {
            'class': 'logging.StreamHandler',
            'formatter': 'utc',
        },
    },
}```
{ },
'console2': {
    'class': 'logging.StreamHandler',
    'formatter': 'local',
},
},
'root': {
    'handlers': ['console1', 'console2'],
}
}

if __name__ == '__main__':
    logging.config.dictConfig(LOGGING)
    logging.warning('The local time is %s', time.asctime())

When this script is run, it should print something like:

```
2015-10-17 12:53:29,501 The local time is Sat Oct 17 13:53:29 2
```

showing how the time is formatted both as local time and UTC, one for each handler.
Using a context manager for selective logging

There are times when it would be useful to temporarily change the logging configuration and revert it back after doing something. For this, a context manager is the most obvious way of saving and restoring the logging context. Here is a simple example of such a context manager, which allows you to optionally change the logging level and add a logging handler purely in the scope of the context manager:

```python
import logging
import sys

class LoggingContext(object):
    def __init__(self, logger, level=None, handler=None, close=True):
        self.logger = logger
        self.level = level
        self.handler = handler
        self.close = close

    def __enter__(self):
        if self.level is not None:
            self.old_level = self.logger.level
            self.logger.setLevel(self.level)
        if self.handler:
            self.logger.addHandler(self.handler)

    def __exit__(self, et, ev, tb):
        if self.level is not None:
            self.logger.setLevel(self.old_level)
        if self.handler:
            self.logger.removeHandler(self.handler)
        if self.handler and self.close:
            self.handler.close()

# implicit return of None => don't swallow exceptions
```

If you specify a level value, the logger’s level is set to that value in
the scope of the with block covered by the context manager. If you specify a handler, it is added to the logger on entry to the block and removed on exit from the block. You can also ask the manager to close the handler for you on block exit - you could do this if you don’t need the handler any more.

To illustrate how it works, we can add the following block of code to the above:

```python
if __name__ == '__main__':
    logger = logging.getLogger('foo')
    logger.addHandler(logging.StreamHandler())
    logger.setLevel(logging.INFO)
    logger.info('1. This should appear just once on stderr.')
    logger.debug('2. This should not appear.')
    with LoggingContext(logger, level=logging.DEBUG):
        logger.debug('3. This should appear once on stderr.')
    logger.debug('4. This should not appear.')
    h = logging.StreamHandler(sys.stdout)
    with LoggingContext(logger, level=logging.DEBUG, handler=h, close=True):
        logger.debug('5. This should appear twice - once on stdout and once on stderr.')
    logger.info('6. This should appear just once on stderr.')
    logger.debug('7. This should not appear.')
```

We initially set the logger’s level to INFO, so message #1 appears and message #2 doesn’t. We then change the level to DEBUG temporarily in the following with block, and so message #3 appears. After the block exits, the logger’s level is restored to INFO and so message #4 doesn’t appear. In the next with block, we set the level to DEBUG again but also add a handler writing to sys.stdout. Thus, message #5 appears twice on the console (once via stderr and once via stdout). After the with statement’s completion, the status is as it was before so message #6 appears (like message #1) whereas message #7 doesn’t (just like message #2).

If we run the resulting script, the result is as follows:
1. This should appear just once on stderr.
2. This should appear once on stderr.
3. This should appear twice - once on stderr and once on stdout.
4. This should appear twice - once on stderr and once on stdout.
5. This should appear just once on stderr.

If we run it again, but pipe stderr to /dev/null, we see the following, which is the only message written to stdout:

$ python logctx.py
5. This should appear twice - once on stderr and once on stdout.

Once again, but piping stdout to /dev/null, we get:

$ python logctx.py
1. This should appear just once on stderr.
2. This should appear once on stderr.
3. This should appear twice - once on stderr and once on stdout.
4. This should appear twice - once on stderr and once on stdout.

In this case, the message #5 printed to stdout doesn’t appear, as expected.

Of course, the approach described here can be generalised, for example to attach logging filters temporarily. Note that the above code works in Python 2 as well as Python 3.
Regular Expression HOWTO

Author: A.M. Kuchling <amk@amk.ca>

Abstract

This document is an introductory tutorial to using regular expressions in Python with the `re` module. It provides a gentler introduction than the corresponding section in the Library Reference.
Introduction

The `re` module was added in Python 1.5, and provides Perl-style regular expression patterns. Earlier versions of Python came with the `regex` module, which provided Emacs-style patterns. The `regex` module was removed completely in Python 2.5.

Regular expressions (called REs, or regexes, or regex patterns) are essentially a tiny, highly specialized programming language embedded inside Python and made available through the `re` module. Using this little language, you specify the rules for the set of possible strings that you want to match; this set might contain English sentences, or e-mail addresses, or TeX commands, or anything you like. You can then ask questions such as “Does this string match the pattern?”, or “Is there a match for the pattern anywhere in this string?”. You can also use REs to modify a string or to split it apart in various ways.

Regular expression patterns are compiled into a series of bytecodes which are then executed by a matching engine written in C. For advanced use, it may be necessary to pay careful attention to how the engine will execute a given RE, and write the RE in a certain way in order to produce bytecode that runs faster. Optimization isn’t covered in this document, because it requires that you have a good understanding of the matching engine’s internals.

The regular expression language is relatively small and restricted, so not all possible string processing tasks can be done using regular expressions. There are also tasks that can be done with regular expressions, but the expressions turn out to be very complicated. In these cases, you may be better off writing Python code to do the processing; while Python code will be slower than an elaborate regular expression, it will also probably be more understandable.
Simple Patterns

We'll start by learning about the simplest possible regular expressions. Since regular expressions are used to operate on strings, we'll begin with the most common task: matching characters.

For a detailed explanation of the computer science underlying regular expressions (deterministic and non-deterministic finite automata), you can refer to almost any textbook on writing compilers.

Matching Characters

Most letters and characters will simply match themselves. For example, the regular expression \texttt{test} will match the string \texttt{test} exactly. (You can enable a case-insensitive mode that would let this RE match \texttt{Test} or \texttt{TEST} as well; more about this later.)

There are exceptions to this rule; some characters are special \textit{metacharacters}, and don’t match themselves. Instead, they signal that some out-of-the-ordinary thing should be matched, or they affect other portions of the RE by repeating them or changing their meaning. Much of this document is devoted to discussing various metacharacters and what they do.

Here's a complete list of the metacharacters; their meanings will be discussed in the rest of this HOWTO.

\begin{verbatim}
 .  ^  $  *  +  ?  {  }  [ ]  \  |  ( )
\end{verbatim}

The first metacharacters we'll look at are [ and ]. They're used for specifying a character class, which is a set of characters that you wish to match. Characters can be listed individually, or a range of
characters can be indicated by giving two characters and separating them by a '-' . For example, [abc] will match any of the characters a, b, or c; this is the same as [a-c] , which uses a range to express the same set of characters. If you wanted to match only lowercase letters, your RE would be [a-z] .

Metacharacters are not active inside classes. For example, [akm$] will match any of the characters 'a', 'k', 'm', or '$'; '$' is usually a metacharacter, but inside a character class it's stripped of its special nature.

You can match the characters not listed within the class by complementing the set. This is indicated by including a '^' as the first character of the class; '^' outside a character class will simply match the '^' character. For example, [^5] will match any character except '5'.

Perhaps the most important metacharacter is the backslash, \\ . As in Python string literals, the backslash can be followed by various characters to signal various special sequences. It's also used to escape all the metacharacters so you can still match them in patterns; for example, if you need to match a [ or \, you can precede them with a backslash to remove their special meaning: \[ or \\.

Some of the special sequences beginning with '\\' represent predefined sets of characters that are often useful, such as the set of digits, the set of letters, or the set of anything that isn't whitespace. The following predefined special sequences are a subset of those available. The equivalent classes are for byte string patterns. For a complete list of sequences and expanded class definitions for Unicode string patterns, see the last part of Regular Expression Syntax.
\d
Matches any decimal digit; this is equivalent to the class \[^0-9\].

\D
Matches any non-digit character; this is equivalent to the class \[^\^0-9\].

\s
Matches any whitespace character; this is equivalent to the class \[^\t\n\r\f\v\].

\S
Matches any non-whitespace character; this is equivalent to the class \[^\^\t\n\r\f\v\].

\w
Matches any alphanumeric character; this is equivalent to the class \[a-zA-Z0-9_\].

\W
Matches any non-alphanumeric character; this is equivalent to the class \[^a-zA-Z0-9_\].

These sequences can be included inside a character class. For example, \[s, .\] is a character class that will match any whitespace character, or ' , ' or '. '.

The final metacharacter in this section is \. It matches anything except a newline character, and there's an alternate mode (re.DOTALL) where it will match even a newline. \. is often used where you want to match “any character”.

**Repeating Things**

Being able to match varying sets of characters is the first thing regular expressions can do that isn’t already possible with the methods available on strings. However, if that was the only additional capability of regexes, they wouldn’t be much of an advance. Another
capability is that you can specify that portions of the RE must be repeated a certain number of times.

The first metacharacter for repeating things that we'll look at is \*\. \* doesn't match the literal character \*\; instead, it specifies that the previous character can be matched zero or more times, instead of exactly once.

For example, `ca*t` will match `ct` (0 a characters), `ca` (1 a), `caaat` (3 a characters), and so forth. The RE engine has various internal limitations stemming from the size of C's `int` type that will prevent it from matching over 2 billion a characters; you probably don't have enough memory to construct a string that large, so you shouldn't run into that limit.

Repetitions such as \*\ are greedy; when repeating a RE, the matching engine will try to repeat it as many times as possible. If later portions of the pattern don't match, the matching engine will then back up and try again with fewer repetitions.

A step-by-step example will make this more obvious. Let's consider the expression `a[bcd]*b`. This matches the letter 'a', zero or more letters from the class `[bcd]`, and finally ends with a 'b'. Now imagine matching this RE against the string `abcbd`.

<table>
<thead>
<tr>
<th>Step</th>
<th>Matched</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>The a in the RE matches.</td>
</tr>
<tr>
<td>2</td>
<td>abcbd</td>
<td>The engine matches <code>[bcd]*</code>, going as far as it can, which is to the end of the string.</td>
</tr>
<tr>
<td>3</td>
<td><strong>Failure</strong></td>
<td>The engine tries to match b, but the current position is at the end of the string, so it fails.</td>
</tr>
<tr>
<td>4</td>
<td>abcba</td>
<td>Back up, so that <code>[bcd]*</code> matches one less character.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Try b again, but the current position is at the</td>
</tr>
</tbody>
</table>
Failure last character, which is a 'd'.

Back up again, so that [bcd]* is only matching bc.

Try b again. This time the character at the current position is 'b', so it succeeds.

The end of the RE has now been reached, and it has matched abcb. This demonstrates how the matching engine goes as far as it can at first, and if no match is found it will then progressively back up and retry the rest of the RE again and again. It will back up until it has tried zero matches for [bcd]*, and if that subsequently fails, the engine will conclude that the string doesn’t match the RE at all.

Another repeating metacharacter is +, which matches one or more times. Pay careful attention to the difference between * and +; * matches zero or more times, so whatever’s being repeated may not be present at all, while + requires at least one occurrence. To use a similar example, ca+t will match cat (1 a), caaat (3 a’s), but won’t match ct.

There are two more repeating qualifiers. The question mark character, ?, matches either once or zero times; you can think of it as marking something as being optional. For example, home-?brew matches either homebrew or home-brew.

The most complicated repeated qualifier is \{m,n\}, where m and n are decimal integers. This qualifier means there must be at least m repetitions, and at most n. For example, a/{1,3}b will match a/b, a//b, and a///b. It won’t match ab, which has no slashes, or a////b, which has four.

You can omit either m or n; in that case, a reasonable value is assumed for the missing value. Omitting m is interpreted as a lower
limit of 0, while omitting $n$ results in an upper bound of infinity — actually, the upper bound is the 2-billion limit mentioned earlier, but that might as well be infinity.

Readers of a reductionist bent may notice that the three other qualifiers can all be expressed using this notation. $\{0,\}$ is the same as $\ast$, $\{1,\}$ is equivalent to $+$, and $\{0,1\}$ is the same as $\?$. It’s better to use $\ast$, $+$, or $\?$ when you can, simply because they’re shorter and easier to read.
Using Regular Expressions

Now that we've looked at some simple regular expressions, how do we actually use them in Python? The `re` module provides an interface to the regular expression engine, allowing you to compile REs into objects and then perform matches with them.

Compiling Regular Expressions

Regular expressions are compiled into pattern objects, which have methods for various operations such as searching for pattern matches or performing string substitutions.

```python
>>> import re
>>> p = re.compile('ab*')
>>> p
<_sre.SRE_Pattern object at 0x...>
```

`re.compile()` also accepts an optional `flags` argument, used to enable various special features and syntax variations. We'll go over the available settings later, but for now a single example will do:

```python
>>> p = re.compile('ab*', re.IGNORECASE)
```

The RE is passed to `re.compile()` as a string. REs are handled as strings because regular expressions aren't part of the core Python language, and no special syntax was created for expressing them. (There are applications that don’t need REs at all, so there’s no need to bloat the language specification by including them.) Instead, the `re` module is simply a C extension module included with Python, just like the `socket` or `zlib` modules.

Putting REs in strings keeps the Python language simpler, but has one disadvantage which is the topic of the next section.
As stated earlier, regular expressions use the backslash character (\") to indicate special forms or to allow special characters to be used without invoking their special meaning. This conflicts with Python's usage of the same character for the same purpose in string literals.

Let's say you want to write a RE that matches the string \section, which might be found in a LaTeX file. To figure out what to write in the program code, start with the desired string to be matched. Next, you must escape any backslashes and other metacharacters by preceding them with a backslash, resulting in the string \section. The resulting string that must be passed to `re.compile()` must be \section. However, to express this as a Python string literal, both backslashes must be escaped again.

<table>
<thead>
<tr>
<th>Characters</th>
<th>Stage</th>
</tr>
</thead>
<tbody>
<tr>
<td>\section</td>
<td>Text string to be matched</td>
</tr>
<tr>
<td>\section</td>
<td>Escaped backslash for <code>re.compile()</code></td>
</tr>
<tr>
<td>&quot;\section&quot;</td>
<td>Escaped backslashes for a string literal</td>
</tr>
</tbody>
</table>

In short, to match a literal backslash, one has to write '\\' as the RE string, because the regular expression must be \, and each backslash must be expressed as \ inside a regular Python string literal. In REs that feature backslashes repeatedly, this leads to lots of repeated backslashes and makes the resulting strings difficult to understand.

The solution is to use Python's raw string notation for regular expressions; backslashes are not handled in any special way in a string literal prefixed with 'r', so r"\n" is a two-character string.
containing \"\" and \"n\", while \"\n\" is a one-character string containing a newline. Regular expressions will often be written in Python code using this raw string notation.

<table>
<thead>
<tr>
<th>Regular String</th>
<th>Raw string</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;ab*&quot;</td>
<td>r&quot;ab*&quot;</td>
</tr>
<tr>
<td>&quot;\section&quot;</td>
<td>r&quot;\section&quot;</td>
</tr>
<tr>
<td>&quot;\w+\s+\1&quot;</td>
<td>r&quot;\w+\s+\1&quot;</td>
</tr>
</tbody>
</table>

Performing Matches

Once you have an object representing a compiled regular expression, what do you do with it? Pattern objects have several methods and attributes. Only the most significant ones will be covered here; consult the re docs for a complete listing.

<table>
<thead>
<tr>
<th>Method/Attribute</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>match()</td>
<td>Determine if the RE matches at the beginning of the string.</td>
</tr>
<tr>
<td>search()</td>
<td>Scan through a string, looking for any location where this RE matches.</td>
</tr>
<tr>
<td>findall()</td>
<td>Find all substrings where the RE matches, and returns them as a list.</td>
</tr>
<tr>
<td>finditer()</td>
<td>Find all substrings where the RE matches, and returns them as an iterator.</td>
</tr>
</tbody>
</table>

match() and search() return None if no match can be found. If they’re successful, a match object instance is returned, containing information about the match: where it starts and ends, the substring it matched, and more.

You can learn about this by interactively experimenting with the re module. If you have Tkinter available, you may also want to look at Tools/scripts/redemo.py, a demonstration program included with the Python distribution. It allows you to enter REs and strings, and
displays whether the RE matches or fails. redemo.py can be quite useful when trying to debug a complicated RE. Phil Schwartz's Kodos is also an interactive tool for developing and testing RE patterns.

This HOWTO uses the standard Python interpreter for its examples. First, run the Python interpreter, import the re module, and compile a RE:

```python
Python 2.2.2 (#1, Feb 10 2003, 12:57:01)
>>> import re
>>> p = re.compile('[a-z]+')
>>> p #doctest: +ELLIPSIS
<_sre.SRE_Pattern object at 0x...>
```

Now, you can try matching various strings against the RE [a-z]+. An empty string shouldn't match at all, since + means 'one or more repetitions'. match() should return None in this case, which will cause the interpreter to print no output. You can explicitly print the result of match() to make this clear.

```python
>>> p.match('')
>>> print p.match('')
None
```

Now, let's try it on a string that it should match, such as tempo. In this case, match() will return a match object, so you should store the result in a variable for later use.

```python
>>> m = p.match('tempo')
>>> m
<_sre.SRE_Match object at 0x...>
```

Now you can query the match object for information about the matching string. match object instances also have several methods and attributes; the most important ones are:
<table>
<thead>
<tr>
<th>Method/Attribute</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>group()</td>
<td>Return the string matched by the RE</td>
</tr>
<tr>
<td>start()</td>
<td>Return the starting position of the match</td>
</tr>
<tr>
<td>end()</td>
<td>Return the ending position of the match</td>
</tr>
<tr>
<td>span()</td>
<td>Return a tuple containing the (start, end) positions of the match</td>
</tr>
</tbody>
</table>

Trying these methods will soon clarify their meaning:

```python
>>> m.group()
'tempo'
>>> m.start(), m.end()
(0, 5)
>>> m.span()
(0, 5)
```

`group()` returns the substring that was matched by the RE. `start()` and `end()` return the starting and ending index of the match. `span()` returns both start and end indexes in a single tuple. Since the `match()` method only checks if the RE matches at the start of a string, `start()` will always be zero. However, the `search()` method of patterns scans through the string, so the match may not start at zero in that case.

```python
>>> print p.match('::: message')
None
>>> m = p.search('::: message'); print m
<_sre.SRE_Match object at 0x...>
>>> m.group()
'message'
>>> m.span()
(4, 11)
```

In actual programs, the most common style is to store the `match object` in a variable, and then check if it was `None`. This usually looks like:

```python
p = re.compile( ... )
```
m = p.match( 'string goes here' )
if m:
    print 'Match found: ', m.group()
else:
    print 'No match'

Two pattern methods return all of the matches for a pattern. findall() returns a list of matching strings:

```python
>>> p = re.compile('\d+')
>>> p.findall('12 drummers drumming, 11 pipers piping, 10 lords ['12', '11', '10']
```

findall() has to create the entire list before it can be returned as the result. The finditer() method returns a sequence of match object instances as an iterator. [1]

```python
>>> iterator = p.finditer('12 drummers drumming, 11 ... 10 ...')
>>> iterator
<callable-iterator object at 0x...>
>>> for match in iterator:
...    print match.span()
...
(0, 2)
(22, 24)
(29, 31)
```

Module-Level Functions

You don’t have to create a pattern object and call its methods; the re module also provides top-level functions called match(), search(), findall(), sub(), and so forth. These functions take the same arguments as the corresponding pattern method, with the RE string added as the first argument, and still return either None or a match object instance.

```python
>>> print re.match(r'From\s+', 'Fromage amk')
```
Under the hood, these functions simply create a pattern object for you and call the appropriate method on it. They also store the compiled object in a cache, so future calls using the same RE are faster.

Should you use these module-level functions, or should you get the pattern and call its methods yourself? That choice depends on how frequently the RE will be used, and on your personal coding style. If the RE is being used at only one point in the code, then the module functions are probably more convenient. If a program contains a lot of regular expressions, or re-uses the same ones in several locations, then it might be worthwhile to collect all the definitions in one place, in a section of code that compiles all the REs ahead of time. To take an example from the standard library, here’s an extract from the deprecated xmllib module:

```python
ref = re.compile( ... )
entityref = re.compile( ... )
charref = re.compile( ... )
starttagopen = re.compile( ... )
```

I generally prefer to work with the compiled object, even for one-time uses, but few people will be as much of a purist about this as I am.

## Compilation Flags

Compilation flags let you modify some aspects of how regular expressions work. Flags are available in the `re` module under two names, a long name such as `IGNORECASE` and a short, one-letter form such as `i`. (If you're familiar with Perl's pattern modifiers, the one-letter forms use the same letters; the short form of `re.VERBOSE` is
Multiple flags can be specified by bitwise OR-ing them; \texttt{re.I | re.M} sets both the \texttt{I} and \texttt{M} flags, for example.

Here's a table of the available flags, followed by a more detailed explanation of each one.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOTALL, S</td>
<td>Make . match any character, including newlines</td>
</tr>
<tr>
<td>IGNORECASE, I</td>
<td>Do case-insensitive matches</td>
</tr>
<tr>
<td>LOCALE, L</td>
<td>Do a locale-aware match</td>
</tr>
<tr>
<td>MULTILINE, M</td>
<td>Multi-line matching, affecting ^ and $</td>
</tr>
<tr>
<td>VERBOSE, X</td>
<td>Enable verbose REs, which can be organized more cleanly and understandably.</td>
</tr>
<tr>
<td>UNICODE, U</td>
<td>Makes several escapes like \w, \b, \s and \d dependent on the Unicode character database.</td>
</tr>
</tbody>
</table>

**I**

**IGNORECASE**

Perform case-insensitive matching; character class and literal strings will match letters by ignoring case. For example, \[A-Z\] will match lowercase letters, too, and \texttt{Spam} will match \texttt{Spam}, \texttt{spam}, or \texttt{spAM}. This lowercasing doesn't take the current locale into account; it will if you also set the \texttt{LOCALE} flag.

**L**

**LOCALE**

Make \w, \w, \b, and \b, dependent on the current locale.

Locales are a feature of the C library intended to help in writing programs that take account of language differences. For example, if you're processing French text, you'd want to be able to write \texttt{\w+} to match words, but \texttt{\w} only matches the character
class [A-Za-z]; it won’t match ‘é’ or ‘ç’. If your system is configured properly and a French locale is selected, certain C functions will tell the program that ‘é’ should also be considered a letter. Setting the **locale** flag when compiling a regular expression will cause the resulting compiled object to use these C functions for \w; this is slower, but also enables \w+ to match French words as you’d expect.

**M**
**MULTILINE**
(\^ and \$ haven’t been explained yet; they’ll be introduced in section **More Metacharacters**.)

Usually \^ matches only at the beginning of the string, and \$ matches only at the end of the string and immediately before the newline (if any) at the end of the string. When this flag is specified, \^ matches at the beginning of the string and at the beginning of each line within the string, immediately following each newline. Similarly, the \$ metacharacter matches either at the end of the string and at the end of each line (immediately preceding each newline).

**S**
**DOTALL**
Makes the ‘.’ special character match any character at all, including a newline; without this flag, ‘.’ will match anything except a newline.

**U**
**UNICODE**
Make \w, \W, \b, \B, \d, \D, \s and \S dependent on the Unicode character properties database.

**X**
**VERBOSE**
This flag allows you to write regular expressions that are more readable by granting you more flexibility in how you can format them. When this flag has been specified, whitespace within the RE string is ignored, except when the whitespace is in a character class or preceded by an unescaped backslash; this lets you organize and indent the RE more clearly. This flag also lets you put comments within a RE that will be ignored by the engine; comments are marked by a '#' that's neither in a character class or preceded by an unescaped backslash.

For example, here's a RE that uses `re.VERBOSE`; see how much easier it is to read?

```python
charref = re.compile(r'""'
    &[#]
    (  
        0[0-7]+     # Octal form
        | [0-9]+     # Decimal form
        | x[0-9a-fA-F]+ # Hexadecimal form
    )
    ;
""', re.VERBOSE)
```

Without the verbose setting, the RE would look like this:

```python
charref = re.compile("&#(0[0-7]+"  
    
    
    "|([0-9]+"  
    "|x([0-9a-fA-F]+);")
```

In the above example, Python’s automatic concatenation of string literals has been used to break up the RE into smaller pieces, but it’s still more difficult to understand than the version using `re.VERBOSE`.
More Pattern Power

So far we've only covered a part of the features of regular expressions. In this section, we'll cover some new metacharacters, and how to use groups to retrieve portions of the text that was matched.

More Metacharacters

There are some metacharacters that we haven't covered yet. Most of them will be covered in this section.

Some of the remaining metacharacters to be discussed are zero-width assertions. They don't cause the engine to advance through the string; instead, they consume no characters at all, and simply succeed or fail. For example, \b is an assertion that the current position is located at a word boundary; the position isn't changed by the \b at all. This means that zero-width assertions should never be repeated, because if they match once at a given location, they can obviously be matched an infinite number of times.

\^ Matches at the beginning of lines. Unless the MULTILINE flag has
been set, this will only match at the beginning of the string. In **MULTILINE** mode, this also matches immediately after each newline within the string.

For example, if you wish to match the word *From* only at the beginning of a line, the RE to use is `^From`.

```python
>>> print re.search('^From', 'From Here to Eternity')
<_sre.SRE_Match object at 0x...>
```

$ Matches at the end of a line, which is defined as either the end of the string, or any location followed by a newline character.

```python
>>> print re.search('}$', '{block}')
<_sre.SRE_Match object at 0x...>
```

To match a literal `$`, use \$ or enclose it inside a character class, as in `[\$]`.

\A Matches only at the start of the string. When not in **MULTILINE** mode, \A and ^ are effectively the same. In **MULTILINE** mode, they're different: \A still matches only at the beginning of the string, but ^ may match at any location inside the string that follows a newline character.

\Z Matches only at the end of the string.

\b Word boundary. This is a zero-width assertion that matches only at the beginning or end of a word. A word is defined as a
sequence of alphanumeric characters, so the end of a word is indicated by whitespace or a non-alphanumeric character.

The following example matches class only when it's a complete word; it won't match when it's contained inside another word.

```python
>>> p = re.compile(r'\bclass\b')
>>> print p.search('no class at all')
<_sre.SRE_Match object at 0x...>
>>> print p.search('the declassified algorithm')
None
>>> print p.search('one subclass is')
None
```

There are two subtleties you should remember when using this special sequence. First, this is the worst collision between Python's string literals and regular expression sequences. In Python's string literals, \b is the backspace character, ASCII value 8. If you're not using raw strings, then Python will convert the \b to a backspace, and your RE won't match as you expect it to. The following example looks the same as our previous RE, but omits the 'r' in front of the RE string.

```python
>>> p = re.compile('\bclass\b')
>>> print p.search('no class at all')
None
>>> print p.search('\b' + 'class' + '\b')
<_sre.SRE_Match object at 0x...>
```

Second, inside a character class, where there's no use for this assertion, \b represents the backspace character, for compatibility with Python's string literals.

Another zero-width assertion, this is the opposite of \b, only matching when the current position is not at a word boundary.
Frequently you need to obtain more information than just whether the RE matched or not. Regular expressions are often used to dissect strings by writing a RE divided into several subgroups which match different components of interest. For example, an RFC-822 header line is divided into a header name and a value, separated by a ':', like this:

```
From: author@example.com
User-Agent: Thunderbird 1.5.0.9 (X11/20061227)
MIME-Version: 1.0
To: editor@example.com
```

This can be handled by writing a regular expression which matches an entire header line, and has one group which matches the header name, and another group which matches the header's value.

Groups are marked by the `(' `)` metacharacters. `(' `)` have much the same meaning as they do in mathematical expressions; they group together the expressions contained inside them, and you can repeat the contents of a group with a repeating qualifier, such as *, +, ?, or {m,n}. For example, `(ab)*` will match zero or more repetitions of `ab`.

```python
>>> p = re.compile('(ab)*')
>>> print p.match('ababababab').span()
(0, 10)
```

Groups indicated with `(' `)` also capture the starting and ending index of the text that they match; this can be retrieved by passing an argument to `group()`, `start()`, `end()`, and `span()`. Groups are numbered starting with 0. Group 0 is always present; it's the whole RE, so `match object` methods all have group 0 as their default argument. Later we'll see how to express groups that don't capture
the span of text that they match.

```python
>>> p = re.compile('(a)b')
>>> m = p.match('ab')
>>> m.group()
'ab'
>>> m.group(0)
'ab'
```

Subgroups are numbered from left to right, from 1 upward. Groups can be nested; to determine the number, just count the opening parenthesis characters, going from left to right.

```python
>>> p = re.compile('(a(b)c)d')
>>> m = p.match('abcd')
>>> m.group(0)
'abcd'
>>> m.group(1)
'abc'
>>> m.group(2)
'b'
```

group() can be passed multiple group numbers at a time, in which case it will return a tuple containing the corresponding values for those groups.

```python
>>> m.group(2, 1, 2)
('b', 'abc', 'b')
```

The groups() method returns a tuple containing the strings for all the subgroups, from 1 up to however many there are.

```python
>>> m.groups()
('abc', 'b')
```

Backreferences in a pattern allow you to specify that the contents of an earlier capturing group must also be found at the current location in the string. For example, \1 will succeed if the exact contents of group 1 can be found at the current position, and fails otherwise.
Remember that Python's string literals also use a backslash followed by numbers to allow including arbitrary characters in a string, so be sure to use a raw string when incorporating backreferences in a RE.

For example, the following RE detects doubled words in a string.

```python
>>> p = re.compile(r'\b\w+\s+\1')
>>> p.search('Paris in the the spring').group()
'the the'
```

Backreferences like this aren't often useful for just searching through a string — there are few text formats which repeat data in this way — but you'll soon find out that they're very useful when performing string substitutions.

Non-capturing and Named Groups

Elaborate REs may use many groups, both to capture substrings of interest, and to group and structure the RE itself. In complex REs, it becomes difficult to keep track of the group numbers. There are two features which help with this problem. Both of them use a common syntax for regular expression extensions, so we'll look at that first.

Perl 5 added several additional features to standard regular expressions, and the Python `re` module supports most of them. It would have been difficult to choose new single-keystroke metacharacters or new special sequences beginning with `\` to represent the new features without making Perl's regular expressions confusingly different from standard REs. If you chose `&` as a new metacharacter, for example, old expressions would be assuming that `&` was a regular character and wouldn’t have escaped it by writing `\&` or `[^&]`.

The solution chosen by the Perl developers was to use `(？...)` as the extension syntax. `？` immediately after a parenthesis was a syntax
error because the ? would have nothing to repeat, so this didn't introduce any compatibility problems. The characters immediately after the ? indicate what extension is being used, so (?=foo) is one thing (a positive lookahead assertion) and (?:foo) is something else (a non-capturing group containing the subexpression foo).

Python adds an extension syntax to Perl's extension syntax. If the first character after the question mark is a P, you know that it's an extension that's specific to Python. Currently there are two such extensions: (?P<name>...) defines a named group, and (?P=name) is a backreference to a named group. If future versions of Perl 5 add similar features using a different syntax, the re module will be changed to support the new syntax, while preserving the Python-specific syntax for compatibility’s sake.

Now that we've looked at the general extension syntax, we can return to the features that simplify working with groups in complex REs. Since groups are numbered from left to right and a complex expression may use many groups, it can become difficult to keep track of the correct numbering. Modifying such a complex RE is annoying, too: insert a new group near the beginning and you change the numbers of everything that follows it.

Sometimes you'll want to use a group to collect a part of a regular expression, but aren't interested in retrieving the group's contents. You can make this fact explicit by using a non-capturing group: (?:. . .), where you can replace the . . . with any other regular expression.

>>> m = re.match("([abc])+", "abc")
>>> m.groups()
('c',)
>>> m = re.match("(?:[abc])+", "abc")
>>> m.groups()
()
Except for the fact that you can’t retrieve the contents of what the group matched, a non-capturing group behaves exactly the same as a capturing group; you can put anything inside it, repeat it with a repetition metacharacter such as *, and nest it within other groups (capturing or non-capturing). (?::...) is particularly useful when modifying an existing pattern, since you can add new groups without changing how all the other groups are numbered. It should be mentioned that there’s no performance difference in searching between capturing and non-capturing groups; neither form is any faster than the other.

A more significant feature is named groups: instead of referring to them by numbers, groups can be referenced by a name.

The syntax for a named group is one of the Python-specific extensions: (?P<name>...). name is, obviously, the name of the group. Named groups also behave exactly like capturing groups, and additionally associate a name with a group. The match object methods that deal with capturing groups all accept either integers that refer to the group by number or strings that contain the desired group’s name. Named groups are still given numbers, so you can retrieve information about a group in two ways:

```python
>>> p = re.compile(r'(?P<word>\b\w+\b)')
>>> m = p.search( '((( Lots of punctuation )))' )
>>> m.group('word')
'Lots'
>>> m.group(1)
'Lots'
```

Named groups are handy because they let you use easily-remembered names, instead of having to remember numbers. Here’s an example RE from the `imaplib` module:

```python
InternalDate = re.compile(r'INTERNALDATE ''
  r'(?P<day>[ 123][0-9])-(?P<mon>[A-Z][a-z][a-z])-'
  r'(?P<year>[0-9][0-9][0-9][0-9])'
)```

It's obviously much easier to retrieve \texttt{m.group('zonem')}, instead of having to remember to retrieve group 9.

The syntax for backreferences in an expression such as \texttt{(\ldots)\1} refers to the number of the group. There's naturally a variant that uses the group name instead of the number. This is another Python extension: \texttt{(?P=name)} indicates that the contents of the group called \textit{name} should again be matched at the current point. The regular expression for finding doubled words, \texttt{([^b\w]+)\s+(?P=word)} can also be written as \texttt{(?P<word>[^b\w]+)\s+(?P=word)}:

```python
>>> p = re.compile(r'(?P<word>[^b\w]+)\s+(?P=word)')
>>> p.search('Paris in the the spring').group()
'the the'
```

**Lookahead Assertions**

Another zero-width assertion is the lookahead assertion. Lookahead assertions are available in both positive and negative form, and look like this:

\texttt{(?=\ldots)}

Positive lookahead assertion. This succeeds if the contained regular expression, represented here by \texttt{\ldots}, successfully matches at the current location, and fails otherwise. But, once the contained expression has been tried, the matching engine doesn't advance at all; the rest of the pattern is tried right where the assertion started.

\texttt{(?![\ldots]}

Negative lookahead assertion. This is the opposite of the positive assertion; it succeeds if the contained expression \textit{doesn't} match
at the current position in the string.

To make this concrete, let’s look at a case where a lookahead is useful. Consider a simple pattern to match a filename and split it apart into a base name and an extension, separated by a `. `. For example, in `news.rc`, `news` is the base name, and `rc` is the filename’s extension.

The pattern to match this is quite simple:

```
.*[.].*$
```

Notice that the `.` needs to be treated specially because it’s a metacharacter; I’ve put it inside a character class. Also notice the trailing `$`; this is added to ensure that all the rest of the string must be included in the extension. This regular expression matches `foo.bar` and `autoexec.bat` and `sendmail.cf` and `printers.conf`.

Now, consider complicating the problem a bit; what if you want to match filenames where the extension is not `bat`? Some incorrect attempts:

```
.*[.][^b].*$
```

The first attempt above tries to exclude `bat` by requiring that the first character of the extension is not a `b`. This is wrong, because the pattern also doesn’t match `foo.bar`.

```
.*[.][^b][^a][^t]$```

The expression gets messier when you try to patch up the first solution by requiring one of the following cases to match: the first character of the extension isn’t `b`; the second character isn’t `a`; or the third character isn’t `t`. This accepts `foo.bar` and rejects `autoexec.bat`, but it requires a three-letter extension and won’t accept a filename with a two-letter extension such as `sendmail.cf`. 
We’ll complicate the pattern again in an effort to fix it.

\.*\.[^b]\.?.?\[^a]\.?.?..?[^t]?\)*$  

In the third attempt, the second and third letters are all made optional in order to allow matching extensions shorter than three characters, such as `sendmail.cf`.

The pattern’s getting really complicated now, which makes it hard to read and understand. Worse, if the problem changes and you want to exclude both `bat` and `exe` as extensions, the pattern would get even more complicated and confusing.

A negative lookahead cuts through all this confusion:

\.*\.[^!.bat$][^.]\)*$  
The negative lookahead means: if the expression `bat` doesn’t match at this point, try the rest of the pattern; if `bat$` does match, the whole pattern will fail. The trailing `$` is required to ensure that something like `sample.bat`, where the extension only starts with `bat`, will be allowed. The `[^.]\)*` makes sure that the pattern works when there are multiple dots in the filename.

Excluding another filename extension is now easy; simply add it as an alternative inside the assertion. The following pattern excludes filenames that end in either `bat` or `exe`:

\.*\.[^!.bat$|exe$][^.]\)*$
Modifying Strings

Up to this point, we've simply performed searches against a static string. Regular expressions are also commonly used to modify strings in various ways, using the following pattern methods:

<table>
<thead>
<tr>
<th>Method/Attribute</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>split()</td>
<td>Split the string into a list, splitting it wherever the RE matches</td>
</tr>
<tr>
<td>sub()</td>
<td>Find all substrings where the RE matches, and replace them with a different string</td>
</tr>
<tr>
<td>subn()</td>
<td>Does the same thing as sub(), but returns the new string and the number of replacements</td>
</tr>
</tbody>
</table>

Splitting Strings

The split() method of a pattern splits a string apart wherever the RE matches, returning a list of the pieces. It's similar to the split() method of strings but provides much more generality in the delimiters that you can split by; split() only supports splitting by whitespace or by a fixed string. As you'd expect, there's a module-level re.split() function, too.

```
.split(string[, maxsplit=0])
```

Split string by the matches of the regular expression. If capturing parentheses are used in the RE, then their contents will also be returned as part of the resulting list. If maxsplit is nonzero, at most maxsplit splits are performed.

You can limit the number of splits made, by passing a value for maxsplit. When maxsplit is nonzero, at most maxsplit splits will be made, and the remainder of the string is returned as the final element of the list. In the following example, the delimiter is any...
sequence of non-alphanumeric characters.

```python
>>> p = re.compile(r'\W+')
>>> p.split('This is a test, short and sweet, of split().')
['This', 'is', 'a', 'test', 'short', 'and', 'sweet', 'of', 'split()']
>>> p.split('This is a test, short and sweet, of split().', 3)
['This', 'is', 'a', 'test, short and sweet, of split().']
```

Sometimes you’re not only interested in what the text between delimiters is, but also need to know what the delimiter was. If capturing parentheses are used in the RE, then their values are also returned as part of the list. Compare the following calls:

```python
>>> p = re.compile(r'\W+')
>>> p2 = re.compile(r'([^\W]+)')
>>> p.split('This... is a test.')
['This', 'is', 'a', 'test', '']
>>> p2.split('This... is a test.')
['This', '...', 'is', '', 'a', '', 'test', '.', '']
```

The module-level function `re.split()` adds the RE to be used as the first argument, but is otherwise the same.

```python
>>> re.split('([^\W]+)', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split('([^\W]+)', 'Words, words, words.')
['Words', '', '', 'words', '', 'words', '.', '', '']
>>> re.split('([^\W]+)', 'Words, words, words.', 1)
['Words', 'words, words. ']
```

**Search and Replace**

Another common task is to find all the matches for a pattern, and replace them with a different string. The `sub()` method takes a replacement value, which can be either a string or a function, and the string to be processed.

```python
sub(replacement, string[, count=0])
```
Returns the string obtained by replacing the leftmost non-overlapping occurrences of the RE in string by the replacement replacement. If the pattern isn’t found, string is returned unchanged.

The optional argument count is the maximum number of pattern occurrences to be replaced; count must be a non-negative integer. The default value of 0 means to replace all occurrences.

Here’s a simple example of using the sub() method. It replaces colour names with the word colour:

```python
>>> p = re.compile('(blue|white|red)')
>>> p.sub('colour', 'blue socks and red shoes')
'colour socks and colour shoes'
>>> p.sub('colour', 'blue socks and red shoes', count=1)
'colour socks and red shoes'
```

The subn() method does the same work, but returns a 2-tuple containing the new string value and the number of replacements that were performed:

```python
>>> p = re.compile('(blue|white|red)')
>>> p.subn('colour', 'blue socks and red shoes')
('colour socks and colour shoes', 2)
>>> p.subn('colour', 'no colours at all')
('no colours at all', 0)
```

Empty matches are replaced only when they’re not adjacent to a previous match.

```python
>>> p = re.compile('x*')
>>> p.sub('-', 'abxd')
'-a-b-d-'
```

If replacement is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted
to a carriage return, and so forth. Unknown escapes such as \j are left alone. Backreferences, such as \6, are replaced with the substring matched by the corresponding group in the RE. This lets you incorporate portions of the original text in the resulting replacement string.

This example matches the word `section` followed by a string enclosed in `{, }`, and changes `section` to `subsection`:

```python
>>> p = re.compile('section{ ( [^}]* ) }', re.VERBOSE)
>>> p.sub(r'subsection{\1}', 'section{First} section{Second}')
'subsection{First} subsection{Second}'
```

There's also a syntax for referring to named groups as defined by the `(\?P<name>...)` syntax. `\g<name>` will use the substring matched by the group named `name`, and `\g<number>` uses the corresponding group number. `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement string such as `\g<2>0`. (`\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character '0'.) The following substitutions are all equivalent, but use all three variations of the replacement string.

```python
>>> p = re.compile('section{ (?P<name> [^}]* ) }', re.VERBOSE)
>>> p.sub(r'subsection{\1}','section{First}')
'subsection{First}'
>>> p.sub(r'subsection{\g<1>}','section{First}')
'subsection{First}'
>>> p.sub(r'subsection{\g<name>}','section{First}')
'subsection{First}'
```

*replacement* can also be a function, which gives you even more control. If *replacement* is a function, the function is called for every non-overlapping occurrence of *pattern*. On each call, the function is passed a *match object* argument for the match and can use this information to compute the desired replacement string and return it.
In the following example, the replacement function translates decimals into hexadecimal:

```python
>>> def hexrepl(match):
...    "Return the hex string for a decimal number"
...    value = int(match.group())
...    return hex(value)
...
>>> p = re.compile(r'\d+')
>>> p.sub(hexrepl, 'Call 65490 for printing, 49152 for user code.
Call 0xfffd2 for printing, 0xc000 for user code.')
```

When using the module-level `re.sub()` function, the pattern is passed as the first argument. The pattern may be provided as an object or as a string; if you need to specify regular expression flags, you must either use a pattern object as the first parameter, or use embedded modifiers in the pattern string, e.g. `sub("(?i)b+", "x", "bbbb BBBB")` returns `x x`.
Common Problems

Regular expressions are a powerful tool for some applications, but in some ways their behaviour isn’t intuitive and at times they don’t behave the way you may expect them to. This section will point out some of the most common pitfalls.

Use String Methods

Sometimes using the `re` module is a mistake. If you’re matching a fixed string, or a single character class, and you’re not using any `re` features such as the `IGNORECASE` flag, then the full power of regular expressions may not be required. Strings have several methods for performing operations with fixed strings and they’re usually much faster, because the implementation is a single small C loop that’s been optimized for the purpose, instead of the large, more generalized regular expression engine.

One example might be replacing a single fixed string with another one; for example, you might replace `word` with `deed`. `re.sub()` seems like the function to use for this, but consider the `replace()` method. Note that `replace()` will also replace `word` inside words, turning `swordfish` into `sdeedfish`, but the naive RE `word` would have done that, too. (To avoid performing the substitution on parts of words, the pattern would have to be `\bword\b`, in order to require that `word` have a word boundary on either side. This takes the job beyond `replace()`'s abilities.)

Another common task is deleting every occurrence of a single character from a string or replacing it with another single character. You might do this with something like `re.sub('\n', '', S)`, but `translate()` is capable of doing both tasks and will be faster than
any regular expression operation can be.

In short, before turning to the `re` module, consider whether your problem can be solved with a faster and simpler string method.

## match() versus search()

The `match()` function only checks if the RE matches at the beginning of the string while `search()` will scan forward through the string for a match. It’s important to keep this distinction in mind. Remember, `match()` will only report a successful match which will start at 0; if the match wouldn’t start at zero, `match()` will *not* report it.

```python
>>> print re.match('super', 'superstition').span()
(0, 5)
>>> print re.match('super', 'insuperable')
None
```

On the other hand, `search()` will scan forward through the string, reporting the first match it finds.

```python
>>> print re.search('super', 'superstition').span()
(0, 5)
>>> print re.search('super', 'insuperable').span()
(2, 7)
```

Sometimes you’ll be tempted to keep using `re.match()`, and just add `.*` to the front of your RE. Resist this temptation and use `re.search()` instead. The regular expression compiler does some analysis of REs in order to speed up the process of looking for a match. One such analysis figures out what the first character of a match must be; for example, a pattern starting with `Crow` must match starting with a `'c'`. The analysis lets the engine quickly scan through the string looking for the starting character, only trying the full match if a `'c'` is found.
Adding .* defeats this optimization, requiring scanning to the end of the string and then backtracking to find a match for the rest of the RE. Use re.search() instead.

## Greedy versus Non-Greedy

When repeating a regular expression, as in a*, the resulting action is to consume as much of the pattern as possible. This fact often bites you when you’re trying to match a pair of balanced delimiters, such as the angle brackets surrounding an HTML tag. The naive pattern for matching a single HTML tag doesn’t work because of the greedy nature of .*.

```python
>>> s = '<html><head><title>Title</title>'
>>> len(s)
32
>>> print re.match('.*', s).span()
(0, 32)
>>> print re.match('.*', s).group()
<html><head><title>Title</title>
```

The RE matches the < in <html>, and the .* consumes the rest of the string. There’s still more left in the RE, though, and the > can’t match at the end of the string, so the regular expression engine has to backtrack character by character until it finds a match for the >. The final match extends from the < in <html> to the > in </title>, which isn’t what you want.

In this case, the solution is to use the non-greedy qualifiers *?, +?, ??, or {m,n}?, which match as little text as possible. In the above example, the > is tried immediately after the first < matches, and when it fails, the engine advances a character at a time, retrying the > at every step. This produces just the right result:

```python
>>> print re.match('.*?', s).group()
<html><head><title>Title</title>
```
(Note that parsing HTML or XML with regular expressions is painful. Quick-and-dirty patterns will handle common cases, but HTML and XML have special cases that will break the obvious regular expression; by the time you've written a regular expression that handles all of the possible cases, the patterns will be very complicated. Use an HTML or XML parser module for such tasks.)

Using `re.VERBOSE`

By now you've probably noticed that regular expressions are a very compact notation, but they're not terribly readable. REs of moderate complexity can become lengthy collections of backslashes, parentheses, and metacharacters, making them difficult to read and understand.

For such REs, specifying the `re.VERBOSE` flag when compiling the regular expression can be helpful, because it allows you to format the regular expression more clearly.

The `re.VERBOSE` flag has several effects. Whitespace in the regular expression that isn't inside a character class is ignored. This means that an expression such as `dog | cat` is equivalent to the less readable `dog|cat`, but `[a b]` will still match the characters 'a', 'b', or a space. In addition, you can also put comments inside a RE; comments extend from a '#' character to the next newline. When used with triple-quoted strings, this enables REs to be formatted more neatly:

```python
pat = re.compile(r'''\s* (?P<header>[^:]+) \s* : (?P<value>.*?) # Skip leading whitespace # Header name # Whitespace, and a colon # The header's value -- *? used to # lose the following trailing whitespace'''
``
This is far more readable than:

```python
pat = re.compile(r'^\s*(?P<header>[^:]+)\s*: (?P<value>.*?)\s*$')
```
Regular expressions are a complicated topic. Did this document help you understand them? Were there parts that were unclear, or Problems you encountered that weren’t covered here? If so, please send suggestions for improvements to the author.

The most complete book on regular expressions is almost certainly Jeffrey Friedl's Mastering Regular Expressions, published by O'Reilly. Unfortunately, it exclusively concentrates on Perl and Java’s flavours of regular expressions, and doesn’t contain any Python material at all, so it won’t be useful as a reference for programming in Python. (The first edition covered Python's now-removed `regex` module, which won't help you much.) Consider checking it out from your library.

Footnotes

[1] Introduced in Python 2.2.2.
Abstract

Sockets are used nearly everywhere, but are one of the most severely misunderstood technologies around. This is a 10,000 foot overview of sockets. It's not really a tutorial - you'll still have work to do in getting things operational. It doesn't cover the fine points (and there are a lot of them), but I hope it will give you enough background to begin using them decently.
Sockets

I'm only going to talk about INET sockets, but they account for at least 99% of the sockets in use. And I'll only talk about STREAM sockets - unless you really know what you're doing (in which case this HOWTO isn't for you!), you'll get better behavior and performance from a STREAM socket than anything else. I will try to clear up the mystery of what a socket is, as well as some hints on how to work with blocking and non-blocking sockets. But I'll start by talking about blocking sockets. You'll need to know how they work before dealing with non-blocking sockets.

Part of the trouble with understanding these things is that “socket” can mean a number of subtly different things, depending on context. So first, let’s make a distinction between a “client” socket - an endpoint of a conversation, and a “server” socket, which is more like a switchboard operator. The client application (your browser, for example) uses “client” sockets exclusively; the web server it’s talking to uses both “server” sockets and “client” sockets.

History

Of the various forms of IPC, sockets are by far the most popular. On any given platform, there are likely to be other forms of IPC that are faster, but for cross-platform communication, sockets are about the only game in town.

They were invented in Berkeley as part of the BSD flavor of Unix. They spread like wildfire with the Internet. With good reason — the combination of sockets with INET makes talking to arbitrary machines around the world unbelievably easy (at least compared to other schemes).
Creating a Socket

Roughly speaking, when you clicked on the link that brought you to this page, your browser did something like the following:

```python
# create an INET, STREAMing socket
s = socket.socket(
    socket.AF_INET, socket.SOCK_STREAM)
# now connect to the web server on port 80
# - the normal http port
s.connect(("www.mcmillan-inc.com", 80))
```

When the `connect` completes, the socket `s` can be used to send in a request for the text of the page. The same socket will read the reply, and then be destroyed. That’s right, destroyed. Client sockets are normally only used for one exchange (or a small set of sequential exchanges).

What happens in the web server is a bit more complex. First, the web server creates a “server socket”:

```python
# create an INET, STREAMing socket
serversocket = socket.socket(
    socket.AF_INET, socket.SOCK_STREAM)
# bind the socket to a public host,
# and a well-known port
serversocket.bind((socket.gethostname(), 80))
# become a server socket
serversocket.listen(5)
```

A couple things to notice: we used `socket.gethostname()` so that the socket would be visible to the outside world. If we had used `s.bind(('localhost', 80))` or `s.bind(('127.0.0.1', 80))` we would still have a “server” socket, but one that was only visible within the same machine. `s.bind(('', 80))` specifies that the socket is reachable by any address the machine happens to have.
A second thing to note: low number ports are usually reserved for “well known” services (HTTP, SNMP etc). If you're playing around, use a nice high number (4 digits).

Finally, the argument to `listen` tells the socket library that we want it to queue up as many as 5 connect requests (the normal max) before refusing outside connections. If the rest of the code is written properly, that should be plenty.

Now that we have a “server” socket, listening on port 80, we can enter the mainloop of the web server:

```python
while 1:
    # accept connections from outside
    (clientsocket, address) = serversocket.accept()
    # now do something with the clientsocket
    # in this case, we'll pretend this is a threaded server
    ct = client_thread(clientsocket)
    ct.run()
```

There's actually 3 general ways in which this loop could work - dispatching a thread to handle `clientsocket`, create a new process to handle `clientsocket`, or restructure this app to use non-blocking sockets, and multiplex between our “server” socket and any active `clientsocket`s using `select`. More about that later. The important thing to understand now is this: this is all a “server” socket does. It doesn’t send any data. It doesn’t receive any data. It just produces “client” sockets. Each `clientsocket` is created in response to some other “client” socket doing a `connect()` to the host and port we’re bound to. As soon as we’ve created that `clientsocket`, we go back to listening for more connections. The two “clients” are free to chat it up - they are using some dynamically allocated port which will be recycled when the conversation ends.
If you need fast IPC between two processes on one machine, you should look into whatever form of shared memory the platform offers. A simple protocol based around shared memory and locks or semaphores is by far the fastest technique.

If you do decide to use sockets, bind the “server” socket to 'localhost'. On most platforms, this will take a shortcut around a couple of layers of network code and be quite a bit faster.
Using a Socket

The first thing to note, is that the web browser’s “client” socket and the web server’s “client” socket are identical beasts. That is, this is a “peer to peer” conversation. Or to put it another way, as the designer, you will have to decide what the rules of etiquette are for a conversation. Normally, the connecting socket starts the conversation, by sending in a request, or perhaps a signon. But that’s a design decision - it’s not a rule of sockets.

Now there are two sets of verbs to use for communication. You can use send and recv, or you can transform your client socket into a file-like beast and use read and write. The latter is the way Java presents its sockets. I’m not going to talk about it here, except to warn you that you need to use flush on sockets. These are buffered “files”, and a common mistake is to write something, and then read for a reply. Without a flush in there, you may wait forever for the reply, because the request may still be in your output buffer.

Now we come to the major stumbling block of sockets - send and recv operate on the network buffers. They do not necessarily handle all the bytes you hand them (or expect from them), because their major focus is handling the network buffers. In general, they return when the associated network buffers have been filled (send) or emptied (recv). They then tell you how many bytes they handled. It is your responsibility to call them again until your message has been completely dealt with.

When a recv returns 0 bytes, it means the other side has closed (or is in the process of closing) the connection. You will not receive any more data on this connection. Ever. You may be able to send data successfully; I’ll talk more about this later.
A protocol like HTTP uses a socket for only one transfer. The client sends a request, then reads a reply. That's it. The socket is discarded. This means that a client can detect the end of the reply by receiving 0 bytes.

But if you plan to reuse your socket for further transfers, you need to realize that there is no EOT on a socket. I repeat: if a socket send or recv returns after handling 0 bytes, the connection has been broken. If the connection has not been broken, you may wait on a recv forever, because the socket will not tell you that there's nothing more to read (for now). Now if you think about that a bit, you'll come to realize a fundamental truth of sockets: messages must either be fixed length (yuck), or be delimited (shrug), or indicate how long they are (much better), or end by shutting down the connection. The choice is entirely yours, (but some ways are righter than others).

Assuming you don't want to end the connection, the simplest solution is a fixed length message:

```python
class mysocket:
    '''demonstration class only
    - coded for clarity, not efficiency
    '''

    def __init__(self, sock=None):
        if sock is None:
            self.sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
        else:
            self.sock = sock

    def connect(self, host, port):
        self.sock.connect((host, port))

    def mysend(self, msg):
        totalsent = 0
        while totalsent < MSGLEN:
            sent = self.sock.send(msg[totalsent:]
            if sent == 0:
                raise RuntimeError("socket connection broken")
```
```python
totalsent = totalsent + sent

def myreceive(self):
    chunks = []
    bytes_recd = 0
    while bytes_recd < MSGLEN:
        chunk = self.sock.recv(min(MSGLEN - bytes_recd, 204)
        if chunk == '':
            raise RuntimeError("socket connection broken")
        chunks.append(chunk)
        bytes_recd = bytes_recd + len(chunk)
    return ''.join(chunks)
```

The sending code here is usable for almost any messaging scheme - in Python you send strings, and you can use `len()` to determine its length (even if it has embedded `\0` characters). It's mostly the receiving code that gets more complex. (And in C, it's not much worse, except you can't use `strlen` if the message has embedded `\0`s.)

The easiest enhancement is to make the first character of the message an indicator of message type, and have the type determine the length. Now you have two `recv`s - the first to get (at least) that first character so you can look up the length, and the second in a loop to get the rest. If you decide to go the delimited route, you'll be receiving in some arbitrary chunk size, (4096 or 8192 is frequently a good match for network buffer sizes), and scanning what you've received for a delimiter.

One complication to be aware of: if your conversational protocol allows multiple messages to be sent back to back (without some kind of reply), and you pass `recv` an arbitrary chunk size, you may end up reading the start of a following message. You'll need to put that aside and hold onto it, until it's needed.

Prefixing the message with its length (say, as 5 numeric characters) gets more complex, because (believe it or not), you may not get all 5
characters in one `recv`. In playing around, you'll get away with it; but in high network loads, your code will very quickly break unless you use two `recv` loops - the first to determine the length, the second to get the data part of the message. Nasty. This is also when you'll discover that `send` does not always manage to get rid of everything in one pass. And despite having read this, you will eventually get bit by it!

In the interests of space, building your character, (and preserving my competitive position), these enhancements are left as an exercise for the reader. Lets move on to cleaning up.

**Binary Data**

It is perfectly possible to send binary data over a socket. The major problem is that not all machines use the same formats for binary data. For example, a Motorola chip will represent a 16 bit integer with the value 1 as the two hex bytes 00 01. Intel and DEC, however, are byte-reversed - that same 1 is 01 00. Socket libraries have calls for converting 16 and 32 bit integers - `ntohl`, `htonl`, `ntohs`, `htons` where “n” means `network` and “h” means `host`, “s” means `short` and “l” means `long`. Where network order is host order, these do nothing, but where the machine is byte-reversed, these swap the bytes around appropriately.

In these days of 32 bit machines, the ascii representation of binary data is frequently smaller than the binary representation. That's because a surprising amount of the time, all those longs have the value 0, or maybe 1. The string “0” would be two bytes, while binary is four. Of course, this doesn't fit well with fixed-length messages. Decisions, decisions.
Disconnected

Strictly speaking, you're supposed to use `shutdown` on a socket before you `close` it. The `shutdown` is an advisory to the socket at the other end. Depending on the argument you pass it, it can mean “I'm not going to send anymore, but I'll still listen”, or “I'm not listening, good riddance!”. Most socket libraries, however, are so used to programmers neglecting to use this piece of etiquette that normally a `close` is the same as `shutdown(); close()`. So in most situations, an explicit `shutdown` is not needed.

One way to use `shutdown` effectively is in an HTTP-like exchange. The client sends a request and then does a `shutdown(1)`. This tells the server “This client is done sending, but can still receive.” The server can detect “EOF” by a receive of 0 bytes. It can assume it has the complete request. The server sends a reply. If the `send` completes successfully then, indeed, the client was still receiving.

Python takes the automatic shutdown a step further, and says that when a socket is garbage collected, it will automatically do a `close` if it's needed. But relying on this is a very bad habit. If your socket just disappears without doing a `close`, the socket at the other end may hang indefinitely, thinking you're just being slow. *Please close* your sockets when you're done.

**When Sockets Die**

Probably the worst thing about using blocking sockets is what happens when the other side comes down hard (without doing a `close`). Your socket is likely to hang. SOCKSTREAM is a reliable protocol, and it will wait a long, long time before giving up on a connection. If you're using threads, the entire thread is essentially
dead. There’s not much you can do about it. As long as you aren’t doing something dumb, like holding a lock while doing a blocking read, the thread isn’t really consuming much in the way of resources. Do not try to kill the thread - part of the reason that threads are more efficient than processes is that they avoid the overhead associated with the automatic recycling of resources. In other words, if you do manage to kill the thread, your whole process is likely to be screwed up.
Non-blocking Sockets

If you've understood the preceding, you already know most of what you need to know about the mechanics of using sockets. You'll still use the same calls, in much the same ways. It's just that, if you do it right, your app will be almost inside-out.

In Python, you use `socket.setblocking(0)` to make it non-blocking. In C, it's more complex, (for one thing, you'll need to choose between the BSD flavor `O_NONBLOCK` and the almost indistinguishable Posix flavor `O_NDELAY`, which is completely different from `TCP_NODELAY`), but it's the exact same idea. You do this after creating the socket, but before using it. (Actually, if you're nuts, you can switch back and forth.)

The major mechanical difference is that `send`, `recv`, `connect` and `accept` can return without having done anything. You have (of course) a number of choices. You can check return code and error codes and generally drive yourself crazy. If you don't believe me, try it sometime. Your app will grow large, buggy and suck CPU. So let's skip the brain-dead solutions and do it right.

Use `select`.

In C, coding `select` is fairly complex. In Python, it's a piece of cake, but it's close enough to the C version that if you understand `select` in Python, you'll have little trouble with it in C:

```python
ready_to_read, ready_to_write, in_error = 
    select.select( 
        potential_readers, 
        potential_writers, 
        potential_errs, 
        timeout)
```
You pass `select` three lists: the first contains all sockets that you might want to try reading; the second all the sockets you might want to try writing to, and the last (normally left empty) those that you want to check for errors. You should note that a socket can go into more than one list. The `select` call is blocking, but you can give it a timeout. This is generally a sensible thing to do - give it a nice long timeout (say a minute) unless you have good reason to do otherwise.

In return, you will get three lists. They contain the sockets that are actually readable, writable and in error. Each of these lists is a subset (possibly empty) of the corresponding list you passed in.

If a socket is in the output readable list, you can be as-close-to-certain-as-we-ever-get-in-this-business that a `recv` on that socket will return something. Same idea for the writable list. You'll be able to send something. Maybe not all you want to, but something is better than nothing. (Actually, any reasonably healthy socket will return as writable - it just means outbound network buffer space is available.)

If you have a “server” socket, put it in the potential_readers list. If it comes out in the readable list, your `accept` will (almost certainly) work. If you have created a new socket to connect to someone else, put it in the potential_writers list. If it shows up in the writable list, you have a decent chance that it has connected.

One very nasty problem with `select`: if somewhere in those input lists of sockets is one which has died a nasty death, the `select` will fail. You then need to loop through every single damn socket in all those lists and do a `select([sock],[[],[],0])` until you find the bad one. That timeout of 0 means it won’t take long, but it’s ugly.

Actually, `select` can be handy even with blocking sockets. It’s one way of determining whether you will block - the socket returns as
readable when there's something in the buffers. However, this still doesn't help with the problem of determining whether the other end is done, or just busy with something else.

**Portability alert**: On Unix, `select` works both with the sockets and files. Don't try this on Windows. On Windows, `select` works with sockets only. Also note that in C, many of the more advanced socket options are done differently on Windows. In fact, on Windows I usually use threads (which work very, very well) with my sockets. Face it, if you want any kind of performance, your code will look very different on Windows than on Unix.

**Performance**

There's no question that the fastest sockets code uses non-blocking sockets and `select` to multiplex them. You can put together something that will saturate a LAN connection without putting any strain on the CPU. The trouble is that an app written this way can't do much of anything else - it needs to be ready to shuffle bytes around at all times.

Assuming that your app is actually supposed to do something more than that, threading is the optimal solution, (and using non-blocking sockets will be faster than using blocking sockets). Unfortunately, threading support in Unixes varies both in API and quality. So the normal Unix solution is to fork a subprocess to deal with each connection. The overhead for this is significant (and don't do this on Windows - the overhead of process creation is enormous there). It also means that unless each subprocess is completely independent, you'll need to use another form of IPC, say a pipe, or shared memory and semaphores, to communicate between the parent and child processes.

Finally, remember that even though blocking sockets are somewhat slower than non-blocking, in many cases they are the “right” solution.
After all, if your app is driven by the data it receives over a socket, there’s not much sense in complicating the logic just so your app can wait on `select` instead of `recv`.
Python lists have a built-in `list.sort()` method that modifies the list in-place. There is also a `sorted()` built-in function that builds a new sorted list from an iterable.

In this document, we explore the various techniques for sorting data using Python.
A simple ascending sort is very easy: just call the `sorted()` function. It returns a new sorted list:

```python
>>> sorted([5, 2, 3, 1, 4])
[1, 2, 3, 4, 5]
```

You can also use the `list.sort()` method of a list. It modifies the list in-place (and returns `None` to avoid confusion). Usually it’s less convenient than `sorted()` - but if you don’t need the original list, it’s slightly more efficient.

```python
>>> a = [5, 2, 3, 1, 4]
>>> a.sort()
>>> a
[1, 2, 3, 4, 5]
```

Another difference is that the `list.sort()` method is only defined for lists. In contrast, the `sorted()` function accepts any iterable.

```python
[1, 2, 3, 4, 5]
```
Key Functions

Starting with Python 2.4, both `list.sort()` and `sorted()` added a `key` parameter to specify a function to be called on each list element prior to making comparisons.

For example, here's a case-insensitive string comparison:

```python
>>> sorted("This is a test string from Andrew".split(), key=str.lower)
['a', 'Andrew', 'from', 'is', 'string', 'test', 'This']
```

The value of the `key` parameter should be a function that takes a single argument and returns a key to use for sorting purposes. This technique is fast because the key function is called exactly once for each input record.

A common pattern is to sort complex objects using some of the object's indices as keys. For example:

```python
>>> student_tuples = [
...   ('john', 'A', 15),
...   ('jane', 'B', 12),
...   ('dave', 'B', 10),
... ]
>>> sorted(student_tuples, key=lambda student: student[2])  # sort by age
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]
```

The same technique works for objects with named attributes. For example:

```python
>>> class Student:
...   def __init__(self, name, grade, age):
...     self.name = name
...     self.grade = grade
...     self.age = age
...   def __repr__(self):
```
... return repr((self.name, self.grade, self.age))

>>> student_objects = [
...     Student('john', 'A', 15),
...     Student('jane', 'B', 12),
...     Student('dave', 'B', 10),
... ]

>>> sorted(student_objects, key=lambda student: student.age)
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]
Operator Module Functions

The key-function patterns shown above are very common, so Python provides convenience functions to make accessor functions easier and faster. The operator module has `operator.itemgetter()`, `operator.attrgetter()`, and starting in Python 2.5 an `operator.methodcaller()` function.

Using those functions, the above examples become simpler and faster:

```python
>>> from operator import itemgetter, attrgetter

>>> sorted(student_tuples, key=itemgetter(2))
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]

>>> sorted(student_objects, key=attrgetter('age'))
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]
```

The operator module functions allow multiple levels of sorting. For example, to sort by `grade` then by `age`:

```python
>>> sorted(student_tuples, key=itemgetter(1,2))
[('john', 'A', 15), ('dave', 'B', 10), ('jane', 'B', 12)]

>>> sorted(student_objects, key=attrgetter('grade', 'age'))
[('john', 'A', 15), ('dave', 'B', 10), ('jane', 'B', 12)]
```

The `operator.methodcaller()` function makes method calls with fixed parameters for each object being sorted. For example, the `str.count()` method could be used to compute message priority by counting the number of exclamation marks in a message:

```python
>>> from operator import methodcaller

>>> messages = ['critical!!!', 'hurry!', 'standby', 'immediate!']
>>> messages.sort(key=methodcaller('count', '!'))
```

```python
[('immediate!', 1), ('hurry!', 1), ('critical!!!', 3), ('standby', 0)]
```
>>> sorted(messages, key=methodcaller('count', '!''))
['standby', 'hurry!', 'immediate!!', 'critical!!']
Ascending and Descending

Both `list.sort()` and `sorted()` accept a `reverse` parameter with a boolean value. This is used to flag descending sorts. For example, to get the student data in reverse age order:

```python
>>> sorted(student_tuples, key=itemgetter(2), reverse=True)
[('john', 'A', 15), ('jane', 'B', 12), ('dave', 'B', 10)]
```

```python
>>> sorted(student_objects, key=attrgetter('age'), reverse=True)
[('john', 'A', 15), ('jane', 'B', 12), ('dave', 'B', 10)]
```
Sort Stability and Complex Sorts

Starting with Python 2.2, sorts are guaranteed to be stable. That means that when multiple records have the same key, their original order is preserved.

```python
>>> data = [('red', 1), ('blue', 1), ('red', 2), ('blue', 2)]
>>> sorted(data, key=itemgetter(0))
[('blue', 1), ('blue', 2), ('red', 1), ('red', 2)]
```

Notice how the two records for blue retain their original order so that ('blue', 1) is guaranteed to precede ('blue', 2).

This wonderful property lets you build complex sorts in a series of sorting steps. For example, to sort the student data by descending grade and then ascending age, do the age sort first and then sort again using grade:

```python
>>> s = sorted(student_objects, key=attrgetter('age'))  # so
>>> sorted(s, key=attrgetter('grade'), reverse=True)  # no
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]
```

The Timsort algorithm used in Python does multiple sorts efficiently because it can take advantage of any ordering already present in a dataset.
The Old Way Using Decorate-Sort-Undecorate

This idiom is called Decorate-Sort-Undecorate after its three steps:

- First, the initial list is decorated with new values that control the sort order.
- Second, the decorated list is sorted.
- Finally, the decorations are removed, creating a list that contains only the initial values in the new order.

For example, to sort the student data by grade using the DSU approach:

```python
>>> decorated = [(student.grade, i, student) for i, student in enumerate(students)]
>>> decorated.sort()
>>> [student for grade, i, student in decorated]
[('john', 'A', 15), ('jane', 'B', 12), ('dave', 'B', 10)]
```

This idiom works because tuples are compared lexicographically; the first items are compared; if they are the same then the second items are compared, and so on.

It is not strictly necessary in all cases to include the index \( i \) in the decorated list, but including it gives two benefits:

- The sort is stable – if two items have the same key, their order will be preserved in the sorted list.
- The original items do not have to be comparable because the ordering of the decorated tuples will be determined by at most the first two items. So for example the original list could contain complex numbers which cannot be sorted directly.

Another name for this idiom is Schwartzian transform, after Randal
L. Schwartz, who popularized it among Perl programmers.

For large lists and lists where the comparison information is expensive to calculate, and Python versions before 2.4, DSU is likely to be the fastest way to sort the list. For 2.4 and later, key functions provide the same functionality.
The Old Way Using the *cmp* Parameter

Many constructs given in this HOWTO assume Python 2.4 or later. Before that, there was no `sorted()` builtin and `list.sort()` took no keyword arguments. Instead, all of the Py2.x versions supported a *cmp* parameter to handle user specified comparison functions.

In Python 3, the *cmp* parameter was removed entirely (as part of a larger effort to simplify and unify the language, eliminating the conflict between rich comparisons and the `__cmp__()` magic method).

In Python 2, `sort()` allowed an optional function which can be called for doing the comparisons. That function should take two arguments to be compared and then return a negative value for less-than, return zero if they are equal, or return a positive value for greater-than. For example, we can do:

```python
>>> def numeric_compare(x, y):
...     return x - y
>>> sorted([5, 2, 4, 1, 3], cmp=numeric_compare)
[1, 2, 3, 4, 5]
```

Or you can reverse the order of comparison with:

```python
>>> def reverse_numeric(x, y):
...     return x - y
>>> sorted([5, 2, 4, 1, 3], cmp=reverse_numeric)
[5, 4, 3, 2, 1]
```

When porting code from Python 2.x to 3.x, the situation can arise when you have the user supplying a comparison function and you need to convert that to a key function. The following wrapper makes that easy to do:

```python
def cmp_to_key(mycmp):
    'Convert a cmp= function into a key= function'
```
class K(object):
    def __init__(self, obj, *args):
        self.obj = obj
    def __lt__(self, other):
        return mycmp(self.obj, other.obj) < 0
    def __gt__(self, other):
        return mycmp(self.obj, other.obj) > 0
    def __eq__(self, other):
        return mycmp(self.obj, other.obj) == 0
    def __le__(self, other):
        return mycmp(self.obj, other.obj) <= 0
    def __ge__(self, other):
        return mycmp(self.obj, other.obj) >= 0
    def __ne__(self, other):
        return mycmp(self.obj, other.obj) != 0
    return K

To convert to a key function, just wrap the old comparison function:

>>> sorted([5, 2, 4, 1, 3], key=cmp_to_key(reverse_numeric))
[5, 4, 3, 2, 1]

In Python 2.7, the functools.cmp_to_key() function was added to the functools module.
Odd and Ends

- For locale aware sorting, use `locale.strxfrm()` for a key function or `locale.strcoll()` for a comparison function.

- The `reverse` parameter still maintains sort stability (so that records with equal keys retain their original order). Interestingly, that effect can be simulated without the parameter by using the builtin `reversed()` function twice:

```python
>>> data = [('red', 1), ('blue', 1), ('red', 2), ('blue', 2)
>>> standard_way = sorted(data, key=itemgetter(0), reverse=True)
>>> double_reversed = list(reversed(sorted(reversed(data), key=itemgetter(0))))
>>> assert standard_way == double_reversed
>>> standard_way
[('red', 1), ('red', 2), ('blue', 1), ('blue', 2)]
```

- To create a standard sort order for a class, just add the appropriate rich comparison methods:

```python
>>> Student.__eq__ = lambda self, other: self.age == other.age
>>> Student.__ne__ = lambda self, other: self.age != other.age
>>> Student.__lt__ = lambda self, other: self.age < other.age
>>> Student.__le__ = lambda self, other: self.age <= other.age
>>> Student.__gt__ = lambda self, other: self.age > other.age
>>> Student.__ge__ = lambda self, other: self.age >= other.age
>>> sorted(student_objects)
[('dave', 'B', 10), ('jane', 'B', 12), ('john', 'A', 15)]
```

For general purpose comparisons, the recommended approach is to define all six rich comparison operators. The `functools.total_ordering()` class decorator makes this easy to implement.

- Key functions need not depend directly on the objects being sorted. A key function can also access external resources. For
instance, if the student grades are stored in a dictionary, they can be used to sort a separate list of student names:

```python
>>> students = ['dave', 'john', 'jane']
>>> grades = {'john': 'F', 'jane': 'A', 'dave': 'C'}
>>> sorted(students, key=grades.__getitem__)
['jane', 'dave', 'john']
```
This HOWTO discusses Python 2.x's support for Unicode, and explains various problems that people commonly encounter when trying to work with Unicode. For the Python 3 version, see <https://docs.python.org/3/howto/unicode.html>. 
Introduction to Unicode

History of Character Codes

In 1968, the American Standard Code for Information Interchange, better known by its acronym ASCII, was standardized. ASCII defined numeric codes for various characters, with the numeric values running from 0 to 127. For example, the lowercase letter ‘a’ is assigned 97 as its code value.

ASCII was an American-developed standard, so it only defined unaccented characters. There was an ‘e’, but no ‘é’ or ‘ï’. This meant that languages which required accented characters couldn’t be faithfully represented in ASCII. (Actually the missing accents matter for English, too, which contains words such as ‘naïve’ and ‘café’, and some publications have house styles which require spellings such as ‘coöperate’.)

For a while people just wrote programs that didn’t display accents. I remember looking at Apple ][ BASIC programs, published in French-language publications in the mid-1980s, that had lines like these:

```
PRINT "MISE A JOUR TERMINEE"
PRINT "PARAMETRES ENREGISTRES"
```

Those messages should contain accents, and they just look wrong to someone who can read French.

In the 1980s, almost all personal computers were 8-bit, meaning that bytes could hold values ranging from 0 to 255. ASCII codes only went up to 127, so some machines assigned values between 128 and 255 to accented characters. Different machines had different codes, however, which led to problems exchanging files. Eventually various commonly used sets of values for the 128–255 range
emerged. Some were true standards, defined by the International Standards Organization, and some were de facto conventions that were invented by one company or another and managed to catch on.

255 characters aren’t very many. For example, you can’t fit both the accented characters used in Western Europe and the Cyrillic alphabet used for Russian into the 128–255 range because there are more than 128 such characters.

You could write files using different codes (all your Russian files in a coding system called KOI8, all your French files in a different coding system called Latin1), but what if you wanted to write a French document that quotes some Russian text? In the 1980s people began to want to solve this problem, and the Unicode standardization effort began.

Unicode started out using 16-bit characters instead of 8-bit characters. 16 bits means you have $2^{16} = 65,536$ distinct values available, making it possible to represent many different characters from many different alphabets; an initial goal was to have Unicode contain the alphabets for every single human language. It turns out that even 16 bits isn’t enough to meet that goal, and the modern Unicode specification uses a wider range of codes, 0–1,114,111 (0x10ffff in base-16).

There’s a related ISO standard, ISO 10646. Unicode and ISO 10646 were originally separate efforts, but the specifications were merged with the 1.1 revision of Unicode.

(This discussion of Unicode’s history is highly simplified. I don’t think the average Python programmer needs to worry about the historical details; consult the Unicode consortium site listed in the References for more information.)
A **character** is the smallest possible component of a text. ‘A’, ‘B’, ‘C’, etc., are all different characters. So are ‘È’ and ‘Í’. Characters are abstractions, and vary depending on the language or context you’re talking about. For example, the symbol for ohms (Ω) is usually drawn much like the capital letter omega (Ω) in the Greek alphabet (they may even be the same in some fonts), but these are two different characters that have different meanings.

The Unicode standard describes how characters are represented by **code points**. A code point is an integer value, usually denoted in base 16. In the standard, a code point is written using the notation U+12ca to mean the character with value 0x12ca (4810 decimal). The Unicode standard contains a lot of tables listing characters and their corresponding code points:

<table>
<thead>
<tr>
<th>Code Point</th>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0061</td>
<td>'a'</td>
<td>LATIN SMALL LETTER A</td>
</tr>
<tr>
<td>0062</td>
<td>'b'</td>
<td>LATIN SMALL LETTER B</td>
</tr>
<tr>
<td>0063</td>
<td>'c'</td>
<td>LATIN SMALL LETTER C</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>007B</td>
<td>'{'</td>
<td>LEFT CURLY BRACKET</td>
</tr>
</tbody>
</table>

Strictly, these definitions imply that it’s meaningless to say ‘this is character U+12ca’. U+12ca is a code point, which represents some particular character; in this case, it represents the character ‘ETHIOPIAN SYLLABLE WI’. In informal contexts, this distinction between code points and characters will sometimes be forgotten.

A character is represented on a screen or on paper by a set of graphical elements that’s called a **glyph**. The glyph for an uppercase A, for example, is two diagonal strokes and a horizontal stroke, though the exact details will depend on the font being used. Most Python code doesn’t need to worry about glyphs; figuring out the correct glyph to display is generally the job of a GUI toolkit or a terminal’s font renderer.

**Encodings**
To summarize the previous section: a Unicode string is a sequence of code points, which are numbers from 0 to 0x10ffff. This sequence needs to be represented as a set of bytes (meaning, values from 0–255) in memory. The rules for translating a Unicode string into a sequence of bytes are called an encoding.

The first encoding you might think of is an array of 32-bit integers. In this representation, the string “Python” would look like this:

```
P  y  t  h  o
0x50 00 00 00 79 00 00 00 74 00 00 00 68 00 00 00 6f 00 00 00 6
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 2
```

This representation is straightforward but using it presents a number of problems.

1. It’s not portable; different processors order the bytes differently.
2. It’s very wasteful of space. In most texts, the majority of the code points are less than 127, or less than 255, so a lot of space is occupied by zero bytes. The above string takes 24 bytes compared to the 6 bytes needed for an ASCII representation. Increased RAM usage doesn’t matter too much (desktop computers have megabytes of RAM, and strings aren’t usually that large), but expanding our usage of disk and network bandwidth by a factor of 4 is intolerable.
3. It’s not compatible with existing C functions such as strlen(), so a new family of wide string functions would need to be used.
4. Many Internet standards are defined in terms of textual data, and can’t handle content with embedded zero bytes.

Generally people don’t use this encoding, instead choosing other encodings that are more efficient and convenient. UTF-8 is probably the most commonly supported encoding; it will be discussed below.

Encodings don’t have to handle every possible Unicode character,
and most encodings don’t. For example, Python’s default encoding is the ‘ascii’ encoding. The rules for converting a Unicode string into the ASCII encoding are simple; for each code point:

1. If the code point is < 128, each byte is the same as the value of the code point.
2. If the code point is 128 or greater, the Unicode string can’t be represented in this encoding. (Python raises a UnicodeEncodeError exception in this case.)

Latin-1, also known as ISO-8859-1, is a similar encoding. Unicode code points 0–255 are identical to the Latin-1 values, so converting to this encoding simply requires converting code points to byte values; if a code point larger than 255 is encountered, the string can’t be encoded into Latin-1.

Encodings don’t have to be simple one-to-one mappings like Latin-1. Consider IBM’s EBCDIC, which was used on IBM mainframes. Letter values weren’t in one block: ‘a’ through ‘i’ had values from 129 to 137, but ‘j’ through ‘r’ were 145 through 153. If you wanted to use EBCDIC as an encoding, you’d probably use some sort of lookup table to perform the conversion, but this is largely an internal detail.

UTF-8 is one of the most commonly used encodings. UTF stands for “Unicode Transformation Format”, and the ‘8’ means that 8-bit numbers are used in the encoding. (There’s also a UTF-16 encoding, but it’s less frequently used than UTF-8.) UTF-8 uses the following rules:

1. If the code point is <128, it’s represented by the corresponding byte value.
2. If the code point is between 128 and 0x7ff, it’s turned into two byte values between 128 and 255.
3. Code points >0x7ff are turned into three- or four-byte sequences, where each byte of the sequence is between 128
UTF-8 has several convenient properties:

1. It can handle any Unicode code point.
2. A Unicode string is turned into a string of bytes containing no embedded zero bytes. This avoids byte-ordering issues, and means UTF-8 strings can be processed by C functions such as `strcpy()` and sent through protocols that can’t handle zero bytes.
3. A string of ASCII text is also valid UTF-8 text.
4. UTF-8 is fairly compact; the majority of code points are turned into two bytes, and values less than 128 occupy only a single byte.
5. If bytes are corrupted or lost, it’s possible to determine the start of the next UTF-8-encoded code point and resynchronize. It’s also unlikely that random 8-bit data will look like valid UTF-8.

References

The Unicode Consortium site at <http://www.unicode.org> has character charts, a glossary, and PDF versions of the Unicode specification. Be prepared for some difficult reading. <http://www.unicode.org/history/> is a chronology of the origin and development of Unicode.

To help understand the standard, Jukka Korpela has written an introductory guide to reading the Unicode character tables, available at <https://www.cs.tut.fi/~jkorpela/unicode/guide.html>.

Another good introductory article was written by Joel Spolsky <http://www.joelonsoftware.com/articles/Unicode.html>. If this introduction didn’t make things clear to you, you should try reading this alternate article before continuing.
Wikipedia entries are often helpful; see the entries for “character encoding” <http://en.wikipedia.org/wiki/Character_encoding> and UTF-8 <http://en.wikipedia.org/wiki/UTF-8>, for example.
Python 2.x’s Unicode Support

Now that you’ve learned the rudiments of Unicode, we can look at Python’s Unicode features.

The Unicode Type

Unicode strings are expressed as instances of the `unicode` type, one of Python’s repertoire of built-in types. It derives from an abstract type called `basestring`, which is also an ancestor of the `str` type; you can therefore check if a value is a string type with `isinstance(value, basestring)`. Under the hood, Python represents Unicode strings as either 16- or 32-bit integers, depending on how the Python interpreter was compiled.

The `unicode()` constructor has the signature `unicode(string[, encoding, errors])`. All of its arguments should be 8-bit strings. The first argument is converted to Unicode using the specified encoding; if you leave off the `encoding` argument, the ASCII encoding is used for the conversion, so characters greater than 127 will be treated as errors:

```python
>>> unicode('abcdef')
u'abcdef'
>>> s = unicode('abcdef')
>>> type(s)
<type 'unicode'>
>>> unicode('abcdef' + chr(255))
Traceback (most recent call last):
...  UnicodeDecodeError: 'ascii' codec can't decode byte 0xff in position 6:
         ordinal not in range(128)
```

The `errors` argument specifies the response when the input string...
can’t be converted according to the encoding’s rules. Legal values for this argument are ‘strict’ (raise a UnicodeDecodeError exception), ‘replace’ (add U+FFFD, ‘REPLACEMENT CHARACTER’), or ‘ignore’ (just leave the character out of the Unicode result). The following examples show the differences:

```python
>>> unicode(\x80abc, errors='strict')
Traceback (most recent call last):
  ...  
UnicodeDecodeError: 'ascii' codec can't decode byte 0x80 in position 0:
  ordinal not in range(128)
>>> unicode(\x80abc, errors='replace')
u'\ufffdabc'
>>> unicode(\x80abc, errors='ignore')
u'abc'
```

Encodings are specified as strings containing the encoding’s name. Python 2.7 comes with roughly 100 different encodings; see the Python Library Reference at Standard Encodings for a list. Some encodings have multiple names; for example, ‘latin-1’, ‘iso_8859_1’ and ‘8859’ are all synonyms for the same encoding.

One-character Unicode strings can also be created with the unichr() built-in function, which takes integers and returns a Unicode string of length 1 that contains the corresponding code point. The reverse operation is the built-in ord() function that takes a one-character Unicode string and returns the code point value:

```python
>>> unichr(40960)
u'\u0000'
>>> ord(u'\u0000')
40960
```

Instances of the unicode type have many of the same methods as the 8-bit string type for operations such as searching and formatting:

```python
>>> s = u'Was ever feather so lightly blown to and fro as this
```
Note that the arguments to these methods can be Unicode strings or 8-bit strings. 8-bit strings will be converted to Unicode before carrying out the operation; Python's default ASCII encoding will be used, so characters greater than 127 will cause an exception:

```python
>>> s.find('Was\x9f')
Traceback (most recent call last):
 ... 
UnicodeDecodeError: 'ascii' codec can't decode byte 0x9f in position 3: ordinal not in range(128)
```

Much Python code that operates on strings will therefore work with Unicode strings without requiring any changes to the code. (Input and output code needs more updating for Unicode; more on this later.)

Another important method is `.encode([encoding], [errors='strict'])`, which returns an 8-bit string version of the Unicode string, encoded in the requested encoding. The `errors` parameter is the same as the parameter of the `unicode()` constructor, with one additional possibility: as well as ‘strict’, ‘ignore’, and ‘replace’, you can also pass ‘xmlcharrefreplace’ which uses XML's character references. The following example shows the different results:
Python's 8-bit strings have a `.decode([encoding], [errors])` method that interprets the string using the given encoding:

```python
>>> u = unichr(40960) + u'abcd' + unichr(1972)  # Assemble a string
>>> utf8_version = u.encode('utf-8')  # Encode as UTF-8
>>> type(utf8_version), utf8_version
(<type 'str'>, '\xea\x80\x80abcd\xde\xb4')
>>> u2 = utf8_version.decode('utf-8')  # Decode using UTF-8
>>> u == u2  # The two strings match
True
```

The low-level routines for registering and accessing the available encodings are found in the `codecs` module. However, the encoding and decoding functions returned by this module are usually more low-level than is comfortable, so I'm not going to describe the `codecs` module here. If you need to implement a completely new encoding, you'll need to learn about the `codecs` module interfaces, but implementing encodings is a specialized task that also won't be covered here. Consult the Python documentation to learn more about this module.

The most commonly used part of the `codecs` module is the `codecs.open()` function which will be discussed in the section on
Unicode Literals in Python Source Code

In Python source code, Unicode literals are written as strings prefixed with the ‘u’ or ‘U’ character: u'abcdefghijk'. Specific code points can be written using the \u escape sequence, which is followed by four hex digits giving the code point. The \U escape sequence is similar, but expects 8 hex digits, not 4.

Unicode literals can also use the same escape sequences as 8-bit strings, including \x, but \x only takes two hex digits so it can’t express an arbitrary code point. Octal escapes can go up to U+01ff, which is octal 777.

```
>>> s = u"a\xac\u1234\u20ac\U00008000"
... # ^^^^ two-digit hex escape
... # ^^^^^^^ four-digit Unicode escape
... # ^^^^^^^^^ eight-digit Unicode escape
>>> for c in s:  print ord(c),
... 97 172 4660 8364 32768
```

Using escape sequences for code points greater than 127 is fine in small doses, but becomes an annoyance if you’re using many accented characters, as you would in a program with messages in French or some other accent-using language. You can also assemble strings using the unichr() built-in function, but this is even more tedious.

Ideally, you’d want to be able to write literals in your language’s natural encoding. You could then edit Python source code with your favorite editor which would display the accented characters naturally, and have the right characters used at runtime.
Python supports writing Unicode literals in any encoding, but you have to declare the encoding being used. This is done by including a special comment as either the first or second line of the source file:

```
#!/usr/bin/env python
# -*- coding: latin-1 -*-

u = u'abcdé'
print ord(u[-1])
```

The syntax is inspired by Emacs's notation for specifying variables local to a file. Emacs supports many different variables, but Python only supports 'coding'. The ` -*- ` symbols indicate to Emacs that the comment is special; they have no significance to Python but are a convention. Python looks for `coding: name` or `coding=name` in the comment.

If you don’t include such a comment, the default encoding used will be ASCII. Versions of Python before 2.4 were Euro-centric and assumed Latin-1 as a default encoding for string literals; in Python 2.4, characters greater than 127 still work but result in a warning. For example, the following program has no encoding declaration:

```
#!/usr/bin/env python
u = u'abcdé'
print ord(u[-1])
```

When you run it with Python 2.4, it will output the following warning:

```
amk:~$ python2.4 p263.py
sys:1: DeprecationWarning: Non-ASCII character '\xe9'
in file p263.py on line 2, but no encoding declared;
see https://www.python.org/peps/pep-0263.html for details
```

Python 2.5 and higher are stricter and will produce a syntax error:

```
amk:~$ python2.5 p263.py
File "*/tmp/p263.py", line 2
```
Unicode Properties

The Unicode specification includes a database of information about code points. For each code point that’s defined, the information includes the character’s name, its category, the numeric value if applicable (Unicode has characters representing the Roman numerals and fractions such as one-third and four-fifths). There are also properties related to the code point’s use in bidirectional text and other display-related properties.

The following program displays some information about several characters, and prints the numeric value of one particular character:

```python
import unicodedata

u = unichr(233) + unichr(0x0bf2) + unichr(3972) + unichr(6000)

for i, c in enumerate(u):
    print i, '%04x' % ord(c), unicodedata.category(c),
    print unicodedata.name(c)

# Get numeric value of second character
print unicodedata.numeric(u[1])
```

When run, this prints:

```
00e9 Ll LATIN SMALL LETTER E WITH ACUTE
10bf2 No TAMIL NUMBER ONE THOUSAND
20f84 Mn TIBETAN MARK HALANTA
31770 Lo TAGBANWA LETTER SA
433af So SQUARE RAD OVER S SQUARED
1000.0
```

The category codes are abbreviations describing the nature of the character. These are grouped into categories such as “Letter”,

“Number”, “Punctuation”, or “Symbol”, which in turn are broken up into subcategories. To take the codes from the above output, 'Ll' means ‘Letter, lowercase’, 'No' means “Number, other”, 'Mn' is “Mark, nonspacing”, and 'So' is “Symbol, other”. See <http://www.unicode.org/reports/tr44/#General_Category_Values> for a list of category codes.

References

The Unicode and 8-bit string types are described in the Python library reference at Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange.

The documentation for the unicedata module.

The documentation for the codecs module.

Marc-André Lemburg gave a presentation at EuroPython 2002 titled “Python and Unicode”. A PDF version of his slides is available at <https://downloads.egenix.com/python/Unicode-EPC2002-Talk.pdf>, and is an excellent overview of the design of Python’s Unicode features.
Once you’ve written some code that works with Unicode data, the next problem is input/output. How do you get Unicode strings into your program, and how do you convert Unicode into a form suitable for storage or transmission?

It’s possible that you may not need to do anything depending on your input sources and output destinations; you should check whether the libraries used in your application support Unicode natively. XML parsers often return Unicode data, for example. Many relational databases also support Unicode-valued columns and can return Unicode values from an SQL query.

Unicode data is usually converted to a particular encoding before it gets written to disk or sent over a socket. It’s possible to do all the work yourself: open a file, read an 8-bit string from it, and convert the string with \texttt{unicode(str, encoding)}. However, the manual approach is not recommended.

One problem is the multi-byte nature of encodings; one Unicode character can be represented by several bytes. If you want to read the file in arbitrary-sized chunks (say, 1K or 4K), you need to write error-handling code to catch the case where only part of the bytes encoding a single Unicode character are read at the end of a chunk. One solution would be to read the entire file into memory and then perform the decoding, but that prevents you from working with files that are extremely large; if you need to read a 2Gb file, you need 2Gb of RAM. (More, really, since for at least a moment you’d need to have both the encoded string and its Unicode version in memory.)

The solution would be to use the low-level decoding interface to catch the case of partial coding sequences. The work of implementing this has already been done for you: the \texttt{codecs} module
includes a version of the `open()` function that returns a file-like object that assumes the file's contents are in a specified encoding and accepts Unicode parameters for methods such as `.read()` and `.write()`.

The function's parameters are `open(filename, mode='rb', encoding=None, errors='strict', buffering=1)`. `mode` can be `'r'`, `'w'`, or `'a'`, just like the corresponding parameter to the regular built-in `open()` function; add a '+' to update the file. `buffering` is similarly parallel to the standard function's parameter. `encoding` is a string giving the encoding to use; if it's left as `None`, a regular Python file object that accepts 8-bit strings is returned. Otherwise, a wrapper object is returned, and data written to or read from the wrapper object will be converted as needed. `errors` specifies the action for encoding errors and can be one of the usual values of ‘strict’, ‘ignore’, and ‘replace’.

Reading Unicode from a file is therefore simple:

```python
import codecs
f = codecs.open('unicode.rst', encoding='utf-8')
for line in f:
    print repr(line)
```

It's also possible to open files in update mode, allowing both reading and writing:

```python
f = codecs.open('test', encoding='utf-8', mode='w+')
f.write(u'\u4500 blah blah blah
')
f.seek(0)
print repr(f.readline()[:1])
f.close()
```

Unicode character U+FEFF is used as a byte-order mark (BOM), and is often written as the first character of a file in order to assist with autodetection of the file's byte ordering. Some encodings, such
as UTF-16, expect a BOM to be present at the start of a file; when such an encoding is used, the BOM will be automatically written as the first character and will be silently dropped when the file is read. There are variants of these encodings, such as ‘utf-16-le' and 'utf-16-be' for little-endian and big-endian encodings, that specify one particular byte ordering and don’t skip the BOM.

### Unicode filenames

Most of the operating systems in common use today support filenames that contain arbitrary Unicode characters. Usually this is implemented by converting the Unicode string into some encoding that varies depending on the system. For example, Mac OS X uses UTF-8 while Windows uses a configurable encoding; on Windows, Python uses the name “mbcs” to refer to whatever the currently configured encoding is. On Unix systems, there will only be a filesystem encoding if you’ve set the `LANG` or `LC_CTYPE` environment variables; if you haven’t, the default encoding is ASCII.

The `sys.getfilesystemencoding()` function returns the encoding to use on your current system, in case you want to do the encoding manually, but there’s not much reason to bother. When opening a file for reading or writing, you can usually just provide the Unicode string as the filename, and it will be automatically converted to the right encoding for you:

```python
filename = u'filename\u4500abc'
f = open(filename, 'w')
f.write('blah\n')
f.close()
```

Functions in the `os` module such as `os.stat()` will also accept Unicode filenames.

`os.listdir()`, which returns filenames, raises an issue: should it
return the Unicode version of filenames, or should it return 8-bit strings containing the encoded versions?\texttt{os.listdir()} will do both, depending on whether you provided the directory path as an 8-bit string or a Unicode string. If you pass a Unicode string as the path, filenames will be decoded using the filesystem's encoding and a list of Unicode strings will be returned, while passing an 8-bit path will return the 8-bit versions of the filenames. For example, assuming the default filesystem encoding is UTF-8, running the following program:

```python
fn = u'filename\u4500abc'
f = open(fn, 'w')
f.close()

import os
print os.listdir('.')
print os.listdir(u'.')
```

will produce the following output:

```
amk:~$ python t.py
['.svn', 'filename\xe4\x94\x80abc', ...]
[u'.svn', u'filename\u4500abc', ...]
```

The first list contains UTF-8-encoded filenames, and the second list contains the Unicode versions.

**Tips for Writing Unicode-aware Programs**

This section provides some suggestions on writing software that deals with Unicode.

The most important tip is:

Software should only work with Unicode strings internally, converting to a particular encoding on output.

If you attempt to write processing functions that accept both Unicode
and 8-bit strings, you will find your program vulnerable to bugs wherever you combine the two different kinds of strings. Python's default encoding is ASCII, so whenever a character with an ASCII value > 127 is in the input data, you'll get a `UnicodeDecodeError` because that character can't be handled by the ASCII encoding.

It's easy to miss such problems if you only test your software with data that doesn't contain any accents; everything will seem to work, but there's actually a bug in your program waiting for the first user who attempts to use characters > 127. A second tip, therefore, is:

Include characters > 127 and, even better, characters > 255 in your test data.

When using data coming from a web browser or some other untrusted source, a common technique is to check for illegal characters in a string before using the string in a generated command line or storing it in a database. If you're doing this, be careful to check the string once it's in the form that will be used or stored; it's possible for encodings to be used to disguise characters. This is especially true if the input data also specifies the encoding; many encodings leave the commonly checked-for characters alone, but Python includes some encodings such as `'base64'` that modify every single character.

For example, let's say you have a content management system that takes a Unicode filename, and you want to disallow paths with a '/' character. You might write this code:

```python
def read_file (filename, encoding):
    if '/' in filename:
        raise ValueError("'/' not allowed in filenames")
    unicode_name = filename.decode(encoding)
f = open(unicode_name, 'r')
# ... return contents of file ...
```
However, if an attacker could specify the 'base64' encoding, they could pass 'L2V0Yy9wYXNzd2Q=', which is the base-64 encoded form of the string '/etc/passwd', to read a system file. The above code looks for '/' characters in the encoded form and misses the dangerous character in the resulting decoded form.

HOWTO Fetch Internet Resources Using urllib2

Author: Michael Foord

Note: There is a French translation of an earlier revision of this HOWTO, available at urllib2 - Le Manuel manquant.
**Introduction**

**urllib2** is a Python module for fetching URLs (Uniform Resource Locators). It offers a very simple interface, in the form of the `urlopen` function. This is capable of fetching URLs using a variety of different protocols. It also offers a slightly more complex interface for handling common situations - like basic authentication, cookies, proxies and so on. These are provided by objects called handlers and openers.

`urllib2` supports fetching URLs for many “URL schemes” (identified by the string before the “:” in URL - for example “ftp” is the URL scheme of “ftp://python.org/”) using their associated network protocols (e.g. FTP, HTTP). This tutorial focuses on the most common case, HTTP.

For straightforward situations `urlopen` is very easy to use. But as soon as you encounter errors or non-trivial cases when opening HTTP URLs, you will need some understanding of the HyperText Transfer Protocol. The most comprehensive and authoritative reference to HTTP is RFC 2616. This is a technical document and not intended to be easy to read. This HOWTO aims to illustrate using `urllib2`, with enough detail about HTTP to help you through. It is not intended to replace the `urllib2` docs, but is supplementary to them.

You may also find useful the following article on fetching web resources with Python:

- **Basic Authentication**

  A tutorial on *Basic Authentication*, with examples in Python.
Fetching URLs

The simplest way to use urllib2 is as follows:

```python
import urllib2
response = urllib2.urlopen('http://python.org/)
html = response.read()
```

Many uses of urllib2 will be that simple (note that instead of an ‘http:’ URL we could have used a URL starting with ‘ftp:’, ‘file:’, etc.). However, it’s the purpose of this tutorial to explain the more complicated cases, concentrating on HTTP.

HTTP is based on requests and responses - the client makes requests and servers send responses. urllib2 mirrors this with a Request object which represents the HTTP request you are making. In its simplest form you create a Request object that specifies the URL you want to fetch. Calling `urlopen` with this Request object returns a response object for the URL requested. This response is a file-like object, which means you can for example call `read()` on the response:

```python
import urllib2
req = urllib2.Request('http://www.voidspace.org.uk')
response = urllib2.urlopen(req)
the_page = response.read()
```

Note that urllib2 makes use of the same Request interface to handle all URL schemes. For example, you can make an FTP request like so:

```python
req = urllib2.Request('ftp://example.com/')
```

In the case of HTTP, there are two extra things that Request objects
allow you to do: First, you can pass data to be sent to the server. Second, you can pass extra information (“metadata”) about the data or the about request itself, to the server - this information is sent as HTTP “headers”. Let's look at each of these in turn.

## Data

Sometimes you want to send data to a URL (often the URL will refer to a CGI (Common Gateway Interface) script [1] or other web application). With HTTP, this is often done using what's known as a POST request. This is often what your browser does when you submit a HTML form that you filled in on the web. Not all POSTs have to come from forms: you can use a POST to transmit arbitrary data to your own application. In the common case of HTML forms, the data needs to be encoded in a standard way, and then passed to the Request object as the data argument. The encoding is done using a function from the urllib library not from urllib2.

```python
import urllib
import urllib2

url = 'http://www.someserver.com/cgi-bin/register.cgi'
values = {'name' : 'Michael Foord',
          'location' : 'Northampton',
          'language' : 'Python' }

data = urllib.urlencode(values)
req = urllib2.Request(url, data)
response = urllib2.urlopen(req)
the_page = response.read()
```

Note that other encodings are sometimes required (e.g. for file upload from HTML forms - see HTML Specification, Form Submission for more details).

If you do not pass the data argument, urllib2 uses a GET request. One way in which GET and POST requests differ is that POST
requests often have “side-effects”: they change the state of the system in some way (for example by placing an order with the website for a hundredweight of tinned spam to be delivered to your door). Though the HTTP standard makes it clear that POSTs are intended to always cause side-effects, and GET requests never to cause side-effects, nothing prevents a GET request from having side-effects, nor a POST requests from having no side-effects. Data can also be passed in an HTTP GET request by encoding it in the URL itself.

This is done as follows:

```python
>>> import urllib2
>>> import urllib
>>> data = {}
>>> data['name'] = 'Somebody Here'
>>> data['location'] = 'Northampton'
>>> data['language'] = 'Python'
>>> url_values = urlliburlencode(data)
>>> print url_values  # The order may differ.
name=Somebody+Here&language=Python&location=Northampton
>>> url = 'http://www.example.com/example.cgi'
>>> full_url = url + '?' + url_values
>>> data = urllib2.urlopen(full_url)
```

Notice that the full URL is created by adding a `?` to the URL, followed by the encoded values.

### Headers

We'll discuss here one particular HTTP header, to illustrate how to add headers to your HTTP request.

Some websites [2] dislike being browsed by programs, or send different versions to different browsers [3]. By default urllib2 identifies itself as `Python-urllib/x.y` (where `x` and `y` are the major and minor version numbers of the Python release, e.g. `Python-urllib/2.5`),
which may confuse the site, or just plain not work. The way a browser identifies itself is through the `User-Agent` header [4]. When you create a Request object you can pass a dictionary of headers in. The following example makes the same request as above, but identifies itself as a version of Internet Explorer [5].

```python
import urllib
import urllib2

url = 'http://www.someserver.com/cgi-bin/register.cgi'
user_agent = 'Mozilla/5.0 (Windows NT 6.1; Win64; x64)'
values = {'name': 'Michael Foord',
          'location': 'Northampton',
          'language': 'Python'}
headers = {'User-Agent': user_agent}

data = urllib.urlencode(values)
req = urllib2.Request(url, data, headers)
response = urllib2.urlopen(req)
the_page = response.read()
```

The response also has two useful methods. See the section on `info` and `geturl` which comes after we have a look at what happens when things go wrong.
Handling Exceptions

`urlopen` raises `URLError` when it cannot handle a response (though as usual with Python APIs, built-in exceptions such as `ValueError`, `TypeError` etc. may also be raised).

`HTTPError` is the subclass of `URLError` raised in the specific case of HTTP URLs.

**URLError**

Often, `URLError` is raised because there is no network connection (no route to the specified server), or the specified server doesn't exist. In this case, the exception raised will have a 'reason' attribute, which is a tuple containing an error code and a text error message.

e.g.

```python
>>> req = urllib2.Request('http://www.pretend_server.org')
>>> try: urllib2.urlopen(req)
... except URLError as e:
...     print e.reason
...
(4, 'getaddrinfo failed')
```

**HTTPError**

Every HTTP response from the server contains a numeric “status code”. Sometimes the status code indicates that the server is unable to fulfil the request. The default handlers will handle some of these responses for you (for example, if the response is a “redirection” that requests the client fetch the document from a different URL, `urllib2` will handle that for you). For those it can’t handle, `urlopen` will raise an `HTTPError`. Typical errors include ‘404’ (page not found), ‘403’
(request forbidden), and ‘401’ (authentication required).

See section 10 of RFC 2616 for a reference on all the HTTP error codes.

The `HTTPError` instance raised will have an integer ‘code’ attribute, which corresponds to the error sent by the server.

## Error Codes

Because the default handlers handle redirects (codes in the 300 range), and codes in the 100–299 range indicate success, you will usually only see error codes in the 400–599 range.

`BaseHTTPServer.BaseHTTPRequestHandler.responses` is a useful dictionary of response codes in that shows all the response codes used by RFC 2616. The dictionary is reproduced here for convenience.

```python
# Table mapping response codes to messages; entries have the
# form {code: (shortmessage, longmessage)}.
responses = {
    100: ('Continue', 'Request received, please continue'),
    101: ('Switching Protocols', 'Switching to new protocol; obey Upgrade header'),
    200: ('OK', 'Request fulfilled, document follows'),
    201: ('Created', 'Document created, URL follows'),
    202: ('Accepted', 'Request accepted, processing continues off-line'),
    203: ('Non-Authoritative Information', 'Request fulfilled from cache'),
    204: ('No Content', 'Request fulfilled, nothing follows'),
    205: ('Reset Content', 'Clear input form for further input'),
    206: ('Partial Content', 'Partial content follows'),
    300: ('Multiple Choices', 'Object has several resources -- see URI list'),
    301: ('Moved Permanently', 'Object moved permanently -- see URI list'),
    302: ('Found', 'Object moved temporarily -- see URI list'),
    303: ('See Other', 'Object moved -- see Method and URL list'),
    304: ('Not Modified',
```
{'Document has not changed since given time'),
305: ('Use Proxy',
   'You must use proxy specified in Location to access this resource'),
307: ('Temporary Redirect',
   'Object moved temporarily -- see URI list'),
400: ('Bad Request',
   'Bad request syntax or unsupported method'),
401: ('Unauthorized',
   'No permission -- see authorization schemes'),
402: ('Payment Required',
   'No payment -- see charging schemes'),
403: ('Forbidden',
   'Request forbidden -- authorization will not help'),
404: ('Not Found',
   'Nothing matches the given URI'),
405: ('Method Not Allowed',
   'Specified method is invalid for this server.'),
406: ('Not Acceptable',
   'URI not available in preferred format'),
407: ('Proxy Authentication Required',
   'You must authenticate with this proxy before proceeding.'),
408: ('Request Timeout',
   'Request timed out; try again later'),
409: ('Conflict',
   'Request conflict'),
410: ('Gone',
   'URI no longer exists and has been permanently removed'),
411: ('Length Required',
   'Client must specify Content-Length'),
412: ('Precondition Failed',
   'Precondition in headers is false'),
413: ('Request Entity Too Large',
   'Entity is too large.'),
414: ('Request-URI Too Long',
   'URI is too long.'),
415: ('Unsupported Media Type',
   'Entity body in unsupported format'),
416: ('Requested Range Not Satisfiable',
   'Cannot satisfy request range.'),
417: ('Expectation Failed',
   'Expect condition could not be satisfied.'),
500: ('Internal Server Error',
   'Server got itself in trouble'),
501: ('Not Implemented',
   'Server does not support this operation'),
502: ('Bad Gateway',
   'Invalid responses from another server'),
503: ('Service Unavailable',
   'The server cannot process the request due to a high'),
504: ('Gateway Timeout',
   'The gateway server did not receive a timely response'),
505: ('HTTP Version Not Supported',
   'Cannot fulfill request')
When an error is raised the server responds by returning an HTTP error code and an error page. You can use the `HTTPError` instance as a response on the page returned. This means that as well as the code attribute, it also has read, geturl, and info, methods.

```python
>>> req = urllib2.Request('http://www.python.org/fish.html')
>>> try:
...     urllib2.urlopen(req)
...     except urllib2.HTTPError as e:
...         print e.code
...         print e.read()
...     404
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
...
<title>Page Not Found</title>
...
```

**Wrapping it Up**

So if you want to be prepared for `HTTPError` or `URLError` there are two basic approaches. I prefer the second approach.

### Number 1

```python
from urllib2 import Request, urlopen, URLError, HTTPError

req = Request(someurl)
try:
    response = urlopen(req)
except HTTPError as e:
    print 'The server couldn\'t fulfill the request.'
    print 'Error code: ', e.code
except URLError as e:
    print 'We failed to reach a server.'
    print 'Reason: ', e.reason
else:
    # everything is fine
```

**Note:** The `except HTTPError` must come first, otherwise `except`
URLError will also catch an HTTPError.

Number 2

```python
from urllib2 import Request, urlopen, URLError
req = Request(someurl)
try:
    response = urlopen(req)
except URLError as e:
    if hasattr(e, 'reason'):
        print 'We failed to reach a server.'
        print 'Reason: ', e.reason
    elif hasattr(e, 'code'):
        print 'The server couldn\'t fulfill the request.'
        print 'Error code: ', e.code
else:
    # everything is fine
```
info and geturl

The response returned by urlopen (or the HTTPError instance) has two useful methods info() and geturl().

**geturl** - this returns the real URL of the page fetched. This is useful because urlopen (or the opener object used) may have followed a redirect. The URL of the page fetched may not be the same as the URL requested.

**info** - this returns a dictionary-like object that describes the page fetched, particularly the headers sent by the server. It is currently an httpclient.HTTPMessage instance.

Typical headers include ‘Content-length’, ‘Content-type’, and so on. See the Quick Reference to HTTP Headers for a useful listing of HTTP headers with brief explanations of their meaning and use.
Openers and Handlers

When you fetch a URL you use an opener (an instance of the perhaps confusingly-named `urllib2.OpenerDirector`). Normally we have been using the default opener - via `urlopen` - but you can create custom openers. Openers use handlers. All the “heavy lifting” is done by the handlers. Each handler knows how to open URLs for a particular URL scheme (http, ftp, etc.), or how to handle an aspect of URL opening, for example HTTP redirec\[d\]ions or HTTP cookies.

You will want to create openers if you want to fetch URLs with specific handlers installed, for example to get an opener that handles cookies, or to get an opener that does not handle redirec\[d\]ions.

To create an opener, instantiate an `OpenerDirector`, and then call `add_handler(some_handler_instance)` repeatedly.

Alternatively, you can use `build_opener`, which is a convenience function for creating opener objects with a single function call. `build_opener` add\[s\] several handlers by default, but provides a quick way to add more and/or override the default handlers.

Other sorts of handlers you might want to can handle proxies, authentication, and other common but slightly specialised situations.

`install_opener` can be used to make an `opener` object the (global) default opener. This means that calls to `urlopen` will use the opener you have installed.

Opener objects have an `open` method, which can be called directly to fetch urls in the same way as the `urlopen` function: there's no need to call `install_opener`, except as a convenience.
Basic Authentication

To illustrate creating and installing a handler we will use the HTTPBasicAuthHandler. For a more detailed discussion of this subject – including an explanation of how Basic Authentication works - see the Basic Authentication Tutorial.

When authentication is required, the server sends a header (as well as the 401 error code) requesting authentication. This specifies the authentication scheme and a ‘realm’. The header looks like: \texttt{WWW-Authenticate: SCHEME realm="REALM"}.

\texttt{WWW-Authenticate: Basic realm="cPanel Users"}

The client should then retry the request with the appropriate name and password for the realm included as a header in the request. This is ‘basic authentication’. In order to simplify this process we can create an instance of \texttt{HTTPBasicAuthHandler} and an opener to use this handler.

The \texttt{HTTPBasicAuthHandler} uses an object called a password manager to handle the mapping of URLs and realms to passwords and usernames. If you know what the realm is (from the authentication header sent by the server), then you can use a \texttt{HTTPPasswordMgr}. Frequently one doesn’t care what the realm is. In that case, it is convenient to use \texttt{HTTPPasswordMgrWithDefaultRealm}. This allows you to specify a default username and password for a URL. This will be supplied in the absence of you providing an alternative combination for a specific realm. We indicate this by providing \texttt{None} as the realm argument to the \texttt{add_password} method.
The top-level URL is the first URL that requires authentication. URLs "deeper" than the URL you pass to .add_password() will also match.

```python
# create a password manager
password_mgr = urllib2.HTTPPasswordMgrWithDefaultRealm()

# Add the username and password.
# If we knew the realm, we could use it instead of None.
top_level_url = "http://example.com/foo/
password_mgr.add_password(None, top_level_url, username, passwo
d
handler = urllib2.HTTPBasicAuthHandler(password_mgr)

# create "opener" (OpenerDirector instance)
 opener = urllib2.build_opener(handler)

# use the opener to fetch a URL
 opener.open(a_url)

# Install the opener.
# Now all calls to urllib2.urlopen use our opener.
 urllib2.install_opener(opener)
```

**Note:** In the above example we only supplied our HTTPBasicAuthHandler to build_opener. By default openers have the handlers for normal situations – ProxyHandler (if a proxy setting such as an http_proxy environment variable is set), UnknownHandler, HTTPHandler, HTTPDefaultErrorHandler, HTTPRedirectHandler, FTPHandler, FileHandler, HTTPErrorProcessor.

top_level_url is in fact either a full URL (including the 'http:' scheme component and the hostname and optionally the port number) e.g. “http://example.com/” or an “authority” (i.e. the hostname, optionally including the port number) e.g. “example.com” or “example.com:8080” (the latter example includes a port number). The authority, if present, must NOT contain the “userinfo” component - for example “joe:password@example.com” is not correct.
Proxies

urllib2 will auto-detect your proxy settings and use those. This is through the ProxyHandler, which is part of the normal handler chain when a proxy setting is detected. Normally that’s a good thing, but there are occasions when it may not be helpful [6]. One way to do this is to setup our own ProxyHandler, with no proxies defined. This is done using similar steps to setting up a Basic Authentication handler:

```python
>>> proxy_support = urllib2.ProxyHandler({})
>>> opener = urllib2.build_opener(proxy_support)
>>> urllib2.install_opener(opener)
```

**Note:** Currently urllib2 does not support fetching of https locations through a proxy. However, this can be enabled by extending urllib2 as shown in the recipe [7].

**Note:** HTTP_PROXY will be ignored if a variable REQUEST_METHOD is set; see the documentation on getproxies().
Sockets and Layers

The Python support for fetching resources from the web is layered. urllib2 uses the httpplib library, which in turn uses the socket library.

As of Python 2.3 you can specify how long a socket should wait for a response before timing out. This can be useful in applications which have to fetch web pages. By default the socket module has no timeout and can hang. Currently, the socket timeout is not exposed at the httpplib or urllib2 levels. However, you can set the default timeout globally for all sockets using

```python
import socket
import urllib2

# timeout in seconds
timeout = 10
socket.setdefaulttimeout(timeout)

# this call to urllib2.urlopen now uses the default timeout
# we have set in the socket module
req = urllib2.Request('http://www.voidspace.org.uk')
response = urllib2.urlopen(req)
```
This document was reviewed and revised by John Lee.

[1] For an introduction to the CGI protocol see Writing Web Applications in Python.

Browser sniffing is a very bad practice for website design - building sites using web standards is much more sensible. Unfortunately a lot of sites still send different versions to different browsers.

[3] The user agent for MSIE 6 is ‘Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; SV1; .NET CLR 1.1.4322)’

[4] For details of more HTTP request headers, see Quick Reference to HTTP Headers.

In my case I have to use a proxy to access the internet at work. If you attempt to fetch localhost URLs through this proxy it blocks them. IE is set to use the proxy, which urllib2 picks up on. In order to test scripts with a localhost server, I have to prevent urllib2 from using the proxy.

HOWTO Use Python in the web

Author: Marek Kubica

Abstract

This document shows how Python fits into the web. It presents some ways to integrate Python with a web server, and general practices useful for developing web sites.

Programming for the Web has become a hot topic since the rise of “Web 2.0”, which focuses on user-generated content on web sites. It has always been possible to use Python for creating web sites, but it was a rather tedious task. Therefore, many frameworks and helper tools have been created to assist developers in creating faster and more robust sites. This HOWTO describes some of the methods used to combine Python with a web server to create dynamic content. It is not meant as a complete introduction, as this topic is far too broad to be covered in one single document. However, a short overview of the most popular libraries is provided.

See also: While this HOWTO tries to give an overview of Python in the web, it cannot always be as up to date as desired. Web development in Python is rapidly moving forward, so the wiki page on Web Programming may be more in sync with recent development.
The Low-Level View

When a user enters a web site, their browser makes a connection to the site’s web server (this is called the request). The server looks up the file in the file system and sends it back to the user’s browser, which displays it (this is the response). This is roughly how the underlying protocol, HTTP, works.

Dynamic web sites are not based on files in the file system, but rather on programs which are run by the web server when a request comes in, and which generate the content that is returned to the user. They can do all sorts of useful things, like display the postings of a bulletin board, show your email, configure software, or just display the current time. These programs can be written in any programming language the server supports. Since most servers support Python, it is easy to use Python to create dynamic web sites.

Most HTTP servers are written in C or C++, so they cannot execute Python code directly – a bridge is needed between the server and the program. These bridges, or rather interfaces, define how programs interact with the server. There have been numerous attempts to create the best possible interface, but there are only a few worth mentioning.

Not every web server supports every interface. Many web servers only support old, now-obsolete interfaces; however, they can often be extended using third-party modules to support newer ones.

Common Gateway Interface

This interface, most commonly referred to as “CGI”, is the oldest, and is supported by nearly every web server out of the box. Programs using CGI to communicate with their web server need to
be started by the server for every request. So, every request starts a new Python interpreter – which takes some time to start up – thus making the whole interface only usable for low load situations.

The upside of CGI is that it is simple – writing a Python program which uses CGI is a matter of about three lines of code. This simplicity comes at a price: it does very few things to help the developer.

Writing CGI programs, while still possible, is no longer recommended. With WSGI, a topic covered later in this document, it is possible to write programs that emulate CGI, so they can be run as CGI if no better option is available.

See also: The Python standard library includes some modules that are helpful for creating plain CGI programs:

- **cgi** – Handling of user input in CGI scripts
- **cgitb** – Displays nice tracebacks when errors happen in CGI applications, instead of presenting a “500 Internal Server Error” message

The Python wiki features a page on CGI scripts with some additional information about CGI in Python.

Simple script for testing CGI

To test whether your web server works with CGI, you can use this short and simple CGI program:

```bash
#!/usr/bin/env python
# -*- coding: UTF-8 -*-

# enable debugging
import cgitb
cgitb.enable()
```
print "Content-Type: text/plain; charset=utf-8"
print
print "Hello World!"

Depending on your web server configuration, you may need to save this code with a .py or .cgi extension. Additionally, this file may also need to be in a cgi-bin folder, for security reasons.

You might wonder what the cgitb line is about. This line makes it possible to display a nice traceback instead of just crashing and displaying an “Internal Server Error” in the user’s browser. This is useful for debugging, but it might risk exposing some confidential data to the user. You should not use cgitb in production code for this reason. You should always catch exceptions, and display proper error pages – end-users don’t like to see nondescript “Internal Server Errors” in their browsers.

### Setting up CGI on your own server

If you don’t have your own web server, this does not apply to you. You can check whether it works as-is, and if not you will need to talk to the administrator of your web server. If it is a big host, you can try filing a ticket asking for Python support.

If you are your own administrator or want to set up CGI for testing purposes on your own computers, you have to configure it by yourself. There is no single way to configure CGI, as there are many web servers with different configuration options. Currently the most widely used free web server is Apache HTTPd, or Apache for short. Apache can be easily installed on nearly every system using the system’s package management tool. lighttpd is another alternative and is said to have better performance. On many systems this server can also be installed using the package management tool, so manually compiling the web server may not be needed.
On Apache you can take a look at the Dynamic Content with CGI tutorial, where everything is described. Most of the time it is enough just to set +ExecCGI. The tutorial also describes the most common gotchas that might arise.

On lighttpd you need to use the CGI module, which can be configured in a straightforward way. It boils down to setting cgi.assign properly.

Common problems with CGI scripts

Using CGI sometimes leads to small annoyances while trying to get these scripts to run. Sometimes a seemingly correct script does not work as expected, the cause being some small hidden problem that’s difficult to spot.

Some of these potential problems are:

- The Python script is not marked as executable. When CGI scripts are not executable most web servers will let the user download it, instead of running it and sending the output to the user. For CGI scripts to run properly on Unix-like operating systems, the +x bit needs to be set. Using chmod a+x your_script.py may solve this problem.

- On a Unix-like system, The line endings in the program file must be Unix style line endings. This is important because the web server checks the first line of the script (called shebang) and tries to run the program specified there. It gets easily confused by Windows line endings (Carriage Return & Line Feed, also called CRLF), so you have to convert the file to Unix line endings (only Line Feed, LF). This can be done automatically by uploading the file via FTP in text mode instead of binary mode, but the preferred way is just telling your editor to save the files with Unix line endings. Most editors support this.

- Your web server must be able to read the file, and you need to
make sure the permissions are correct. On unix-like systems, the server often runs as user and group `www-data`, so it might be worth a try to change the file ownership, or making the file world readable by using `chmod a+r your_script.py`.

- The web server must know that the file you're trying to access is a CGI script. Check the configuration of your web server, as it may be configured to expect a specific file extension for CGI scripts.
- On Unix-like systems, the path to the interpreter in the shebang (`#!/usr/bin/env python`) must be correct. This line calls `/usr/bin/env` to find Python, but it will fail if there is no `/usr/bin/env`, or if Python is not in the web server's path. If you know where your Python is installed, you can also use that full path. The commands `whereis python` and `type -p python` could help you find where it is installed. Once you know the path, you can change the shebang accordingly: `#!/usr/bin/python`.
- The file must not contain a BOM (Byte Order Mark). The BOM is meant for determining the byte order of UTF-16 and UTF-32 encodings, but some editors write this also into UTF-8 files. The BOM interferes with the shebang line, so be sure to tell your editor not to write the BOM.
- If the web server is using `mod_python`, `mod_python` may be having problems. `mod_python` is able to handle CGI scripts by itself, but it can also be a source of issues.

mod_python

People coming from PHP often find it hard to grasp how to use Python in the web. Their first thought is mostly `mod_python`, because they think that this is the equivalent to `mod_php`. Actually, there are many differences. What `mod_python` does is embed the interpreter into the Apache process, thus speeding up requests by not having to start a Python interpreter for each request. On the
other hand, it is not “Python intermixed with HTML” in the way that PHP is often intermixed with HTML. The Python equivalent of that is a template engine. ```mod_python``` itself is much more powerful and provides more access to Apache internals. It can emulate CGI, work in a “Python Server Pages” mode (similar to JSP) which is “HTML intermingled with Python”, and it has a “Publisher” which designates one file to accept all requests and decide what to do with them.

```mod_python``` does have some problems. Unlike the PHP interpreter, the Python interpreter uses caching when executing files, so changes to a file will require the web server to be restarted. Another problem is the basic concept – Apache starts child processes to handle the requests, and unfortunately every child process needs to load the whole Python interpreter even if it does not use it. This makes the whole web server slower. Another problem is that, because ```mod_python``` is linked against a specific version of ```libpython```, it is not possible to switch from an older version to a newer (e.g. 2.4 to 2.5) without recompiling ```mod_python```. ```mod_python``` is also bound to the Apache web server, so programs written for ```mod_python``` cannot easily run on other web servers.

These are the reasons why ```mod_python``` should be avoided when writing new programs. In some circumstances it still might be a good idea to use ```mod_python``` for deployment, but WSGI makes it possible to run WSGI programs under ```mod_python``` as well.

### FastCGI and SCGI

FastCGI and SCGI try to solve the performance problem of CGI in another way. Instead of embedding the interpreter into the web server, they create long-running background processes. There is still a module in the web server which makes it possible for the web server to “speak” with the background process. As the background process is independent of the server, it can be written in any
language, including Python. The language just needs to have a library which handles the communication with the webserver.

The difference between FastCGI and SCGI is very small, as SCGI is essentially just a “simpler FastCGI”. As the web server support for SCGI is limited, most people use FastCGI instead, which works the same way. Almost everything that applies to SCGI also applies to FastCGI as well, so we'll only cover the latter.

These days, FastCGI is never used directly. Just like mod_python, it is only used for the deployment of WSGI applications.

### Setting up FastCGI

Each web server requires a specific module.

- Apache has both mod_fastcgi and mod_fcgid. mod_fastcgi is the original one, but it has some licensing issues, which is why it is sometimes considered non-free. mod_fcgid is a smaller, compatible alternative. One of these modules needs to be loaded by Apache.
- lighttpd ships its own FastCGI module as well as an SCGI module.
- nginx also supports FastCGI.

Once you have installed and configured the module, you can test it with the following WSGI-application:

```python
#!/usr/bin/env python
# -*- coding: UTF-8 -*-

from cgi import escape
import sys, os
from flup.server.fcgi import WSGIServer

def app(environ, start_response):
    start_response('200 OK', [('Content-Type', 'text/html')])
```
mod_wsgi

mod_wsgi is an attempt to get rid of the low level gateways. Given that FastCGI, SCGI, and mod_python are mostly used to deploy WSGI applications, mod_wsgi was started to directly embed WSGI applications into the Apache web server. mod_wsgi is specifically designed to host WSGI applications. It makes the deployment of WSGI applications much easier than deployment using other low level methods, which need glue code. The downside is that mod_wsgi is limited to the Apache web server; other servers would need their own implementations of mod_wsgi.

mod_wsgi supports two modes: embedded mode, in which it integrates with the Apache process, and daemon mode, which is more FastCGI-like. Unlike FastCGI, mod_wsgi handles the worker-processes by itself, which makes administration easier.
Step back: WSGI

WSGI has already been mentioned several times, so it has to be something important. In fact it really is, and now it is time to explain it.

The Web Server Gateway Interface, or WSGI for short, is defined in PEP 333 and is currently the best way to do Python web programming. While it is great for programmers writing frameworks, a normal web developer does not need to get in direct contact with it. When choosing a framework for web development it is a good idea to choose one which supports WSGI.

The big benefit of WSGI is the unification of the application programming interface. When your program is compatible with WSGI – which at the outer level means that the framework you are using has support for WSGI – your program can be deployed via any web server interface for which there are WSGI wrappers. You do not need to care about whether the application user uses mod_python or FastCGI or mod_wsgi – with WSGI your application will work on any gateway interface. The Python standard library contains its own WSGI server, wsgiref, which is a small web server that can be used for testing.

A really great WSGI feature is middleware. Middleware is a layer around your program which can add various functionality to it. There is quite a bit of middleware already available. For example, instead of writing your own session management (HTTP is a stateless protocol, so to associate multiple HTTP requests with a single user your application must create and manage such state via a session), you can just download middleware which does that, plug it in, and get on with coding the unique parts of your application. The same thing with compression – there is existing middleware which handles
compressing your HTML using gzip to save on your server’s bandwidth. Authentication is another problem that is easily solved using existing middleware.

Although WSGI may seem complex, the initial phase of learning can be very rewarding because WSGI and the associated middleware already have solutions to many problems that might arise while developing web sites.

WSGI Servers

The code that is used to connect to various low level gateways like CGI or mod_python is called a WSGI server. One of these servers is flup, which supports FastCGI and SCGI, as well as AJP. Some of these servers are written in Python, as flup is, but there also exist others which are written in C and can be used as drop-in replacements.

There are many servers already available, so a Python web application can be deployed nearly anywhere. This is one big advantage that Python has compared with other web technologies.

See also: A good overview of WSGI-related code can be found in the WSGI homepage, which contains an extensive list of WSGI servers which can be used by any application supporting WSGI.

You might be interested in some WSGI-supporting modules already contained in the standard library, namely:

- wsgiref – some tiny utilities and servers for WSGI

Case study: MoinMoin

What does WSGI give the web application developer? Let's take a
look at an application that’s been around for a while, which was written in Python without using WSGI.

One of the most widely used wiki software packages is MoinMoin. It was created in 2000, so it predates WSGI by about three years. Older versions needed separate code to run on CGI, mod_python, FastCGI and standalone.

It now includes support for WSGI. Using WSGI, it is possible to deploy MoinMoin on any WSGI compliant server, with no additional glue code. Unlike the pre-WSGI versions, this could include WSGI servers that the authors of MoinMoin know nothing about.
The term \textit{MVC} is often encountered in statements such as “framework \textit{foo} supports MVC”. MVC is more about the overall organization of code, rather than any particular API. Many web frameworks use this model to help the developer bring structure to their program. Bigger web applications can have lots of code, so it is a good idea to have an effective structure right from the beginning. That way, even users of other frameworks (or even other languages, since MVC is not Python-specific) can easily understand the code, given that they are already familiar with the MVC structure.

MVC stands for three components:

- The \textit{model}. This is the data that will be displayed and modified. In Python frameworks, this component is often represented by the classes used by an object-relational mapper.
- The \textit{view}. This component’s job is to display the data of the model to the user. Typically this component is implemented via templates.
- The \textit{controller}. This is the layer between the user and the model. The controller reacts to user actions (like opening some specific URL), tells the model to modify the data if necessary, and tells the view code what to display,

While one might think that MVC is a complex design pattern, in fact it is not. It is used in Python because it has turned out to be useful for creating clean, maintainable web sites.

\textbf{Note}: While not all Python frameworks explicitly support MVC, it is often trivial to create a web site which uses the MVC pattern by separating the data logic (the model) from the user interaction logic (the controller) and the templates (the view). That’s why it is
important not to write unnecessary Python code in the templates – it works against the MVC model and creates chaos in the code base, making it harder to understand and modify.

**See also:** The English Wikipedia has an article about the **Model-View-Controller pattern**. It includes a long list of web frameworks for various programming languages.
Ingredients for Websites

Websites are complex constructs, so tools have been created to help web developers make their code easier to write and more maintainable. Tools like these exist for all web frameworks in all languages. Developers are not forced to use these tools, and often there is no “best” tool. It is worth learning about the available tools because they can greatly simplify the process of developing a website.

See also: There are far more components than can be presented here. The Python wiki has a page about these components, called Web Components.

Templates

Mixing of HTML and Python code is made possible by a few libraries. While convenient at first, it leads to horribly unmaintainable code. That's why templates exist. Templates are, in the simplest case, just HTML files with placeholders. The HTML is sent to the user's browser after filling in the placeholders.

Python already includes two ways to build simple templates:

```python
>>> template = "<html><body><h1>Hello %s!</h1></body></html>"
>>> print template % "Reader"
<html><body><h1>Hello Reader!</h1></body></html>
```

```python
>>> from string import Template
>>> template = Template("<html><body><h1>Hello $name</h1></body></html>
```

To generate complex HTML based on non-trivial model data,
conditional and looping constructs like Python’s *for* and *if* are generally needed. *Template engines* support templates of this complexity.

There are a lot of template engines available for Python which can be used with or without a *framework*. Some of these define a plain-text programming language which is easy to learn, partly because it is limited in scope. Others use XML, and the template output is guaranteed to be always be valid XML. There are many other variations.

Some *frameworks* ship their own template engine or recommend one in particular. In the absence of a reason to use a different template engine, using the one provided by or recommended by the framework is a good idea.

Popular template engines include:

- Mako
- Genshi
- Jinja

**See also:** There are many template engines competing for attention, because it is pretty easy to create them in Python. The page *Templating* in the wiki lists a big, ever-growing number of these. The three listed above are considered “second generation” template engines and are a good place to start.

### Data persistence

*Data persistence*, while sounding very complicated, is just about storing data. This data might be the text of blog entries, the postings on a bulletin board or the text of a wiki page. There are, of course, a number of different ways to store information on a web server.
Often, relational database engines like MySQL or PostgreSQL are used because of their good performance when handling very large databases consisting of millions of entries. There is also a small database engine called SQLite, which is bundled with Python in the sqlite3 module, and which uses only one file. It has no other dependencies. For smaller sites SQLite is just enough.

Relational databases are queried using a language called SQL. Python programmers in general do not like SQL too much, as they prefer to work with objects. It is possible to save Python objects into a database using a technology called ORM (Object Relational Mapping). ORM translates all object-oriented access into SQL code under the hood, so the developer does not need to think about it. Most frameworks use ORMs, and it works quite well.

A second possibility is storing data in normal, plain text files (some times called “flat files”). This is very easy for simple sites, but can be difficult to get right if the web site is performing many updates to the stored data.

A third possibility are object oriented databases (also called “object databases”). These databases store the object data in a form that closely parallels the way the objects are structured in memory during program execution. (By contrast, ORMs store the object data as rows of data in tables and relations between those rows.) Storing the objects directly has the advantage that nearly all objects can be saved in a straightforward way, unlike in relational databases where some objects are very hard to represent.

Frameworks often give hints on which data storage method to choose. It is usually a good idea to stick to the data store recommended by the framework unless the application has special requirements better satisfied by an alternate storage mechanism.

See also:
- **Persistence Tools** lists possibilities on how to save data in the file system. Some of these modules are part of the standard library.
- **Database Programming** helps with choosing a method for saving data.
- **SQLAlchemy**, the most powerful OR-Mapper for Python, and **Elixir**, which makes SQLAlchemy easier to use.
- **SQLObject**, another popular OR-Mapper.
- **ZODB** and **Durus**, two object oriented databases.
The process of creating code to run web sites involves writing code to provide various services. The code to provide a particular service often works the same way regardless of the complexity or purpose of the web site in question. Abstracting these common solutions into reusable code produces what are called “frameworks” for web development. Perhaps the most well-known framework for web development is Ruby on Rails, but Python has its own frameworks. Some of these were partly inspired by Rails, or borrowed ideas from Rails, but many existed a long time before Rails.

Originally Python web frameworks tended to incorporate all of the services needed to develop web sites as a giant, integrated set of tools. No two web frameworks were interoperable: a program developed for one could not be deployed on a different one without considerable re-engineering work. This led to the development of “minimalist” web frameworks that provided just the tools to communicate between the Python code and the http protocol, with all other services to be added on top via separate components. Some ad hoc standards were developed that allowed for limited interoperability between frameworks, such as a standard that allowed different template engines to be used interchangeably.

Since the advent of WSGI, the Python web framework world has been evolving toward interoperability based on the WSGI standard. Now many web frameworks, whether “full stack” (providing all the tools one needs to deploy the most complex web sites) or minimalist, or anything in between, are built from collections of reusable components that can be used with more than one framework.

The majority of users will probably want to select a “full stack” framework that has an active community. These frameworks tend to be well documented, and provide the easiest path to producing a
fully functional web site in minimal time.

Some notable frameworks

There are an incredible number of frameworks, so they cannot all be covered here. Instead we will briefly touch on some of the most popular.

Django

Django is a framework consisting of several tightly coupled elements which were written from scratch and work together very well. It includes an ORM which is quite powerful while being simple to use, and has a great online administration interface which makes it possible to edit the data in the database with a browser. The template engine is text-based and is designed to be usable for page designers who cannot write Python. It supports template inheritance and filters (which work like Unix pipes). Django has many handy features bundled, such as creation of RSS feeds or generic views, which make it possible to create web sites almost without writing any Python code.

It has a big, international community, the members of which have created many web sites. There are also a lot of add-on projects which extend Django's normal functionality. This is partly due to Django's well written online documentation and the Django book.

**Note:** Although Django is an MVC-style framework, it names the elements differently, which is described in the Django FAQ.

TurboGears

Another popular web framework for Python is TurboGears. TurboGears takes the approach of using already existing
components and combining them with glue code to create a seamless experience. TurboGears gives the user flexibility in choosing components. For example the ORM and template engine can be changed to use packages different from those used by default.

The documentation can be found in the TurboGears documentation, where links to screencasts can be found. TurboGears has also an active user community which can respond to most related questions. There is also a TurboGears book published, which is a good starting point.

The newest version of TurboGears, version 2.0, moves even further in direction of WSGI support and a component-based architecture. TurboGears 2 is based on the WSGI stack of another popular component-based web framework, Pylons.

### Zope

The Zope framework is one of the “old original” frameworks. Its current incarnation in Zope2 is a tightly integrated full-stack framework. One of its most interesting feature is its tight integration with a powerful object database called the ZODB (Zope Object Database). Because of its highly integrated nature, Zope wound up in a somewhat isolated ecosystem: code written for Zope wasn’t very usable outside of Zope, and vice-versa. To solve this problem the Zope 3 effort was started. Zope 3 re-engineers Zope as a set of more cleanly isolated components. This effort was started before the advent of the WSGI standard, but there is WSGI support for Zope 3 from the Repoze project. Zope components have many years of production use behind them, and the Zope 3 project gives access to these components to the wider Python community. There is even a separate framework based on the Zope components: Grok.

Zope is also the infrastructure used by the Plone content
management system, one of the most powerful and popular content management systems available.

Other notable frameworks

Of course these are not the only frameworks that are available. There are many other frameworks worth mentioning.

Another framework that’s already been mentioned is Pylons. Pylons is much like TurboGears, but with an even stronger emphasis on flexibility, which comes at the cost of being more difficult to use. Nearly every component can be exchanged, which makes it necessary to use the documentation of every single component, of which there are many. Pylons builds upon Paste, an extensive set of tools which are handy for WSGI.

And that’s still not everything. The most up-to-date information can always be found in the Python wiki.

See also: The Python wiki contains an extensive list of web frameworks.

Most frameworks also have their own mailing lists and IRC channels, look out for these on the projects' web sites.
This tutorial is intended to be a gentle introduction to `argparse`, the recommended command-line parsing module in the Python standard library. This was written for argparse in Python 3. A few details are different in 2.x, especially some exception messages, which were improved in 3.x.

**Note:** There are two other modules that fulfill the same task, namely `getopt` (an equivalent for `getopt()` from the C language) and the deprecated `optparse`. Note also that `argparse` is based on `optparse`, and therefore very similar in terms of usage.
Let's show the sort of functionality that we are going to explore in this introductory tutorial by making use of the `ls` command:

```
$ ls
cpython devguide prog.py pypy rm-unused-function.patch
$ ls pypy
ctypes_configure demo dotviewer include lib_pypy lib-python
$ ls -l
```

```
total 20
drwxr-xr-x  19 wena wena   4096 Feb 18 18:51 cpython
drwxr-xr-x   4 wena wena   4096 Feb  8 12:04 devguide
-rwxr-xr-x  1 wena wena    535 Feb 19 00:05 prog.py
drwxr-xr-x  14 wena wena   4096 Feb  7 00:59 pypy
-rw-r--r--  1 wena wena    741 Feb 18 01:01 rm-unused-function.patch
```

```
$ ls --help
Usage: ls [OPTION]... [FILE]...
List information about the FILEs (the current directory by defa
Sort entries alphabetically if none of -cftuvSUX nor --sort is
```

A few concepts we can learn from the four commands:

- The `ls` command is useful when run without any options at all. It defaults to displaying the contents of the current directory.
- If we want beyond what it provides by default, we tell it a bit more. In this case, we want it to display a different directory, `pypy`. What we did is specify what is known as a positional argument. It's named so because the program should know what to do with the value, solely based on where it appears on the command line. This concept is more relevant to a command like `cp`, whose most basic usage is `cp SRC DEST`. The first position is *what you want copied*, and the second position is *where you want it copied to*.
- Now, say we want to change behaviour of the program. In our example, we display more info for each file instead of just
showing the file names. The `-l` in that case is known as an optional argument.

- That's a snippet of the help text. It's very useful in that you can come across a program you have never used before, and can figure out how it works simply by reading its help text.
Let us start with a very simple example which does (almost) nothing:

```python
import argparse
parser = argparse.ArgumentParser()
parser.parse_args()
```

Following is a result of running the code:

```
$ python prog.py
$ python prog.py --help
usage: prog.py [-h]

optional arguments:
  -h, --help    show this help message and exit
$ python prog.py --verbose
usage: prog.py [-h]
prog.py: error: unrecognized arguments: --verbose
$ python prog.py foo
usage: prog.py [-h]
prog.py: error: unrecognized arguments: foo
```

Here is what is happening:

- Running the script without any options results in nothing displayed to stdout. Not so useful.
- The second one starts to display the usefulness of the `argparse` module. We have done almost nothing, but already we get a nice help message.
- The `--help` option, which can also be shortened to `-h`, is the only option we get for free (i.e. no need to specify it). Specifying anything else results in an error. But even then, we do get a useful usage message, also for free.
Introducing Positional arguments

An example:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("echo")
args = parser.parse_args()
print(args.echo)
```

And running the code:

```
$ python prog.py
usage: prog.py [-h] echo
prog.py: error: the following arguments are required: echo
$ python prog.py --help
usage: prog.py [-h] echo

positional arguments:
  echo

optional arguments:
  -h, --help    show this help message and exit
```

```
$ python prog.py foo
foo
```

Here is what's happening:

- We've added the `add_argument()` method, which is what we use to specify which command-line options the program is willing to accept. In this case, I've named it `echo` so that it's in line with its function.
- Calling our program now requires us to specify an option.
- The `parse_args()` method actually returns some data from the options specified, in this case, `echo`.
- The variable is some form of 'magic' that `argparse` performs for free (i.e. no need to specify which variable that value is stored
You will also notice that its name matches the string argument given to the method, `echo`.

Note however that, although the help display looks nice and all, it currently is not as helpful as it can be. For example we see that we got `echo` as a positional argument, but we don’t know what it does, other than by guessing or by reading the source code. So, let’s make it a bit more useful:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("echo", help="echo the string you use here")
args = parser.parse_args()
print args.echo
```

And we get:

```
$ python prog.py -h
usage: prog.py [-h] echo

positional arguments:
  echo         echo the string you use here

optional arguments:
  -h, --help    show this help message and exit
```

Now, how about doing something even more useful:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", help="display a square of a given")
args = parser.parse_args()
print args.square**2
```

Following is a result of running the code:

```
$ python prog.py 4
Traceback (most recent call last):
  File "prog.py", line 5, in <module>
```
That didn’t go so well. That’s because `argparse` treats the options we give it as strings, unless we tell it otherwise. So, let’s tell `argparse` to treat that input as an integer:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square",
                    help="display a square of a given
type=int")
args = parser.parse_args()
print args.square**2
```

Following is a result of running the code:

```
$ python prog.py 4
16
$ python prog.py four
usage: prog.py [-h] square
prog.py: error: argument square: invalid int value: 'four'
```

That went well. The program now even helpfully quits on bad illegal input before proceeding.
Introducing Optional arguments

So far we, have been playing with positional arguments. Let us have a look on how to add optional ones:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("--verbosity", help="increase output verbosity"
args = parser.parse_args()
if args.verbosity:
    print "verbosity turned on"
```

And the output:

```
$ python prog.py --verbosity 1
verbosity turned on
$ python prog.py
$ python prog.py --help
usage: prog.py [-h] [--verbosity VERBOSITY]

optional arguments:
  -h, --help                      show this help message and exit
  --verbosity VERBOSITY           increase output verbosity
$ python prog.py --verbosity
usage: prog.py [-h] [--verbosity VERBOSITY]
prog.py: error: argument --verbosity: expected one argument
```

Here is what is happening:

- The program is written so as to display something when `--verbosity` is specified and display nothing when not.
- To show that the option is actually optional, there is no error when running the program without it. Note that by default, if an optional argument isn’t used, the relevant variable, in this case `args.verbosity`, is given `None` as a value, which is the reason it fails the truth test of the `if` statement.
• The help message is a bit different.
• When using the `--verbosity` option, one must also specify some value, any value.

The above example accepts arbitrary integer values for `--verbosity`, but for our simple program, only two values are actually useful, `True` or `False`. Let’s modify the code accordingly:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("--verbose", help="increase output verbosity", action="store_true")
args = parser.parse_args()
if args.verbose:
    print "verbosity turned on"
```

And the output:

```
$ python prog.py --verbose
verbosity turned on
$ python prog.py --verbose 1
usage: prog.py [-h] [--verbose]
prog.py: error: unrecognized arguments: 1
$ python prog.py --help
usage: prog.py [-h] [--verbose]

optional arguments:
    -h, --help    show this help message and exit
    --verbose    increase output verbosity
```

Here is what is happening:

• The option is now more of a flag than something that requires a value. We even changed the name of the option to match that idea. Note that we now specify a new keyword, `action`, and give it the value `"store_true"`. This means that, if the option is specified, assign the value `True` to `args.verbose`. Not specifying it implies `False`. 
- It complains when you specify a value, in true spirit of what flags actually are.
- Notice the different help text.

**Short options**

If you are familiar with command line usage, you will notice that I haven’t yet touched on the topic of short versions of the options. It’s quite simple:

```python
import argparse
defparser = argparse.ArgumentParser()
defparser.add_argument("-v", "--verbose", help="increase output verbosity", action="store_true")
args = parser.parse_args()
if args.verbose:
    print "verbosity turned on"
```

And here goes:

```
$ python prog.py -v
verbosity turned on
$ python prog.py --help
usage: prog.py [-h] [-v]
optional arguments:
  -h, --help    show this help message and exit
  -v, --verbose increase output verbosity
```

Note that the new ability is also reflected in the help text.
Combining Positional and Optional arguments

Our program keeps growing in complexity:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                     help="display a square of a given number")
parser.add_argument("-v", "--verbose", action="store_true",
                     help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbose:
    print "the square of {} equals {}".format(args.square, answer)
else:
    print answer
```

And now the output:

```
$ python prog.py
usage: prog.py [-h] [-v] square
prog.py: error: the following arguments are required: square
$ python prog.py 4
16
$ python prog.py 4 --verbose
the square of 4 equals 16
$ python prog.py --verbose 4
the square of 4 equals 16
```

- We’ve brought back a positional argument, hence the complaint.
- Note that the order does not matter.

How about we give this program of ours back the ability to have multiple verbosity values, and actually get to use them:

```
import argparse
parser = argparse.ArgumentParser()
```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
        help="display a square of a given number")
parser.add_argument("-v", "--verbosity", type=int,
        help="increase output verbosity")

args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
    print "the square of {} equals {}".format(args.square, answer)
elif args.verbosity == 1:
    print "{}^2 == {}".format(args.square, answer)
else:
    print answer

And the output:

$ python prog.py 4
16
$ python prog.py 4 -v
usage: prog.py [-h] [-v VERBOSITY] square
prog.py: error: argument -v/--verbosity: expected one argument
$ python prog.py 4 -v 1
4^2 == 16
$ python prog.py 4 -v 2
the square of 4 equals 16
$ python prog.py 4 -v 3
16

These all look good except the last one, which exposes a bug in our program. Let's fix it by restricting the values the --verbosity option can accept:

import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
        help="display a square of a given number")
parser.add_argument("-v", "--verbosity", type=int, choices=[0,
        help="increase output verbosity")

args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
    print "the square of {} equals {}".format(args.square, answer)
elif args.verbosity == 1:
    print "{}^2 == {}".format(args.square, answer)
else:
    print answer

And the output:

$ python prog.py 4 -v 3
usage: prog.py [-h] [-v {0,1,2}] square
prog.py: error: argument -v/--verbosity: invalid choice: 3 (choose from 0, 1, 2)
$ python prog.py 4 -h
usage: prog.py [-h] [-v {0,1,2}] square

positional arguments:
    square                display a square of a given number

optional arguments:
    -h, --help            show this help message and exit
    -v {0,1,2}, --verbosity {0,1,2}
                        increase output verbosity

Note that the change also reflects both in the error message as well as the help string.

Now, let’s use a different approach of playing with verbosity, which is pretty common. It also matches the way the CPython executable handles its own verbosity argument (check the output of python --help):

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display the square of a given number")
parser.add_argument("-v", "--verbosity", action="count",
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
    print "the square of {} equals {}".format(args.square, answer)
elif args.verbosity == 1:
    print "{}^2 == {}".format(args.square, answer)
else:
    print answer
```
We have introduced another action, “count”, to count the number of occurrences of a specific optional arguments:

```bash
$ python prog.py 4
16
$ python prog.py 4 -v
4^2 == 16
$ python prog.py 4 -vv
the square of 4 equals 16
$ python prog.py 4 --verbosity --verbosity
the square of 4 equals 16
$ python prog.py 4 -v 1
usage: prog.py [-h] [-v] square
prog.py: error: unrecognized arguments: 1
$ python prog.py 4 -h
usage: prog.py [-h] [-v] square

positional arguments:
  square           display a square of a given number

optional arguments:
  -h, --help       show this help message and exit
  -v, --verbosity  increase output verbosity
$ python prog.py 4 -vvv
16
```

- Yes, it's now more of a flag (similar to `action="store_true"`) in the previous version of our script. That should explain the complaint.
- It also behaves similar to “store_true” action.
- Now here's a demonstration of what the “count” action gives. You've probably seen this sort of usage before.
- And, just like the “store_true” action, if you don't specify the `-v` flag, that flag is considered to have `None` value.
- As should be expected, specifying the long form of the flag, we should get the same output.
- Sadly, our help output isn’t very informative on the new ability our script has acquired, but that can always be fixed by
improving the documentation for our script (e.g. via the `help`
keyword argument).
- That last output exposes a bug in our program.

Let's fix:

```python
import argparse
parser = argparse.ArgumentParser(
    "square", type=int,
    help="display a square of a given number")
parser.add_argument("-v", "--verbosity", action="count",
    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2

# bugfix: replace == with >=
if args.verbosity >= 2:
    print "the square of {} equals {}".format(args.square, answer)
elif args.verbosity >= 1:
    print "{}^2 == {}".format(args.square, answer)
else:
    print answer
```

And this is what it gives:

```
$ python prog.py 4 -vvv
the square of 4 equals 16
$ python prog.py 4 -vvvv
the square of 4 equals 16
$ python prog.py 4
Traceback (most recent call last):
  File "prog.py", line 11, in <module>
    if args.verbosity >= 2:
TypeError: unorderable types: NoneType() >= int()
```

- First output went well, and fixes the bug we had before. That is,
  we want any value >= 2 to be as verbose as possible.
- Third output not so good.

Let's fix that bug:
```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
        help="display a square of a given number")
parser.add_argument("-v", "--verbosity", action="count", default
        help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity >= 2:
    print "the square of {} equals {}".format(args.square, answer)
elif args.verbosity >= 1:
    print "{}^2 == {}".format(args.square, answer)
else:
    print answer
```

We've just introduced yet another keyword, `default`. We've set it to `0` in order to make it comparable to the other `int` values. Remember that by default, if an optional argument isn't specified, it gets the `None` value, and that cannot be compared to an `int` value (hence the `TypeError` exception).

And:

```
$ python prog.py 4
16
```

You can go quite far just with what we've learned so far, and we have only scratched the surface. The `argparse` module is very powerful, and we'll explore a bit more of it before we end this tutorial.
Getting a little more advanced

What if we wanted to expand our tiny program to perform other powers, not just squares:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("x", type=int, help="the base")
parser.add_argument("y", type=int, help="the exponent")
parser.add_argument("-v", "--verbosity", action="count", default=0)
args = parser.parse_args()
answer = args.x**args.y
if args.verbosity >= 2:
    print "{} to the power {} equals {}".format(args.x, args.y, answer)
elif args.verbosity >= 1:
    print "{}^{} == {}".format(args.x, args.y, answer)
else:
    print answer
```

Output:

```
$ python prog.py
usage: prog.py [-h] [x y]
prog.py: error: the following arguments are required: x, y
$ python prog.py -h
usage: prog.py [-h] [x y]

positional arguments:
    x    the base
    y    the exponent

optional arguments:
    -h, --help    show this help message and exit
    -v, --verbosity
$ python prog.py 4 2 -v
4^2 == 16
```

Notice that so far we've been using verbosity level to change the text that gets displayed. The following example instead uses verbosity level to display more text instead:
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("x", type=int, help="the base")
parser.add_argument("y", type=int, help="the exponent")
parser.add_argument("-v", "--verbosity", action="count", default=0)
args = parser.parse_args()
answer = args.x**args.y
if args.verbosity >= 2:
    print "Running '{}".format(__file__)
if args.verbosity >= 1:
    print "{}^{} ==".format(args.x, args.y),
print answer

Output:

$ python prog.py 4 2
16
$ python prog.py 4 2 -v
4^2 == 16
$ python prog.py 4 2 -vv
Running 'prog.py'
4^2 == 16

Conflicting options

So far, we have been working with two methods of an argparse.ArgumentParser instance. Let's introduce a third one, add_mutually_exclusive_group(). It allows for us to specify options that conflict with each other. Let's also change the rest of the program so that the new functionality makes more sense: we'll introduce the --quiet option, which will be the opposite of the --verbose one:

import argparse
parser = argparse.ArgumentParser()
group = parser.add_mutually_exclusive_group()
group.add_argument("-v", "--verbose", action="store_true")
group.add_argument("-q", "--quiet", action="store_true")
parser.add_argument("x", type=int, help="the base")
Before we conclude, you probably want to tell your users the main purpose of your program, just in case they don't know:

```
import argparse

import argparse
parser = argparse.ArgumentParser(description="calculate X to the power Y")
group = parser.add_mutually_exclusive_group()
group.add_argument("-v", "--verbose", action="store_true")
group.add_argument("-q", "--quiet", action="store_true")
parsed.add_argument("x", type=int, help="the base")
```
parser.add_argument("y", type=int, help="the exponent")
args = parser.parse_args()
answer = args.x**args.y

if args.quiet:
    print answer
elif args.verbose:
    print "{} to the power {} equals {}".format(args.x, args.y,
else:
    print "{}^{} == {}".format(args.x, args.y, answer)

Note that slight difference in the usage text. Note the [-v | -q],
which tells us that we can either use -v or -q, but not both at the
same time:

$ python prog.py --help
usage: prog.py [-h] [-v | -q] x y

calculate X to the power of Y

positional arguments:
  x            the base
  y            the exponent

optional arguments:
  -h, --help   show this help message and exit
  -v, --verbose
  -q, --quiet
Conclusion

The `argparse` module offers a lot more than shown here. Its docs are quite detailed and thorough, and full of examples. Having gone through this tutorial, you should easily digest them without feeling overwhelmed.

General Information

What is Python?

Python is an interpreted, interactive, object-oriented programming language. It incorporates modules, exceptions, dynamic typing, very high level dynamic data types, and classes. Python combines remarkable power with very clear syntax. It has interfaces to many system calls and libraries, as well as to various window systems, and is extensible in C or C++. It is also usable as an extension language for applications that need a programmable interface. Finally, Python is portable: it runs on many Unix variants, on the Mac, and on PCs under MS-DOS, Windows, Windows NT, and OS/2.

To find out more, start with The Python Tutorial. The Beginner’s Guide to Python links to other introductory tutorials and resources for learning Python.

What is the Python Software Foundation?

The Python Software Foundation is an independent non-profit organization that holds the copyright on Python versions 2.1 and newer. The PSF’s mission is to advance open source technology related to the Python programming language and to publicize the use of Python. The PSF’s home page is at https://www.python.org/psf/.

Donations to the PSF are tax-exempt in the US. If you use Python and find it helpful, please contribute via the PSF donation page.

Are there copyright restrictions on the use of Python?
You can do anything you want with the source, as long as you leave the copyrights in and display those copyrights in any documentation about Python that you produce. If you honor the copyright rules, it’s OK to use Python for commercial use, to sell copies of Python in source or binary form (modified or unmodified), or to sell products that incorporate Python in some form. We would still like to know about all commercial use of Python, of course.

See the PSF license page to find further explanations and a link to the full text of the license.

The Python logo is trademarked, and in certain cases permission is required to use it. Consult the Trademark Usage Policy for more information.

Why was Python created in the first place?

Here’s a very brief summary of what started it all, written by Guido van Rossum:

I had extensive experience with implementing an interpreted language in the ABC group at CWI, and from working with this group I had learned a lot about language design. This is the origin of many Python features, including the use of indentation for statement grouping and the inclusion of very-high-level data types (although the details are all different in Python).

I had a number of gripes about the ABC language, but also liked many of its features. It was impossible to extend the ABC language (or its implementation) to remedy my complaints – in fact its lack of extensibility was one of its biggest problems. I had some experience with using Modula-2+ and talked with the designers of Modula-3 and read the Modula-3 report. Modula-3 is the origin of the syntax and semantics used for exceptions, and some other Python features.
I was working in the Amoeba distributed operating system group at CWI. We needed a better way to do system administration than by writing either C programs or Bourne shell scripts, since Amoeba had its own system call interface which wasn’t easily accessible from the Bourne shell. My experience with error handling in Amoeba made me acutely aware of the importance of exceptions as a programming language feature.

It occurred to me that a scripting language with a syntax like ABC but with access to the Amoeba system calls would fill the need. I realized that it would be foolish to write an Amoeba-specific language, so I decided that I needed a language that was generally extensible.

During the 1989 Christmas holidays, I had a lot of time on my hand, so I decided to give it a try. During the next year, while still mostly working on it in my own time, Python was used in the Amoeba project with increasing success, and the feedback from colleagues made me add many early improvements.

In February 1991, after just over a year of development, I decided to post to USENET. The rest is in the Misc/HISTORY file.

What is Python good for?

Python is a high-level general-purpose programming language that can be applied to many different classes of problems.

The language comes with a large standard library that covers areas such as string processing (regular expressions, Unicode, calculating differences between files), Internet protocols (HTTP, FTP, SMTP, XML-RPC, POP, IMAP, CGI programming), software engineering (unit testing, logging, profiling, parsing Python code), and operating system interfaces (system calls, filesystems, TCP/IP sockets). Look at the table of contents for The Python Standard Library to get an
idea of what's available. A wide variety of third-party extensions are also available. Consult the Python Package Index to find packages of interest to you.

**How does the Python version numbering scheme work?**

Python versions are numbered A.B.C or A.B. A is the major version number – it is only incremented for really major changes in the language. B is the minor version number, incremented for less earth-shattering changes. C is the micro-level – it is incremented for each bugfix release. See PEP 6 for more information about bugfix releases.

Not all releases are bugfix releases. In the run-up to a new major release, a series of development releases are made, denoted as alpha, beta, or release candidate. Alphas are early releases in which interfaces aren't yet finalized; it's not unexpected to see an interface change between two alpha releases. Betas are more stable, preserving existing interfaces but possibly adding new modules, and release candidates are frozen, making no changes except as needed to fix critical bugs.

Alpha, beta and release candidate versions have an additional suffix. The suffix for an alpha version is “aN” for some small number N, the suffix for a beta version is “bN” for some small number N, and the suffix for a release candidate version is “cN” for some small number N. In other words, all versions labeled 2.0aN precede the versions labeled 2.0bN, which precede versions labeled 2.0cN, and *those* precede 2.0.

You may also find version numbers with a “+” suffix, e.g. “2.2+”. These are unreleased versions, built directly from the CPython development repository. In practice, after a final minor release is
made, the version is incremented to the next minor version, which becomes the “a0” version, e.g. “2.4a0”.

See also the documentation for `sys.version`, `sys.hexversion`, and `sys.version_info`.

### How do I obtain a copy of the Python source?

The latest Python source distribution is always available from python.org, at [https://www.python.org/downloads/](https://www.python.org/downloads/). The latest development sources can be obtained via anonymous Mercurial access at [https://hg.python.org/cpython](https://hg.python.org/cpython).

The source distribution is a gzipped tar file containing the complete C source, Sphinx-formatted documentation, Python library modules, example programs, and several useful pieces of freely distributable software. The source will compile and run out of the box on most UNIX platforms.

Consult the [Getting Started section of the Python Developer's Guide](https://docs.python.org/3/) for more information on getting the source code and compiling it.

### How do I get documentation on Python?

The standard documentation for the current stable version of Python is available at [https://docs.python.org/3/](https://docs.python.org/3/). PDF, plain text, and downloadable HTML versions are also available at [https://docs.python.org/3/download.html](https://docs.python.org/3/download.html).

The documentation is written in reStructuredText and processed by the [Sphinx documentation tool](https://sphinx.readthedocs.io). The reStructuredText source for the documentation is part of the Python source distribution.

I’ve never programmed before. Is there a Python
tutorial?

There are numerous tutorials and books available. The standard documentation includes The Python Tutorial.

Consult the Beginner's Guide to find information for beginning Python programmers, including lists of tutorials.

Is there a newsgroup or mailing list devoted to Python?

There is a newsgroup, comp.lang.python, and a mailing list, python-list. The newsgroup and mailing list are gatewayed into each other – if you can read news it's unnecessary to subscribe to the mailing list. comp.lang.python is high-traffic, receiving hundreds of postings every day, and Usenet readers are often more able to cope with this volume.

Announcements of new software releases and events can be found in comp.lang.python.announce, a low-traffic moderated list that receives about five postings per day. It's available as the python-announce mailing list.

More info about other mailing lists and newsgroups can be found at https://www.python.org/community/lists/.

How do I get a beta test version of Python?

Alpha and beta releases are available from https://www.python.org/downloads/. All releases are announced on the comp.lang.python and comp.lang.python.announce newsgroups and on the Python home page at https://www.python.org/; an RSS feed of news is available.
You can also access the development version of Python through Mercurial. See https://docs.python.org/devguide/faq.html for details.

**How do I submit bug reports and patches for Python?**

To report a bug or submit a patch, please use the Roundup installation at https://bugs.python.org/.

You must have a Roundup account to report bugs; this makes it possible for us to contact you if we have follow-up questions. It will also enable Roundup to send you updates as we act on your bug. If you had previously used SourceForge to report bugs to Python, you can obtain your Roundup password through Roundup’s password reset procedure.

For more information on how Python is developed, consult the Python Developer’s Guide.

**Are there any published articles about Python that I can reference?**

It's probably best to cite your favorite book about Python.

The very first article about Python was written in 1991 and is now quite outdated.

**Are there any books on Python?**
Yes, there are many, and more are being published. See the python.org wiki at https://wiki.python.org/moin/PythonBooks for a list.

You can also search online bookstores for “Python” and filter out the Monty Python references; or perhaps search for “Python” and “language”.

**Where in the world is www.python.org located?**

The Python project’s infrastructure is located all over the world. www.python.org is graciously hosted by Rackspace, with CDN caching provided by Fastly. Upfront Systems hosts bugs.python.org. Many other Python services like the Wiki are hosted by Oregon State University Open Source Lab.

**Why is it called Python?**

When he began implementing Python, Guido van Rossum was also reading the published scripts from “Monty Python’s Flying Circus”, a BBC comedy series from the 1970s. Van Rossum thought he needed a name that was short, unique, and slightly mysterious, so he decided to call the language Python.

**Do I have to like “Monty Python’s Flying Circus”?**

No, but it helps. :)
Python in the real world

How stable is Python?

Very stable. New, stable releases have been coming out roughly every 6 to 18 months since 1991, and this seems likely to continue. Currently there are usually around 18 months between major releases.

The developers issue “bugfix” releases of older versions, so the stability of existing releases gradually improves. Bugfix releases, indicated by a third component of the version number (e.g. 2.5.3, 2.6.2), are managed for stability; only fixes for known problems are included in a bugfix release, and it’s guaranteed that interfaces will remain the same throughout a series of bugfix releases.

The latest stable releases can always be found on the Python download page. There are two recommended production-ready versions at this point in time, because at the moment there are two branches of stable releases: 2.x and 3.x. Python 3.x may be less useful than 2.x, since currently there is more third party software available for Python 2 than for Python 3. Python 2 code will generally not run unchanged in Python 3.

How many people are using Python?

There are probably tens of thousands of users, though it’s difficult to obtain an exact count.

Python is available for free download, so there are no sales figures, and it’s available from many different sites and packaged with many Linux distributions, so download statistics don’t tell the whole story either.
The comp.lang.python newsgroup is very active, but not all Python users post to the group or even read it.

Have any significant projects been done in Python?

See https://www.python.org/about/success for a list of projects that use Python. Consulting the proceedings for past Python conferences will reveal contributions from many different companies and organizations.

High-profile Python projects include the Mailman mailing list manager and the Zope application server. Several Linux distributions, most notably Red Hat, have written part or all of their installer and system administration software in Python. Companies that use Python internally include Google, Yahoo, and Lucasfilm Ltd.

What new developments are expected for Python in the future?

See https://www.python.org/dev/peps/ for the Python Enhancement Proposals (PEPs). PEPs are design documents describing a suggested new feature for Python, providing a concise technical specification and a rationale. Look for a PEP titled “Python X.Y Release Schedule”, where X.Y is a version that hasn’t been publicly released yet.

New development is discussed on the python-dev mailing list.

Is it reasonable to propose incompatible changes to Python?

In general, no. There are already millions of lines of Python code around the world, so any change in the language that invalidates more than a very small fraction of existing programs has to be
frowned upon. Even if you can provide a conversion program, there’s still the problem of updating all documentation; many books have been written about Python, and we don’t want to invalidate them all at a single stroke.

Providing a gradual upgrade path is necessary if a feature has to be changed. PEP 5 describes the procedure followed for introducing backward-incompatible changes while minimizing disruption for users.

Is Python a good language for beginning programmers?

Yes.

It is still common to start students with a procedural and statically typed language such as Pascal, C, or a subset of C++ or Java. Students may be better served by learning Python as their first language. Python has a very simple and consistent syntax and a large standard library and, most importantly, using Python in a beginning programming course lets students concentrate on important programming skills such as problem decomposition and data type design. With Python, students can be quickly introduced to basic concepts such as loops and procedures. They can probably even work with user-defined objects in their very first course.

For a student who has never programmed before, using a statically typed language seems unnatural. It presents additional complexity that the student must master and slows the pace of the course. The students are trying to learn to think like a computer, decompose problems, design consistent interfaces, and encapsulate data. While learning to use a statically typed language is important in the long term, it is not necessarily the best topic to address in the students’ first programming course.
Many other aspects of Python make it a good first language. Like Java, Python has a large standard library so that students can be assigned programming projects very early in the course that do something. Assignments aren’t restricted to the standard four-function calculator and check balancing programs. By using the standard library, students can gain the satisfaction of working on realistic applications as they learn the fundamentals of programming. Using the standard library also teaches students about code reuse. Third-party modules such as PyGame are also helpful in extending the students’ reach.

Python’s interactive interpreter enables students to test language features while they’re programming. They can keep a window with the interpreter running while they enter their program’s source in another window. If they can’t remember the methods for a list, they can do something like this:

```
>>> L = []
>>> dir(L)
['__add__', '__class__', '__contains__', '__delattr__', '__delvalue__', '__delslice__', '__doc__', '__eq__', '__format__', '__ge__', '__getattribute__', '__getitem__', '__getslice__', '__gt__', '__hash__', '__iadd__', '__imul__', '__init__', '__iter__', '__len__', '__lt__', '__mul__', '__ne__', '__new__', '__reduce__', '__reduce_ex__', '__repr__', '__reversed__', '__rmul__', '__setattr__', '__setitem__', '__setslice__', '__sizeof__', '__str__', '__subclasshook__', 'append', 'count', 'extend', 'index', 'insert', 'pop', 'remove', 'reverse', 'sort']
>>> help(L.append)
Help on built-in function append:

append(...)
    L.append(object) -- append object to end

>>> L.append(1)
>>> L
[1]
```

With the interpreter, documentation is never far from the student as
he's programming.

There are also good IDEs for Python. IDLE is a cross-platform IDE for Python that is written in Python using Tkinter. PythonWin is a Windows-specific IDE. Emacs users will be happy to know that there is a very good Python mode for Emacs. All of these programming environments provide syntax highlighting, auto-indenting, and access to the interactive interpreter while coding. Consult the Python wiki for a full list of Python editing environments.

If you want to discuss Python's use in education, you may be interested in joining the edu-sig mailing list.
Upgrading Python

What is this bsddb185 module my application keeps complaining about?

Starting with Python2.3, the distribution includes the PyBSDDB package <http://pybsddb.sf.net/> as a replacement for the old bsddb module. It includes functions which provide backward compatibility at the API level, but requires a newer version of the underlying Berkeley DB library. Files created with the older bsddb module can’t be opened directly using the new module.

Using your old version of Python and a pair of scripts which are part of Python 2.3 (db2pickle.py and pickle2db.py, in the Tools/scripts directory) you can convert your old database files to the new format. Using your old Python version, run the db2pickle.py script to convert it to a pickle, e.g.:

```
python2.2 <pathto>/db2pickle.py database.db database.pck
```

Rename your database file:

```
mv database.db olddatabase.db
```

Now convert the pickle file to a new format database:

```
python <pathto>/pickle2db.py database.db database.pck
```

The precise commands you use will vary depending on the particulars of your installation. For full details about operation of these two scripts check the doc string at the start of each one.

- How do I find the current module name?
- How can I have modules that mutually import each other?
- __import__('x.y.z') returns <module 'x'>; how do I get z?
- When I edit an imported module and reimport it, the changes don’t show up. Why does this happen?
Yes.

The `pdb` module is a simple but adequate console-mode debugger for Python. It is part of the standard Python library, and is documented in the Library Reference Manual. You can also write your own debugger by using the code for `pdb` as an example.

The IDLE interactive development environment, which is part of the standard Python distribution (normally available as Tools/scripts/idle), includes a graphical debugger.

PythonWin is a Python IDE that includes a GUI debugger based on `pdb`. The Pythonwin debugger colors breakpoints and has quite a few cool features such as debugging non-Pythonwin programs. Pythonwin is available as part of the Python for Windows Extensions project and as a part of the ActivePython distribution (see https://www.activestate.com/activepython).

**Boa Constructor** is an IDE and GUI builder that uses wxWidgets. It offers visual frame creation and manipulation, an object inspector, many views on the source like object browsers, inheritance hierarchies, doc string generated html documentation, an advanced debugger, integrated help, and Zope support.

**Eric** is an IDE built on PyQt and the Scintilla editing component.

Pydb is a version of the standard Python debugger `pdb`, modified for use with DDD (Data Display Debugger), a popular graphical
There are a number of commercial Python IDEs that include graphical debuggers. They include:

- Wing IDE (https://wingware.com/)
- Komodo IDE (https://komodoide.com/)
- PyCharm (https://www.jetbrains.com/pycharm/)

Is there a tool to help find bugs or perform static analysis?

Yes.

PyChecker is a static analysis tool that finds bugs in Python source code and warns about code complexity and style. You can get PyChecker from http://pychecker.sourceforge.net/.

Pylint is another tool that checks if a module satisfies a coding standard, and also makes it possible to write plug-ins to add a custom feature. In addition to the bug checking that PyChecker performs, Pylint offers some additional features such as checking line length, whether variable names are well-formed according to your coding standard, whether declared interfaces are fully implemented, and more. https://docs.pylint.org/ provides a full list of Pylint's features.

How can I create a stand-alone binary from a Python script?

You don't need the ability to compile Python to C code if all you want is a stand-alone program that users can download and run without
having to install the Python distribution first. There are a number of tools that determine the set of modules required by a program and bind these modules together with a Python binary to produce a single executable.

One is to use the freeze tool, which is included in the Python source tree as `Tools/freeze`. It converts Python byte code to C arrays; a C compiler you can embed all your modules into a new program, which is then linked with the standard Python modules.

It works by scanning your source recursively for import statements (in both forms) and looking for the modules in the standard Python path as well as in the source directory (for built-in modules). It then turns the bytecode for modules written in Python into C code (array initializers that can be turned into code objects using the marshal module) and creates a custom-made config file that only contains those built-in modules which are actually used in the program. It then compiles the generated C code and links it with the rest of the Python interpreter to form a self-contained binary which acts exactly like your script.

Obviously, freeze requires a C compiler. There are several other utilities which don’t. One is Thomas Heller’s py2exe (Windows only) at

http://www.py2exe.org/

Another tool is Anthony Tuininga’s cx_Freeze.

Are there coding standards or a style guide for Python programs?

Yes. The coding style required for standard library modules is documented as PEP 8.
My program is too slow. How do I speed it up?

That’s a tough one, in general. There are many tricks to speed up Python code; consider rewriting parts in C as a last resort.

In some cases it’s possible to automatically translate Python to C or x86 assembly language, meaning that you don’t have to modify your code to gain increased speed.

**Pyrex** can compile a slightly modified version of Python code into a C extension, and can be used on many different platforms.

**Psyco** is a just-in-time compiler that translates Python code into x86 assembly language. If you can use it, Psyco can provide dramatic speedups for critical functions.

The rest of this answer will discuss various tricks for squeezing a bit more speed out of Python code. *Never* apply any optimization tricks unless you know you need them, after profiling has indicated that a particular function is the heavily executed hot spot in the code. Optimizations almost always make the code less clear, and you shouldn’t pay the costs of reduced clarity (increased development time, greater likelihood of bugs) unless the resulting performance benefit is worth it.

There is a page on the wiki devoted to performance tips.

Guido van Rossum has written up an anecdote related to optimization at [https://www.python.org/doc/essays/list2str](https://www.python.org/doc/essays/list2str).

One thing to notice is that function and (especially) method calls are rather expensive; if you have designed a purely OO interface with lots of tiny functions that don’t do much more than get or set an instance variable or call another method, you might consider using a more direct way such as directly accessing instance variables. Also
see the standard module `profile` which makes it possible to find out where your program is spending most of its time (if you have some patience – the profiling itself can slow your program down by an order of magnitude).

Remember that many standard optimization heuristics you may know from other programming experience may well apply to Python. For example it may be faster to send output to output devices using larger writes rather than smaller ones in order to reduce the overhead of kernel system calls. Thus CGI scripts that write all output in “one shot” may be faster than those that write lots of small pieces of output.

Also, be sure to use Python’s core features where appropriate. For example, slicing allows programs to chop up lists and other sequence objects in a single tick of the interpreter’s mainloop using highly optimized C implementations. Thus to get the same effect as:

```python
L2 = []
for i in range(3):
    L2.append(L1[i])
```

it is much shorter and far faster to use

```python
L2 = list(L1[:3])  # "list" is redundant if L1 is a list.
```

Note that the functionally-oriented built-in functions such as `map()`, `zip()`, and friends can be a convenient accelerator for loops that perform a single task. For example to pair the elements of two lists together:

```python
>>> zip([1, 2, 3], [4, 5, 6])
[(1, 4), (2, 5), (3, 6)]
```

or to compute a number of sines:
The operation completes very quickly in such cases.

Other examples include the `join()` and `split()` methods of string objects. For example if `s1..s7` are large (10K+) strings then 

```
''.join([s1, s2, s3, s4, s5, s6, s7])
```

may be far faster than the more obvious `s1+s2+s3+s4+s5+s6+s7`, since the “summation” will compute many subexpressions, whereas `join()` does all the copying in one pass. For manipulating strings, use the `replace()` and the `format()` methods on string objects. Use regular expressions only when you’re not dealing with constant string patterns. You may still use the old `% operations` string % tuple and string % dictionary.

Be sure to use the `list.sort()` built-in method to do sorting, and see the sorting mini-HOWTO for examples of moderately advanced usage. `list.sort()` beats other techniques for sorting in all but the most extreme circumstances.

Another common trick is to “push loops into functions or methods.” For example suppose you have a program that runs slowly and you use the profiler to determine that a Python function `ff()` is being called lots of times. If you notice that `ff()`:

```python
def ff(x):
    ... # do something with x computing result...
    return result
```

tends to be called in loops like:

```python
list = map(ff, oldlist)
```

or:

```python
list = map(lambda x: ff(x), oldlist)
```
for x in sequence:
    value = ff(x)
    ... # do something with value...

then you can often eliminate function call overhead by rewriting `ff()` to:

```python
def ffseq(seq):
    resultseq = []
    for x in seq:
        ... # do something with x computing result...
        resultseq.append(result)
    return resultseq
```

and rewrite the two examples to `list = ffseq(oldlist)` and to:

```python
for value in ffseq(sequence):
    ... # do something with value...
```

Single calls to `ff(x)` translate to `ffseq([x])[0]` with little penalty. Of course this technique is not always appropriate and there are other variants which you can figure out.

You can gain some performance by explicitly storing the results of a function or method lookup into a local variable. A loop like:

```python
for key in token:
    dict[key] = dict.get(key, 0) + 1
```

resolves `dict.get` every iteration. If the method isn't going to change, a slightly faster implementation is:

```python
dict_get = dict.get  # look up the method once
for key in token:
    dict[key] = dict_get(key, 0) + 1
```

Default arguments can be used to determine values once, at compile time instead of at run time. This can only be done for functions or
objects which will not be changed during program execution, such as replacing

```python
def degree_sin(deg):
    return math.sin(deg * math.pi / 180.0)
```

with

```python
def degree_sin(deg, factor=math.pi/180.0, sin=math.sin):
    return sin(deg * factor)
```

Because this trick uses default arguments for terms which should not be changed, it should only be used when you are not concerned with presenting a possibly confusing API to your users.
Core Language

Why am I getting an UnboundLocalError when the variable has a value?

It can be a surprise to get the UnboundLocalError in previously working code when it is modified by adding an assignment statement somewhere in the body of a function.

This code:

```python
>>> x = 10
>>> def bar():
...    print x
>>> bar()
10
```

works, but this code:

```python
>>> x = 10
>>> def foo():
...    print x
...    x += 1
```

results in an UnboundLocalError:

```python
>>> foo()
Traceback (most recent call last):
...  UnboundLocalError: local variable 'x' referenced before assignment
```

This is because when you make an assignment to a variable in a scope, that variable becomes local to that scope and shadows any similarly named variable in the outer scope. Since the last statement in foo assigns a new value to x, the compiler recognizes it as a local
variable. Consequently when the earlier `print x` attempts to print the uninitialized local variable and an error results.

In the example above you can access the outer scope variable by declaring it global:

```python
>>> x = 10
>>> def foobar():
...    global x
...    print x
...    x += 1
>>> foobar()
10
```

This explicit declaration is required in order to remind you that (unlike the superficially analogous situation with class and instance variables) you are actually modifying the value of the variable in the outer scope:

```python
>>> print x
11
```

What are the rules for local and global variables in Python?

In Python, variables that are only referenced inside a function are implicitly global. If a variable is assigned a value anywhere within the function’s body, it’s assumed to be a local unless explicitly declared as global.

Though a bit surprising at first, a moment’s consideration explains this. On one hand, requiring `global` for assigned variables provides a bar against unintended side-effects. On the other hand, if `global` was required for all global references, you’d be using `global` all the time. You’d have to declare as global every reference to a built-in function or to a component of an imported module. This clutter would
defeat the usefulness of the `global` declaration for identifying side-effects.

**Why do lambdas defined in a loop with different values all return the same result?**

Assume you use a for loop to define a few different lambdas (or even plain functions), e.g.:

```python
>>> squares = []
>>> for x in range(5):
...     squares.append(lambda: x**2)
```

This gives you a list that contains 5 lambdas that calculate `x**2`. You might expect that, when called, they would return, respectively, 0, 1, 4, 9, and 16. However, when you actually try you will see that they all return 16:

```python
>>> squares[2]()
16
>>> squares[4]()
16
```

This happens because `x` is not local to the lambdas, but is defined in the outer scope, and it is accessed when the lambda is called — not when it is defined. At the end of the loop, the value of `x` is 4, so all the functions now return `4**2`, i.e. 16. You can also verify this by changing the value of `x` and see how the results of the lambdas change:

```python
>>> x = 8
>>> squares[2]()
64
```

In order to avoid this, you need to save the values in variables local
to the lambdas, so that they don’t rely on the value of the global $x$:

```python
>>> squares = []
>>> for x in range(5):
...     squares.append(lambda n=x: n**2)
```

Here, $n=x$ creates a new variable $n$ local to the lambda and computed when the lambda is defined so that it has the same value that $x$ had at that point in the loop. This means that the value of $n$ will be 0 in the first lambda, 1 in the second, 2 in the third, and so on. Therefore each lambda will now return the correct result:

```python
>>> squares[2]()
4
>>> squares[4]()
16
```

Note that this behaviour is not peculiar to lambdas, but applies to regular functions too.

### How do I share global variables across modules?

The canonical way to share information across modules within a single program is to create a special module (often called config or cfg). Just import the config module in all modules of your application; the module then becomes available as a global name. Because there is only one instance of each module, any changes made to the module object get reflected everywhere. For example:

**config.py:**

```python
x = 0  # Default value of the 'x' configuration setting
```

**mod.py:**

```python
import config
config.x = 1
```
main.py:

```python
import config
import mod
print config.x
```

Note that using a module is also the basis for implementing the Singleton design pattern, for the same reason.

**What are the “best practices” for using import in a module?**

In general, don’t use `from modulename import *`. Doing so clutters the importer’s namespace, and makes it much harder for linters to detect undefined names.

Import modules at the top of a file. Doing so makes it clear what other modules your code requires and avoids questions of whether the module name is in scope. Using one import per line makes it easy to add and delete module imports, but using multiple imports per line uses less screen space.

It’s good practice if you import modules in the following order:

1. standard library modules – e.g. `sys`, `os`, `getopt`, `re`
2. third-party library modules (anything installed in Python’s site-packages directory) – e.g. `mx.DateTime`, `ZODB`, `PIL.Image`, etc.
3. locally-developed modules

Only use explicit relative package imports. If you’re writing code that’s in the `package.sub.m1` module and want to import `package.sub.m2`, do not just write `import m2`, even though it’s legal. Write `from package.sub import m2` or `from . import m2` instead.
It is sometimes necessary to move imports to a function or class to avoid problems with circular imports. Gordon McMillan says:

Circular imports are fine where both modules use the “import <module>” form of import. They fail when the 2nd module wants to grab a name out of the first (“from module import name”) and the import is at the top level. That’s because names in the 1st are not yet available, because the first module is busy importing the 2nd.

In this case, if the second module is only used in one function, then the import can easily be moved into that function. By the time the import is called, the first module will have finished initializing, and the second module can do its import.

It may also be necessary to move imports out of the top level of code if some of the modules are platform-specific. In that case, it may not even be possible to import all of the modules at the top of the file. In this case, importing the correct modules in the corresponding platform-specific code is a good option.

Only move imports into a local scope, such as inside a function definition, if it’s necessary to solve a problem such as avoiding a circular import or are trying to reduce the initialization time of a module. This technique is especially helpful if many of the imports are unnecessary depending on how the program executes. You may also want to move imports into a function if the modules are only ever used in that function. Note that loading a module the first time may be expensive because of the one time initialization of the module, but loading a module multiple times is virtually free, costing only a couple of dictionary lookups. Even if the module name has gone out of scope, the module is probably available in `sys.modules`.

**Why are default values shared between objects?**
This type of bug commonly bites neophyte programmers. Consider this function:

```python
def foo(mydict={}):  # Danger: shared reference to one dict for ...
    # compute something ...
    mydict[key] = value
    return mydict
```

The first time you call this function, `mydict` contains a single item. The second time, `mydict` contains two items because when `foo()` begins executing, `mydict` starts out with an item already in it.

It is often expected that a function call creates new objects for default values. This is not what happens. Default values are created exactly once, when the function is defined. If that object is changed, like the dictionary in this example, subsequent calls to the function will refer to this changed object.

By definition, immutable objects such as numbers, strings, tuples, and `None`, are safe from change. Changes to mutable objects such as dictionaries, lists, and class instances can lead to confusion.

Because of this feature, it is good programming practice to not use mutable objects as default values. Instead, use `None` as the default value and inside the function, check if the parameter is `None` and create a new list/dictionary/whatever if it is. For example, don’t write:

```python
def foo(mydict={}):
    ...
```

but:

```python
def foo(mydict=None):
    if mydict is None:
        mydict = {}  # create a new dict for local namespace
```
This feature can be useful. When you have a function that’s time-consuming to compute, a common technique is to cache the parameters and the resulting value of each call to the function, and return the cached value if the same value is requested again. This is called “memoizing”, and can be implemented like this:

```python
# Callers will never provide a third parameter for this function.
def expensive(arg1, arg2, _cache={}):
    if (arg1, arg2) in _cache:
        return _cache[(arg1, arg2)]
    # Calculate the value
    result = ... expensive computation ...
    _cache[(arg1, arg2)] = result  # Store result in the cache
    return result
```

You could use a global variable containing a dictionary instead of the default value; it’s a matter of taste.

**How can I pass optional or keyword parameters from one function to another?**

Collect the arguments using the `*` and `**` specifiers in the function’s parameter list; this gives you the positional arguments as a tuple and the keyword arguments as a dictionary. You can then pass these arguments when calling another function by using `*` and `**`:

```python
def f(x, *args, **kwargs):
    ...
    kwargs['width'] = '14.3c'
    ...
    g(x, *args, **kwargs)
```

In the unlikely case that you care about Python versions older than 2.0, use `apply()`:

```python
def f(x, *args, **kwargs):
```
What is the difference between arguments and parameters?

Parameters are defined by the names that appear in a function definition, whereas arguments are the values actually passed to a function when calling it. Parameters define what types of arguments a function can accept. For example, given the function definition:

```python
def func(foo, bar=None, **kwargs):
    pass
```

`foo`, `bar` and `kwargs` are parameters of `func`. However, when calling `func`, for example:

```python
func(42, bar=314, extra=somevar)
```

the values 42, 314, and `somevar` are arguments.

Why did changing list ‘y’ also change list ‘x’?

If you wrote code like:

```python
>>> x = []
>>> y = x
>>> y.append(10)
>>> y
[10]
>>> x
[10]
```

you might be wondering why appending an element to `y` changed `x` too.
There are two factors that produce this result:

1. Variables are simply names that refer to objects. Doing \( y = x \) doesn't create a copy of the list – it creates a new variable \( y \) that refers to the same object \( x \) refers to. This means that there is only one object (the list), and both \( x \) and \( y \) refer to it.

2. Lists are mutable, which means that you can change their content.

After the call to `append()`, the content of the mutable object has changed from `[]` to `[10]`. Since both the variables refer to the same object, using either name accesses the modified value `[10]`.

If we instead assign an immutable object to `x`:

```python
>>> x = 5  # ints are immutable
>>> y = x
>>> x = x + 1  # 5 can't be mutated, we are creating a new obj
>>> x
6
>>> y
5
```

we can see that in this case \( x \) and \( y \) are not equal anymore. This is because integers are immutable, and when we do \( x = x + 1 \) we are not mutating the int 5 by incrementing its value; instead, we are creating a new object (the int 6) and assigning it to \( x \) (that is, changing which object \( x \) refers to). After this assignment we have two objects (the ints 6 and 5) and two variables that refer to them (\( x \) now refers to 6 but \( y \) still refers to 5).

Some operations (for example \( y.append(10) \) and \( y.sort() \)) mutate the object, whereas superficially similar operations (for example \( y = y + [10] \) and \( sorted(y) \)) create a new object. In general in Python
(and in all cases in the standard library) a method that mutates an object will return None to help avoid getting the two types of operations confused. So if you mistakenly write y.sort() thinking it will give you a sorted copy of y, you’ll instead end up with None, which will likely cause your program to generate an easily diagnosed error.

However, there is one class of operations where the same operation sometimes has different behaviors with different types: the augmented assignment operators. For example, += mutates lists but not tuples or ints (a_list += [1, 2, 3] is equivalent to a_list.extend([1, 2, 3]) and mutates a_list, whereas some_tuple += (1, 2, 3) and some_int += 1 create new objects).

In other words:

- If we have a mutable object (list, dict, set, etc.), we can use some specific operations to mutate it and all the variables that refer to it will see the change.
- If we have an immutable object (str, int, tuple, etc.), all the variables that refer to it will always see the same value, but operations that transform that value into a new value always return a new object.

If you want to know if two variables refer to the same object or not, you can use the is operator, or the built-in function id().

How do I write a function with output parameters (call by reference)?

Remember that arguments are passed by assignment in Python. Since assignment just creates references to objects, there’s no alias between an argument name in the caller and callee, and so no call-by-reference per se. You can achieve the desired effect in a number
of ways.

1. By returning a tuple of the results:

```python
def func2(a, b):
    a = 'new-value'  # a and b are local names
    b = b + 1        # assigned to new objects
    return a, b      # return new values

x, y = 'old-value', 99
x, y = func2(x, y)
print x, y  # output: new-value 100
```

This is almost always the clearest solution.

2. By using global variables. This isn't thread-safe, and is not recommended.

3. By passing a mutable (changeable in-place) object:

```python
def func1(a):
    a[0] = 'new-value'  # 'a' references a mutable list
    a[1] = a[1] + 1     # changes a shared object

args = ['old-value', 99]
func1(args)
print args[0], args[1]  # output: new-value 100
```

4. By passing in a dictionary that gets mutated:

```python
def func3(args):
    args['a'] = 'new-value'  # args is a mutable diction
    args['b'] = args['b'] + 1  # change it in-place

args = {'a': 'old-value', 'b': 99}
func3(args)
print args['a'], args['b']
```

5. Or bundle up values in a class instance:

```python
class callByRef:
```
```python
def __init__(self, **args):
    for (key, value) in args.items():
        setattr(self, key, value)

def func4(args):
    args.a = 'new-value'  # args is a mutable callByRef
    args.b = args.b + 1   # change object in-place

args = callByRef(a='old-value', b=99)
func4(args)
print args.a, args.b
```

There's almost never a good reason to get this complicated.

Your best choice is to return a tuple containing the multiple results.

How do you make a higher order function in Python?

You have two choices: you can use nested scopes or you can use callable objects. For example, suppose you wanted to define `linear(a, b)` which returns a function $f(x)$ that computes the value $a*x+b$. Using nested scopes:

```python
def linear(a, b):
    def result(x):
        return a * x + b
    return result
```

Or using a callable object:

```python
class linear:
    def __init__(self, a, b):
        self.a, self.b = a, b
    def __call__(self, x):
        return self.a * x + self.b
```
In both cases,

```python
taxes = linear(0.3, 2)
```

gives a callable object where `taxes(10e6) == 0.3 * 10e6 + 2`.

The callable object approach has the disadvantage that it is a bit slower and results in slightly longer code. However, note that a collection of callables can share their signature via inheritance:

```python
class exponential(linear):
    # __init__ inherited
    def __call__(self, x):
        return self.a * (x ** self.b)
```

Object can encapsulate state for several methods:

```python
class counter:
    value = 0

    def set(self, x):
        self.value = x

    def up(self):
        self.value = self.value + 1

    def down(self):
        self.value = self.value - 1

count = counter()
inc, dec, reset = count.up, count.down, count.set
```

Here `inc()`, `dec()` and `reset()` act like functions which share the same counting variable.

**How do I copy an object in Python?**

In general, try `copy.copy()` or `copy.deepcopy()` for the general case.
Not all objects can be copied, but most can.

Some objects can be copied more easily. Dictionaries have a `copy()` method:

```python
newdict = olddict.copy()
```

Sequences can be copied by slicing:

```python
new_l = l[:]
```

---

**How can I find the methods or attributes of an object?**

For an instance `x` of a user-defined class, `dir(x)` returns an alphabetized list of the names containing the instance attributes and methods and attributes defined by its class.

---

**How can my code discover the name of an object?**

Generally speaking, it can’t, because objects don’t really have names. Essentially, assignment always binds a name to a value; The same is true of `def` and `class` statements, but in that case the value is a callable. Consider the following code:

```python
>>> class A:
...   pass
... >>> B = A
>>> a = B()
>>> b = a
>>> print b
<__main__.A instance at 0x16D07CC>
>>> print a
<__main__.A instance at 0x16D07CC>
```

Arguably the class has a name: even though it is bound to two
names and invoked through the name B the created instance is still reported as an instance of class A. However, it is impossible to say whether the instance's name is a or b, since both names are bound to the same value.

Generally speaking it should not be necessary for your code to “know the names” of particular values. Unless you are deliberately writing introspective programs, this is usually an indication that a change of approach might be beneficial.

In comp.lang.python, Fredrik Lundh once gave an excellent analogy in answer to this question:

The same way as you get the name of that cat you found on your porch: the cat (object) itself cannot tell you its name, and it doesn’t really care – so the only way to find out what it's called is to ask all your neighbours (namespaces) if it’s their cat (object)...

....and don’t be surprised if you'll find that it's known by many names, or no name at all!

What’s up with the comma operator’s precedence?

Comma is not an operator in Python. Consider this session:

```python
>>> "a" in "b", "a"
(False, 'a')
```

Since the comma is not an operator, but a separator between expressions the above is evaluated as if you had entered:

```python
("a" in "b"), "a"
```

not:
The same is true of the various assignment operators (=, += etc). They are not truly operators but syntactic delimiters in assignment statements.

Is there an equivalent of C's "?:" ternary operator?

Yes, this feature was added in Python 2.5. The syntax would be as follows:

```
[on_true] if [expression] else [on_false]
x, y = 50, 25
small = x if x < y else y
```

For versions previous to 2.5 the answer would be ‘No’.

Is it possible to write obfuscated one-liners in Python?

Yes. Usually this is done by nesting `lambda` within `lambda`. See the following three examples, due to Ulf Bartelt:

```
# Primes < 1000
print filter(None, map(lambda y:y*reduce(lambda x,y:x*y!=0,
map(lambda x,y=y:y%x, range(2,int(pow(y,0.5)+1))),1),range(2,1000))),

# First 10 Fibonacci numbers
print map(lambda x,f=lambda x,y:(x-1,f)+f(x-2,f)) if x>1 else range(10)

# Mandelbrot set
print (lambda Ru,Ro,Iu,Io,IM,Sx,Sy:reduce(lambda x,y:x+y,map(lambda x,y=x+7,map(lambda x,y=yc,Ru=Ru,Ro=Ro,Sy=Sy,L=lambda yc,Iu=Iu,Io=Io,Ru=Ru,Ro=Ro,Sx=Sx,Sy=Sy:reduce(lambda x,y:x+y,map(lambda x,y=yc,Ru=Ru,Ro=Ro,Fi=F=lambda xc,yc,x,y,k,F=lambda xc,yc,x,y,k,F:(k<=0)or
>=4.0) or 1+f(xc,yc,x*yc-y*yc,2.0*x+yc,k-1,f):f(xc,yc,x,y,k,))
```
Don’t try this at home, kids!
Numbers and strings

How do I specify hexadecimal and octal integers?

To specify an octal digit, precede the octal value with a zero, and then a lower or uppercase “o”. For example, to set the variable “a” to the octal value “10” (8 in decimal), type:

```python
>>> a = 0o10
>>> a
8
```

Hexadecimal is just as easy. Simply precede the hexadecimal number with a zero, and then a lower or uppercase “x”. Hexadecimal digits can be specified in lower or uppercase. For example, in the Python interpreter:

```python
>>> a = 0xa5
>>> a
165
>>> b = 0XB2
>>> b
178
```

Why does -22 // 10 return -3?

It’s primarily driven by the desire that \( \text{i} \% \text{j} \) have the same sign as \( \text{j} \). If you want that, and also want:

\[
\text{i} = (\text{i} // \text{j}) \times \text{j} + (\text{i} \% \text{j})
\]

then integer division has to return the floor. C also requires that identity to hold, and then compilers that truncate \( \text{i} // \text{j} \) need to make \( \text{i} \% \text{j} \) have the same sign as \( \text{i} \).
There are few real use cases for $i \% j$ when $j$ is negative. When $j$ is positive, there are many, and in virtually all of them it's more useful for $i \% j$ to be $\geq 0$. If the clock says 10 now, what did it say 200 hours ago? $-190 \% 12 == 2$ is useful; $-190 \% 12 == -10$ is a bug waiting to bite.

**Note:** On Python 2, $a / b$ returns the same as $a // b$ if `__future__.division` is not in effect. This is also known as “classic” division.

---

**How do I convert a string to a number?**

For integers, use the built-in `int()` type constructor, e.g. `int('144') == 144`. Similarly, `float()` converts to floating-point, e.g. `float('144') == 144.0`.

By default, these interpret the number as decimal, so that `int('0144') == 144` and `int('0x144')` raises `ValueError`. `int(string, base)` takes the base to convert from as a second optional argument, so `int('0x144', 16) == 324`. If the base is specified as 0, the number is interpreted using Python's rules: a leading ‘0’ indicates octal, and ‘0x’ indicates a hex number.

Do not use the built-in function `eval()` if all you need is to convert strings to numbers. `eval()` will be significantly slower and it presents a security risk: someone could pass you a Python expression that might have unwanted side effects. For example, someone could pass `__import__('os').system("rm -rf $HOME")` which would erase your home directory.

`eval()` also has the effect of interpreting numbers as Python expressions, so that e.g. `eval('09')` gives a syntax error because Python regards numbers starting with ‘0’ as octal (base 8).
How do I convert a number to a string?

To convert, e.g., the number 144 to the string ‘144’, use the built-in type constructor `str()`. If you want a hexadecimal or octal representation, use the built-in functions `hex()` or `oct()`. For fancy formatting, see the Format String Syntax section, e.g. `{:04d}`.format(144) yields '0144' and `{:3f}`.format(1/3) yields '0.333'. You may also use the % operator on strings. See the library reference manual for details.

How do I modify a string in place?

You can’t, because strings are immutable. If you need an object with this ability, try converting the string to a list or use the array module:

```python
>>> import io
>>> s = "Hello, world"
>>> a = list(s)
>>> print a
['H', 'e', 'l', 'l', 'o', ',', ' ', 'w', 'o', 'r', 'l', 'd']
>>> a[7:] = list("there!")
>>> ''.join(a)
'Hello, there!

>>> import array
>>> a = array.array('c', s)
>>> print a
array('c', 'Hello, world')
>>> a[0] = 'y'; print a
array('c', 'yello, world')
>>> a.tostring()
yello, world
```

How do I use strings to call functions/methods?

There are various techniques.
• The best is to use a dictionary that maps strings to functions. The primary advantage of this technique is that the strings do not need to match the names of the functions. This is also the primary technique used to emulate a case construct:

```python
def a():
    pass
def b():
    pass
dispatch = {'go': a, 'stop': b}  # Note lack of parens for
dispatch[get_input()]()  # Note trailing parens to call fun
```

• Use the built-in function `getattr()`:

```python
import foo
getattr(foo, 'bar')()
```

Note that `getattr()` works on any object, including classes, class instances, modules, and so on.

This is used in several places in the standard library, like this:

```python
class Foo:
    def do_foo(self):
        ...

    def do_bar(self):
        ...

f = getattr(foo_instance, 'do_' + opname)
f()
```

• Use `locals()` or `eval()` to resolve the function name:

```python
def myFunc():
    print "hello"
```
fname = "myFunc"

f = locals()[fname]
f()

f = eval(fname)
f()

Note: Using `eval()` is slow and dangerous. If you don’t have absolute control over the contents of the string, someone could pass a string that resulted in an arbitrary function being executed.

**Is there an equivalent to Perl’s chomp() for removing trailing newlines from strings?**

Starting with Python 2.2, you can use `s.rstrip("\r\n")` to remove all occurrences of any line terminator from the end of the string `s` without removing other trailing whitespace. If the string `s` represents more than one line, with several empty lines at the end, the line terminators for all the blank lines will be removed:

```python
>>> lines = ("line 1 \r\n" ... "\r\n" ... "\r\n")
>>> lines.rstrip("\n\r")
'line 1 '  
```

Since this is typically only desired when reading text one line at a time, using `s.rstrip()` this way works well.

For older versions of Python, there are two partial substitutes:

- If you want to remove all trailing whitespace, use the `rstrip()` method of string objects. This removes all trailing whitespace, not just a single newline.
- Otherwise, if there is only one line in the string `s`, use
Is there a scanf() or sscanf() equivalent?

Not as such.

For simple input parsing, the easiest approach is usually to split the line into whitespace-delimited words using the `split()` method of string objects and then convert decimal strings to numeric values using `int()` or `float()`. `split()` supports an optional “sep” parameter which is useful if the line uses something other than whitespace as a separator.

For more complicated input parsing, regular expressions are more powerful than C’s `sscanf()` and better suited for the task.

What does ‘UnicodeError: ASCII [decoding,encoding] error: ordinal not in range(128)’ mean?

This error indicates that your Python installation can handle only 7-bit ASCII strings. There are a couple ways to fix or work around the problem.

If your programs must handle data in arbitrary character set encodings, the environment the application runs in will generally identify the encoding of the data it is handing you. You need to convert the input to Unicode data using that encoding. For example, a program that handles email or web input will typically find character set encoding information in Content-Type headers. This can then be used to properly convert input data to Unicode. Assuming the string referred to by `value` is encoded as UTF-8:

```python
value = unicode(value, "utf-8")
```
will return a Unicode object. If the data is not correctly encoded as UTF-8, the above call will raise a `UnicodeError` exception.

If you only want strings converted to Unicode which have non-ASCII data, you can try converting them first assuming an ASCII encoding, and then generate Unicode objects if that fails:

```python
try:
    x = unicode(value, "ascii")
except UnicodeError:
    value = unicode(value, "utf-8")
else:
    # value was valid ASCII data
    pass
```

It's possible to set a default encoding in a file called `sitecustomize.py` that's part of the Python library. However, this isn't recommended because changing the Python-wide default encoding may cause third-party extension modules to fail.

Note that on Windows, there is an encoding known as “mbcs”, which uses an encoding specific to your current locale. In many cases, and particularly when working with COM, this may be an appropriate default encoding to use.
Sequences (Tuples/Lists)

How do I convert between tuples and lists?

The type constructor `tuple(seq)` converts any sequence (actually, any iterable) into a tuple with the same items in the same order.

For example, `tuple([1, 2, 3])` yields `(1, 2, 3)` and `tuple('abc')` yields `(a, b, c)`. If the argument is a tuple, it does not make a copy but returns the same object, so it is cheap to call `tuple()` when you aren't sure that an object is already a tuple.

The type constructor `list(seq)` converts any sequence or iterable into a list with the same items in the same order. For example, `list((1, 2, 3))` yields `[1, 2, 3]` and `list('abc')` yields ['a', 'b', 'c']`. If the argument is a list, it makes a copy just like `seq[:]` would.

What’s a negative index?

Python sequences are indexed with positive numbers and negative numbers. For positive numbers 0 is the first index 1 is the second index and so forth. For negative indices -1 is the last index and -2 is the penultimate (next to last) index and so forth. Think of `seq[-n]` as the same as `seq[len(seq)-n]`.

Using negative indices can be very convenient. For example `s[:-1]` is all of the string except for its last character, which is useful for removing the trailing newline from a string.

How do I iterate over a sequence in reverse order?

Use the `reversed()` built-in function, which is new in Python 2.4:
for x in reversed(sequence):
    ... # do something with x ...

This won’t touch your original sequence, but build a new copy with reversed order to iterate over.

With Python 2.3, you can use an extended slice syntax:

for x in sequence[::-1]:
    ... # do something with x ...

How do you remove duplicates from a list?

See the Python Cookbook for a long discussion of many ways to do this:

https://code.activestate.com/recipes/52560/

If you don’t mind reordering the list, sort it and then scan from the end of the list, deleting duplicates as you go:

if mylist:
    mylist.sort()
    last = mylist[-1]
    for i in range(len(mylist)-2, -1, -1):
        if last == mylist[i]:
            del mylist[i]
        else:
            last = mylist[i]

If all elements of the list may be used as dictionary keys (i.e. they are all hashable) this is often faster

    d = {}
    for x in mylist:
        d[x] = 1
    mylist = list(d.keys())

In Python 2.5 and later, the following is possible instead:
mylist = list(set(mylist))

This converts the list into a set, thereby removing duplicates, and then back into a list.

How do you make an array in Python?

Use a list:

"this", 1, "is", "an", "array"

Lists are equivalent to C or Pascal arrays in their time complexity; the primary difference is that a Python list can contain objects of many different types.

The array module also provides methods for creating arrays of fixed types with compact representations, but they are slower to index than lists. Also note that the Numeric extensions and others define array-like structures with various characteristics as well.

To get Lisp-style linked lists, you can emulate cons cells using tuples:

lisp_list = ("like", ("this", ("example", None)) )

If mutability is desired, you could use lists instead of tuples. Here the analogue of lisp car is lisp_list[0] and the analogue of cdr is lisp_list[1]. Only do this if you're sure you really need to, because it's usually a lot slower than using Python lists.

How do I create a multidimensional list?

You probably tried to make a multidimensional array like this:

```python
>>> A = [[None] * 2] * 3
```
This looks correct if you print it:

```python
>>> A
[[None, None], [None, None], [None, None]]
```

But when you assign a value, it shows up in multiple places:

```python
>>> A[0][0] = 5
>>> A
[[5, None], [5, None], [5, None]]
```

The reason is that replicating a list with `*` doesn’t create copies, it only creates references to the existing objects. The `*3` creates a list containing 3 references to the same list of length two. Changes to one row will show in all rows, which is almost certainly not what you want.

The suggested approach is to create a list of the desired length first and then fill in each element with a newly created list:

```python
A = [None] * 3
for i in range(3):
    A[i] = [None] * 2
```

This generates a list containing 3 different lists of length two. You can also use a list comprehension:

```python
w, h = 2, 3
A = [[None] * w for i in range(h)]
```

Or, you can use an extension that provides a matrix datatype; `NumPy` is the best known.

**How do I apply a method to a sequence of objects?**

Use a list comprehension:
result = [obj.method() for obj in mylist]

More generically, you can try the following function:

```python
def method_map(objects, method, arguments):
    """method_map([a,b], "meth", (1,2)) gives [a.meth(1,2), b.meth(2,2)]""
    objects = len(objects)
    methods = map(getattr, objects, [method]*nobjects)
    return map(apply, methods, [arguments]*nobjects)
```

Why does a_tuple[i] += ['item'] raise an exception when the addition works?

This is because of a combination of the fact that augmented assignment operators are assignment operators, and the difference between mutable and immutable objects in Python.

This discussion applies in general when augmented assignment operators are applied to elements of a tuple that point to mutable objects, but we'll use a list and += as our exemplar.

If you wrote:

```python
>>> a_tuple = (1, 2)
>>> a_tuple[0] += 1
Traceback (most recent call last):
  ...  
TypeError: 'tuple' object does not support item assignment
```

The reason for the exception should be immediately clear: 1 is added to the object a_tuple[0] points to (1), producing the result object, 2, but when we attempt to assign the result of the computation, 2, to element 0 of the tuple, we get an error because we can’t change what an element of a tuple points to.

Under the covers, what this augmented assignment statement is
doing is approximately this:

```python
>>> result = a_tuple[0] + 1
>>> a_tuple[0] = result
Traceback (most recent call last):
 ... 
TypeError: 'tuple' object does not support item assignment
```

It is the assignment part of the operation that produces the error, since a tuple is immutable.

When you write something like:

```python
>>> a_tuple = (["foo", 'bar'])
>>> a_tuple[0] += ['item']
Traceback (most recent call last):
 ... 
TypeError: 'tuple' object does not support item assignment
```

The exception is a bit more surprising, and even more surprising is the fact that even though there was an error, the append worked:

```python
>>> a_tuple[0]
['foo', 'item']
```

To see why this happens, you need to know that (a) if an object implements an `__iadd__` magic method, it gets called when the `+=` augmented assignment is executed, and its return value is what gets used in the assignment statement; and (b) for lists, `__iadd__` is equivalent to calling `extend` on the list and returning the list. That’s why we say that for lists, `+=` is a “shorthand” for `list.extend`:

```python
>>> a_list = []
>>> a_list += [1]
>>> a_list
[1]
```

This is equivalent to:
>>> result = a_list.__iadd__( [1] )
>>> a_list = result

The object pointed to by a_list has been mutated, and the pointer to the mutated object is assigned back to a_list. The end result of the assignment is a no-op, since it is a pointer to the same object that a_list was previously pointing to, but the assignment still happens.

Thus, in our tuple example what is happening is equivalent to:

```python
>>> result = a_tuple[0].__iadd__( ['item'] )
>>> a_tuple[0] = result
```

```
Traceback (most recent call last):
 ...
TypeError: 'tuple' object does not support item assignment
```

The __iadd__ succeeds, and thus the list is extended, but even though result points to the same object that a_tuple[0] already points to, that final assignment still results in an error, because tuples are immutable.
Dictionaries

How can I get a dictionary to display its keys in a consistent order?

You can’t. Dictionaries store their keys in an unpredictable order, so the display order of a dictionary’s elements will be similarly unpredictable.

This can be frustrating if you want to save a printable version to a file, make some changes and then compare it with some other printed dictionary. In this case, use the `pprint` module to pretty-print the dictionary; the items will be presented in order sorted by the key.

A more complicated solution is to subclass `dict` to create a `SortedDict` class that prints itself in a predictable order. Here’s one simpleminded implementation of such a class:

```python
class SortedDict(dict):
    def __repr__(self):
        keys = sorted(self.keys())
        result = '{{{{}}}}'.format(', '.join(result))
        result = result.format(k, self[k]) for k in keys
        return '{!r}: {!r}'.format(k, self[k])

__str__ = __repr__
```

This will work for many common situations you might encounter, though it’s far from a perfect solution. The largest flaw is that if some values in the dictionary are also dictionaries, their values won’t be presented in any particular order.

I want to do a complicated sort: can you do a Schwartzian Transform in Python?
The technique, attributed to Randal Schwartz of the Perl community, sorts the elements of a list by a metric which maps each element to its “sort value”. In Python, use the `key` argument for the `sort()` function:

```
Isorted = L[:]
Isorted.sort(key=lambda s: int(s[10:15]))
```

How can I sort one list by values from another list?

Merge them into a single list of tuples, sort the resulting list, and then pick out the element you want.

```
>>> list1 = ["what", "I'm", "sorting", "by"]
>>> list2 = ["something", "else", "to", "sort"]
>>> pairs = zip(list1, list2)
>>> pairs
[('what', 'something'), ('I'm', 'else'), ('sorting', 'to'), ('by', 'sort')]
>>> pairs.sort()
>>> result = [ x[1] for x in pairs ]
>>> result
['else', 'sort', 'to', 'something']
```

An alternative for the last step is:

```
>>> result = []
>>> for p in pairs: result.append(p[1])
```

If you find this more legible, you might prefer to use this instead of the final list comprehension. However, it is almost twice as slow for long lists. Why? First, the `append()` operation has to reallocate memory, and while it uses some tricks to avoid doing that each time, it still has to do it occasionally, and that costs quite a bit. Second, the expression “result.append” requires an extra attribute lookup, and third, there’s a speed reduction from having to make all those function calls.
Objects

What is a class?

A class is the particular object type created by executing a class statement. Class objects are used as templates to create instance objects, which embody both the data (attributes) and code (methods) specific to a datatype.

A class can be based on one or more other classes, called its base class(es). It then inherits the attributes and methods of its base classes. This allows an object model to be successively refined by inheritance. You might have a generic Mailbox class that provides basic accessor methods for a mailbox, and subclasses such as MboxMailbox, MaildirMailbox, OutlookMailbox that handle various specific mailbox formats.

What is a method?

A method is a function on some object x that you normally call as x.name(arguments...). Methods are defined as functions inside the class definition:

```python
class C:
    def meth(self, arg):
        return arg * 2 + self.attribute
```

What is self?

Self is merely a conventional name for the first argument of a method. A method defined as meth(self, a, b, c) should be called as x.meth(a, b, c) for some instance x of the class in which the
definition occurs; the called method will think it is called as \texttt{meth(x, a, b, c)}.

See also \textit{Why must ‘self’ be used explicitly in method definitions and calls?}.

How do I check if an object is an instance of a given class or of a subclass of it?

Use the built-in function \texttt{isinstance(obj, cls)}. You can check if an object is an instance of any of a number of classes by providing a tuple instead of a single class, e.g. \texttt{isinstance(obj, (class1, class2, ...))}, and can also check whether an object is one of Python's built-in types, e.g. \texttt{isinstance(obj, str)} or \texttt{isinstance(obj, (int, long, float, complex))}.

Note that most programs do not use \texttt{isinstance()} on user-defined classes very often. If you are developing the classes yourself, a more proper object-oriented style is to define methods on the classes that encapsulate a particular behaviour, instead of checking the object's class and doing a different thing based on what class it is. For example, if you have a function that does something:

```python
def search(obj):
    if isinstance(obj, Mailbox):
        ... # code to search a mailbox
    elif isinstance(obj, Document):
        ... # code to search a document
    elif ...
```

A better approach is to define a \texttt{search()} method on all the classes and just call it:

```python
class Mailbox:
    def search(self):
        ... # code to search a mailbox
```
class Document:
    def search(self):
        ...
        # code to search a document

obj.search()

What is delegation?

Delegation is an object oriented technique (also called a design pattern). Let’s say you have an object \( x \) and want to change the behaviour of just one of its methods. You can create a new class that provides a new implementation of the method you're interested in changing and delegates all other methods to the corresponding method of \( x \).

Python programmers can easily implement delegation. For example, the following class implements a class that behaves like a file but converts all written data to uppercase:

class UpperOut:
    def __init__(self, outfile):
        self._outfile = outfile

    def write(self, s):
        self._outfile.write(s.upper())

    def __getattr__(self, name):
        return getattr(self._outfile, name)

Here the UpperOut class redefines the write() method to convert the argument string to uppercase before calling the underlying self._outfile.write() method. All other methods are delegated to the underlying self._outfile object. The delegation is accomplished via the __getattr__ method; consult the language reference for more information about controlling attribute access.
Note that for more general cases delegation can get trickier. When attributes must be set as well as retrieved, the class must define a __setattr__() method too, and it must do so carefully. The basic implementation of __setattr__() is roughly equivalent to the following:

```python
class X:
    ...
    def __setattr__(self, name, value):
        self.__dict__[name] = value
    ...
```

Most __setattr__() implementations must modify self.__dict__ to store local state for self without causing an infinite recursion.

How do I call a method defined in a base class from a derived class that overrides it?

If you’re using new-style classes, use the built-in super() function:

```python
class Derived(Base):
    def meth(self):
        super(Derived, self).meth()
```

If you’re using classic classes: For a class definition such as class Derived(Base): ... you can call method meth() defined in Base (or one of Base’s base classes) as Base.meth(self, arguments...). Here, Base.meth is an unbound method, so you need to provide the self argument.

How can I organize my code to make it easier to change the base class?

You could define an alias for the base class, assign the real base class to it before your class definition, and use the alias throughout
your class. Then all you have to change is the value assigned to the alias. Incidentally, this trick is also handy if you want to decide dynamically (e.g. depending on availability of resources) which base class to use. Example:

```python
BaseAlias = <real base class>

class Derived(BaseAlias):
    def meth(self):
        BaseAlias.meth(self)
        ...
```

**How do I create static class data and static class methods?**

Both static data and static methods (in the sense of C++ or Java) are supported in Python.

For static data, simply define a class attribute. To assign a new value to the attribute, you have to explicitly use the class name in the assignment:

```python
class C:
    count = 0  # number of times C.__init__ called

    def __init__(self):
        C.count = C.count + 1

    def getcount(self):
        return C.count  # or return self.count

C.count also refers to C.count for any c such that `isinstance(c, C)` holds, unless overridden by c itself or by some class on the base-class search path from c.__class__ back to C.

Caution: within a method of C, an assignment like `self.count = 42` creates a new and unrelated instance named “count” in self's own
dict. Rebinding of a class-static data name must always specify the class whether inside a method or not:

```python
C.count = 314
```

Static methods are possible since Python 2.2:

```python
class C:
    def static(arg1, arg2, arg3):
        # No 'self' parameter!
        ...
    static = staticmethod(static)
```

With Python 2.4's decorators, this can also be written as

```python
class C:
    @staticmethod
    def static(arg1, arg2, arg3):
        # No 'self' parameter!
        ...
```

However, a far more straightforward way to get the effect of a static method is via a simple module-level function:

```python
def getcount():
    return C.count
```

If your code is structured so as to define one class (or tightly related class hierarchy) per module, this supplies the desired encapsulation.

**How can I overload constructors (or methods) in Python?**

This answer actually applies to all methods, but the question usually comes up first in the context of constructors.

In C++ you’d write
```cpp
class C {
    C() { cout << "No arguments\n"; }
    C(int i) { cout << "Argument is " << i << "\n"; }
}
```

In Python you have to write a single constructor that catches all cases using default arguments. For example:

```python
class C:
    def __init__(self, i=None):
        if i is None:
            print "No arguments"
        else:
            print "Argument is", i
```

This is not entirely equivalent, but close enough in practice.

You could also try a variable-length argument list, e.g.

```python
def __init__(self, *args):
    ...
```

The same approach works for all method definitions.

I try to use __spam and I get an error about _SomeClassName__spam.

Variable names with double leading underscores are “mangled” to provide a simple but effective way to define class private variables. Any identifier of the form __spam (at least two leading underscores, at most one trailing underscore) is textually replaced with _classname__spam, where classname is the current class name with any leading underscores stripped.

This doesn’t guarantee privacy: an outside user can still deliberately access the "_classname__spam" attribute, and private values are visible in the object’s __dict__. Many Python programmers never
bother to use private variable names at all.

My class defines \texttt{\_\_del\_\_} but it is not called when I delete the object.

There are several possible reasons for this.

The \texttt{del} statement does not necessarily call \texttt{\_\_del\_\_()} – it simply decrements the object's reference count, and if this reaches zero \texttt{\_\_del\_\_()} is called.

If your data structures contain circular links (e.g. a tree where each child has a parent reference and each parent has a list of children) the reference counts will never go back to zero. Once in a while Python runs an algorithm to detect such cycles, but the garbage collector might run some time after the last reference to your data structure vanishes, so your \texttt{\_\_del\_\_()} method may be called at an inconvenient and random time. This is inconvenient if you're trying to reproduce a problem. Worse, the order in which object's \texttt{\_\_del\_\_()} methods are executed is arbitrary. You can run \texttt{gc.collect()} to force a collection, but there \textit{are} pathological cases where objects will never be collected.

Despite the cycle collector, it's still a good idea to define an explicit \texttt{close()} method on objects to be called whenever you're done with them. The \texttt{close()} method can then remove attributes that refer to subobjects. Don't call \texttt{\_\_del\_\_()} directly – \texttt{\_\_del\_\_()} should call \texttt{close()} and \texttt{close()} should make sure that it can be called more than once for the same object.

Another way to avoid cyclical references is to use the \texttt{weakref} module, which allows you to point to objects without incrementing their reference count. Tree data structures, for instance, should use weak references for their parent and sibling references (if they need
them!)

If the object has ever been a local variable in a function that caught an expression in an except clause, chances are that a reference to the object still exists in that function's stack frame as contained in the stack trace. Normally, calling `sys.exc_clear()` will take care of this by clearing the last recorded exception.

Finally, if your `__del__()` method raises an exception, a warning message is printed to `sys.stderr`.

### How do I get a list of all instances of a given class?

Python does not keep track of all instances of a class (or of a built-in type). You can program the class's constructor to keep track of all instances by keeping a list of weak references to each instance.

### Why does the result of `id()` appear to be not unique?

The `id()` built-in returns an integer that is guaranteed to be unique during the lifetime of the object. Since in CPython, this is the object's memory address, it happens frequently that after an object is deleted from memory, the next freshly created object is allocated at the same position in memory. This is illustrated by this example:

```python
>>> id(1000)
13901272
>>> id(2000)
13901272
```

The two ids belong to different integer objects that are created before, and deleted immediately after execution of the `id()` call. To be sure that objects whose id you want to examine are still alive, create another reference to the object:
>>> a = 1000; b = 2000
>>> id(a)
13901272
>>> id(b)
13891296
How do I create a .pyc file?

When a module is imported for the first time (or when the source is more recent than the current compiled file) a .pyc file containing the compiled code should be created in the same directory as the .py file.

One reason that a .pyc file may not be created is permissions problems with the directory. This can happen, for example, if you develop as one user but run as another, such as if you are testing with a web server. Creation of a .pyc file is automatic if you’re importing a module and Python has the ability (permissions, free space, etc...) to write the compiled module back to the directory.

Running Python on a top level script is not considered an import and no .pyc will be created. For example, if you have a top-level module foo.py that imports another module xyz.py, when you run foo, xyz.pyc will be created since xyz is imported, but no foo.pyc file will be created since foo.py isn’t being imported.

If you need to create foo.pyc – that is, to create a .pyc file for a module that is not imported – you can, using the py_compile and compileall modules.

The py_compile module can manually compile any module. One way is to use the compile() function in that module interactively:

```python
>>> import py_compile
>>> py_compile.compile('foo.py')
```
This will write the `.pyc` to the same location as `foo.py` (or you can override that with the optional parameter `cfile`).

You can also automatically compile all files in a directory or directories using the `compileall` module. You can do it from the shell prompt by running `compileall.py` and providing the path of a directory containing Python files to compile:

```bash
python -m compileall .
```

**How do I find the current module name?**

A module can find out its own module name by looking at the predefined global variable `__name__`. If this has the value `'__main__'`, the program is running as a script. Many modules that are usually used by importing them also provide a command-line interface or a self-test, and only execute this code after checking `__name__`:

```python
def main():
    print 'Running test...'
    ...

if __name__ == '__main__':
    main()
```

**How can I have modules that mutually import each other?**

Suppose you have the following modules:

`foo.py`:

```python
from bar import bar_var
foo_var = 1
```
bar.py:

```python
from foo import foo_var
bar_var = 2
```

The problem is that the interpreter will perform the following steps:

- main imports foo
- Empty globals for foo are created
- foo is compiled and starts executing
- foo imports bar
- Empty globals for bar are created
- bar is compiled and starts executing
- bar imports foo (which is a no-op since there already is a module named foo)
- bar.foo_var = foo.foo_var

The last step fails, because Python isn’t done with interpreting foo yet and the global symbol dictionary for foo is still empty.

The same thing happens when you use `import foo`, and then try to access `foo.foo_var` in global code.

There are (at least) three possible workarounds for this problem.

Guido van Rossum recommends avoiding all uses of `from <module> import ...`, and placing all code inside functions. Initializations of global variables and class variables should use constants or built-in functions only. This means everything from an imported module is referenced as `<module>.<name>`.

Jim Roskind suggests performing steps in the following order in each module:

- exports (globals, functions, and classes that don’t need imported
base classes
- *import* statements
- active code (including globals that are initialized from imported values).

van Rossum doesn’t like this approach much because the imports appear in a strange place, but it does work.

Matthias Urlichs recommends restructuring your code so that the recursive import is not necessary in the first place.

These solutions are not mutually exclusive.

```python
__import__('x.y.z') returns <module 'x'>; how do I get z?
```

Consider using the convenience function `import_module()` from `importlib` instead:

```python
z = importlib.import_module('x.y.z')
```

When I edit an imported module and reimport it, the changes don’t show up. Why does this happen?

For reasons of efficiency as well as consistency, Python only reads the module file on the first time a module is imported. If it didn’t, in a program consisting of many modules where each one imports the same basic module, the basic module would be parsed and re-parsed many times. To force rereading of a changed module, do this:

```python
import modname
reload(modname)
```

Warning: this technique is not 100% fool-proof. In particular, modules
containing statements like

```python
from modname import some_objects
```

will continue to work with the old version of the imported objects. If the module contains class definitions, existing class instances will not be updated to use the new class definition. This can result in the following paradoxical behaviour:

```python
>>> import cls
>>> c = cls.C()  # Create an instance of C
>>> reload(cls)
<module 'cls' from 'cls.pyc'>
>>> isinstance(c, cls.C)  # isinstance is false?!?
False
```

The nature of the problem is made clear if you print out the class objects:

```python
>>> c.__class__
<class cls.C at 0x7352a0>
>>> cls.C
<class cls.C at 0x4198d0>
```
Design and History FAQ
Why does Python use indentation for grouping of statements?

Guido van Rossum believes that using indentation for grouping is extremely elegant and contributes a lot to the clarity of the average Python program. Most people learn to love this feature after a while.

Since there are no begin/end brackets there cannot be a disagreement between grouping perceived by the parser and the human reader. Occasionally C programmers will encounter a fragment of code like this:

```python
if (x <= y)
    x++;  
    y--; 
z++; 
```

Only the `x++` statement is executed if the condition is true, but the indentation leads you to believe otherwise. Even experienced C programmers will sometimes stare at it a long time wondering why `y` is being decremented even for `x > y`.

Because there are no begin/end brackets, Python is much less prone to coding-style conflicts. In C there are many different ways to place the braces. If you’re used to reading and writing code that uses one style, you will feel at least slightly uneasy when reading (or being required to write) another style.

Many coding styles place begin/end brackets on a line by themselves. This makes programs considerably longer and wastes valuable screen space, making it harder to get a good overview of a program. Ideally, a function should fit on one screen (say, 20–30 lines). 20 lines of Python can do a lot more work than 20 lines of C. This is not solely due to the lack of begin/end brackets – the lack of
declarations and the high-level data types are also responsible – but the indentation-based syntax certainly helps.
Why am I getting strange results with simple arithmetic operations?

See the next question.
Why are floating point calculations so inaccurate?

People are often very surprised by results like this:

```python
>>> 1.2 - 1.0
0.19999999999999996
```

and think it is a bug in Python. It’s not. This has nothing to do with Python, but with how the underlying C platform handles floating point numbers, and ultimately with the inaccuracies introduced when writing down numbers as a string of a fixed number of digits.

The internal representation of floating point numbers uses a fixed number of binary digits to represent a decimal number. Some decimal numbers can’t be represented exactly in binary, resulting in small roundoff errors.

In decimal math, there are many numbers that can’t be represented with a fixed number of decimal digits, e.g. $1/3 = 0.3333333333.......$

In base 2, $1/2 = 0.1$, $1/4 = 0.01$, $1/8 = 0.001$, etc. $.2$ equals $2/10$ equals $1/5$, resulting in the binary fractional number $0.001100110011001...$

Floating point numbers only have 32 or 64 bits of precision, so the digits are cut off at some point, and the resulting number is $0.19999999999999996$ in decimal, not $0.2$.

A floating point number’s `repr()` function prints as many digits are necessary to make `eval(repr(f)) == f` true for any float f. The `str()` function prints fewer digits and this often results in the more sensible number that was probably intended:
One of the consequences of this is that it is error-prone to compare the result of some computation to a float with `==`. Tiny inaccuracies may mean that `==` fails. Instead, you have to check that the difference between the two numbers is less than a certain threshold:

```python
epsilon = 0.0000000000001  # Tiny allowed error
expected_result = 0.4

if expected_result - epsilon <= computation() <= expected_result + epsilon:
    ...
```

Please see the chapter on floating point arithmetic in the Python tutorial for more information.
Why are Python strings immutable?

There are several advantages.

One is performance: knowing that a string is immutable means we can allocate space for it at creation time, and the storage requirements are fixed and unchanging. This is also one of the reasons for the distinction between tuples and lists.

Another advantage is that strings in Python are considered as “elemental” as numbers. No amount of activity will change the value 8 to anything else, and in Python, no amount of activity will change the string “eight” to anything else.
Why must ‘self’ be used explicitly in method definitions and calls?

The idea was borrowed from Modula-3. It turns out to be very useful, for a variety of reasons.

First, it’s more obvious that you are using a method or instance attribute instead of a local variable. Reading `self.x` or `self.meth()` makes it absolutely clear that an instance variable or method is used even if you don’t know the class definition by heart. In C++, you can sort of tell by the lack of a local variable declaration (assuming globals are rare or easily recognizable) – but in Python, there are no local variable declarations, so you’d have to look up the class definition to be sure. Some C++ and Java coding standards call for instance attributes to have an `m_` prefix, so this explicitness is still useful in those languages, too.

Second, it means that no special syntax is necessary if you want to explicitly reference or call the method from a particular class. In C++, if you want to use a method from a base class which is overridden in a derived class, you have to use the `::` operator – in Python you can write `baseclass.methodname(self, <argument list>)`. This is particularly useful for `__init__()` methods, and in general in cases where a derived class method wants to extend the base class method of the same name and thus has to call the base class method somehow.

Finally, for instance variables it solves a syntactic problem with assignment: since local variables in Python are (by definition!) those variables to which a value is assigned in a function body (and that aren’t explicitly declared global), there has to be some way to tell the interpreter that an assignment was meant to assign to an instance
variable instead of to a local variable, and it should preferably be syntactic (for efficiency reasons). C++ does this through declarations, but Python doesn’t have declarations and it would be a pity having to introduce them just for this purpose. Using the explicit \texttt{self.var} solves this nicely. Similarly, for using instance variables, having to write \texttt{self.var} means that references to unqualified names inside a method don’t have to search the instance’s directories. To put it another way, local variables and instance variables live in two different namespaces, and you need to tell Python which namespace to use.
Why can’t I use an assignment in an expression?

Many people used to C or Perl complain that they want to use this C idiom:

```c
while (line = readline(f)) {
    // do something with line
}
```

where in Python you’re forced to write this:

```python
while True:
    line = f.readline()
    if not line:
        break
...  # do something with line
```

The reason for not allowing assignment in Python expressions is a common, hard-to-find bug in those other languages, caused by this construct:

```python
if (x = 0) {
    // error handling
}
else {
    // code that only works for nonzero x
}
```

The error is a simple typo: `x = 0`, which assigns 0 to the variable `x`, was written while the comparison `x == 0` is certainly what was intended.

Many alternatives have been proposed. Most are hacks that save some typing but use arbitrary or cryptic syntax or keywords, and fail the simple criterion for language change proposals: it should
intuitively suggest the proper meaning to a human reader who has not yet been introduced to the construct.

An interesting phenomenon is that most experienced Python programmers recognize the while True idiom and don’t seem to be missing the assignment in expression construct much; it’s only newcomers who express a strong desire to add this to the language.

There’s an alternative way of spelling this that seems attractive but is generally less robust than the “while True” solution:

```python
line = f.readline()
while line:
    ...  # do something with line...
    line = f.readline()
```

The problem with this is that if you change your mind about exactly how you get the next line (e.g. you want to change it into sys.stdin.readline()) you have to remember to change two places in your program – the second occurrence is hidden at the bottom of the loop.

The best approach is to use iterators, making it possible to loop through objects using the for statement. For example, in the current version of Python file objects support the iterator protocol, so you can now write simply:

```python
for line in f:
    ...  # do something with line...
```
Why does Python use methods for some functionality (e.g. list.index()) but functions for other (e.g. len(list))?  

The major reason is history. Functions were used for those operations that were generic for a group of types and which were intended to work even for objects that didn’t have methods at all (e.g. tuples). It is also convenient to have a function that can readily be applied to an amorphous collection of objects when you use the functional features of Python (map(), zip() et al).

In fact, implementing len(), max(), min() as a built-in function is actually less code than implementing them as methods for each type. One can quibble about individual cases but it’s a part of Python, and it’s too late to make such fundamental changes now. The functions have to remain to avoid massive code breakage.

**Note:** For string operations, Python has moved from external functions (the string module) to methods. However, len() is still a function.
Why is `join()` a string method instead of a list or tuple method?

Strings became much more like other standard types starting in Python 1.6, when methods were added which give the same functionality that has always been available using the functions of the string module. Most of these new methods have been widely accepted, but the one which appears to make some programmers feel uncomfortable is:

```
"",".join(['1', '2', '4', '8', '16'])
```

which gives the result:

```
"1, 2, 4, 8, 16"
```

There are two common arguments against this usage.

The first runs along the lines of: “It looks really ugly using a method of a string literal (string constant)”, to which the answer is that it might, but a string literal is just a fixed value. If the methods are to be allowed on names bound to strings there is no logical reason to make them unavailable on literals.

The second objection is typically cast as: “I am really telling a sequence to join its members together with a string constant”. Sadly, you aren’t. For some reason there seems to be much less difficulty with having `split()` as a string method, since in that case it is easy to see that

```
"1, 2, 4, 8, 16".split("", "")
```

is an instruction to a string literal to return the substrings delimited by
the given separator (or, by default, arbitrary runs of white space). In this case a Unicode string returns a list of Unicode strings, an ASCII string returns a list of ASCII strings, and everyone is happy.

join() is a string method because in using it you are telling the separator string to iterate over a sequence of strings and insert itself between adjacent elements. This method can be used with any argument which obeys the rules for sequence objects, including any new classes you might define yourself.

Because this is a string method it can work for Unicode strings as well as plain ASCII strings. If join() were a method of the sequence types then the sequence types would have to decide which type of string to return depending on the type of the separator.

If none of these arguments persuade you, then for the moment you can continue to use the join() function from the string module, which allows you to write

```python
string.join([ '1', '2', '4', '8', '16' ], ', ', )
```
How fast are exceptions?

A try/except block is extremely efficient if no exceptions are raised. Actually catching an exception is expensive. In versions of Python prior to 2.0 it was common to use this idiom:

```python
try:
    value = mydict[key]
except KeyError:
    mydict[key] = getvalue(key)
    value = mydict[key]
```

This only made sense when you expected the dict to have the key almost all the time. If that wasn’t the case, you coded it like this:

```python
if key in mydict:
    value = mydict[key]
else:
    value = mydict[key] = getvalue(key)
```

Note: In Python 2.0 and higher, you can code this as `value = mydict.setdefault(key, getvalue(key)).`
Why isn’t there a switch or case statement in Python?

You can do this easily enough with a sequence of `if... elif... else`. There have been some proposals for switch statement syntax, but there is no consensus (yet) on whether and how to do range tests. See PEP 275 for complete details and the current status.

For cases where you need to choose from a very large number of possibilities, you can create a dictionary mapping case values to functions to call. For example:

```python
def function_1(...):
...

functions = {'a': function_1,
              'b': function_2,
              'c': self.method_1,
              ...}

func = functions[value]
func()
```

For calling methods on objects, you can simplify yet further by using the `getattr()` built-in to retrieve methods with a particular name:

```python
def visit_a(self, ...):
...

def dispatch(self, value):
    method_name = 'visit_' + str(value)
    method = getattr(self, method_name)
    method()
```

It’s suggested that you use a prefix for the method names, such as `visit_` in this example. Without such a prefix, if values are coming
from an untrusted source, an attacker would be able to call any method on your object.
Can’t you emulate threads in the interpreter instead of relying on an OS-specific thread implementation?

Answer 1: Unfortunately, the interpreter pushes at least one C stack frame for each Python stack frame. Also, extensions can call back into Python at almost random moments. Therefore, a complete threads implementation requires thread support for C.

Answer 2: Fortunately, there is Stackless Python, which has a completely redesigned interpreter loop that avoids the C stack.
Why can’t lambda expressions contain statements?

Python lambda expressions cannot contain statements because Python’s syntactic framework can’t handle statements nested inside expressions. However, in Python, this is not a serious problem. Unlike lambda forms in other languages, where they add functionality, Python lambdas are only a shorthand notation if you’re too lazy to define a function.

Functions are already first class objects in Python, and can be declared in a local scope. Therefore the only advantage of using a lambda instead of a locally-defined function is that you don’t need to invent a name for the function – but that’s just a local variable to which the function object (which is exactly the same type of object that a lambda expression yields) is assigned!
Can Python be compiled to machine code, C or some other language?

Not easily. Python's high level data types, dynamic typing of objects and run-time invocation of the interpreter (using `eval()` or `exec`) together mean that a “compiled” Python program would probably consist mostly of calls into the Python run-time system, even for seemingly simple operations like `x+1`.

Several projects described in the Python newsgroup or at past Python conferences have shown that this approach is feasible, although the speedups reached so far are only modest (e.g. 2x). Jython uses the same strategy for compiling to Java bytecode. (Jim Hugunin has demonstrated that in combination with whole-program analysis, speedups of 1000x are feasible for small demo programs. See the proceedings from the 1997 Python conference for more information.)

Internally, Python source code is always translated into a bytecode representation, and this bytecode is then executed by the Python virtual machine. In order to avoid the overhead of repeatedly parsing and translating modules that rarely change, this byte code is written into a file whose name ends in "\(\text{.pyc}\)" whenever a module is parsed. When the corresponding .py file is changed, it is parsed and translated again and the .pyc file is rewritten.

There is no performance difference once the .pyc file has been loaded, as the bytecode read from the .pyc file is exactly the same as the bytecode created by direct translation. The only difference is that loading code from a .pyc file is faster than parsing and translating a .py file, so the presence of precompiled .pyc files improves the start-up time of Python scripts. If desired, the Lib/compileall.py module can be used to create valid .pyc files for a
given set of modules.

Note that the main script executed by Python, even if its filename ends in .py, is not compiled to a .pyc file. It is compiled to bytecode, but the bytecode is not saved to a file. Usually main scripts are quite short, so this doesn’t cost much speed.

There are also several programs which make it easier to intermingle Python and C code in various ways to increase performance. See, for example, **Cython**, **Psyco**, **Pyrex**, **PyInline**, **Py2Cmod**, and **Weave**.
How does Python manage memory?

The details of Python memory management depend on the implementation. The standard C implementation of Python uses reference counting to detect inaccessible objects, and another mechanism to collect reference cycles, periodically executing a cycle detection algorithm which looks for inaccessible cycles and deletes the objects involved. The `gc` module provides functions to perform a garbage collection, obtain debugging statistics, and tune the collector's parameters.

Jython relies on the Java runtime so the JVM's garbage collector is used. This difference can cause some subtle porting problems if your Python code depends on the behavior of the reference counting implementation.

Sometimes objects get stuck in tracebacks temporarily and hence are not deallocated when you might expect. Clear the tracebacks with:

```python
import sys
sys.exc_clear()
sys.exc_traceback = sys.last_traceback = None
```

Tracebacks are used for reporting errors, implementing debuggers and related things. They contain a portion of the program state extracted during the handling of an exception (usually the most recent exception).

In the absence of circularities and tracebacks, Python programs do not need to manage memory explicitly.

Why doesn’t Python use a more traditional garbage collection scheme? For one thing, this is not a C standard feature and hence
it's not portable. (Yes, we know about the Boehm GC library. It has bits of assembler code for most common platforms, not for all of them, and although it is mostly transparent, it isn't completely transparent; patches are required to get Python to work with it.)

Traditional GC also becomes a problem when Python is embedded into other applications. While in a standalone Python it's fine to replace the standard malloc() and free() with versions provided by the GC library, an application embedding Python may want to have its own substitute for malloc() and free(), and may not want Python's. Right now, Python works with anything that implements malloc() and free() properly.

In Jython, the following code (which is fine in CPython) will probably run out of file descriptors long before it runs out of memory:

```python
for file in very_long_list_of_files:
    f = open(file)
    c = f.read(1)
```

Using the current reference counting and destructor scheme, each new assignment to f closes the previous file. Using GC, this is not guaranteed. If you want to write code that will work with any Python implementation, you should explicitly close the file or use the `with` statement; this will work regardless of GC:

```python
for file in very_long_list_of_files:
    with open(file) as f:
        c = f.read(1)
```
Why isn’t all memory freed when Python exits?

Objects referenced from the global namespaces of Python modules are not always deallocated when Python exits. This may happen if there are circular references. There are also certain bits of memory that are allocated by the C library that are impossible to free (e.g. a tool like Purify will complain about these). Python is, however, aggressive about cleaning up memory on exit and does try to destroy every single object.

If you want to force Python to delete certain things on deallocation use the `atexit` module to run a function that will force those deletions.
Why are there separate tuple and list data types?

Lists and tuples, while similar in many respects, are generally used in fundamentally different ways. Tuples can be thought of as being similar to Pascal records or C structs; they're small collections of related data which may be of different types which are operated on as a group. For example, a Cartesian coordinate is appropriately represented as a tuple of two or three numbers.

Lists, on the other hand, are more like arrays in other languages. They tend to hold a varying number of objects all of which have the same type and which are operated on one-by-one. For example, `os.listdir('.')` returns a list of strings representing the files in the current directory. Functions which operate on this output would generally not break if you added another file or two to the directory.

Tuples are immutable, meaning that once a tuple has been created, you can't replace any of its elements with a new value. Lists are mutable, meaning that you can always change a list's elements. Only immutable elements can be used as dictionary keys, and hence only tuples and not lists can be used as keys.
How are lists implemented?

Python’s lists are really variable-length arrays, not Lisp-style linked lists. The implementation uses a contiguous array of references to other objects, and keeps a pointer to this array and the array's length in a list head structure.

This makes indexing a list \texttt{a[i]} an operation whose cost is independent of the size of the list or the value of the index.

When items are appended or inserted, the array of references is resized. Some cleverness is applied to improve the performance of appending items repeatedly; when the array must be grown, some extra space is allocated so the next few times don’t require an actual resize.
How are dictionaries implemented?

Python’s dictionaries are implemented as resizable hash tables. Compared to B-trees, this gives better performance for lookup (the most common operation by far) under most circumstances, and the implementation is simpler.

Dictionaries work by computing a hash code for each key stored in the dictionary using the `hash()` built-in function. The hash code varies widely depending on the key; for example, “Python” hashes to -539294296 while “python”, a string that differs by a single bit, hashes to 1142331976. The hash code is then used to calculate a location in an internal array where the value will be stored. Assuming that you’re storing keys that all have different hash values, this means that dictionaries take constant time – O(1), in computer science notation – to retrieve a key. It also means that no sorted order of the keys is maintained, and traversing the array as the `.keys()` and `.items()` do will output the dictionary’s content in some arbitrary jumbled order.
Why must dictionary keys be immutable?

The hash table implementation of dictionaries uses a hash value calculated from the key value to find the key. If the key were a mutable object, its value could change, and thus its hash could also change. But since whoever changes the key object can't tell that it was being used as a dictionary key, it can't move the entry around in the dictionary. Then, when you try to look up the same object in the dictionary it won't be found because its hash value is different. If you tried to look up the old value it wouldn't be found either, because the value of the object found in that hash bin would be different.

If you want a dictionary indexed with a list, simply convert the list to a tuple first; the function \texttt{tuple(L)} creates a tuple with the same entries as the list \texttt{L}. Tuples are immutable and can therefore be used as dictionary keys.

Some unacceptable solutions that have been proposed:

- Hash lists by their address (object ID). This doesn't work because if you construct a new list with the same value it won't be found; e.g.:

  ```python
  mydict = {[1, 2]: '12'}
  print mydict[[1, 2]]
  ```

  would raise a KeyError exception because the id of the \texttt{[1, 2]} used in the second line differs from that in the first line. In other words, dictionary keys should be compared using \texttt{==}, not using \texttt{is}.

- Make a copy when using a list as a key. This doesn't work because the list, being a mutable object, could contain a reference to itself, and then the copying code would run into an
infinite loop.

- Allow lists as keys but tell the user not to modify them. This would allow a class of hard-to-track bugs in programs when you forgot or modified a list by accident. It also invalidates an important invariant of dictionaries: every value in `d.keys()` is usable as a key of the dictionary.

- Mark lists as read-only once they are used as a dictionary key. The problem is that it's not just the top-level object that could change its value; you could use a tuple containing a list as a key. Entering anything as a key into a dictionary would require marking all objects reachable from there as read-only – and again, self-referential objects could cause an infinite loop.

There is a trick to get around this if you need to, but use it at your own risk: You can wrap a mutable structure inside a class instance which has both a `__eq__()` and a `__hash__()` method. You must then make sure that the hash value for all such wrapper objects that reside in a dictionary (or other hash based structure), remain fixed while the object is in the dictionary (or other structure).

class ListWrapper:
    def __init__(self, the_list):
        self.the_list = the_list

    def __eq__(self, other):
        return self.the_list == other.the_list

    def __hash__(self):
        l = self.the_list
        result = 98767 - len(l)*555
        for i, el in enumerate(l):
            try:
                result = result + (hash(el) % 9999999) * 1001 +
            except Exception:
                result = (result % 7777777) + i * 333
        return result
Note that the hash computation is complicated by the possibility that some members of the list may be unhashable and also by the possibility of arithmetic overflow.

Furthermore it must always be the case that if \( o1 == o2 \) (ie \( o1.__eq__(o2) \) is True) then \( \text{hash}(o1) == \text{hash}(o2) \) (ie, \( o1.__hash__() == o2.__hash__() \)), regardless of whether the object is in a dictionary or not. If you fail to meet these restrictions dictionaries and other hash based structures will misbehave.

In the case of ListWrapper, whenever the wrapper object is in a dictionary the wrapped list must not change to avoid anomalies. Don't do this unless you are prepared to think hard about the requirements and the consequences of not meeting them correctly. Consider yourself warned.
Why doesn’t list.sort() return the sorted list?

In situations where performance matters, making a copy of the list just to sort it would be wasteful. Therefore, list.sort() sorts the list in place. In order to remind you of that fact, it does not return the sorted list. This way, you won’t be fooled into accidentally overwriting a list when you need a sorted copy but also need to keep the unsorted version around.

In Python 2.4 a new built-in function – sorted() – has been added. This function creates a new list from a provided iterable, sorts it and returns it. For example, here’s how to iterate over the keys of a dictionary in sorted order:

```python
for key in sorted(mydict):
    ... # do whatever with mydict[key]...
```
How do you specify and enforce an interface spec in Python?

An interface specification for a module as provided by languages such as C++ and Java describes the prototypes for the methods and functions of the module. Many feel that compile-time enforcement of interface specifications helps in the construction of large programs.

Python 2.6 adds an `abc` module that lets you define Abstract Base Classes (ABCs). You can then use `isinstance()` and `issubclass()` to check whether an instance or a class implements a particular ABC. The `collections` module defines a set of useful ABCs such as `Iterable`, `Container`, and `MutableMapping`.

For Python, many of the advantages of interface specifications can be obtained by an appropriate test discipline for components. There is also a tool, PyChecker, which can be used to find problems due to subclassing.

A good test suite for a module can both provide a regression test and serve as a module interface specification and a set of examples. Many Python modules can be run as a script to provide a simple “self test.” Even modules which use complex external interfaces can often be tested in isolation using trivial “stub” emulations of the external interface. The `doctest` and `unittest` modules or third-party test frameworks can be used to construct exhaustive test suites that exercise every line of code in a module.

An appropriate testing discipline can help build large complex applications in Python as well as having interface specifications would. In fact, it can be better because an interface specification cannot test certain properties of a program. For example, the `append()` method is expected to add new elements to the end of
some internal list; an interface specification cannot test that your `append()` implementation will actually do this correctly, but it's trivial to check this property in a test suite.

Writing test suites is very helpful, and you might want to design your code with an eye to making it easily tested. One increasingly popular technique, test-directed development, calls for writing parts of the test suite first, before you write any of the actual code. Of course Python allows you to be sloppy and not write test cases at all.
Why is there no goto?

You can use exceptions to provide a “structured goto” that even works across function calls. Many feel that exceptions can conveniently emulate all reasonable uses of the “go” or “goto” constructs of C, Fortran, and other languages. For example:

```python
class label: pass  # declare a label
try:
    ...
    if condition: raise label()  # goto label
    ...
except label:    # where to goto
    pass
    ...
```

This doesn’t allow you to jump into the middle of a loop, but that’s usually considered an abuse of goto anyway. Use sparingly.
Why can’t raw strings (r-strings) end with a backslash?

More precisely, they can’t end with an odd number of backslashes: the unpaired backslash at the end escapes the closing quote character, leaving an unterminated string.

Raw strings were designed to ease creating input for processors (chiefly regular expression engines) that want to do their own backslash escape processing. Such processors consider an unmatched trailing backslash to be an error anyway, so raw strings disallow that. In return, they allow you to pass on the string quote character by escaping it with a backslash. These rules work well when r-strings are used for their intended purpose.

If you’re trying to build Windows pathnames, note that all Windows system calls accept forward slashes too:

```python
f = open("/mydir/file.txt")  # works fine!
```

If you’re trying to build a pathname for a DOS command, try e.g. one of

```python
dir = r"\this\is\my\dos\dir" "\\"
dir = r"\this\is\my\dos\dir\ "[\:-1]
dir = "\this\is\my\dos\dir\\"
```
Why doesn’t Python have a “with” statement for attribute assignments?

Python has a ‘with’ statement that wraps the execution of a block, calling code on the entrance and exit from the block. Some languages have a construct that looks like this:

```python
with obj:
    a = 1  # equivalent to obj.a = 1
    total = total + 1  # obj.total = obj.total + 1
```

In Python, such a construct would be ambiguous.

Other languages, such as Object Pascal, Delphi, and C++, use static types, so it’s possible to know, in an unambiguous way, what member is being assigned to. This is the main point of static typing – the compiler always knows the scope of every variable at compile time.

Python uses dynamic types. It is impossible to know in advance which attribute will be referenced at runtime. Member attributes may be added or removed from objects on the fly. This makes it impossible to know, from a simple reading, what attribute is being referenced: a local one, a global one, or a member attribute?

For instance, take the following incomplete snippet:

```python
def foo(a):
    with a:
        print x
```

The snippet assumes that “a” must have a member attribute called “x”. However, there is nothing in Python that tells the interpreter this. What should happen if “a” is, let us say, an integer? If there is a global variable named “x”, will it be used inside the with block? As
you see, the dynamic nature of Python makes such choices much harder.

The primary benefit of “with” and similar language features (reduction of code volume) can, however, easily be achieved in Python by assignment. Instead of:

```python
function(args).mydict[index][index].a = 21
function(args).mydict[index][index].b = 42
function(args).mydict[index][index].c = 63
```

write this:

```python
ref = function(args).mydict[index][index]
ref.a = 21
ref.b = 42
ref.c = 63
```

This also has the side-effect of increasing execution speed because name bindings are resolved at run-time in Python, and the second version only needs to perform the resolution once.
Why are colons required for the if/while/def/class statements?

The colon is required primarily to enhance readability (one of the results of the experimental ABC language). Consider this:

```python
if a == b
    print a
```

versus

```python
if a == b:
    print a
```

Notice how the second one is slightly easier to read. Notice further how a colon sets off the example in this FAQ answer; it's a standard usage in English.

Another minor reason is that the colon makes it easier for editors with syntax highlighting; they can look for colons to decide when indentation needs to be increased instead of having to do a more elaborate parsing of the program text.
Why does Python allow commas at the end of lists and tuples?

Python lets you add a trailing comma at the end of lists, tuples, and dictionaries:

```python
[1, 2, 3,]
('a', 'b', 'c',)
d = {
    "A": [1, 5],
    "B": [6, 7],  # last trailing comma is optional but good st.
}
```

There are several reasons to allow this.

When you have a literal value for a list, tuple, or dictionary spread across multiple lines, it’s easier to add more elements because you don’t have to remember to add a comma to the previous line. The lines can also be reordered without creating a syntax error.

Accidentally omitting the comma can lead to errors that are hard to diagnose. For example:

```python
x = ["fee",
     "fie"
   "foo",
   "fum"
]
```

This list looks like it has four elements, but it actually contains three: “fee”, “fiefoo” and “fum”. Always adding the comma avoids this source of error.

Allowing the trailing comma may also make programmatic code generation easier.

General Library Questions

How do I find a module or application to perform task X?

Check the Library Reference to see if there’s a relevant standard library module. (Eventually you’ll learn what’s in the standard library and will be able to skip this step.)

For third-party packages, search the Python Package Index or try Google or another Web search engine. Searching for “Python” plus a keyword or two for your topic of interest will usually find something helpful.

Where is the math.py (socket.py, regex.py, etc.) source file?

If you can’t find a source file for a module it may be a built-in or dynamically loaded module implemented in C, C++ or other compiled language. In this case you may not have the source file or it may be something like `mathmodule.c`, somewhere in a C source directory (not on the Python Path).

There are (at least) three kinds of modules in Python:

1. modules written in Python (.py);

2. modules written in C and dynamically loaded (.dll, .pyd, .so, .sl, etc);

3. modules written in C and linked with the interpreter; to get a list of these, type:
import sys
print sys.builtin_module_names

How do I make a Python script executable on Unix?

You need to do two things: the script file's mode must be executable and the first line must begin with `#!` followed by the path of the Python interpreter.

The first is done by executing `chmod +x scriptfile` or perhaps `chmod 755 scriptfile`.

The second can be done in a number of ways. The most straightforward way is to write

```
#!/usr/local/bin/python
```

as the very first line of your file, using the pathname for where the Python interpreter is installed on your platform.

If you would like the script to be independent of where the Python interpreter lives, you can use the `env` program. Almost all Unix variants support the following, assuming the Python interpreter is in a directory on the user's `PATH`:

```
#!/usr/bin/env python
```

Don't do this for CGI scripts. The `PATH` variable for CGI scripts is often very minimal, so you need to use the actual absolute pathname of the interpreter.

Occasionally, a user's environment is so full that the `usr/bin/env` program fails; or there's no env program at all. In that case, you can try the following hack (due to Alex Rezinsky):
The minor disadvantage is that this defines the script's __doc__ string. However, you can fix that by adding

```python
__doc__ = """...Whatever..."""
```

Is there a curses/termcap package for Python?

For Unix variants the standard Python source distribution comes with a curses module in the Modules subdirectory, though it's not compiled by default. (Note that this is not available in the Windows distribution – there is no curses module for Windows.)

The curses module supports basic curses features as well as many additional functions from ncurses and SYSV curses such as colour, alternative character set support, pads, and mouse support. This means the module isn’t compatible with operating systems that only have BSD curses, but there don’t seem to be any currently maintained OSes that fall into this category.

For Windows: use the consolelib module.

Is there an equivalent to C’s onexit() in Python?

The atexit module provides a register function that is similar to C’s onexit().

Why don't my signal handlers work?

The most common problem is that the signal handler is declared with the wrong argument list. It is called as
handler(signum, frame)

so it should be declared with two arguments:

```python
def handler(signum, frame):
    ...
```
Common tasks

How do I test a Python program or component?

Python comes with two testing frameworks. The `doctest` module finds examples in the docstrings for a module and runs them, comparing the output with the expected output given in the docstring.

The `unittest` module is a fancier testing framework modelled on Java and Smalltalk testing frameworks.

To make testing easier, you should use good modular design in your program. Your program should have almost all functionality encapsulated in either functions or class methods – and this sometimes has the surprising and delightful effect of making the program run faster (because local variable accesses are faster than global accesses). Furthermore the program should avoid depending on mutating global variables, since this makes testing much more difficult to do.

The “global main logic” of your program may be as simple as

```python
if __name__ == "__main__":
    main_logic()
```

at the bottom of the main module of your program.

Once your program is organized as a tractable collection of functions and class behaviours you should write test functions that exercise the behaviours. A test suite that automates a sequence of tests can be associated with each module. This sounds like a lot of work, but since Python is so terse and flexible it's surprisingly easy. You can make coding much more pleasant and fun by writing your test functions in parallel with the “production code”, since this makes it
easy to find bugs and even design flaws earlier.

“Support modules” that are not intended to be the main module of a program may include a self-test of the module.

```python
if __name__ == '__main__':
    self_test()
```

Even programs that interact with complex external interfaces may be tested when the external interfaces are unavailable by using “fake” interfaces implemented in Python.

### How do I create documentation from doc strings?

The `pydoc` module can create HTML from the doc strings in your Python source code. An alternative for creating API documentation purely from docstrings is `epydoc`. `Sphinx` can also include docstring content.

### How do I get a single keypress at a time?

For Unix variants there are several solutions. It’s straightforward to do this using curses, but curses is a fairly large module to learn. Here’s a solution without curses:

```python
import termios, fcntl, sys, os
fd = sys.stdin.fileno()

oldterm = termios.tcgetattr(fd)
newattr = termios.tcgetattr(fd)
termios.tcsetattr(fd, termios.TCSANOW, newattr)

oldflags = fcntl.fcntl(fd, fcntl.F_GETFL)
fcntl.fcntl(fd, fcntl.F_SETFL, oldflags | os.O_NONBLOCK)

try:
    while 1:
```
try:
    c = sys.stdin.read(1)
    print "Got character", repr(c)
except IOError:  pass
finally:
    termios.tcsetattr(fd, termios.TCSAFLUSH, oldterm)
    fcntl.fcntl(fd, fcntl.F_SETFL, oldflags)

You need the `termios` and the `fcntl` module for any of this to work, and I've only tried it on Linux, though it should work elsewhere. In this code, characters are read and printed one at a time.

`termios.tcsetattr()` turns off stdin's echoing and disables canonical mode. `fcntl.fcntl()` is used to obtain stdin's file descriptor flags and modify them for non-blocking mode. Since reading stdin when it is empty results in an `IOError`, this error is caught and ignored.
Threads

How do I program using threads?

Be sure to use the `threading` module and not the `thread` module. The `threading` module builds convenient abstractions on top of the low-level primitives provided by the `thread` module.

Aahz has a set of slides from his threading tutorial that are helpful; see http://www.pythoncraft.com/OSCON2001/.

None of my threads seem to run: why?

As soon as the main thread exits, all threads are killed. Your main thread is running too quickly, giving the threads no time to do any work.

A simple fix is to add a sleep to the end of the program that’s long enough for all the threads to finish:

```python
import threading, time

def thread_task(name, n):
    for i in range(n): print name, i

for i in range(10):
    T = threading.Thread(target=thread_task, args=(str(i), i))
    T.start()

time.sleep(10) # <-----------------------------!
```

But now (on many platforms) the threads don’t run in parallel, but appear to run sequentially, one at a time! The reason is that the OS thread scheduler doesn’t start a new thread until the previous thread is blocked.
A simple fix is to add a tiny sleep to the start of the run function:

```python
def thread_task(name, n):
    time.sleep(0.001) # <---------------------!
    for i in range(n): print name, i

for i in range(10):
    T = threading.Thread(target=thread_task, args=(str(i), i))
    T.start()

time.sleep(10)
```

Instead of trying to guess a good delay value for `time.sleep()`, it's better to use some kind of semaphore mechanism. One idea is to use the `Queue` module to create a queue object, let each thread append a token to the queue when it finishes, and let the main thread read as many tokens from the queue as there are threads.

How do I parcel out work among a bunch of worker threads?

Use the `Queue` module to create a queue containing a list of jobs. The `Queue` class maintains a list of objects and has a `.put(obj)` method that adds items to the queue and a `.get()` method to return them. The class will take care of the locking necessary to ensure that each job is handed out exactly once.

Here's a trivial example:

```python
import threading, Queue, time

# The worker thread gets jobs off the queue. When the queue is empty, it
# assumes there will be no more work and exits.
# (Realistically workers will run until terminated.)
def worker():
    print 'Running worker'
    time.sleep(0.1)
    while True:
        try:
```
arg = q.get(block=False)

except Queue.Empty:
    print 'Worker', threading.currentThread(),
    print 'queue empty'
    break
else:
    print 'Worker', threading.currentThread(),
    print 'running with argument', arg
    time.sleep(0.5)

# Create queue
q = Queue.Queue()

# Start a pool of 5 workers
for i in range(5):
    t = threading.Thread(target=worker, name='worker %i' % (i+1)
    t.start()

# Begin adding work to the queue
for i in range(50):
    q.put(i)

# Give threads time to run
print 'Main thread sleeping'
time.sleep(5)

When run, this will produce the following output:

Running worker
Running worker
Running worker
Running worker
Running worker
Main thread sleeping
Worker <Thread(worker 1, started)> running with argument 0
Worker <Thread(worker 2, started)> running with argument 1
Worker <Thread(worker 3, started)> running with argument 2
Worker <Thread(worker 4, started)> running with argument 3
Worker <Thread(worker 5, started)> running with argument 4
Worker <Thread(worker 1, started)> running with argument 5
...

Consult the module's documentation for more details; the Queue class provides a featureful interface.
What kinds of global value mutation are thread-safe?

A global interpreter lock (GIL) is used internally to ensure that only one thread runs in the Python VM at a time. In general, Python offers to switch among threads only between bytecode instructions; how frequently it switches can be set via `sys.setcheckinterval()`. Each bytecode instruction and therefore all the C implementation code reached from each instruction is therefore atomic from the point of view of a Python program.

In theory, this means an exact accounting requires an exact understanding of the PVM bytecode implementation. In practice, it means that operations on shared variables of built-in data types (ints, lists, dicts, etc) that “look atomic” really are.

For example, the following operations are all atomic (L, L1, L2 are lists, D, D1, D2 are dicts, x, y are objects, i, j are ints):

```python
L.append(x)
L1.extend(L2)
x = L[i]
x = L.pop()
L1[i:j] = L2
L.sort()
x = y
x.field = y
D[x] = y
D1.update(D2)
D.keys()
```

These aren't:

```python
i = i+1
L.append(L[-1])
L[i] = L[j]
D[x] = D[x] + 1
```
Operations that replace other objects may invoke those other objects’ \texttt{\_del\_}() method when their reference count reaches zero, and that can affect things. This is especially true for the mass updates to dictionaries and lists. When in doubt, use a mutex!

Can’t we get rid of the Global Interpreter Lock?

The \texttt{global interpreter lock} (GIL) is often seen as a hindrance to Python's deployment on high-end multiprocessor server machines, because a multi-threaded Python program effectively only uses one CPU, due to the insistence that (almost) all Python code can only run while the GIL is held.

Back in the days of Python 1.5, Greg Stein actually implemented a comprehensive patch set (the “free threading” patches) that removed the GIL and replaced it with fine-grained locking. Unfortunately, even on Windows (where locks are very efficient) this ran ordinary Python code about twice as slow as the interpreter using the GIL. On Linux the performance loss was even worse because pthread locks aren’t as efficient.

Since then, the idea of getting rid of the GIL has occasionally come up but nobody has found a way to deal with the expected slowdown, and users who don’t use threads would not be happy if their code ran at half the speed. Greg's free threading patch set has not been kept up-to-date for later Python versions.

This doesn’t mean that you can’t make good use of Python on multi-CPU machines! You just have to be creative with dividing the work up between multiple \texttt{processes} rather than multiple \texttt{threads}. Judicious use of C extensions will also help; if you use a C extension to perform a time-consuming task, the extension can release the GIL while the thread of execution is in the C code and allow other threads to get some work done.
It has been suggested that the GIL should be a per-interpreter-state lock rather than truly global; interpreters then wouldn’t be able to share objects. Unfortunately, this isn’t likely to happen either. It would be a tremendous amount of work, because many object implementations currently have global state. For example, small integers and short strings are cached; these caches would have to be moved to the interpreter state. Other object types have their own free list; these free lists would have to be moved to the interpreter state. And so on.

And I doubt that it can even be done in finite time, because the same problem exists for 3rd party extensions. It is likely that 3rd party extensions are being written at a faster rate than you can convert them to store all their global state in the interpreter state.

And finally, once you have multiple interpreters not sharing any state, what have you gained over running each interpreter in a separate process?
How do I delete a file? (And other file questions...)

Use `os.remove(filename)` or `os.unlink(filename)`; for documentation, see the `os` module. The two functions are identical; `unlink()` is simply the name of the Unix system call for this function.

To remove a directory, use `os.rmdir()`; use `os.mkdir()` to create one. `os.makedirs(path)` will create any intermediate directories in `path` that don’t exist. `os.removedirs(path)` will remove intermediate directories as long as they’re empty; if you want to delete an entire directory tree and its contents, use `shutil.rmtree()`.

To rename a file, use `os.rename(old_path, new_path)`.

To truncate a file, open it using `f = open(filename, "r+"), and use `f.truncate(offset)`; offset defaults to the current seek position. There’s also `os.ftruncate(fd, offset)` for files opened with `os.open()`, where `fd` is the file descriptor (a small integer).

The `shutil` module also contains a number of functions to work on files including `copyfile()`, `copytree()`, and `rmtree()`.

How do I copy a file?

The `shutil` module contains a `copyfile()` function. Note that on MacOS 9 it doesn’t copy the resource fork and Finder info.

How do I read (or write) binary data?

To read or write complex binary data formats, it’s best to use the
**struct** module. It allows you to take a string containing binary data (usually numbers) and convert it to Python objects; and vice versa.

For example, the following code reads two 2-byte integers and one 4-byte integer in big-endian format from a file:

```python
import struct
f = open(filename, "rb")  # Open in binary mode for portability
s = f.read(8)
x, y, z = struct.unpack(">hhh", s)
```

The ‘>’ in the format string forces big-endian data; the letter ‘h’ reads one “short integer” (2 bytes), and ‘l’ reads one “long integer” (4 bytes) from the string.

For data that is more regular (e.g. a homogeneous list of ints or floats), you can also use the **array** module.

I can’t seem to use `os.read()` on a pipe created with `os.popen()`; why?

`os.read()` is a low-level function which takes a file descriptor, a small integer representing the opened file. `os.popen()` creates a high-level file object, the same type returned by the built-in `open()` function. Thus, to read *n* bytes from a pipe *p* created with `os.popen()`, you need to use `p.read(n)`.

How do I run a subprocess with pipes connected to both input and output?

Use the **popen2** module. For example:

```python
import popen2
```
Warning: in general it is unwise to do this because you can easily cause a deadlock where your process is blocked waiting for output from the child while the child is blocked waiting for input from you. This can be caused by the parent expecting the child to output more text than it does or by data being stuck in stdio buffers due to lack of flushing. The Python parent can of course explicitly flush the data it sends to the child before it reads any output, but if the child is a naive C program it may have been written to never explicitly flush its output, even if it is interactive, since flushing is normally automatic.

Note that a deadlock is also possible if you use `popen3()` to read stdout and stderr. If one of the two is too large for the internal buffer (increasing the buffer size does not help) and you `read()` the other one first, there is a deadlock, too.

Note on a bug in popen2: unless your program calls `wait()` or `waitpid()`, finished child processes are never removed, and eventually calls to popen2 will fail because of a limit on the number of child processes. Calling `os.waitpid()` with the `os.WNOHANG` option can prevent this; a good place to insert such a call would be before calling `popen2` again.

In many cases, all you really need is to run some data through a command and get the result back. Unless the amount of data is very large, the easiest way to do this is to write it to a temporary file and run the command with that temporary file as input. The standard module `tempfile` exports a `mktemp()` function to generate unique temporary file names.
class Popen3:
    ""
    This is a deadlock-safe version of popen that returns an object with errorlevel, out (a string) and err (a string (capturestderr may not work under windows.)
    Example: print Popen3('grep spam','\n\nhere spam\n\n').out
    ""
    def __init__(self, command, input=None, capturestderr=None):
        outfile = tempfile.mktemp()
        command = "( %s ) > %s" % (command, outfile)
        if input:
            infile = tempfile.mktemp()
            open(infile, "w").write(input)
            command = command + " <" + infile
        if capturestderr:
            errfile = tempfile.mktemp()
            command = command + " 2>" + errfile
            self.errorlevel = os.system(command) >> 8
        self.out = open(outfile, "r").read()
        os.remove(outfile)
        if input:
            os.remove(infile)
        if capturestderr:
            self.err = open(errfile, "r").read()
            os.remove(errfile)

Note that many interactive programs (e.g. vi) don't work well with pipes substituted for standard input and output. You will have to use pseudo ttys (“ptys”) instead of pipes. Or you can use a Python interface to Don Libes' “expect” library. A Python extension that interfaces to expect is called “expy” and available from http://expectpy.sourceforge.net. A pure Python solution that works like expect is pexpect.

How do I access the serial (RS232) port?

For Win32, POSIX (Linux, BSD, etc.), Jython:

http://pyserial.sourceforge.net
For Unix, see a Usenet post by Mitch Chapman:

https://groups.google.com/groups?selm=34A04430.CF9@ohioee.com

**Why doesn’t closing sys.stdout (stdin, stderr) really close it?**

Python file objects are a high-level layer of abstraction on top of C streams, which in turn are a medium-level layer of abstraction on top of (among other things) low-level C file descriptors.

For most file objects you create in Python via the built-in `file` constructor, `f.close()` marks the Python file object as being closed from Python’s point of view, and also arranges to close the underlying C stream. This also happens automatically in `f`'s destructor, when `f` becomes garbage.

But stdin, stdout and stderr are treated specially by Python, because of the special status also given to them by C. Running `sys.stdout.close()` marks the Python-level file object as being closed, but does *not* close the associated C stream.

To close the underlying C stream for one of these three, you should first be sure that’s what you really want to do (e.g., you may confuse extension modules trying to do I/O). If it is, use `os.close`:

```
  os.close(0)  # close C's stdin stream
  os.close(1)  # close C's stdout stream
  os.close(2)  # close C's stderr stream
```
Network/Internet Programming

What WWW tools are there for Python?

See the chapters titled Internet Protocols and Support and Internet Data Handling in the Library Reference Manual. Python has many modules that will help you build server-side and client-side web systems.

A summary of available frameworks is maintained by Paul Boddie at https://wiki.python.org/moin/WebProgramming.

How can I mimic CGI form submission (METHOD=POST)?

I would like to retrieve web pages that are the result of POSTing a form. Is there existing code that would let me do this easily?

Yes. Here's a simple example that uses httplib:

```python
#!/usr/local/bin/python

import httpplib, sys, time

# build the query string
qs = "First=Josephine&MI=Q&Last=Public"

# connect and send the server a path
httpobj = httpplib.HTTP('www.some-server.out-there', 80)
httpobj.putrequest('POST', '/cgi-bin/some-cgi-script')
# now generate the rest of the HTTP headers...
httpobj.putheader('Accept', '/*/*')
```
httpobj.putheader('Connection', 'Keep-Alive')
httpobj.putheader('Content-type', 'application/x-www-form-urlencoded')
httpobj.putheader('Content-length', '%d' % len(qs))
httpobj.endheaders()
httpobj.send(qs)

# find out what the server said in response...
reply, msg, hdrs = httpobj.getreply()
if reply != 200:
    sys.stdout.write(httpobj.getfile().read())

Note that in general for percent-encoded POST operations, query strings must be quoted using urllib.urlencode(). For example, to send name=Guy Steele, Jr.:

```python
>>> import urllib
>>> urllib.urlencode({'name': 'Guy Steele, Jr.'})
'name=Guy+Steele%2C+Jr.'
```

What module should I use to help with generating HTML?

You can find a collection of useful links on the Web Programming wiki page.

How do I send mail from a Python script?

Use the standard library module smtplib.

Here's a very simple interactive mail sender that uses it. This method will work on any host that supports an SMTP listener.

```python
import sys, smtplib
fromaddr = raw_input("From: ")
toaddrs = raw_input("To: ").split(',,')
print "Enter message, end with ^D:" msg = '
while True:
```
```python
line = sys.stdin.readline()
if not line:
    break
msg += line

# The actual mail send
server = smtplib.SMTP('localhost')
server.sendmail(fromaddr, toaddrs, msg)
server.quit()
```

A Unix-only alternative uses sendmail. The location of the sendmail program varies between systems; sometimes it is `/usr/lib/sendmail`, sometimes `/usr/sbin/sendmail`. The sendmail manual page will help you out. Here's some sample code:

```python
import os
SENDMAIL = "/usr/sbin/sendmail"  # sendmail location
p = os.popen("%s -t -i" % SENDMAIL, "w")
p.write("To: receiver@example.com\n")
p.write("Subject: test\n")
p.write("\n"  # blank line separating headers from body
p.write("Some text\n")
p.write("some more text\n")
sts = p.close()
if sts != 0:
    print "Sendmail exit status", sts
```

How do I avoid blocking in the connect() method of a socket?

The select module is commonly used to help with asynchronous I/O on sockets.

To prevent the TCP connect from blocking, you can set the socket to non-blocking mode. Then when you do the `connect()`, you will either connect immediately (unlikely) or get an exception that contains the error number as `.errno`. `.errno.EINPROGRESS` indicates that the connection is in progress, but hasn’t finished yet. Different OSes will
return different values, so you’re going to have to check what’s returned on your system.

You can use the `connect_ex()` method to avoid creating an exception. It will just return the `errno` value. To poll, you can call `connect_ex()` again later – 0 or `errno.EISCONN` indicate that you’re connected – or you can pass this socket to `select` to check if it’s writable.
Databases

Are there any interfaces to database packages in Python?

Yes.

Python 2.3 includes the **bsddb** package which provides an interface to the BerkeleyDB library. Interfaces to disk-based hashes such as **DBM** and **GDBM** are also included with standard Python.

Support for most relational databases is available. See the [DatabaseProgramming wiki page](https://wiki.python.org/moin/DatabaseProgramming) for details.

How do you implement persistent objects in Python?

The **pickle** library module solves this in a very general way (though you still can't store things like open files, sockets or windows), and the **shelve** library module uses pickle and (g)dbm to create persistent mappings containing arbitrary Python objects. For better performance, you can use the **cPickle** module.

A more awkward way of doing things is to use pickle's little sister, marshal. The **marshal** module provides very fast ways to store noncircular basic Python types to files and strings, and back again. Although marshal does not do fancy things like store instances or handle shared references properly, it does run extremely fast. For example, loading a half megabyte of data may take less than a third of a second. This often beats doing something more complex and general such as using gdbm with pickle/shelve.
Why is cPickle so slow?

By default `pickle` uses a relatively old and slow format for backward compatibility. You can however specify other protocol versions that are faster:

```python
largeString = 'z' * (100 * 1024)
myPickle = cPickle.dumps(largeString, protocol=1)
```

If my program crashes with a bsddb (or anydbm) database open, it gets corrupted. How come?

Databases opened for write access with the bsddb module (and often by the anydbm module, since it will preferentially use bsddb) must explicitly be closed using the `.close()` method of the database. The underlying library caches database contents which need to be converted to on-disk form and written.

If you have initialized a new bsddb database but not written anything to it before the program crashes, you will often wind up with a zero-length file and encounter an exception the next time the file is opened.

I tried to open Berkeley DB file, but bsddb produces bsddb.error: (22, ‘Invalid argument’). Help! How can I restore my data?

Don’t panic! Your data is probably intact. The most frequent cause for the error is that you tried to open an earlier Berkeley DB file with a later version of the Berkeley DB library.

Many Linux systems now have all three versions of Berkeley DB available. If you are migrating from version 1 to a newer version use
db_dump185 to dump a plain text version of the database. If you are migrating from version 2 to version 3 use db2_dump to create a plain text version of the database. In either case, use db_load to create a new native database for the latest version installed on your computer. If you have version 3 of Berkeley DB installed, you should be able to use db2_load to create a native version 2 database.

You should move away from Berkeley DB version 1 files because the hash file code contains known bugs that can corrupt your data.
How do I generate random numbers in Python?

The standard module `random` implements a random number generator. Usage is simple:

```python
import random
random.random()
```

This returns a random floating point number in the range [0, 1).

There are also many other specialized generators in this module, such as:

- `randrange(a, b)` chooses an integer in the range [a, b).
- `uniform(a, b)` chooses a floating point number in the range [a, b).
- `normalvariate(mean, sdev)` samples the normal (Gaussian) distribution.

Some higher-level functions operate on sequences directly, such as:

- `choice(S)` chooses random element from a given sequence
- `shuffle(L)` shuffles a list in-place, i.e. permutes it randomly

There’s also a `Random` class you can instantiate to create independent multiple random number generators.

  - How do I find undefined g++ symbols __builtin_new or __pure_virtual?
  - Can I create an object class with some methods implemented in C and others in Python (e.g. through inheritance)?
  - When importing module X, why do I get “undefined
symbol: PyUnicodeUCS2*""?
Can I create my own functions in C?

Yes, you can create built-in modules containing functions, variables, exceptions and even new types in C. This is explained in the document Extending and Embedding the Python Interpreter.

Most intermediate or advanced Python books will also cover this topic.
Can I create my own functions in C++?

Yes, using the C compatibility features found in C++. Place `extern "C" { ... }` around the Python include files and put `extern "C"` before each function that is going to be called by the Python interpreter. Global or static C++ objects with constructors are probably not a good idea.
Writing C is hard; are there any alternatives?

There are a number of alternatives to writing your own C extensions, depending on what you're trying to do.

If you need more speed, Psyco generates x86 assembly code from Python bytecode. You can use Psyco to compile the most time-critical functions in your code, and gain a significant improvement with very little effort, as long as you’re running on a machine with an x86-compatible processor.

Cython and its relative Pyrex are compilers that accept a slightly modified form of Python and generate the corresponding C code. Pyrex makes it possible to write an extension without having to learn Python’s C API.

If you need to interface to some C or C++ library for which no Python extension currently exists, you can try wrapping the library’s data types and functions with a tool such as SWIG. SIP, CXX Boost, or Weave are also alternatives for wrapping C++ libraries.
How can I execute arbitrary Python statements from C?

The highest-level function to do this is `PyRun_SimpleString()` which takes a single string argument to be executed in the context of the module `__main__` and returns 0 for success and -1 when an exception occurred (including `SyntaxError`). If you want more control, use `PyRun_String()`; see the source for `PyRun_SimpleString()` in Python/pythonrun.c.
How can I evaluate an arbitrary Python expression from C?

Call the function `PyRun_String()` from the previous question with the start symbol `Py_eval_input`; it parses an expression, evaluates it and returns its value.
How do I extract C values from a Python object?

That depends on the object's type. If it's a tuple, `PyTuple_Size()` returns its length and `PyTuple_GetItem()` returns the item at a specified index. Lists have similar functions, `PyListSize()` and `PyList_GetItem()`.

For strings, `PyString_Size()` returns its length and `PyString_AsString()` a pointer to its value. Note that Python strings may contain null bytes so C's `strlen()` should not be used.

To test the type of an object, first make sure it isn't `NULL`, and then use `PyString_Check()`, `PyTuple_Check()`, `PyList_Check()`, etc.

There is also a high-level API to Python objects which is provided by the so-called 'abstract' interface – read `include/abstract.h` for further details. It allows interfacing with any kind of Python sequence using calls like `PySequence_Length()`, `PySequence_GetItem()`, etc.) as well as many other useful protocols.
How do I use Py_BuildValue() to create a tuple of arbitrary length?

You can’t. Use \( t = \text{PyTuple\_New}(n) \) instead, and fill it with objects using \( \text{PyTuple\_SetItem}(t, i, o) \) – note that this “eats” a reference count of \( o \), so you have to \( \text{Py\_INCREF}() \) it. Lists have similar functions \( \text{PyList\_New}(n) \) and \( \text{PyList\_SetItem}(l, i, o) \). Note that you \textit{must} set all the tuple items to some value before you pass the tuple to Python code – \( \text{PyTuple\_New}(n) \) initializes them to NULL, which isn’t a valid Python value.
How do I call an object’s method from C?

The `PyObject_CallMethod()` function can be used to call an arbitrary method of an object. The parameters are the object, the name of the method to call, a format string like that used with `Py_BuildValue()`, and the argument values:

```c
PyObject *
PyObject_CallMethod(PyObject *object, char *method_name,
        char *arg_format, ...);
```

This works for any object that has methods – whether built-in or user-defined. You are responsible for eventually `Py_DECREF()`'ing the return value.

To call, e.g., a file object’s “seek” method with arguments 10, 0 (assuming the file object pointer is “f”):

```c
res = PyObject_CallMethod(f, "seek", "(ii)", 10, 0);
if (res == NULL) {
    ... an exception occurred ...
} else {
    Py_DECREF(res);
}
```

Note that since `PyObject_CallObject()` always wants a tuple for the argument list, to call a function without arguments, pass “()” for the format, and to call a function with one argument, surround the argument in parentheses, e.g. “(i)”. 
How do I catch the output from PyErr_Print() (or anything that prints to stdout/stderr)?

In Python code, define an object that supports the `write()` method. Assign this object to `sys.stdout` and `sys.stderr`. Call print_error, or just allow the standard traceback mechanism to work. Then, the output will go wherever your `write()` method sends it.

The easiest way to do this is to use the StringIO class in the standard library.

Sample code and use for catching stdout:

```python
>>> class StdoutCatcher:
...     def __init__(self):
...         self.data = ''
...     def write(self, stuff):
...         self.data = self.data + stuff

>>> import sys
>>> sys.stdout = StdoutCatcher()
>>> print 'foo'
>>> print 'hello world!'
>>> sys.stderr.write(sys.stdout.data)
foo
hello world!
```
How do I access a module written in Python from C?

You can get a pointer to the module object as follows:

\[
\text{module} = \text{PyImport_ImportModule}("<\text{modulename}>"); \]

If the module hasn't been imported yet (i.e. it is not yet present in \texttt{sys.modules}), this initializes the module; otherwise it simply returns the value of \texttt{sys.modules["<\text{modulename}>"]}. Note that it doesn't enter the module into any namespace – it only ensures it has been initialized and is stored in \texttt{sys.modules}.

You can then access the module's attributes (i.e. any name defined in the module) as follows:

\[
\text{attr} = \text{PyObject_GetAttrString}(<\text{module}, "<\text{attrname}>"}); \]

Calling \texttt{PyObject_SetAttrString()} to assign to variables in the module also works.
How do I interface to C++ objects from Python?

Depending on your requirements, there are many approaches. To do this manually, begin by reading the “Extending and Embedding” document. Realize that for the Python run-time system, there isn’t a whole lot of difference between C and C++ – so the strategy of building a new Python type around a C structure (pointer) type will also work for C++ objects.

For C++ libraries, see Writing C is hard; are there any alternatives?
I added a module using the Setup file and the make fails; why?

Setup must end in a newline, if there is no newline there, the build process fails. (Fixing this requires some ugly shell script hackery, and this bug is so minor that it doesn't seem worth the effort.)
How do I debug an extension?

When using GDB with dynamically loaded extensions, you can’t set a breakpoint in your extension until your extension is loaded.

In your `.gdbinit` file (or interactively), add the command:

```
br _PyImport_LoadDynamicModule
```

Then, when you run GDB:

```
$ gdb /local/bin/python
(gdb) run myscript.py
(gdb) continue # repeat until your extension is loaded
(gdb) finish     # so that your extension is loaded
(gdb) br myfunction.c:50
(gdb) continue
```
I want to compile a Python module on my Linux system, but some files are missing. Why?

Most packaged versions of Python don’t include the /usr/lib/python2.x/config/ directory, which contains various files required for compiling Python extensions.

For Red Hat, install the python-devel RPM to get the necessary files.

For Debian, run `apt-get install python-dev`. 
What does “SystemError: _PyImport_FixupExtension: module yourmodule not loaded” mean?

This means that you have created an extension module named “yourmodule”, but your module init function does not initialize with that name.

Every module init function will have a line similar to:

```python
module = Py_InitModule("yourmodule", yourmodule_functions);
```

If the string passed to this function is not the same name as your extension module, the `SystemError` exception will be raised.
How do I tell “incomplete input” from “invalid input”?

Sometimes you want to emulate the Python interactive interpreter’s behavior, where it gives you a continuation prompt when the input is incomplete (e.g. you typed the start of an “if” statement or you didn’t close your parentheses or triple string quotes), but it gives you a syntax error message immediately when the input is invalid.

In Python you can use the codeop module, which approximates the parser’s behavior sufficiently. IDLE uses this, for example.

The easiest way to do it in C is to call PyRun_InteractiveLoop() (perhaps in a separate thread) and let the Python interpreter handle the input for you. You can also set the PyOS_ReadlineFunctionPointer() to point at your custom input function. See Modules/readline.c and Parser/myreadline.c for more hints.

However sometimes you have to run the embedded Python interpreter in the same thread as your rest application and you can’t allow the PyRun_InteractiveLoop() to stop while waiting for user input. The one solution then is to call PyParser_ParseString() and test for e.error equal to E_EOF, which means the input is incomplete). Here’s a sample code fragment, untested, inspired by code from Alex Farber:

```c
#include <Python.h>
#include <node.h>
#include <errcode.h>
#include <grammar.h>
#include <parsetok.h>
#include <compile.h>
```
int testcomplete(char *code)  
/* code should end in \n */  
/* return -1 for error, 0 for incomplete, 1 for complete */  
{
    node *n;
    perrdetail e;

    n = PyParser_ParseString(code, &_PyParser_Grammar, Py_file_input, &e);
    if (n == NULL) {
        if (e.error == E_EOF)
            return 0;
        return -1;
    }

    PyNode_Free(n);
    return 1;
}

Another solution is trying to compile the received string with Py_CompileString(). If it compiles without errors, try to execute the returned code object by calling PyEval_EvalCode(). Otherwise save the input for later. If the compilation fails, find out if it’s an error or just more input is required - by extracting the message string from the exception tuple and comparing it to the string “unexpected EOF while parsing”. Here is a complete example using the GNU readline library (you may want to ignore SIGINT while calling readline()):

#include <stdio.h>
#include <readline.h>

#include <Python.h>
#include <object.h>
#include <compile.h>
#include <eval.h>

int main(int argc, char* argv[])
{
    int i, j, done = 0;  /* lengths of line */
    char ps1[] = ">>> ";
    char ps2[] = "... ";
    char *prompt = ps1;
    char *msg, *line, *code = NULL;

PyObject *src, *glb, *loc;

Py_Initialize();
loc = PyDict_New();
glb = PyDict_New();
PyDict_SetItemString (glb, "__builtins__", PyEval_GetBuiltins());

while (!done) {
    line = readline (prompt);

    if (NULL == line) /* Ctrl-D pressed */
        { done = 1; }
    else
    {
        i = strlen (line);

        if (i > 0)
            add_history (line); /* save non-empty lines */

        if (NULL == code) /* nothing in code yet */
            j = 0;
        else
            j = strlen (code);

        code = realloc (code, i + j + 2);

        if (NULL == code) /* out of memory */
            exit (1);

        if (0 == j) /* code was empty, so keep \0 */
            code[0] = '\0';

        strncat (code, line, i); /* append line to code */
        code[i + j] = '\n'; /* append \n to code */
        code[i + j + 1] = '\0';

        src = Py_CompileString (code, "<stdin>", Py_single_input);
        if (NULL != src) /* compiled just fine */
            {
                if (ps1 == prompt || /* ">>> " or */
                    '\n' == code[i + j - 1]) /* "... " and do */
                    /* so eval */
                    dum = PyEval_EvalCode ((PyCodeObject *)src, glb, loc);
Py_XDECREF (dum);
Py_XDECREF (src);
free (code);
    code = NULL;
    if (PyErr_Occurred ())
        PyErr_Print ();
    prompt = ps1;
}
    /* syntax error */
else if (PyErr_ExceptionMatches (PyExc_SyntaxError))
{
    PyErr_Fetch (&exc, &val, &trb);  /* clears exception! */

    if (PyArg_ParseTuple (val, "sO", &msg, &obj) &&
            !strcmp (msg, "unexpected EOF while parsing")) /* E_EOF */
    {
        Py_XDECREF (exc);
        Py_XDECREF (val);
        Py_XDECREF (trb);
        prompt = ps2;
    }
else  /* some other syntax error */
    {
        PyErr_Restore (exc, val, trb);
        PyErr_Print ();
        free (code);
        code = NULL;
        prompt = ps1;
    }
}
else  /* some non-syntax errors */
{
    PyErr_Print ();
    free (code);
    code = NULL;
    prompt = ps1;
}
free (line);
}

Py_XDECREF(glb);
Py_XDECREF(loc);
Py_Finalize();
exit(0);
How do I find undefined g++ symbols \_\_builtin\_new or \_\_pure\_virtual?

To dynamically load g++ extension modules, you must recompile Python, relink it using g++ (change LINKCC in the Python Modules Makefile), and link your extension module using g++ (e.g., `g++ -shared -o mymodule.so mymodule.o`).
Can I create an object class with some methods implemented in C and others in Python (e.g. through inheritance)?

Yes, you can inherit from built-in classes such as `int`, `list`, `dict`, etc.

The Boost Python Library (BPL, http://www.boost.org/libs/python/doc/index.html) provides a way of doing this from C++ (i.e. you can inherit from an extension class written in C++ using the BPL).
When importing module X, why do I get “undefined symbol: PyUnicodeUCS2*”?  

You are using a version of Python that uses a 4-byte representation for Unicode characters, but some C extension module you are importing was compiled using a Python that uses a 2-byte representation for Unicode characters (the default).

If instead the name of the undefined symbol starts with `PyUnicodeUCS4`, the problem is the reverse: Python was built using 2-byte Unicode characters, and the extension module was compiled using a Python with 4-byte Unicode characters.

This can easily occur when using pre-built extension packages. RedHat Linux 7.x, in particular, provided a “python2” binary that is compiled with 4-byte Unicode. This only causes the link failure if the extension uses any of the `PyUnicode_*()` functions. It is also a problem if an extension uses any of the Unicode-related format specifiers for `Py_BuildValue()` (or similar) or parameter specifications for `PyArg_ParseTuple()`.

You can check the size of the Unicode character a Python interpreter is using by checking the value of `sys.maxunicode`:

```python
>>> import sys
>>> if sys.maxunicode > 65535:
...     print 'UCS4 build'
... else:
...     print 'UCS2 build'
```

The only way to solve this problem is to use extension modules compiled with a Python binary built using the same size for Unicode characters.

How do I run a Python program under Windows?

This is not necessarily a straightforward question. If you are already familiar with running programs from the Windows command line then everything will seem obvious; otherwise, you might need a little more guidance.

Unless you use some sort of integrated development environment, you will end up typing Windows commands into what is variously referred to as a “DOS window” or “Command prompt window”. Usually you can create such a window from your Start menu; under Windows 7 the menu selection is Start ▶ Programs ▶ Accessories ▶ Command Prompt. You should be able to recognize when you have started such a window because you will see a Windows “command prompt”, which usually looks like this:

C:>

The letter may be different, and there might be other things after it, so you might just as easily see something like:

D:\YourName\Projects\Python>

depending on how your computer has been set up and what else
you have recently done with it. Once you have started such a window, you are well on the way to running Python programs.

You need to realize that your Python scripts have to be processed by another program called the Python interpreter. The interpreter reads your script, compiles it into bytecodes, and then executes the bytecodes to run your program. So, how do you arrange for the interpreter to handle your Python?

First, you need to make sure that your command window recognises the word “python” as an instruction to start the interpreter. If you have opened a command window, you should try entering the command python and hitting return.:

C:\Users\YourName> python

You should then see something like:

Python 2.7.3 (default, Apr 10 2012, 22:71:26) [MSC v.1500 32 bi
Type "help", "copyright", "credits" or "license" for more infor
>>>

You have started the interpreter in “interactive mode”. That means you can enter Python statements or expressions interactively and have them executed or evaluated while you wait. This is one of Python’s strongest features. Check it by entering a few expressions of your choice and seeing the results:

>>> print "Hello"
Hello
>>> "Hello" * 3
'HelloHelloHello'

Many people use the interactive mode as a convenient yet highly programmable calculator. When you want to end your interactive Python session, hold the ctrl key down while you enter a z, then hit
the “Enter” key to get back to your Windows command prompt.

You may also find that you have a Start-menu entry such as Start ▶ Programs ▶ Python 2.7 ▶ Python (command line) that results in you seeing the >>> prompt in a new window. If so, the window will disappear after you enter the ctrl-z character; Windows is running a single “python” command in the window, and closes it when you terminate the interpreter.

If the python command, instead of displaying the interpreter prompt >>>, gives you a message like:

```
'python' is not recognized as an internal or external command,
```

or:

```
Bad command or filename
```

then you need to make sure that your computer knows where to find the Python interpreter. To do this you will have to modify a setting called PATH, which is a list of directories where Windows will look for programs.

You should arrange for Python's installation directory to be added to the PATH of every command window as it starts. If you installed Python fairly recently then the command

```
dir C:\py*
```
will probably tell you where it is installed; the usual location is something like \texttt{C:\Python27}. Otherwise you will be reduced to a search of your whole disk ... use Tools $\Rightarrow$ Find or hit the Search button and look for “python.exe”. Supposing you discover that Python is installed in the \texttt{C:\Python27} directory (the default at the time of writing), you should make sure that entering the command

\begin{verbatim}
C:\Python27\python
\end{verbatim}

starts up the interpreter as above (and don’t forget you’ll need a “\texttt{Ctrl-Z}” and an “\texttt{Enter}” to get out of it). Once you have verified the directory, you can add it to the system path to make it easier to start Python by just running the \texttt{python} command. This is currently an option in the installer as of CPython 2.7.

More information about environment variables can be found on the \texttt{Using Python on Windows} page.
How do I make Python scripts executable?

On Windows, the standard Python installer already associates the .py extension with a file type (Python.File) and gives that file type an open command that runs the interpreter (D:\Program Files\Python\python.exe "%1" %*). This is enough to make scripts executable from the command prompt as ‘foo.py’. If you’d rather be able to execute the script by simple typing ‘foo’ with no extension you need to add .py to the PATHEXT environment variable.
Why does Python sometimes take so long to start?

Usually Python starts very quickly on Windows, but occasionally there are bug reports that Python suddenly begins to take a long time to start up. This is made even more puzzling because Python will work fine on other Windows systems which appear to be configured identically.

The problem may be caused by a misconfiguration of virus checking software on the problem machine. Some virus scanners have been known to introduce startup overhead of two orders of magnitude when the scanner is configured to monitor all reads from the filesystem. Try checking the configuration of virus scanning software on your systems to ensure that they are indeed configured identically. McAfee, when configured to scan all file system read activity, is a particular offender.
How do I make an executable from a Python script?

See [http://www.py2exe.org/](http://www.py2exe.org/) for a distutils extension that allows you to create console and GUI executables from Python code.
Is a *.pyd file the same as a DLL?

Yes, .pyd files are dll’s, but there are a few differences. If you have a DLL named foo.pyd, then it must have a function initfoo(). You can then write Python “import foo”, and Python will search for foo.pyd (as well as foo.py, foo.pyc) and if it finds it, will attempt to call initfoo() to initialize it. You do not link your .exe with foo.lib, as that would cause Windows to require the DLL to be present.

Note that the search path for foo.pyd is PYTHONPATH, not the same as the path that Windows uses to search for foo.dll. Also, foo.pyd need not be present to run your program, whereas if you linked your program with a dll, the dll is required. Of course, foo.pyd is required if you want to say import foo. In a DLL, linkage is declared in the source code with __declspec(dllexport). In a .pyd, linkage is defined in a list of available functions.
How can I embed Python into a Windows application?

Embedding the Python interpreter in a Windows app can be summarized as follows:

1. Do _not_ build Python into your .exe file directly. On Windows, Python must be a DLL to handle importing modules that are themselves DLL's. (This is the first key undocumented fact.) Instead, link to `pythonNN.dll`; it is typically installed in `C:\Windows\System`. `NN` is the Python version, a number such as “27” for Python 2.7.

   You can link to Python in two different ways. Load-time linking means linking against `pythonNN.lib`, while run-time linking means linking against `pythonNN.dll`. (General note: `pythonNN.lib` is the so-called “import lib” corresponding to `pythonNN.dll`. It merely defines symbols for the linker.)

   Run-time linking greatly simplifies link options; everything happens at run time. Your code must load `pythonNN.dll` using the Windows `LoadLibraryEx()` routine. The code must also use access routines and data in `pythonNN.dll` (that is, Python's C API's) using pointers obtained by the Windows `GetProcAddress()` routine. Macros can make using these pointers transparent to any C code that calls routines in Python's C API.

   Borland note: convert `pythonNN.lib` to OMF format using `Coff2Omf.exe` first.

2. If you use SWIG, it is easy to create a Python “extension
module” that will make the app’s data and methods available to Python. SWIG will handle just about all the grungy details for you. The result is C code that you link into your .exe file (!) You do _not_ have to create a DLL file, and this also simplifies linking.

3. SWIG will create an init function (a C function) whose name depends on the name of the extension module. For example, if the name of the module is leo, the init function will be called initleo(). If you use SWIG shadow classes, as you should, the init function will be called initleoc(). This initializes a mostly hidden helper class used by the shadow class.

The reason you can link the C code in step 2 into your .exe file is that calling the initialization function is equivalent to importing the module into Python! (This is the second key undocumented fact.)

4. In short, you can use the following code to initialize the Python interpreter with your extension module.

```c
#include "python.h"
...
Py_Initialize(); // Initialize Python.
initmyAppc(); // Initialize (import) the helper class.
PyRun_SimpleString("import myApp"); // Import the shadow class.
```

5. There are two problems with Python’s C API which will become apparent if you use a compiler other than MSVC, the compiler used to build pythonNN.dll.

Problem 1: The so-called “Very High Level” functions that take FILE * arguments will not work in a multi-compiler environment because each compiler’s notion of a struct FILE will be different. From an implementation standpoint these are very _low_ level functions.
Problem 2: SWIG generates the following code when generating wrappers to void functions:

```c
Py_INCREF(Py_None);
_resultobj = Py_None;
return _resultobj;
```

Alas, Py_None is a macro that expands to a reference to a complex data structure called _Py_NoneStruct inside pythonNN.dll. Again, this code will fail in a mult-compiler environment. Replace such code by:

```c
return Py_BuildValue(" ");
```

It may be possible to use SWIG's `%typemap` command to make the change automatically, though I have not been able to get this to work (I'm a complete SWIG newbie).

6. Using a Python shell script to put up a Python interpreter window from inside your Windows app is not a good idea; the resulting window will be independent of your app's windowing system. Rather, you (or the wxPythonWindow class) should create a “native” interpreter window. It is easy to connect that window to the Python interpreter. You can redirect Python's i/o to _any_ object that supports read and write, so all you need is a Python object (defined in your extension module) that contains read() and write() methods.
How do I keep editors from inserting tabs into my Python source?

The FAQ does not recommend using tabs, and the Python style guide, PEP 8, recommends 4 spaces for distributed Python code; this is also the Emacs python-mode default.

Under any editor, mixing tabs and spaces is a bad idea. MSVC is no different in this respect, and is easily configured to use spaces: Take Tools ▶ Options ▶ Tabs, and for file type “Default” set “Tab size” and “Indent size” to 4, and select the “Insert spaces” radio button.

If you suspect mixed tabs and spaces are causing problems in leading whitespace, run Python with the -t switch or run Tools/Scripts/tabnanny.py to check a directory tree in batch mode.
How do I check for a keypress without blocking?

Use the msvcrt module. This is a standard Windows-specific extension module. It defines a function `kbhit()` which checks whether a keyboard hit is present, and `getch()` which gets one character without echoing it.
How do I emulate os.kill() in Windows?

Prior to Python 2.7 and 3.2, to terminate a process, you can use `ctypes`:

```python
import ctypes

def kill(pid):
    """kill function for Win32""
    kernel32 = ctypes.windll.kernel32
    handle = kernel32.OpenProcess(1, 0, pid)
    return (0 != kernel32.TerminateProcess(handle, 0))
```

In 2.7 and 3.2, `os.kill()` is implemented similar to the above function, with the additional feature of being able to send `Ctrl+C` and `Ctrl+Break` to console subprocesses which are designed to handle those signals. See `os.kill()` for further details.
How do I extract the downloaded documentation on Windows?

Sometimes, when you download the documentation package to a Windows machine using a web browser, the file extension of the saved file ends up being .EXE. This is a mistake; the extension should be .TGZ.

Simply rename the downloaded file to have the .TGZ extension, and WinZip will be able to handle it. (If your copy of WinZip doesn’t, get a newer one from https://www.winzip.com.)

    - I can't get key bindings to work in Tkinter: why?
What platform-independent GUI toolkits exist for Python?

Depending on what platform(s) you are aiming at, there are several.

Tkinter

Standard builds of Python include an object-oriented interface to the Tcl/Tk widget set, called Tkinter. This is probably the easiest to install and use. For more info about Tk, including pointers to the source, see the Tcl/Tk home page at [https://www.tcl.tk](https://www.tcl.tk). Tcl/Tk is fully portable to the Mac OS X, Windows, and Unix platforms.

wxWidgets

wxWidgets ([https://www.wxwidgets.org](https://www.wxwidgets.org)) is a free, portable GUI class library written in C++ that provides a native look and feel on a number of platforms, with Windows, Mac OS X, GTK, X11, all listed as current stable targets. Language bindings are available for a number of languages including Python, Perl, Ruby, etc.

wxPython ([http://www.wxpython.org](http://www.wxpython.org)) is the Python binding for wxwidgets. While it often lags slightly behind the official wxWidgets releases, it also offers a number of features via pure Python extensions that are not available in other language bindings. There is an active wxPython user and developer community.

Both wxWidgets and wxPython are free, open source, software with permissive licences that allow their use in commercial products as well as in freeware or shareware.

Qt
There are bindings available for the Qt toolkit (using either PyQt or PySide) and for KDE (PyKDE4). PyQt is currently more mature than PySide, but you must buy a PyQt license from Riverbank Computing if you want to write proprietary applications. PySide is free for all applications.

Qt 4.5 upwards is licensed under the LGPL license; also, commercial licenses are available from The Qt Company.

**Gtk+**

PyGtk bindings for the Gtk+ toolkit have been implemented by James Henstridge; see <http://www.pygtk.org>.

**FLTK**

Python bindings for the FLTK toolkit, a simple yet powerful and mature cross-platform windowing system, are available from the PyFLTK project.

**FOX**

A wrapper for the FOX toolkit called FXpy is available. FOX supports both Unix variants and Windows.

**OpenGL**

For OpenGL bindings, see PyOpenGL.
What platform-specific GUI toolkits exist for Python?

By installing the PyObjc Objective-C bridge, Python programs can use Mac OS X’s Cocoa libraries.

Pythonwin by Mark Hammond includes an interface to the Microsoft Foundation Classes and a Python programming environment that’s written mostly in Python using the MFC classes.
Tkinter questions

How do I freeze Tkinter applications?

Freeze is a tool to create stand-alone applications. When freezing Tkinter applications, the applications will not be truly stand-alone, as the application will still need the Tcl and Tk libraries.

One solution is to ship the application with the Tcl and Tk libraries, and point to them at run-time using the `TCL_LIBRARY` and `TK_LIBRARY` environment variables.

To get truly stand-alone applications, the Tcl scripts that form the library have to be integrated into the application as well. One tool supporting that is SAM (stand-alone modules), which is part of the Tix distribution (http://tix.sourceforge.net/).

Build Tix with SAM enabled, perform the appropriate call to `Tclsam_init()`, etc. inside Python’s `Modules/tkappinit.c`, and link with `libtclsam` and `libtksam` (you might include the Tix libraries as well).

Can I have Tk events handled while waiting for I/O?

On platforms other than Windows, yes, and you don't even need threads! But you'll have to restructure your I/O code a bit. Tk has the equivalent of Xt’s `XtAddInput()` call, which allows you to register a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. See File Handlers.

I can’t get key bindings to work in Tkinter: why?

An often-heard complaint is that event handlers bound to events with
the `bind()` method don’t get handled even when the appropriate key is pressed.

The most common cause is that the widget to which the binding applies doesn’t have “keyboard focus”. Check out the Tk documentation for the focus command. Usually a widget is given the keyboard focus by clicking in it (but not for labels; see the takefocus option).
“Why is Python Installed on my Computer?” FAQ
What is Python?

Python is a programming language. It’s used for many different applications. It’s used in some high schools and colleges as an introductory programming language because Python is easy to learn, but it’s also used by professional software developers at places such as Google, NASA, and Lucasfilm Ltd.

If you wish to learn more about Python, start with the Beginner's Guide to Python.
Why is Python installed on my machine?

If you find Python installed on your system but don't remember installing it, there are several possible ways it could have gotten there.

- Perhaps another user on the computer wanted to learn programming and installed it; you'll have to figure out who's been using the machine and might have installed it.
- A third-party application installed on the machine might have been written in Python and included a Python installation. For a home computer, the most common such application is PySol, a solitaire game that includes over 1000 different games and variations.
- Some Windows machines also have Python installed. At this writing we're aware of computers from Hewlett-Packard and Compaq that include Python. Apparently some of HP/Compaq's administrative tools are written in Python.
- All Apple computers running Mac OS X have Python installed; it's included in the base installation.
Can I delete Python?

That depends on where Python came from.

If someone installed it deliberately, you can remove it without hurting anything. On Windows, use the Add/Remove Programs icon in the Control Panel.

If Python was installed by a third-party application, you can also remove it, but that application will no longer work. You should use that application’s uninstaller rather than removing Python directly.

If Python came with your operating system, removing it is not recommended. If you remove it, whatever tools were written in Python will no longer run, and some of them might be important to you. Reinstalling the whole system would then be required to fix things again.
The default Python prompt of the interactive shell. Often seen for code examples which can be executed interactively in the interpreter.

The default Python prompt of the interactive shell when entering code for an indented code block or within a pair of matching left and right delimiters (parentheses, square brackets or curly braces).

2to3
A tool that tries to convert Python 2.x code to Python 3.x code by handling most of the incompatibilities which can be detected by parsing the source and traversing the parse tree.

2to3 is available in the standard library as `lib2to3`; a standalone entry point is provided as `Tools/scripts/2to3`. See 2to3 - Automated Python 2 to 3 code translation.

**abstract base class**
Abstract base classes complement duck-typing by providing a way to define interfaces when other techniques like `hasattr()` would be clumsy or subtly wrong (for example with magic methods). ABCs introduce virtual subclasses, which are classes that don’t inherit from a class but are still recognized by `isinstance()` and `issubclass()`; see the `abc` module documentation. Python comes with many built-in ABCs for data structures (in the `collections` module), numbers (in the `numbers` module), and streams (in the `io` module). You can create your own ABCs with the `abc` module.

**argument**
A value passed to a function (or method) when calling the function. There are two types of arguments:

- **keyword argument**: an argument preceded by an identifier (e.g. `name=`) in a function call or passed as a value in a dictionary preceded by `**`. For example, 3 and 5 are both keyword arguments in the following calls to `complex()`:

  ```python
  complex(real=3, imag=5)
  complex(**{'real': 3, 'imag': 5})
  ```

- **positional argument**: an argument that is not a keyword argument. Positional arguments can appear at the beginning of an argument list and/or be passed as elements of an iterable preceded by `*`. For example, 3 and 5 are both positional arguments in the following calls:

  ```python
  complex(3, 5)
  complex(*[3, 5])
  ```

Arguments are assigned to the named local variables in a function body. See the Calls section for the rules governing this assignment. Syntactically, any expression can be used to represent an argument; the evaluated value is assigned to the local variable.

See also the parameter glossary entry and the FAQ question on the difference between arguments and parameters.

**attribute**

A value associated with an object which is referenced by name using dotted expressions. For example, if an object `o` has an attribute `a` it would be referenced as `o.a`.

**BDFL**

Benevolent Dictator For Life, a.k.a. Guido van Rossum, Python's
creator.

**bytes-like object**

An object that supports the buffer protocol, like `str`, `bytearray` or `memoryview`. Bytes-like objects can be used for various operations that expect binary data, such as compression, saving to a binary file or sending over a socket. Some operations need the binary data to be mutable, in which case not all bytes-like objects can apply.

**bytecode**

Python source code is compiled into bytecode, the internal representation of a Python program in the CPython interpreter. The bytecode is also cached in `.pyc` and `.pyo` files so that executing the same file is faster the second time (recompilation from source to bytecode can be avoided). This “intermediate language” is said to run on a virtual machine that executes the machine code corresponding to each bytecode. Do note that bytecodes are not expected to work between different Python virtual machines, nor to be stable between Python releases.

A list of bytecode instructions can be found in the documentation for the `dis` module.

**class**

A template for creating user-defined objects. Class definitions normally contain method definitions which operate on instances of the class.

**classic class**

Any class which does not inherit from `object`. See new-style class. Classic classes have been removed in Python 3.

**coercion**

The implicit conversion of an instance of one type to another during an operation which involves two arguments of the same
type. For example, \texttt{int(3.15)} converts the floating point number to the integer 3, but in \texttt{3+4.5}, each argument is of a different type (one int, one float), and both must be converted to the same type before they can be added or it will raise a \texttt{TypeError}. Coercion between two operands can be performed with the \texttt{coerce} built-in function; thus, \texttt{3+4.5} is equivalent to calling \texttt{operator.add(*coerce(3, 4.5))} and results in \texttt{operator.add(3.0, 4.5)}. Without coercion, all arguments of even compatible types would have to be normalized to the same value by the programmer, e.g., \texttt{float(3)+4.5} rather than just \texttt{3+4.5}.

**complex number**

An extension of the familiar real number system in which all numbers are expressed as a sum of a real part and an imaginary part. Imaginary numbers are real multiples of the imaginary unit (the square root of \(-1\)), often written \texttt{i} in mathematics or \texttt{j} in engineering. Python has built-in support for complex numbers, which are written with this latter notation; the imaginary part is written with a \texttt{j} suffix, e.g., \texttt{3+1j}. To get access to complex equivalents of the \texttt{math} module, use \texttt{cmath}. Use of complex numbers is a fairly advanced mathematical feature. If you’re not aware of a need for them, it’s almost certain you can safely ignore them.

**context manager**

An object which controls the environment seen in a \texttt{with} statement by defining \texttt{__enter__()} and \texttt{__exit__()} methods. See \texttt{PEP 343}.

**CPython**

The canonical implementation of the Python programming language, as distributed on \texttt{python.org}. The term “CPython” is used when necessary to distinguish this implementation from others such as Jython or IronPython.
**decorator**

A function returning another function, usually applied as a function transformation using the `@wrapper` syntax. Common examples for decorators are `classmethod()` and `staticmethod()`.

The decorator syntax is merely syntactic sugar, the following two function definitions are semantically equivalent:

```python
def f(...):
    ...
    f = staticmethod(f)

@staticmethod
def f(...):
    ...
```

The same concept exists for classes, but is less commonly used there. See the documentation for function definitions and class definitions for more about decorators.

**descriptor**

Any *new-style* object which defines the methods `__get__()`, `__set__()`, or `__delete__()`. When a class attribute is a descriptor, its special binding behavior is triggered upon attribute lookup. Normally, using `a.b` to get, set or delete an attribute looks up the object named `b` in the class dictionary for `a`, but if `b` is a descriptor, the respective descriptor method gets called. Understanding descriptors is a key to a deep understanding of Python because they are the basis for many features including functions, methods, properties, class methods, static methods, and reference to super classes.

For more information about descriptors’ methods, see Implementing Descriptors.

**dictionary**
An associative array, where arbitrary keys are mapped to values. The keys can be any object with \_\_hash\_() and \_\_eq\_() methods. Called a hash in Perl.

dictionary view
The objects returned from \_\_viewkeys\_(), \_\_viewvalues\_(), and \_\_viewitems\_() are called dictionary views. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes. To force the dictionary view to become a full list use \_\_list\_(). See Dictionary view objects.

docstring
A string literal which appears as the first expression in a class, function or module. While ignored when the suite is executed, it is recognized by the compiler and put into the \_\_doc\_ attribute of the enclosing class, function or module. Since it is available via introspection, it is the canonical place for documentation of the object.

duck-typing
A programming style which does not look at an object's type to determine if it has the right interface; instead, the method or attribute is simply called or used ("If it looks like a duck and quacks like a duck, it must be a duck."") By emphasizing interfaces rather than specific types, well-designed code improves its flexibility by allowing polymorphic substitution. Duck-typing avoids tests using \_\_type\_() or \_\_instance\_(). (Note, however, that duck-typing can be complemented with abstract base classes.) Instead, it typically employs \_\_hasattr\_() tests or EAFP programming.

EAFP
Easier to ask for forgiveness than permission. This common Python coding style assumes the existence of valid keys or
attributes and catches exceptions if the assumption proves false. This clean and fast style is characterized by the presence of many try and except statements. The technique contrasts with the LBYL style common to many other languages such as C.

**expression**
A piece of syntax which can be evaluated to some value. In other words, an expression is an accumulation of expression elements like literals, names, attribute access, operators or function calls which all return a value. In contrast to many other languages, not all language constructs are expressions. There are also statements which cannot be used as expressions, such as print or if. Assignments are also statements, not expressions.

**extension module**
A module written in C or C++, using Python’s C API to interact with the core and with user code.

**file object**
An object exposing a file-oriented API (with methods such as read() or write()) to an underlying resource. Depending on the way it was created, a file object can mediate access to a real on-disk file or to another type of storage or communication device (for example standard input/output, in-memory buffers, sockets, pipes, etc.). File objects are also called file-like objects or streams.

There are actually three categories of file objects: raw binary files, buffered binary files and text files. Their interfaces are defined in the io module. The canonical way to create a file object is by using the open() function.

**file-like object**
A synonym for file object.

**finder**
An object that tries to find the loader for a module. It must implement a method named find_module(). See PEP 302 for details.

floor division
Mathematical division that rounds down to nearest integer. The floor division operator is //. For example, the expression 11 // 4 evaluates to 2 in contrast to the 2.75 returned by float true division. Note that (-11) // 4 is -3 because that is -2.75 rounded downward. See PEP 238.

function
A series of statements which returns some value to a caller. It can also be passed zero or more arguments which may be used in the execution of the body. See also parameter, method, and the Function definitions section.

__future__
A pseudo-module which programmers can use to enable new language features which are not compatible with the current interpreter. For example, the expression 11/4 currently evaluates to 2. If the module in which it is executed had enabled true division by executing:

```python
from __future__ import division
```

the expression 11/4 would evaluate to 2.75. By importing the __future__ module and evaluating its variables, you can see when a new feature was first added to the language and when it will become the default:

```python
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```
**garbage collection**

The process of freeing memory when it is not used anymore. Python performs garbage collection via reference counting and a cyclic garbage collector that is able to detect and break reference cycles.

**generator**

A function which returns an iterator. It looks like a normal function except that it contains `yield` statements for producing a series of values usable in a for-loop or that can be retrieved one at a time with the `next()` function. Each `yield` temporarily suspends processing, remembering the location execution state (including local variables and pending try-statements). When the generator resumes, it picks-up where it left-off (in contrast to functions which start fresh on every invocation).

**generator expression**

An expression that returns an iterator. It looks like a normal expression followed by a `for` expression defining a loop variable, range, and an optional `if` expression. The combined expression generates values for an enclosing function:

```python
>>> sum(i*i for i in range(10))  # sum of squares 0, 1, 4, ..., 81
285
```

**GIL**

See global interpreter lock.

**global interpreter lock**

The mechanism used by the CPython interpreter to assure that only one thread executes Python bytecode at a time. This simplifies the CPython implementation by making the object model (including critical built-in types such as `dict`) implicitly safe against concurrent access. Locking the entire interpreter makes it easier for the interpreter to be multi-threaded, at the expense of
much of the parallelism afforded by multi-processor machines.

However, some extension modules, either standard or third-party, are designed so as to release the GIL when doing computationally-intensive tasks such as compression or hashing. Also, the GIL is always released when doing I/O.

Past efforts to create a “free-threaded” interpreter (one which locks shared data at a much finer granularity) have not been successful because performance suffered in the common single-processor case. It is believed that overcoming this performance issue would make the implementation much more complicated and therefore costlier to maintain.

**hashable**

An object is *hashable* if it has a hash value which never changes during its lifetime (it needs a `__hash__()` method), and can be compared to other objects (it needs an `__eq__() ` or `__cmp__() ` method). Hashable objects which compare equal must have the same hash value.

Hashability makes an object usable as a dictionary key and a set member, because these data structures use the hash value internally.

All of Python’s immutable built-in objects are hashable, while no mutable containers (such as lists or dictionaries) are. Objects which are instances of user-defined classes are hashable by default; they all compare unequal (except with themselves), and their hash value is derived from their `id()`.

**IDLE**

An Integrated Development Environment for Python. IDLE is a basic editor and interpreter environment which ships with the standard distribution of Python.
immutable
An object with a fixed value. Immutable objects include numbers, strings and tuples. Such an object cannot be altered. A new object has to be created if a different value has to be stored. They play an important role in places where a constant hash value is needed, for example as a key in a dictionary.

integer division
Mathematical division discarding any remainder. For example, the expression \( \frac{11}{4} \) currently evaluates to 2 in contrast to the 2.75 returned by float division. Also called floor division. When dividing two integers the outcome will always be another integer (having the floor function applied to it). However, if one of the operands is another numeric type (such as a float), the result will be coerced (see coercion) to a common type. For example, an integer divided by a float will result in a float value, possibly with a decimal fraction. Integer division can be forced by using the `//` operator instead of the `/` operator. See also `__future__`.

importing
The process by which Python code in one module is made available to Python code in another module.

importer
An object that both finds and loads a module; both a finder and loader object.

interactive
Python has an interactive interpreter which means you can enter statements and expressions at the interpreter prompt, immediately execute them and see their results. Just launch `python` with no arguments (possibly by selecting it from your computer’s main menu). It is a very powerful way to test out new ideas or inspect modules and packages (remember `help(x)`).

interpreted
Python is an interpreted language, as opposed to a compiled one, though the distinction can be blurry because of the presence of the bytecode compiler. This means that source files can be run directly without explicitly creating an executable which is then run. Interpreted languages typically have a shorter development/debug cycle than compiled ones, though their programs generally also run more slowly. See also interactive.

**iterable**

An object capable of returning its members one at a time. Examples of iterables include all sequence types (such as list, str, and tuple) and some non-sequence types like dict and file and objects of any classes you define with an __iter__() or __getitem__() method. Iterables can be used in a for loop and in many other places where a sequence is needed (zip(), map(), ...). When an iterable object is passed as an argument to the built-in function iter(), it returns an iterator for the object. This iterator is good for one pass over the set of values. When using iterables, it is usually not necessary to call iter() or deal with iterator objects yourself. The for statement does that automatically for you, creating a temporary unnamed variable to hold the iterator for the duration of the loop. See also iterator, sequence, and generator.

**iterator**

An object representing a stream of data. Repeated calls to the iterator’s next() method return successive items in the stream. When no more data are available a StopIteration exception is raised instead. At this point, the iterator object is exhausted and any further calls to its next() method just raise StopIteration again. Iterators are required to have an __iter__() method that returns the iterator object itself so every iterator is also iterable and may be used in most places where other iterables are accepted. One notable exception is code which attempts multiple
iteration passes. A container object (such as a list) produces a fresh new iterator each time you pass it to the iter() function or use it in a for loop. Attempting this with an iterator will just return the same exhausted iterator object used in the previous iteration pass, making it appear like an empty container.

More information can be found in Iterator Types.

**key function**

A key function or collation function is a callable that returns a value used for sorting or ordering. For example, locale.strxfrm() is used to produce a sort key that is aware of locale specific sort conventions.

A number of tools in Python accept key functions to control how elements are ordered or grouped. They include min(), max(), sorted(), list.sort(), heapq.nsmallest(), heapq.nlargest(), and itertools.groupby().

There are several ways to create a key function. For example, the str.lower() method can serve as a key function for case insensitive sorts. Alternatively, an ad-hoc key function can be built from a lambda expression such as lambda r: (r[0], r[2]). Also, the operator module provides three key function constructors: attrgetter(), itemgetter(), and methodcaller(). See the Sorting HOW TO for examples of how to create and use key functions.

**keyword argument**

See argument.

**lambda**

An anonymous inline function consisting of a single expression which is evaluated when the function is called. The syntax to
create a lambda function is `lambda [arguments]: expression`

**LBYL**
Look before you leap. This coding style explicitly tests for preconditions before making calls or lookups. This style contrasts with the EAFP approach and is characterized by the presence of many `if` statements.

In a multi-threaded environment, the LBYL approach can risk introducing a race condition between “the looking” and “the leaping”. For example, the code, `if key in mapping: return mapping[key]` can fail if another thread removes `key` from `mapping` after the test, but before the lookup. This issue can be solved with locks or by using the EAFP approach.

**list**
A built-in Python sequence. Despite its name it is more akin to an array in other languages than to a linked list since access to elements are O(1).

**list comprehension**
A compact way to process all or part of the elements in a sequence and return a list with the results. `result = ["0x%02x" % x for x in range(256) if x % 2 == 0]` generates a list of strings containing even hex numbers (0x..) in the range from 0 to 255. The `if` clause is optional. If omitted, all elements in `range(256)` are processed.

**loader**
An object that loads a module. It must define a method named `load_module()`. A loader is typically returned by a `finder`. See PEP 302 for details.

**mapping**
A container object that supports arbitrary key lookups and
implements the methods specified in the `Mapping` or `MutableMapping` abstract base classes. Examples include `dict`, `collections.defaultdict`, `collections.OrderedDict` and `collections.Counter`.

**metaclass**

The class of a class. Class definitions create a class name, a class dictionary, and a list of base classes. The metaclass is responsible for taking those three arguments and creating the class. Most object-oriented programming languages provide a default implementation. What makes Python special is that it is possible to create custom metaclasses. Most users never need this tool, but when the need arises, metaclasses can provide powerful, elegant solutions. They have been used for logging attribute access, adding thread-safety, tracking object creation, implementing singletons, and many other tasks.

More information can be found in **Customizing class creation**.

**method**

A function which is defined inside a class body. If called as an attribute of an instance of that class, the method will get the instance object as its first argument (which is usually called `self`). See function and **nested scope**.

**method resolution order**

Method Resolution Order is the order in which base classes are searched for a member during lookup. See [The Python 2.3 Method Resolution Order](https://docs.python.org/3.8/c-api/class.html) for details of the algorithm used by the Python interpreter since the 2.3 release.

**module**

An object that serves as an organizational unit of Python code. Modules have a namespace containing arbitrary Python objects. Modules are loaded into Python by the process of **importing**.
See also package.

**MRO**

See method resolution order.

**mutable**

Mutable objects can change their value but keep their id(). See also immutable.

**named tuple**

Any tuple-like class whose indexable elements are also accessible using named attributes (for example, `time.localtime()` returns a tuple-like object where the year is accessible either with an index such as `t[0]` or with a named attribute like `t.tm_year`).

A named tuple can be a built-in type such as `time.struct_time`, or it can be created with a regular class definition. A full featured named tuple can also be created with the factory function `collections.namedtuple()`. The latter approach automatically provides extra features such as a self-documenting representation like `Employee(name='jones', title='programmer')`.

**namespace**

The place where a variable is stored. Namespaces are implemented as dictionaries. There are the local, global and built-in namespaces as well as nested namespaces in objects (in methods). Namespaces support modularity by preventing naming conflicts. For instance, the functions `__builtin__.open()` and `os.open()` are distinguished by their namespaces. Namespaces also aid readability and maintainability by making it clear which module implements a function. For instance, writing `random.seed()` or `itertools.izip()` makes it clear that those functions are implemented by the `random` and `itertools` modules,
respectively.

**nested scope**
The ability to refer to a variable in an enclosing definition. For instance, a function defined inside another function can refer to variables in the outer function. Note that nested scopes work only for reference and not for assignment which will always write to the innermost scope. In contrast, local variables both read and write in the innermost scope. Likewise, global variables read and write to the global namespace.

**new-style class**
Any class which inherits from `object`. This includes all built-in types like `list` and `dict`. Only new-style classes can use Python’s newer, versatile features like `__slots__`, descriptors, properties, and `__getattribute__()`. More information can be found in New-style and classic classes.

**object**
Any data with state (attributes or value) and defined behavior (methods). Also the ultimate base class of any new-style class.

**package**
A Python module which can contain submodules or recursively, subpackages. Technically, a package is a Python module with an `__path__` attribute.

**parameter**
A named entity in a function (or method) definition that specifies an argument (or in some cases, arguments) that the function can accept. There are four types of parameters:

- *positional-or-keyword*: specifies an argument that can be passed either **positionally** or as a **keyword argument**. This is the default kind of parameter, for example `foo` and `bar` in the
following:

```python
def func(foo, bar=None):
...
```

- **positional-only**: specifies an argument that can be supplied only by position. Python has no syntax for defining positional-only parameters. However, some built-in functions have positional-only parameters (e.g. `abs()`).

- **var-positional**: specifies that an arbitrary sequence of positional arguments can be provided (in addition to any positional arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with `*`, for example `args` in the following:

```python
def func(*args, **kwargs):
...
```

- **var-keyword**: specifies that arbitrarily many keyword arguments can be provided (in addition to any keyword arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with `**`, for example `kwargs` in the example above.

Parameters can specify both optional and required arguments, as well as default values for some optional arguments.

See also the argument glossary entry, the FAQ question on the difference between arguments and parameters, and the Function definitions section.

**positional argument**

See argument.

**Python 3000**

Nickname for the Python 3.x release line (coined long ago when the release of version 3 was something in the distant future.) This
is also abbreviated “Py3k”.

**Pythonic**

An idea or piece of code which closely follows the most common idioms of the Python language, rather than implementing code using concepts common to other languages. For example, a common idiom in Python is to loop over all elements of an iterable using a `for` statement. Many other languages don’t have this type of construct, so people unfamiliar with Python sometimes use a numerical counter instead:

```python
for i in range(len(food)):
    print food[i]
```

As opposed to the cleaner, Pythonic method:

```python
for piece in food:
    print piece
```

**reference count**

The number of references to an object. When the reference count of an object drops to zero, it is deallocated. Reference counting is generally not visible to Python code, but it is a key element of the CPython implementation. The `sys` module defines a `getrefcount()` function that programmers can call to return the reference count for a particular object.

**__slots__**

A declaration inside a **new-style class** that saves memory by pre-declaring space for instance attributes and eliminating instance dictionaries. Though popular, the technique is somewhat tricky to get right and is best reserved for rare cases where there are large numbers of instances in a memory-critical application.

**sequence**

An **iterable** which supports efficient element access using integer
indices via the __getitem__() special method and defines a len() method that returns the length of the sequence. Some built-in sequence types are list, str, tuple, and unicode. Note that dict also supports __getitem__() and __len__(), but is considered a mapping rather than a sequence because the lookups use arbitrary immutable keys rather than integers.

slice
An object usually containing a portion of a sequence. A slice is created using the subscript notation, [] with colons between numbers when several are given, such as in variable_name[1:3:5]. The bracket (subscript) notation uses slice objects internally (or in older versions, __getslice__() and __setslice__()).

special method
A method that is called implicitly by Python to execute a certain operation on a type, such as addition. Such methods have names starting and ending with double underscores. Special methods are documented in Special method names.

statement
A statement is part of a suite (a “block” of code). A statement is either an expression or one of several constructs with a keyword, such as if, while or for.

struct sequence
A tuple with named elements. Struct sequences expose an interface similar to named tuple in that elements can either be accessed either by index or as an attribute. However, they do not have any of the named tuple methods like _make() or _asdict(). Examples of struct sequences include sys.float_info and the return value of os.stat().

triple-quoted string
A string which is bound by three instances of either a quotation mark (" ) or an apostrophe ('). While they don't provide any functionality not available with single-quoted strings, they are useful for a number of reasons. They allow you to include unescaped single and double quotes within a string and they can span multiple lines without the use of the continuation character, making them especially useful when writing docstrings.

**type**

The type of a Python object determines what kind of object it is; every object has a type. An object’s type is accessible as its `__class__` attribute or can be retrieved with `type(obj)`.

**universal newlines**

A manner of interpreting text streams in which all of the following are recognized as ending a line: the Unix end-of-line convention `
`, the Windows convention `
`, and the old Macintosh convention ``. See [PEP 278](https://peps.python.org/pep-0278/) and [PEP 3116](https://peps.python.org/pep-03116/), as well as `str.splitlines()` for an additional use.

**virtual environment**

A cooperatively isolated runtime environment that allows Python users and applications to install and upgrade Python distribution packages without interfering with the behaviour of other Python applications running on the same system.

**virtual machine**

A computer defined entirely in software. Python’s virtual machine executes the bytecode emitted by the bytecode compiler.

**Zen of Python**

Listing of Python design principles and philosophies that are helpful in understanding and using the language. The listing can be found by typing “`import this`” at the interactive prompt.
About these documents

These documents are generated from reStructuredText sources by Sphinx, a document processor specifically written for the Python documentation.

Development of the documentation and its toolchain is an entirely volunteer effort, just like Python itself. If you want to contribute, please take a look at the Reporting Bugs page for information on how to do so. New volunteers are always welcome!

Many thanks go to:

- Fred L. Drake, Jr., the creator of the original Python documentation toolset and writer of much of the content;
- the Docutils project for creating reStructuredText and the Docutils suite;
- Fredrik Lundh for his Alternative Python Reference project from which Sphinx got many good ideas.
Many people have contributed to the Python language, the Python standard library, and the Python documentation. See Misc/ACKS in the Python source distribution for a partial list of contributors.

It is only with the input and contributions of the Python community that Python has such wonderful documentation – Thank You!
Reporting Bugs

Python is a mature programming language which has established a reputation for stability. In order to maintain this reputation, the developers would like to know of any deficiencies you find in Python.
Documentation bugs

If you find a bug in this documentation or would like to propose an improvement, please submit a bug report on the tracker. If you have a suggestion how to fix it, include that as well.

If you’re short on time, you can also email documentation bug reports to docs@python.org (behavioral bugs can be sent to python-list@python.org). ‘docs@’ is a mailing list run by volunteers; your request will be noticed, though it may take a while to be processed.

See also: Documentation bugs on the Python issue tracker
Using the Python issue tracker

Bug reports for Python itself should be submitted via the Python Bug Tracker (https://bugs.python.org/). The bug tracker offers a Web form which allows pertinent information to be entered and submitted to the developers.

The first step in filing a report is to determine whether the problem has already been reported. The advantage in doing so, aside from saving the developers time, is that you learn what has been done to fix it; it may be that the problem has already been fixed for the next release, or additional information is needed (in which case you are welcome to provide it if you can!). To do this, search the bug database using the search box on the top of the page.

If the problem you’re reporting is not already in the bug tracker, go back to the Python Bug Tracker and log in. If you don’t already have a tracker account, select the “Register” link or, if you use OpenID, one of the OpenID provider logos in the sidebar. It is not possible to submit a bug report anonymously.

Being now logged in, you can submit a bug. Select the “Create New” link in the sidebar to open the bug reporting form.

The submission form has a number of fields. For the “Title” field, enter a very short description of the problem; less than ten words is good. In the “Type” field, select the type of your problem; also select the “Component” and “Versions” to which the bug relates.

In the “Comment” field, describe the problem in detail, including what you expected to happen and what did happen. Be sure to include whether any extension modules were involved, and what hardware and software platform you were using (including version information as appropriate).
Each bug report will be assigned to a developer who will determine what needs to be done to correct the problem. You will receive an update each time action is taken on the bug.

See also:

**How to Report Bugs Effectively**
Article which goes into some detail about how to create a useful bug report. This describes what kind of information is useful and why it is useful.

**Bug Writing Guidelines**
Information about writing a good bug report. Some of this is specific to the Mozilla project, but describes general good practices.
Getting started contributing to Python yourself

Beyond just reporting bugs that you find, you are also welcome to submit patches to fix them. You can find more information on how to get started patching Python in the Python Developer’s Guide. If you have questions, the core-mentorship mailing list is a friendly place to get answers to any and all questions pertaining to the process of fixing issues in Python.

History and License
History of the software

Python was created in the early 1990s by Guido van Rossum at Stichting Mathematisch Centrum (CWI, see https://www.cwi.nl/) in the Netherlands as a successor of a language called ABC. Guido remains Python’s principal author, although it includes many contributions from others.

In 1995, Guido continued his work on Python at the Corporation for National Research Initiatives (CNRI, see https://www.cnri.reston.va.us/) in Reston, Virginia where he released several versions of the software.

In May 2000, Guido and the Python core development team moved to BeOpen.com to form the BeOpen PythonLabs team. In October of the same year, the PythonLabs team moved to Digital Creations (now Zope Corporation; see http://www.zope.com/). In 2001, the Python Software Foundation (PSF, see https://www.python.org/psf/) was formed, a non-profit organization created specifically to own Python-related Intellectual Property. Zope Corporation is a sponsoring member of the PSF.

All Python releases are Open Source (see https://opensource.org/ for the Open Source Definition). Historically, most, but not all, Python releases have also been GPL-compatible; the table below summarizes the various releases.

**Note:** GPL-compatible doesn’t mean that we’re distributing Python under the GPL. All Python licenses, unlike the GPL, let you distribute a modified version without making your changes open source. The GPL-compatible licenses make it possible to combine Python with other software that is released under the GPL; the others don’t.

Thanks to the many outside volunteers who have worked under Guido’s direction to make these releases possible.
1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 2.7.13 software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 2.7.13 alone or in any version, provided, however, that PSF's License Agreement and copyright, i.e., "Copyright © 2001-2016 Python Software Foundation; All Rights Reserved" are retained in Python 2.7.13 alone or in any derivative version prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 2.7.13 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee agrees to include in any such work a brief summary of the changes made to Python 2.7.13.

4. PSF is making Python 2.7.13 available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 2.7.13 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 2.7.13 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSSES RESULTING FROM THE USE OF PYTHON 2.7.13, OR OTHERWISE USING PYTHON 2.7.13 OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create a relationship of agency, partnership, or joint venture between PSF and Licensee.
Agreement does not grant permission to use PSF trademarks or trademark sense to endorse or promote products or services of a third party.

8. By copying, installing or otherwise using Python 2.7.13, Licensee agrees to be bound by the terms and conditions of this License Agreement.

BEOPEN.COM LICENSE AGREEMENT FOR PYTHON 2.0

BEOPEN PYTHON OPEN SOURCE LICENSE AGREEMENT
VERSION 1

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization ("Licensee") accessing and otherwise using this software in source or binary form and its associated documentation ("the Software").

2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, to reproduce, analyze, test, perform and/or display publicly works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.

3. BeOpen is making the Software available to Licensee on an "AS IS" basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF.

5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

6. This License Agreement shall be governed by and interpreted by the law of the State of California, excluding conflict of Nothing in this License Agreement shall be deemed to create agency, partnership, or joint venture between BeOpen and Lic
Agreement does not grant permission to use BeOpen trademarks in a trademark sense to endorse or promote products or services of a third party. As an exception, the "BeOpen Python" logos available at http://www.pythonlabs.com/logos.html may be used according to the permissions granted on that web page.

7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

CNRI LICENSE AGREEMENT FOR PYTHON 1.6.1

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 ("CNRI"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI's License Agreement and CNRI's notice, i.e., "Copyright © 1995-2001 Corporation for National Research Rights Reserved" are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI's License Agreement, Licensee may substitute the following text (omitting the quotes) is made available subject to the terms and conditions in CNRI's License Agreement. This Agreement together with Python 1.6.1 may be obtained from the Internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the Internet using the following URL: http://hdl.handle.net/1895.22/1013.

3. In the event Licensee prepares a derivative work that is based on Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.

4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS" BASIS. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATIONS OR WARRANTIES OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the Commonwealth of Virginia, excluding Virginia's conflict of law rules. Notwithstanding the foregoing, with regard to derivative works based on Python 1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. This License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee or any third party.

8. By clicking on the "ACCEPT" button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.
OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF SOFTWARE.
Licenses and Acknowledgements for Incorporated Software

This section is an incomplete, but growing list of licenses and acknowledgements for third-party software incorporated in the Python distribution.

Mersenne Twister

The `_random` module includes code based on a download from http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html. The following are the verbatim comments from the original code:

A C-program for MT19937, with initialization improved 2002/1/26
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using `init_genrand(seed)` or `init_by_array(init_key, key_length)`.  

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura
All rights reserved.

DISCLAIMER

This software was prepared as an account of work sponsored
agency of the United States Government. Neither the United
Government nor the University of California nor any of its
employees, makes any warranty, express or implied, or assume
liability or responsibility for the accuracy, completeness
usefulness of any information, apparatus, product, or
information, apparatus, product, or process disclosed, or
represents that its use would not infringe privately-owned
rights. Reference herein to any specific
commercial products, process, or service by trade name, trad
manufacturer, or otherwise, does not necessarily constitute
imply its endorsement, recommendation, or favoring by the
States Government or the University of California. The views
opinions of authors expressed herein do not necessarily
reflect those of the United States Government or the University
of California, and shall not be used for advertising or
endorsement purposes.
MD5 message digest algorithm

The source code for the md5 module contains the following notice:

Copyright (C) 1999, 2002 Aladdin Enterprises. All rights reserved.

This software is provided 'as-is', without any express or implied warranty. In no event will the authors be held liable for any arising from the use of this software.

Permission is granted to anyone to use this software for any purpose including commercial applications, and to alter it and redistribute it freely, subject to the following restrictions:

1. The origin of this software must not be misrepresented; you may not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.
2. Altered source versions must be plainly marked as such, and not misrepresented as being the original software.
3. This notice may not be removed or altered from any source distribution.

L. Peter Deutsch
ghost@aladdin.com

Independent implementation of MD5 (RFC 1321).

This code implements the MD5 Algorithm defined in RFC 1321, whose text is available at
    http://www.ietf.org/rfc/rfc1321.txt
The code is derived from the text of the RFC, including the test suite (section A.5) but excluding the rest of Appendix A. It does not include any code or documentation that is identified in the RFC as being copyrighted.

The original and principal author of md5.h is L. Peter Deutsch <ghost@aladdin.com>. Other authors are noted in the change history that follows (in reverse chronological order):

2002-04-13 lpd Removed support for non-ANSI compilers; removed references to Ghostscript; clarified derivation from RFC now handles byte order either statically or dynamically.
Asynchronous socket services

The `asynchat` and `asyncore` modules contain the following notice:

Copyright 1996 by Sam Rushing

All Rights Reserved

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Rushing not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL SAM RUSHING BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Cookie management

The `cookie` module contains the following notice:

Copyright 2000 by Timothy O'Malley <timo@alum.mit.edu>

All Rights Reserved

Permission to use, copy, modify, and distribute this software
Execution tracing

The `trace` module contains the following notice:

```plaintext

```
UUencode and UUdecode functions

The `uu` module contains the following notice:

```
Copyright 1994 by Lance Ellinghouse
Cathedral City, California Republic, United States of America.
   All Rights Reserved
Permission to use, copy, modify, and distribute this software and
its documentation for any purpose and without fee is hereby granted,
provided that the above copyright notice appear in all copies and
that the name of Lance Ellinghouse not be used in advertising or
publicity pertaining to distribution of the software without specific,
written prior permission.
LANCE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO
THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY
AND FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE
FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER
ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING
USED IN ADVERTISING OR PUBLICITY PERTAINING TO DISTRIBUTION
OF THE SOFTWARE WITHOUT SPECIFIC, WRITTEN PRIOR PERMISSION.

Modified by Jack Jansen, CWI, July 1995:
- Use binascii module to do the actual line-by-line conversion
  between ascii and binary. This results in a 1000-fold speedup
  version is still 5 times faster, though.
- Arguments more compliant with Python standard
```

XML Remote Procedure Calls

The `xmlrpcclib` module contains the following notice:

```
The XML-RPC client interface is

Copyright (c) 1999-2002 by Secret Labs AB
Copyright (c) 1999-2002 by Fredrik Lundh
```
By obtaining, using, and/or copying this software and/or its associated documentation, you agree that you have read, understood and will comply with the following terms and conditions:

Permission to use, copy, modify, and distribute this software and its associated documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear all copies, and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Secret Labs AB or the author not be used in advertising or publication pertaining to distribution of the software without specific, written prior permission.

SECRET LABS AB AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL SECRET LABS AB OR THE AUTHOR BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

test_epoll

The test_epoll contains the following notice:

INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN
CONTRACT, TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING OUT OF THE USE
OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

strtod and dtoa

The file Python/dtoa.c, which supplies C functions dtoa and strtod for conversion of C doubles to and from strings, is derived from the file of the same name by David M. Gay, currently available from http://www.netlib.org/fp/. The original file, as retrieved on March 16,
2009, contains the following copyright and licensing notice:

```c
****************************************************************
* The author of this software is David M. Gay.

* Copyright (c) 1991, 2000, 2001 by Lucent Technologies.

* Permission to use, copy, modify, and distribute this software
  without fee is hereby granted, provided that this entire
  notice is included in all copies of any software which is or
  includes or modification of this software and in all copies of
  the supporting documentation for such software.

* THIS SOFTWARE IS BEING PROVIDED "AS IS", WITHOUT ANY EXPRESS
  WARRANTY. IN PARTICULAR, NEITHER THE AUTHOR NOR LUCENT MAKE
  REPRESENTATION OR WARRANTY OF ANY KIND CONCERNING THE MERCHANDISE
  OF THIS SOFTWARE OR ITS FITNESS FOR ANY PARTICULAR PURPOSE.

****************************************************************
```

OpenSSL

The modules `hashlib`, `posix`, `ssl`, `crypt` use the OpenSSL library for added performance if made available by the operating system. Additionally, the Windows and Mac OS X installers for Python may include a copy of the OpenSSL libraries, so we include a copy of the OpenSSL license here:

**LICENSE ISSUES**

The OpenSSL toolkit stays under a dual license, i.e. both the conditions of the OpenSSL License and the original SSLeay license apply to this software. See below for the actual license texts. Actually both licenses are BSD-style Open Source licenses. In case of any license issues related to OpenSSL please contact openssl-core@openssl.org.

What’s New in Python

The “What’s New in Python” series of essays takes tours through the most important changes between major Python versions. They are a “must read” for anyone wishing to stay up-to-date after a new release.

- **What’s New in Python 2.7**
  - The Future for Python 2.x
  - Changes to the Handling of Deprecation Warnings
  - Python 3.1 Features
  - PEP 372: Adding an Ordered Dictionary to collections
  - PEP 378: Format Specifier for Thousands Separator
  - PEP 389: The argparse Module for Parsing Command Lines
  - PEP 391: Dictionary-Based Configuration For Logging
  - PEP 3106: Dictionary Views
  - PEP 3137: The memoryview Object
  - Other Language Changes
  - New and Improved Modules
  - Build and C API Changes
  - Other Changes and Fixes
  - Porting to Python 2.7
  - New Features Added to Python 2.7 Maintenance Releases
  - Acknowledgements

- **What’s New in Python 2.6**
  - Python 3.0
  - Changes to the Development Process
  - PEP 343: The ‘with’ statement
  - PEP 366: Explicit Relative Imports From a Main Module
  - PEP 370: Per-user site-packages Directory
  - PEP 371: The multiprocessing Package
  - PEP 3101: Advanced String Formatting
- PEP 3105: `print` As a Function
- PEP 3110: Exception-Handling Changes
- PEP 3112: Byte Literals
- PEP 3116: New I/O Library
- PEP 3118: Revised Buffer Protocol
- PEP 3119: Abstract Base Classes
- PEP 3127: Integer Literal Support and Syntax
- PEP 3129: Class Decorators
- PEP 3141: A Type Hierarchy for Numbers
- Other Language Changes
- New and Improved Modules
- Deprecations and Removals
- Build and C API Changes
- Porting to Python 2.6
- Acknowledgements

- **What’s New in Python 2.5**
  - PEP 308: Conditional Expressions
  - PEP 309: Partial Function Application
  - PEP 314: Metadata for Python Software Packages v1.1
  - PEP 328: Absolute and Relative Imports
  - PEP 338: Executing Modules as Scripts
  - PEP 341: Unified `try/except/finally`
  - PEP 342: New Generator Features
  - PEP 343: The ‘with’ statement
  - PEP 352: Exceptions as New-Style Classes

The Python Tutorial

Python is an easy to learn, powerful programming language. It has efficient high-level data structures and a simple but effective approach to object-oriented programming. Python’s elegant syntax and dynamic typing, together with its interpreted nature, make it an ideal language for scripting and rapid application development in many areas on most platforms.

The Python interpreter and the extensive standard library are freely available in source or binary form for all major platforms from the Python Web site, https://www.python.org/, and may be freely distributed. The same site also contains distributions of and pointers to many free third party Python modules, programs and tools, and additional documentation.

The Python interpreter is easily extended with new functions and data types implemented in C or C++ (or other languages callable from C). Python is also suitable as an extension language for customizable applications.

This tutorial introduces the reader informally to the basic concepts and features of the Python language and system. It helps to have a Python interpreter handy for hands-on experience, but all examples are self-contained, so the tutorial can be read off-line as well.

For a description of standard objects and modules, see The Python Standard Library. The Python Language Reference gives a more formal definition of the language. To write extensions in C or C++, read Extending and Embedding the Python Interpreter and Python/C API Reference Manual. There are also several books covering Python in depth.

This tutorial does not attempt to be comprehensive and cover every
single feature, or even every commonly used feature. Instead, it introduces many of Python's most noteworthy features, and will give you a good idea of the language's flavor and style. After reading it, you will be able to read and write Python modules and programs, and you will be ready to learn more about the various Python library modules described in The Python Standard Library.

The Glossary is also worth going through.

    ■ 15.1.3. The Interactive Startup File
    ■ 15.1.4. The Customization Modules
While The Python Language Reference describes the exact syntax and semantics of the Python language, this library reference manual describes the standard library that is distributed with Python. It also describes some of the optional components that are commonly included in Python distributions.

Python’s standard library is very extensive, offering a wide range of facilities as indicated by the long table of contents listed below. The library contains built-in modules (written in C) that provide access to system functionality such as file I/O that would otherwise be inaccessible to Python programmers, as well as modules written in Python that provide standardized solutions for many problems that occur in everyday programming. Some of these modules are explicitly designed to encourage and enhance the portability of Python programs by abstracting away platform-specifics into platform-neutral APIs.

The Python installers for the Windows platform usually include the entire standard library and often also include many additional components. For Unix-like operating systems Python is normally provided as a collection of packages, so it may be necessary to use the packaging tools provided with the operating system to obtain some or all of the optional components.

In addition to the standard library, there is a growing collection of several thousand components (from individual programs and modules to packages and entire application development frameworks), available from the Python Package Index.

- 1. Introduction
- 2. Built-in Functions
- 3. Non-essential Built-in Functions
• 4. Built-in Constants
  ○ 4.1. Constants added by the site module

• 5. Built-in Types
  ○ 5.1. Truth Value Testing
  ○ 5.2. Boolean Operations — and, or, not
  ○ 5.3. Comparisons
  ○ 5.4. Numeric Types — int, float, long, complex
  ○ 5.5. Iterator Types
  ○ 5.6. Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange
  ○ 5.7. Set Types — set, frozenset
  ○ 5.8. Mapping Types — dict
  ○ 5.9. File Objects
  ○ 5.10. memoryview type
  ○ 5.11. Context Manager Types
  ○ 5.12. Other Built-in Types
  ○ 5.13. Special Attributes

• 6. Built-in Exceptions
  ○ 6.1. Exception hierarchy

• 7. String Services
  ○ 7.1. string — Common string operations
  ○ 7.2. re — Regular expression operations
  ○ 7.3. struct — Interpret strings as packed binary data
  ○ 7.4. difflib — Helpers for computing deltas
  ○ 7.5. StringIO — Read and write strings as files
  ○ 7.6. cStringIO — Faster version of StringIO
  ○ 7.7. textwrap — Text wrapping and filling
  ○ 7.8. codecs — Codec registry and base classes
  ○ 7.9. unicodedata — Unicode Database
  ○ 7.10. stringprep — Internet String Preparation
  ○ 7.11. fpformat — Floating point conversions

• 8. Data Types
8.1. **datetime** — Basic date and time types
8.2. **calendar** — General calendar-related functions
8.3. **collections** — High-performance container datatypes
8.4. **heapq** — Heap queue algorithm
8.5. **bisect** — Array bisection algorithm
8.6. **array** — Efficient arrays of numeric values
8.7. **sets** — Unordered collections of unique elements
8.8. **sched** — Event scheduler
8.9. **mutex** — Mutual exclusion support
8.10. **Queue** — A synchronized queue class
8.11. **weakref** — Weak references
8.12. **UserDict** — Class wrapper for dictionary objects
8.13. **UserList** — Class wrapper for list objects
8.14. **UserString** — Class wrapper for string objects
8.15. **types** — Names for built-in types
8.16. **new** — Creation of runtime internal objects
8.17. **copy** — Shallow and deep copy operations
8.18. **pprint** — Data pretty printer
8.19. **repr** — Alternate `repr()` implementation

9. Numeric and Mathematical Modules
9.1. **numbers** — Numeric abstract base classes
9.2. **math** — Mathematical functions
9.3. **cmath** — Mathematical functions for complex numbers
9.4. **decimal** — Decimal fixed point and floating point arithmetic
9.5. **fractions** — Rational numbers
9.6. **random** — Generate pseudo-random numbers
9.7. **itertools** — Functions creating iterators for efficient looping
9.8. **functools** — Higher-order functions and operations on callable objects
9.9. **operator** — Standard operators as functions

- **10. File and Directory Access**
  - 10.1. **os.path** — Common pathname manipulations
  - 10.2. **fileinput** — Iterate over lines from multiple input streams
  - 10.3. **stat** — Interpreting `stat()` results
  - 10.4. **statvfs** — Constants used with `os.statvfs()`
  - 10.5. **filecmp** — File and Directory Comparisons
  - 10.6. **tempfile** — Generate temporary files and directories
  - 10.7. **glob** — Unix style pathname pattern expansion
  - 10.8. **fnmatch** — Unix filename pattern matching
  - 10.9. **linecache** — Random access to text lines
  - 10.10. **shutil** — High-level file operations
  - 10.11. **dircache** — Cached directory listings
  - 10.12. **macpath** — Mac OS 9 path manipulation functions

- **11. Data Persistence**
  - 11.1. **pickle** — Python object serialization
  - 11.2. **cPickle** — A faster `pickle`
  - 11.3. **copy_reg** — Register `pickle` support functions
  - 11.4. **shelve** — Python object persistence
  - 11.5. **marshal** — Internal Python object serialization
  - 11.6. **anydbm** — Generic access to DBM-style databases
  - 11.7. **whichdb** — Guess which DBM module created a database
  - 11.8. **dbm** — Simple “database” interface
  - 11.9. **gdbm** — GNU’s reinterpretation of dbm
  - 11.10. **dbhash** — DBM-style interface to the BSD database library
  - 11.11. **bsddb** — Interface to Berkeley DB library
  - 11.12. **dumbdbm** — Portable DBM implementation
  - 11.13. **sqlite3** — DB-API 2.0 interface for SQLite
databases

- **12. Data Compression and Archiving**
  - 12.1. **zlib** — Compression compatible with **gzip**
  - 12.2. **gzip** — Support for **gzip** files
  - 12.3. **bz2** — Compression compatible with **bzip2**
  - 12.4. **zipfile** — Work with ZIP archives
  - 12.5. **tarfile** — Read and write tar archive files

- **13. File Formats**
  - 13.1. **csv** — CSV File Reading and Writing
  - 13.2. **ConfigParser** — Configuration file parser
  - 13.3. **robotparser** — Parser for robots.txt
  - 13.4. **netrc** — netrc file processing
  - 13.5. **xdrplib** — Encode and decode XDR data
  - 13.6. **plistlib** — Generate and parse Mac OS X .plist files

- **14. Cryptographic Services**
  - 14.1. **hashlib** — Secure hashes and message digests
  - 14.2. **hmac** — Keyed-Hashing for Message Authentication
  - 14.3. **md5** — MD5 message digest algorithm
  - 14.4. **sha** — SHA-1 message digest algorithm

- **15. Generic Operating System Services**
  - 15.1. **os** — Miscellaneous operating system interfaces
  - 15.2. **io** — Core tools for working with streams
  - 15.3. **time** — Time access and conversions
  - 15.4. **argparse** — Parser for command-line options, arguments and sub-commands
  - 15.5. **optparse** — Parser for command line options
  - 15.6. **getopt** — C-style parser for command line options
  - 15.7. **logging** — Logging facility for Python
  - 15.8. **logging.config** — Logging configuration
  - 15.9. **logging.handlers** — Logging handlers
• 15.10. `getpass` — Portable password input
• 15.11. `curses` — Terminal handling for character-cell displays
• 15.12. `curses.textpad` — Text input widget for curses programs
• 15.13. `curses.ascii` — Utilities for ASCII characters
• 15.14. `curses.panel` — A panel stack extension for curses
• 15.15. `platform` — Access to underlying platform’s identifying data
• 15.16. `errno` — Standard errno system symbols
• 15.17. `ctypes` — A foreign function library for Python

• 16. Optional Operating System Services
  • 16.1. `select` — Waiting for I/O completion
  • 16.2. `threading` — Higher-level threading interface
  • 16.3. `thread` — Multiple threads of control
  • 16.4. `dummy_threading` — Drop-in replacement for the `threading` module
  • 16.5. `dummy_thread` — Drop-in replacement for the `thread` module
  • 16.6. `multiprocessing` — Process-based “threading” interface
  • 16.7. `mmap` — Memory-mapped file support
  • 16.8. `readline` — GNU readline interface
  • 16.9. `rlcompleter` — Completion function for GNU readline

• 17. Interprocess Communication and Networking
  • 17.1. `subprocess` — Subprocess management
  • 17.2. `socket` — Low-level networking interface
  • 17.3. `ssl` — TLS/SSL wrapper for socket objects
  • 17.4. `signal` — Set handlers for asynchronous events
  • 17.5. `popen2` — Subprocesses with accessible I/O streams
  • 17.6. `asyncore` — Asynchronous socket handler
17.7. `asynchat` — Asynchronous socket command/response handler

18. Internet Data Handling
- 18.1. `email` — An email and MIME handling package
- 18.2. `json` — JSON encoder and decoder
- 18.3. `mailcap` — Mailcap file handling
- 18.4. `mailbox` — Manipulate mailboxes in various formats
- 18.5. `mhlib` — Access to MH mailboxes
- 18.6. `mimetools` — Tools for parsing MIME messages
- 18.7. `mimetypes` — Map filenames to MIME types
- 18.8. `MimeWriter` — Generic MIME file writer
- 18.9. `mimify` — MIME processing of mail messages
- 18.10. `multifile` — Support for files containing distinct parts
- 18.11. `rfc822` — Parse RFC 2822 mail headers
- 18.12. `base64` — RFC 3548: Base16, Base32, Base64 Data Encodings
- 18.13. `binhex` — Encode and decode binhex4 files
- 18.14. `binascii` — Convert between binary and ASCII
- 18.15. `quopri` — Encode and decode MIME quoted-printable data
- 18.16. `uu` — Encode and decode uuencode files

19. Structured Markup Processing Tools
- 19.1. `HTMLParser` — Simple HTML and XHTML parser
- 19.2. `sgmllib` — Simple SGML parser
- 19.3. `httplib` — A parser for HTML documents
- 19.4. `htmlentitydefs` — Definitions of HTML general entities
- 19.5. XML Processing Modules
- 19.6. XML vulnerabilities
- 19.7. `xml.etree.ElementTree` — The ElementTree XML API
19.8. `xml.dom` — The Document Object Model API
19.9. `xml.dom.minidom` — Minimal DOM implementation
19.10. `xml.dom.pulldom` — Support for building partial DOM trees
19.11. `xml.sax` — Support for SAX2 parsers
19.12. `xml.sax.handler` — Base classes for SAX handlers
19.13. `xml.sax.saxutils` — SAX Utilities
19.14. `xml.sax.xmlreader` — Interface for XML parsers
19.15. `xml.parsers.expat` — Fast XML parsing using Expat

20. Internet Protocols and Support
20.1. `webbrowser` — Convenient Web-browser controller
20.2. `cgi` — Common Gateway Interface support
20.3. `cgitb` — Traceback manager for CGI scripts
20.4. `wsgiref` — WSGI Utilities and Reference Implementation
20.5. `urllib` — Open arbitrary resources by URL
20.6. `urllib2` — extensible library for opening URLs
20.7. `httplib` — HTTP protocol client
20.8. `ftplib` — FTP protocol client
20.9. `poplib` — POP3 protocol client
20.10. `imaplib` — IMAP4 protocol client
20.11. `nntplib` — NNTP protocol client
20.12. `smtplib` — SMTP protocol client
20.13. `smtpd` — SMTP Server
20.14. `telnetlib` — Telnet client
20.15. `uuid` — UUID objects according to RFC 4122
20.16. `urlparse` — Parse URLs into components
20.17. `SocketServer` — A framework for network servers
20.18. `BaseHTTPServer` — Basic HTTP server
20.19. `SimpleHTTPServer` — Simple HTTP request handler
20.20. `CGIHTTPServer` — CGI-capable HTTP request
• 20.21. cookie — Cookie handling for HTTP clients
• 20.22. Cookie — HTTP state management
• 20.23. xmlrpclib — XML-RPC client access
• 20.24. SimpleXMLRPCServer — Basic XML-RPC server
• 20.25. DocXMLRPCServer — Self-documenting XML-RPC server

• 21. Multimedia Services
  • 21.1. audioop — Manipulate raw audio data
  • 21.2. imageop — Manipulate raw image data
  • 21.3. aifc — Read and write AIFF and AIFC files
  • 21.4. sunau — Read and write Sun AU files
  • 21.5. wave — Read and write WAV files
  • 21.6. chunk — Read IFF chunked data
  • 21.7. colorsys — Conversions between color systems
  • 21.8. imghdr — Determine the type of an image
  • 21.9. sndhdr — Determine type of sound file
  • 21.10. ossaudiodev — Access to OSS-compatible audio devices

• 22. Internationalization
  • 22.1. gettext — Multilingual internationalization services
  • 22.2. locale — Internationalization services

• 23. Program Frameworks
  • 23.1. cmd — Support for line-oriented command interpreters
  • 23.2. shlex — Simple lexical analysis

• 24. Graphical User Interfaces with Tk
  • 24.1. Tkinter — Python interface to Tcl/Tk
  • 24.2. ttk — Tk themed widgets
  • 24.3. Tix — Extension widgets for Tk
  • 24.4. ScrolledText — Scrolled Text Widget
  • 24.5. turtle — Turtle graphics for Tk
24.6. IDLE
24.7. Other Graphical User Interface Packages

25. Development Tools
25.1. pydoc — Documentation generator and online help system
25.2. doctest — Test interactive Python examples
25.3. unittest — Unit testing framework
25.4. 2to3 - Automated Python 2 to 3 code translation
25.5. test — Regression tests package for Python
25.6. test.test_support — Utility functions for tests

26. Debugging and Profiling
26.1. bdb — Debugger framework
26.2. pdb — The Python Debugger
26.3. Debugger Commands
26.4. The Python Profilers
26.5. hotshot — High performance logging profiler
26.6. timeit — Measure execution time of small code snippets
26.7. trace — Trace or track Python statement execution

27. Software Packaging and Distribution
27.1. distutils — Building and installing Python modules
27.2. ensurepip — Bootstrapping the pip installer

28. Python Runtime Services
28.1. sys — System-specific parameters and functions
28.2. sysconfig — Provide access to Python’s configuration information
28.3. __builtin__ — Built-in objects
28.4. future_builtins — Python 3 builtins
28.5. __main__ — Top-level script environment
28.6. warnings — Warning control
28.7. contextlib — Utilities for with-statement contexts
28.8. abc — Abstract Base Classes
28.9. `atexit` — Exit handlers
28.10. `traceback` — Print or retrieve a stack traceback
28.11. `__future__` — Future statement definitions
28.12. `gc` — Garbage Collector interface
28.13. `inspect` — Inspect live objects
28.14. `site` — Site-specific configuration hook
28.15. `user` — User-specific configuration hook
28.16. `fpectl` — Floating point exception control

29. Custom Python Interpreters
29.1. `code` — Interpreter base classes
29.2. `codeop` — Compile Python code

30. Restricted Execution
30.1. `rexec` — Restricted execution framework
30.2. `Bastion` — Restricting access to objects

31. Importing Modules
31.1. `imp` — Access the `import` internals
31.2. `importlib` — Convenience wrappers for `__import__()`
31.3. `imputil` — Import utilities
31.4. `zipimport` — Import modules from Zip archives
31.5. `pkgutil` — Package extension utility
31.6. `modulefinder` — Find modules used by a script
31.7. `runpy` — Locating and executing Python modules

32. Python Language Services
32.1. `parser` — Access Python parse trees
32.2. `ast` — Abstract Syntax Trees
32.3. `symtable` — Access to the compiler’s symbol tables
32.4. `symbol` — Constants used with Python parse trees
32.5. `token` — Constants used with Python parse trees
32.6. `keyword` — Testing for Python keywords
32.7. `tokenize` — Tokenizer for Python source
32.8. `tabnanny` — Detection of ambiguous indentation
32.9. pyc1br — Python class browser support
32.10. py_compile — Compile Python source files
32.11. compileall — Byte-compile Python libraries
32.12. dis — Disassembler for Python bytecode
32.13. pickletools — Tools for pickle developers

33. Python compiler package
   33.1. The basic interface
   33.2. Limitations

   33.4. Using Visitors to Walk ASTs
   33.5. Bytecode Generation

34. Miscellaneous Services
   34.1. formatter — Generic output formatting

35. MS Windows Specific Services
   35.1. msilib — Read and write Microsoft Installer files
   35.2. msvcrt — Useful routines from the MS VC++ runtime
   35.3. _winreg — Windows registry access
   35.4. winsound — Sound-playing interface for Windows

36. Unix Specific Services
   36.1. posix — The most common POSIX system calls
   36.2. pwd — The password database
   36.3. spwd — The shadow password database
   36.4. grp — The group database
   36.5. crypt — Function to check Unix passwords
   36.6. dl — Call C functions in shared objects
   36.7. termios — POSIX style tty control
   36.8. tty — Terminal control functions
   36.9. pty — Pseudo-terminal utilities
   36.10. fcntl — The fcntl and ioctl system calls
   36.11. pipes — Interface to shell pipelines
   36.12. posixfile — File-like objects with locking support
- 36.13. resource — Resource usage information
- 36.14. nis — Interface to Sun's NIS (Yellow Pages)
- 36.15. syslog — Unix syslog library routines
- 36.16. commands — Utilities for running commands

- 37. Mac OS X specific services
  - 37.1. ic — Access to the Mac OS X Internet Config
  - 37.2. MacOS — Access to Mac OS interpreter features
  - 37.3. macostools — Convenience routines for file manipulation
  - 37.4. findertools — The finder's Apple Events interface
  - 37.5. EasyDialogs — Basic Macintosh dialogs
  - 37.6. FrameWork — Interactive application framework
  - 37.7. autoGIL — Global Interpreter Lock handling in event loops
  - 37.8. Mac OS Toolbox Modules
  - 37.9. ColorPicker — Color selection dialog

- 38. MacPython OSA Modules
  - 38.1. gensuitemodule — Generate OSA stub packages
  - 38.2. aetools — OSA client support
  - 38.3. aepack — Conversion between Python variables and AppleEvent data containers
  - 38.4. aetypes — AppleEvent objects
  - 38.5. MiniAEFrame — Open Scripting Architecture server support

- 39. SGI IRIX Specific Services
  - 39.1. a1 — Audio functions on the SGI
  - 39.2. AL — Constants used with the a1 module
  - 39.3. cd — CD-ROM access on SGI systems
  - 39.4. f1 — FORMS library for graphical user interfaces
  - 39.5. FL — Constants used with the f1 module
  - 39.6. flp — Functions for loading stored FORMS designs
39.7. fm — *Font Manager* interface
39.8. gl — *Graphics Library* interface
39.9. **DEVICE** — Constants used with the **gl** module
39.10. **GL** — Constants used with the **gl** module
39.11. **imgfile** — Support for SGI imglib files
39.12. **jpeg** — Read and write JPEG files

- **40. SunOS Specific Services**
  - 40.1. **sunaudiodev** — Access to Sun audio hardware
  - 40.2. **SUNAUDIODEV** — Constants used with **sunaudiodev**

- **41. Undocumented Modules**
  - 41.1. Miscellaneous useful utilities
  - 41.2. Platform specific modules
  - 41.3. Multimedia
  - 41.4. Undocumented Mac OS modules
  - 41.5. Obsolete
  - 41.6. SGI-specific Extension modules
The Python Language Reference

This reference manual describes the syntax and “core semantics” of the language. It is terse, but attempts to be exact and complete. The semantics of non-essential built-in object types and of the built-in functions and modules are described in The Python Standard Library. For an informal introduction to the language, see The Python Tutorial. For C or C++ programmers, two additional manuals exist: Extending and Embedding the Python Interpreter describes the high-level picture of how to write a Python extension module, and the Python/C API Reference Manual describes the interfaces available to C/C++ programmers in detail.

- 1. Introduction
  - 1.1. Alternate Implementations
  - 1.2. Notation

4.6. Other Resources
Python HOWTOs

Python HOWTOs are documents that cover a single, specific topic, and attempt to cover it fairly completely. Modelled on the Linux Documentation Project’s HOWTO collection, this collection is an effort to foster documentation that’s more detailed than the Python Library Reference.

Currently, the HOWTOs are:

- Porting Python 2 Code to Python 3
- Porting Extension Modules to Python 3
- Curses Programming with Python
- Descriptor HowTo Guide
- Idioms and Anti-Idioms in Python
- Functional Programming HOWTO
- Logging HOWTO
- Logging Cookbook
- Regular Expression HOWTO
- Socket Programming HOWTO
- Sorting HOW TO
- Unicode HOWTO
- HOWTO Fetch Internet Resources Using urllib2
- HOWTO Use Python in the web
- Argparse Tutorial
Installing Python Modules

Email: distutils-sig@python.org

As a popular open source development project, Python has an active supporting community of contributors and users that also make their software available for other Python developers to use under open source license terms.

This allows Python users to share and collaborate effectively, benefiting from the solutions others have already created to common (and sometimes even rare!) problems, as well as potentially contributing their own solutions to the common pool.

This guide covers the installation part of the process. For a guide to creating and sharing your own Python projects, refer to the distribution guide.

Note: For corporate and other institutional users, be aware that many organisations have their own policies around using and contributing to open source software. Please take such policies into account when making use of the distribution and installation tools provided with Python.
Key terms

- **pip** is the preferred installer program. Starting with Python 2.7.9, it is included by default with the Python binary installers.
- A virtual environment is a semi-isolated Python environment that allows packages to be installed for use by a particular application, rather than being installed system-wide.
- **virtualenv** is a third party tool for creating virtual environments; it defaults to installing `pip` into all created virtual environments.
- The **Python Packaging Index** is a public repository of open source licensed packages made available for use by other Python users.
- The **Python Packaging Authority** are the group of developers and documentation authors responsible for the maintenance and evolution of the standard packaging tools and the associated metadata and file format standards. They maintain a variety of tools, documentation and issue trackers on both GitHub and BitBucket.
- **distutils** is the original build and distribution system first added to the Python standard library in 1998. While direct use of **distutils** is being phased out, it still laid the foundation for the current packaging and distribution infrastructure, and it not only remains part of the standard library, but its name lives on in other ways (such as the name of the mailing list used to coordinate Python packaging standards development).
Basic usage

The standard packaging tools are all designed to be used from the command line.

The following command will install the latest version of a module and its dependencies from the Python Packaging Index:

```
python -m pip install SomePackage
```

**Note:** For POSIX users (including Mac OS X and Linux users), the examples in this guide assume the use of a virtual environment. You may install virtualenv to provide such environments using either pip (``pip install virtualenv``) or through your system package manager (commonly called virtualenv or python-virtualenv).

For Windows users, the examples in this guide assume that the option to adjust the system PATH environment variable was selected when installing Python.

It's also possible to specify an exact or minimum version directly on the command line. When using comparator operators such as `>`, `<` or some other special character which get interpreted by shell, the package name and the version should be enclosed within double quotes:

```
python -m pip install SomePackage==1.0.4    # specific version
python -m pip install "SomePackage>=1.0.4"  # minimum version
```

Normally, if a suitable module is already installed, attempting to install it again will have no effect. Upgrading existing modules must be requested explicitly:
python -m pip install --upgrade SomePackage

More information and resources regarding pip and its capabilities can be found in the Python Packaging User Guide.

See also: Python Packaging User Guide: Installing Python Distribution Packages
How do I ...?

These are quick answers or links for some common tasks.

... install `pip` in versions of Python prior to Python 2.7.9?

Python only started bundling `pip` with Python 2.7.9. For earlier versions, `pip` needs to be “bootstrapped” as described in the Python Packaging User Guide.

**See also:** [Python Packaging User Guide: Requirements for Installing Packages](#)

... install packages just for the current user?

Passing the `--user` option to `python -m pip install` will install a package just for the current user, rather than for all users of the system.

... install scientific Python packages?

A number of scientific Python packages have complex binary dependencies, and aren’t currently easy to install using `pip` directly. At this point in time, it will often be easier for users to install these packages by **other means** rather than attempting to install them with `pip`.

**See also:** [Python Packaging User Guide: Installing Scientific Packages](#)
... work with multiple versions of Python installed in parallel?

On Linux, Mac OS X and other POSIX systems, use the versioned Python commands in combination with the `-m` switch to run the appropriate copy of `pip`:

```
python2   -m pip install SomePackage  # default Python 2
python2.7 -m pip install SomePackage  # specifically Python 2.7
python3   -m pip install SomePackage  # default Python 3
python3.4 -m pip install SomePackage  # specifically Python 3.4
```

(appropriately versioned `pip` commands may also be available)

On Windows, use the `py` Python launcher in combination with the `-m` switch:

```
py -2    -m pip install SomePackage  # default Python 2
py -2.7  -m pip install SomePackage  # specifically Python 2.7
py -3    -m pip install SomePackage  # default Python 3
py -3.4  -m pip install SomePackage  # specifically Python 3.4
```
Common installation issues

Installing into the system Python on Linux

On Linux systems, a Python installation will typically be included as part of the distribution. Installing into this Python installation requires root access to the system, and may interfere with the operation of the system package manager and other components of the system if a component is unexpectedly upgraded using `pip`.

On such systems, it is often better to use a virtual environment or a per-user installation when installing packages with `pip`.

Installing binary extensions

Python has typically relied heavily on source based distribution, with end users being expected to compile extension modules from source as part of the installation process.

With the introduction of support for the binary `wheel` format, and the ability to publish wheels for at least Windows and Mac OS X through the Python Packaging Index, this problem is expected to diminish over time, as users are more regularly able to install pre-built extensions rather than needing to build them themselves.

Some of the solutions for installing scientific software that is not yet available as pre-built `wheel` files may also help with obtaining other binary extensions without needing to build them locally.

See also: Python Packaging User Guide: Binary Extensions
As a popular open source development project, Python has an active supporting community of contributors and users that also make their software available for other Python developers to use under open source license terms.

This allows Python users to share and collaborate effectively, benefiting from the solutions others have already created to common (and sometimes even rare!) problems, as well as potentially contributing their own solutions to the common pool.

This guide covers the distribution part of the process. For a guide to installing other Python projects, refer to the installation guide.

**Note:** For corporate and other institutional users, be aware that many organisations have their own policies around using and contributing to open source software. Please take such policies into account when making use of the distribution and installation tools provided with Python.
Key terms

- **the Python Packaging Index** is a public repository of open source licensed packages made available for use by other Python users.
- **the Python Packaging Authority** are the group of developers and documentation authors responsible for the maintenance and evolution of the standard packaging tools and the associated metadata and file format standards. They maintain a variety of tools, documentation and issue trackers on both GitHub and BitBucket.
- **distutils** is the original build and distribution system first added to the Python standard library in 1998. While direct use of **distutils** is being phased out, it still laid the foundation for the current packaging and distribution infrastructure, and it not only remains part of the standard library, but its name lives on in other ways (such as the name of the mailing list used to coordinate Python packaging standards development).
- **setuptools** is a (largely) drop-in replacement for **distutils** first published in 2004. Its most notable addition over the unmodified **distutils** tools was the ability to declare dependencies on other packages. It is currently recommended as a more regularly updated alternative to **distutils** that offers consistent support for more recent packaging standards across a wide range of Python versions.
- **wheel** (in this context) is a project that adds the `bdist_wheel` command to **distutils/setuptools**. This produces a cross platform binary packaging format (called “wheels” or “wheel files” and defined in PEP 427) that allows Python libraries, even those including binary extensions, to be installed on a system without needing to be built locally.
Open source licensing and collaboration

In most parts of the world, software is automatically covered by copyright. This means that other developers require explicit permission to copy, use, modify and redistribute the software.

Open source licensing is a way of explicitly granting such permission in a relatively consistent way, allowing developers to share and collaborate efficiently by making common solutions to various problems freely available. This leaves many developers free to spend more time focusing on the problems that are relatively unique to their specific situation.

The distribution tools provided with Python are designed to make it reasonably straightforward for developers to make their own contributions back to that common pool of software if they choose to do so.

The same distribution tools can also be used to distribute software within an organisation, regardless of whether that software is published as open source software or not.
Installing the tools

The standard library does not include build tools that support modern Python packaging standards, as the core development team has found that it is important to have standard tools that work consistently, even on older versions of Python.

The currently recommended build and distribution tools can be installed by invoking the `pip` module at the command line:

```
python -m pip install setuptools wheel twine
```

**Note:** For POSIX users (including Mac OS X and Linux users), these instructions assume the use of a virtual environment.

For Windows users, these instructions assume that the option to adjust the system PATH environment variable was selected when installing Python.

The Python Packaging User Guide includes more details on the currently recommended tools.
The Python Packaging User Guide covers the various key steps and elements involved in creating a project:

- Project structure
- Building and packaging the project
- Uploading the project to the Python Packaging Index
How do I...?

These are quick answers or links for some common tasks.

... choose a name for my project?

This isn’t an easy topic, but here are a few tips:

- check the Python Packaging Index to see if the name is already in use
- check popular hosting sites like GitHub, BitBucket, etc to see if there is already a project with that name
- check what comes up in a web search for the name you’re considering
- avoid particularly common words, especially ones with multiple meanings, as they can make it difficult for users to find your software when searching for it

... create and distribute binary extensions?

This is actually quite a complex topic, with a variety of alternatives available depending on exactly what you’re aiming to achieve. See the Python Packaging User Guide for more information and recommendations.

**See also:** [Python Packaging User Guide: Binary Extensions](python-packaging-user-guide-binary-extensions)
Extending and Embedding the Python Interpreter

This document describes how to write modules in C or C++ to extend the Python interpreter with new modules. Those modules can not only define new functions but also new object types and their methods. The document also describes how to embed the Python interpreter in another application, for use as an extension language. Finally, it shows how to compile and link extension modules so that they can be loaded dynamically (at run time) into the interpreter, if the underlying operating system supports this feature.

This document assumes basic knowledge about Python. For an informal introduction to the language, see The Python Tutorial. The Python Language Reference gives a more formal definition of the language. The Python Standard Library documents the existing object types, functions and modules (both built-in and written in Python) that give the language its wide application range.

For a detailed description of the whole Python/C API, see the separate Python/C API Reference Manual.

Note: This guide only covers the basic tools for creating extensions provided as part of this version of CPython. Third party tools may offer simpler alternatives. Refer to the binary extensions section in the Python Packaging User Guide for more information.

Build and C API Changes
Port-Specific Changes

- Porting to Python 2.4
- Acknowledgements

What’s New in Python 2.3

- PEP 218: A Standard Set Datatype
- PEP 255: Simple Generators
- PEP 263: Source Code Encodings
- PEP 273: Importing Modules from ZIP Archives
- PEP 277: Unicode file name support for Windows NT
- PEP 278: Universal Newline Support
- PEP 279: enumerate()
- PEP 282: The logging Package
- PEP 285: A Boolean Type
- PEP 293: Codec Error Handling Callbacks
- PEP 301: Package Index and Metadata for Distutils
- PEP 302: New Import Hooks
- PEP 305: Comma-separated Files
- PEP 307: Pickle Enhancements
- Extended Slices
- Other Language Changes
  - String Changes
  - Optimizations
- New, Improved, and Deprecated Modules
  - Date/Time Type
  - The optparse Module
- Pymalloc: A Specialized Object Allocator
- Build and C API Changes
  - Port-Specific Changes
- Other Changes and Fixes
- Porting to Python 2.3
- Acknowledgements

What’s New in Python 2.2

- Introduction
- PEPs 252 and 253: Type and Class Changes
Old and New Classes
- Descriptors
  - Multiple Inheritance: The Diamond Rule
  - Attribute Access
  - Related Links
- PEP 234: Iterators
- PEP 255: Simple Generators
- PEP 237: Unifying Long Integers and Integers
- PEP 238: Changing the Division Operator
- Unicode Changes
- PEP 227: Nested Scopes
- New and Improved Modules
- Interpreter Changes and Fixes
- Other Changes and Fixes
- Acknowledgements

- What’s New in Python 2.1
  - Introduction
  - PEP 227: Nested Scopes
  - PEP 236: __future__ Directives
  - PEP 207: Rich Comparisons
  - PEP 230: Warning Framework
  - PEP 229: New Build System
  - PEP 205: Weak References
  - PEP 232: Function Attributes
  - PEP 235: Importing Modules on Case-Insensitive Platforms
  - PEP 217: Interactive Display Hook
  - PEP 208: New Coercion Model
  - PEP 241: Metadata in Python Packages
  - New and Improved Modules
  - Other Changes and Fixes
  - Acknowledgements

- What’s New in Python 2.0
  - Introduction
• What About Python 1.6?
• New Development Process
• Unicode
• List Comprehensions
• Augmented Assignment
• String Methods
• Garbage Collection of Cycles
• Other Core Changes
  • Minor Language Changes
  • Changes to Built-in Functions
• Porting to 2.0
• Extending/Embedding Changes
• Distutils: Making Modules Easy to Install
• XML Modules
  • SAX2 Support
  • DOM Support
  • Relationship to PyXML
• Module changes
• New modules
• IDLE Improvements
• Deleted and Deprecated Modules
• Acknowledgements

The Python Tutorial
  • 1. Whetting Your Appetite
  • 2. Using the Python Interpreter
    • 2.1. Invoking the Interpreter
      • 2.1.1. Argument Passing
      • 2.1.2. Interactive Mode
    • 2.2. The Interpreter and Its Environment
      • 2.2.1. Source Code Encoding
  • 3. An Informal Introduction to Python
    • 3.1. Using Python as a Calculator
      • 3.1.1. Numbers
      • 3.1.2. Strings
3.1.3. Unicode Strings
3.1.4. Lists
3.2. First Steps Towards Programming
4. More Control Flow Tools
  4.1. if Statements
  4.2. for Statements
  4.3. The range() Function
  4.4. break and continue Statements, and else Clauses on Loops
  4.5. pass Statements
  4.6. Defining Functions
  4.7. More on Defining Functions
    4.7.1. Default Argument Values
    4.7.2. Keyword Arguments
    4.7.3. Arbitrary Argument Lists
    4.7.4. Unpacking Argument Lists
    4.7.5. Lambda Expressions
    4.7.6. Documentation Strings
  4.8. Intermezzo: Coding Style
5. Data Structures
  5.1. More on Lists
    5.1.1. Using Lists as Stacks
    5.1.2. Using Lists as Queues
    5.1.3. Functional Programming Tools
    5.1.4. List Comprehensions
      5.1.4.1. Nested List Comprehensions
  5.2. The del statement
  5.3. Tuples and Sequences
  5.4. Sets
  5.5. Dictionaries
  5.6. Looping Techniques
  5.7. More on Conditions
  5.8. Comparing Sequences and Other Types
6. Modules
   ■ 6.1. More on Modules
      ■ 6.1.1. Executing modules as scripts
      ■ 6.1.2. The Module Search Path
      ■ 6.1.3. “Compiled” Python files
   ■ 6.2. Standard Modules
   ■ 6.3. The dir() Function
   ■ 6.4. Packages
      ■ 6.4.1. Importing * From a Package
      ■ 6.4.2. Intra-package References
      ■ 6.4.3. Packages in Multiple Directories

7. Input and Output
   ■ 7.1. Fancier Output Formatting
      ■ 7.1.1. Old string formatting
   ■ 7.2. Reading and Writing Files
      ■ 7.2.1. Methods of File Objects
      ■ 7.2.2. Saving structured data with json

8. Errors and Exceptions
   ■ 8.1. Syntax Errors
   ■ 8.2. Exceptions
   ■ 8.3. Handling Exceptions
   ■ 8.4. Raising Exceptions
   ■ 8.5. User-defined Exceptions
   ■ 8.6. Defining Clean-up Actions
   ■ 8.7. Predefined Clean-up Actions

9. Classes
   ■ 9.1. A Word About Names and Objects
   ■ 9.2. Python Scopes and Namespaces

    - 15.1.3. The Interactive Startup File
    - 15.1.4. The Customization Modules

- Python Setup and Usage
  - 1. Command line and environment
    - 1.1. Command line
      - 1.1.1. Interface options
      - 1.1.2. Generic options
      - 1.1.3. Miscellaneous options
      - 1.1.4. Options you shouldn’t use
    - 1.2. Environment variables
      - 1.2.1. Debug-mode variables
  - 2. Using Python on Unix platforms
    - 2.1. Getting and installing the latest version of Python
      - 2.1.1. On Linux
      - 2.1.2. On FreeBSD and OpenBSD
      - 2.1.3. On OpenSolaris
    - 2.2. Building Python
    - 2.3. Python-related paths and files
    - 2.4. Miscellaneous
    - 2.5. Editors
  - 3. Using Python on Windows
    - 3.1. Installing Python
    - 3.2. Alternative bundles
    - 3.3. Configuring Python
3.3.1. Excursus: Setting environment variables
3.3.2. Finding the Python executable
3.3.3. Finding modules
3.3.4. Executing scripts
3.4. Additional modules
  3.4.1. PyWin32
  3.4.2. Py2exe
  3.4.3. WConio
3.5. Compiling Python on Windows
3.6. Other resources

4. Using Python on a Macintosh
  4.1. Getting and Installing MacPython
    4.1.1. How to run a Python script
    4.1.2. Running scripts with a GUI
    4.1.3. Configuration
  4.2. The IDE
  4.3. Installing Additional Python Packages
  4.4. GUI Programming on the Mac
  4.5. Distributing Python Applications on the Mac
  4.6. Other Resources

The Python Language Reference
  1. Introduction
    1.1. Alternate Implementations
    1.2. Notation
  2. Lexical analysis
    2.1. Line structure
      2.1.1. Logical lines
      2.1.2. Physical lines
      2.1.3. Comments
      2.1.4. Encoding declarations
      2.1.5. Explicit line joining
      2.1.6. Implicit line joining
      2.1.7. Blank lines
      2.1.8. Indentation
2.1.9. Whitespace between tokens

2.2. Other tokens

2.3. Identifiers and keywords
   2.3.1. Keywords
   2.3.2. Reserved classes of identifiers

2.4. Literals
   2.4.1. String literals
   2.4.2. String literal concatenation
   2.4.3. Numeric literals
   2.4.4. Integer and long integer literals
   2.4.5. Floating point literals
   2.4.6. Imaginary literals

2.5. Operators

2.6. Delimiters

3. Data model
   3.1. Objects, values and types
   3.2. The standard type hierarchy
   3.3. New-style and classic classes
   3.4. Special method names
      3.4.1. Basic customization
      3.4.2. Customizing attribute access
         3.4.2.1. More attribute access for new-style classes
         3.4.2.2. Implementing Descriptors
         3.4.2.3. Invoking Descriptors
         3.4.2.4. __slots__
      3.4.3. Customizing class creation
      3.4.4. Customizing instance and subclass checks
      3.4.5. Emulating callable objects
      3.4.6. Emulating container types
      3.4.7. Additional methods for emulation of sequence types
      3.4.8. Emulating numeric types
      3.4.9. Coercion rules
3.4.10. With Statement Context Managers
3.4.11. Special method lookup for old-style classes
3.4.12. Special method lookup for new-style classes

4. Execution model
   4.1. Naming and binding
      4.1.1. Interaction with dynamic features
   4.2. Exceptions

5. Expressions
   5.1. Arithmetic conversions
   5.2. Atoms
      5.2.1. Identifiers (Names)
      5.2.2. Literals
      5.2.3. Parenthesized forms
      5.2.4. List displays
      5.2.5. Displays for sets and dictionaries
      5.2.6. Generator expressions
      5.2.7. Dictionary displays
      5.2.8. Set displays
      5.2.9. String conversions
      5.2.10. Yield expressions
         5.2.10.1. Generator-iterator methods
   5.3. Primaries
      5.3.1. Attribute references
      5.3.2. Subscriptions
      5.3.3. Slicings
      5.3.4. Calls
   5.4. The power operator
   5.5. Unary arithmetic and bitwise operations
   5.6. Binary arithmetic operations
   5.7. Shifting operations
   5.8. Binary bitwise operations
   5.9. Comparisons
   5.10. Boolean operations
5.11. Conditional Expressions
5.12. Lambdas
5.13. Expression lists
5.14. Evaluation order
5.15. Operator precedence

6. Simple statements
   6.1. Expression statements
   6.2. Assignment statements
      6.2.1. Augmented assignment statements
   6.3. The assert statement
   6.4. The pass statement
   6.5. The del statement
   6.6. The print statement
   6.7. The return statement
   6.8. The yield statement
   6.9. The raise statement
   6.10. The break statement
   6.11. The continue statement
   6.12. The import statement
      6.12.1. Future statements
   6.13. The global statement
   6.14. The exec statement

7. Compound statements
   7.1. The if statement
   7.2. The while statement
   7.3. The for statement
   7.4. The try statement
   7.5. The with statement
   7.6. Function definitions
   7.7. Class definitions

8. Top-level components
   8.1. Complete Python programs
8.2. File input
8.3. Interactive input
8.4. Expression input
9. Full Grammar specification

The Python Standard Library
1. Introduction
2. Built-in Functions
3. Non-essential Built-in Functions
4. Built-in Constants
   4.1. Constants added by the site module
5. Built-in Types
   5.1. Truth Value Testing
   5.2. Boolean Operations — and, or, not
   5.3. Comparisons
   5.4. Numeric Types — int, float, long, complex
      5.4.1. Bitwise Operations on Integer Types
      5.4.2. Additional Methods on Integer Types
      5.4.3. Additional Methods on Float
   5.5. Iterator Types
      5.5.1. Generator Types
   5.6. Sequence Types — str, unicode, list, tuple, bytearray, buffer, xrange
      5.6.1. String Methods
      5.6.2. String Formatting Operations
      5.6.3. XRange Type
      5.6.4. Mutable Sequence Types
   5.7. Set Types — set, frozenset
   5.8. Mapping Types — dict
      5.8.1. Dictionary view objects
   5.9. File Objects
   5.10. memoryview type
   5.11. Context Manager Types
   5.12. Other Built-in Types
- 5.12.1. Modules
- 5.12.2. Classes and Class Instances
- 5.12.3. Functions
- 5.12.4. Methods
- 5.12.5. Code Objects
- 5.12.6. Type Objects
- 5.12.7. The Null Object
- 5.12.8. The Ellipsis Object
- 5.12.9. The Not Implemented Object
- 5.12.10. Boolean Values
- 5.12.11. Internal Objects
- 5.13. Special Attributes
- 6. Built-in Exceptions
  - 6.1. Exception hierarchy
- 7. String Services
  - 7.1. string — Common string operations
    - 7.1.1. String constants
    - 7.1.2. Custom String Formatting
    - 7.1.3. Format String Syntax
      - 7.1.3.1. Format Specification Mini-Language
      - 7.1.3.2. Format examples
    - 7.1.4. Template strings
    - 7.1.5. String functions
    - 7.1.6. Deprecated string functions
  - 7.2. re — Regular expression operations
    - 7.2.1. Regular Expression Syntax
    - 7.2.2. Module Contents
    - 7.2.3. Regular Expression Objects
    - 7.2.4. Match Objects
    - 7.2.5. Examples
      - 7.2.5.1. Checking For a Pair
      - 7.2.5.2. Simulating scanf()
      - 7.2.5.3. search() vs. match()
      - 7.2.5.4. Making a Phonebook
- 7.2.5.5. Text Munging
- 7.2.5.6. Finding all Adverbs
- 7.2.5.7. Finding all Adverbs and their Positions
- 7.2.5.8. Raw String Notation
- 7.3. `struct` — Interpret strings as packed binary data
  - 7.3.1. Functions and Exceptions
  - 7.3.2. Format Strings
    - 7.3.2.1. Byte Order, Size, and Alignment
    - 7.3.2.2. Format Characters
    - 7.3.2.3. Examples
  - 7.3.3. Classes
- 7.4. `difflib` — Helpers for computing deltas
  - 7.4.1. SequenceMatcher Objects
  - 7.4.2. SequenceMatcher Examples
  - 7.4.3. Differ Objects
  - 7.4.4. Differ Example
  - 7.4.5. A command-line interface to difflib
- 7.5. `StringIO` — Read and write strings as files
- 7.6. `cStringIO` — Faster version of `StringIO`
- 7.7. `textwrap` — Text wrapping and filling
- 7.8. `codecs` — Codec registry and base classes
  - 7.8.1. Codec Base Classes
    - 7.8.1.1. Codec Objects
    - 7.8.1.2. IncrementalEncoder Objects
    - 7.8.1.3. IncrementalDecoder Objects
    - 7.8.1.4. StreamWriter Objects
    - 7.8.1.5. StreamReader Objects
    - 7.8.1.6. StreamReaderWriter Objects
    - 7.8.1.7. StreamRecoder Objects
  - 7.8.2. Encodings and Unicode
  - 7.8.3. Standard Encodings
  - 7.8.4. Python Specific Encodings
- 7.8.5. **encodings.idna** — Internationalized Domain Names in Applications
- 7.8.6. **encodings.utf_8_sig** — UTF-8 codec with BOM signature
- 7.9. **unicodedata** — Unicode Database
- 7.10. **stringprep** — Internet String Preparation
- 7.11. **fpformat** — Floating point conversions
- 8. Data Types
  - 8.1. **datetime** — Basic date and time types
    - 8.1.1. Available Types
    - 8.1.2. **timedelta** Objects
    - 8.1.3. **date** Objects
    - 8.1.4. **datetime** Objects
    - 8.1.5. **time** Objects
    - 8.1.6. **tzinfo** Objects
    - 8.1.7. **strftime()** and **strptime()** Behavior
  - 8.2. **calendar** — General calendar-related functions
  - 8.3. **collections** — High-performance container datatypes
    - 8.3.1. **Counter** objects
    - 8.3.2. **deque** objects
      - 8.3.2.1. **deque** Recipes
    - 8.3.3. **defaultdict** objects
      - 8.3.3.1. **defaultdict** Examples
    - 8.3.4. **namedtuple()** Factory Function for Tuples with Named Fields
    - 8.3.5. **OrderedDict** objects
      - 8.3.5.1. **OrderedDict** Examples and Recipes
    - 8.3.6. Collections Abstract Base Classes
  - 8.4. **heapq** — Heap queue algorithm
    - 8.4.1. Basic Examples
8.4.2. Priority Queue Implementation Notes
8.4.3. Theory
8.5. bisect — Array bisection algorithm
  8.5.1. Searching Sorted Lists
  8.5.2. Other Examples
8.6. array — Efficient arrays of numeric values
8.7. sets — Unordered collections of unique elements
  8.7.1. Set Objects
  8.7.2. Example
  8.7.3. Protocol for automatic conversion to immutable
  8.7.4. Comparison to the built-in set types
8.8. sched — Event scheduler
  8.8.1. Scheduler Objects
8.9. mutex — Mutual exclusion support
  8.9.1. Mutex Objects
8.10. Queue — A synchronized queue class
  8.10.1. Queue Objects
8.11. weakref — Weak references
  8.11.1. Weak Reference Objects
  8.11.2. Example
8.12. UserDict — Class wrapper for dictionary objects
8.13. UserList — Class wrapper for list objects
8.14. UserString — Class wrapper for string objects
8.15. types — Names for built-in types
8.16. new — Creation of runtime internal objects
8.17. copy — Shallow and deep copy operations
8.18. pprint — Data pretty printer
  8.18.1. PrettyPrinter Objects
  8.18.2. pprint Example
8.19. repr — Alternate repr() implementation
  8.19.1. Repr Objects
- 8.19.2. Subclassing Repr Objects
- 9. Numeric and Mathematical Modules
  - 9.1. numbers — Numeric abstract base classes
    - 9.1.1. The numeric tower
    - 9.1.2. Notes for type implementors
      - 9.1.2.1. Adding More Numeric ABCs
      - 9.1.2.2. Implementing the arithmetic operations
  - 9.2. math — Mathematical functions
    - 9.2.1. Number-theoretic and representation functions
    - 9.2.2. Power and logarithmic functions
    - 9.2.3. Trigonometric functions
    - 9.2.4. Angular conversion
    - 9.2.5. Hyperbolic functions
    - 9.2.6. Special functions
    - 9.2.7. Constants
  - 9.3. cmath — Mathematical functions for complex numbers
    - 9.3.1. Conversions to and from polar coordinates
    - 9.3.2. Power and logarithmic functions
    - 9.3.3. Trigonometric functions
    - 9.3.4. Hyperbolic functions
    - 9.3.5. Classification functions
    - 9.3.6. Constants
  - 9.4. decimal — Decimal fixed point and floating point arithmetic
    - 9.4.1. Quick-start Tutorial
    - 9.4.2. Decimal objects
      - 9.4.2.1. Logical operands
    - 9.4.3. Context objects
    - 9.4.4. Signals
    - 9.4.5. Floating Point Notes
      - 9.4.5.1. Mitigating round-off error with
increased precision

-  9.4.5.2. Special values
-  9.4.6. Working with threads
-  9.4.7. Recipes
-  9.4.8. Decimal FAQ

-  9.5. fractions — Rational numbers
-  9.6. random — Generate pseudo-random numbers
-  9.7. itertools — Functions creating iterators for efficient looping
  -  9.7.1. Itertool functions
  -  9.7.2. Recipes
-  9.8. functools — Higher-order functions and operations on callable objects
  -  9.8.1. partial Objects
-  9.9. operator — Standard operators as functions
  -  9.9.1. Mapping Operators to Functions

-  10. File and Directory Access
  -  10.1. os.path — Common pathname manipulations
  -  10.2. fileinput — Iterate over lines from multiple input streams
  -  10.3. stat — Interpreting stat() results
  -  10.4. statvfs — Constants used with os.statvfs()
  -  10.5. filecmp — File and Directory Comparisons
    -  10.5.1. The dircmp class
  -  10.6. tempfile — Generate temporary files and directories
  -  10.7. glob — Unix style pathname pattern expansion
  -  10.8. fnmatch — Unix filename pattern matching
  -  10.9. linecache — Random access to text lines
  -  10.10. shutil — High-level file operations
    -  10.10.1. Directory and files operations
      -  10.10.1.1. copytree example
- 10.10.2. Archiving operations
  - 10.10.2.1. Archiving example
- 10.11. dircache — Cached directory listings
- 10.12. macpath — Mac OS 9 path manipulation functions
- 11. Data Persistence
  - 11.1. pickle — Python object serialization
    - 11.1.1. Relationship to other Python modules
    - 11.1.2. Data stream format
    - 11.1.3. Usage
    - 11.1.4. What can be pickled and unpickled?
    - 11.1.5. The pickle protocol
      - 11.1.5.1. Pickling and unpickling normal class instances
      - 11.1.5.2. Pickling and unpickling extension types
      - 11.1.5.3. Pickling and unpickling external objects
    - 11.1.6. Subclassing Unpicklers
    - 11.1.7. Example
  - 11.2. cPickle — A faster pickle
  - 11.3. copy_reg — Register pickle support functions
    - 11.3.1. Example
  - 11.4. shelve — Python object persistence
    - 11.4.1. Restrictions
    - 11.4.2. Example
  - 11.5. marshal — Internal Python object serialization
  - 11.6. anydbm — Generic access to DBM-style databases
  - 11.7. whichdb — Guess which DBM module created a database
  - 11.8. dbm — Simple “database” interface
  - 11.9. gdbm — GNU’s reinterpretation of dbm
- 11.10. dbhash — DBM-style interface to the BSD database library
  - 11.10.1. Database Objects

- 11.11. bsddb — Interface to Berkeley DB library
  - 11.11.1. Hash, BTree and Record Objects

- 11.12. dumbdbm — Portable DBM implementation
  - 11.12.1. Dumbdbm Objects

- 11.13. sqlite3 — DB-API 2.0 interface for SQLite databases
  - 11.13.1. Module functions and constants
  - 11.13.2. Connection Objects
  - 11.13.3. Cursor Objects
  - 11.13.4. Row Objects
  - 11.13.5. SQLite and Python types
    - 11.13.5.1. Introduction
    - 11.13.5.2. Using adapters to store additional Python types in SQLite databases
      - 11.13.5.2.1. Letting your object adapt itself
      - 11.13.5.2.2. Registering an adapter callable
    - 11.13.5.3. Converting SQLite values to custom Python types
    - 11.13.5.4. Default adapters and converters
  - 11.13.6. Controlling Transactions
  - 11.13.7. Using sqlite3 efficiently
    - 11.13.7.1. Using shortcut methods
    - 11.13.7.2. Accessing columns by name instead of by index
    - 11.13.7.3. Using the connection as a context manager
  - 11.13.8. Common issues
    - 11.13.8.1. Multithreading

- 12. Data Compression and Archiving
12.1. **zlib** — Compression compatible with **gzip**

12.2. **gzip** — Support for **gzip** files
   - 12.2.1. Examples of usage

12.3. **bz2** — Compression compatible with **bzip2**
   - 12.3.1. (De)compression of files
   - 12.3.2. Sequential (de)compression
   - 12.3.3. One-shot (de)compression

12.4. **zipfile** — Work with ZIP archives
   - 12.4.1. ZipFile Objects
   - 12.4.2. PyZipFile Objects
   - 12.4.3. ZipInfo Objects
   - 12.4.4. Command-Line Interface
     - 12.4.4.1. Command-line options

12.5. **tarfile** — Read and write tar archive files
   - 12.5.1. TarFile Objects
   - 12.5.2. TarInfo Objects
   - 12.5.3. Examples
   - 12.5.4. Supported tar formats
   - 12.5.5. Unicode issues

13. File Formats
   - 13.1. **csv** — CSV File Reading and Writing
     - 13.1.1. Module Contents
     - 13.1.2. Dialects and Formatting Parameters
     - 13.1.3. Reader Objects
     - 13.1.4. Writer Objects
     - 13.1.5. Examples

13.2. **ConfigParser** — Configuration file parser
   - 13.2.1. RawConfigParser Objects
   - 13.2.2. ConfigParser Objects
   - 13.2.3. SafeConfigParser Objects
   - 13.2.4. Examples

13.3. **robotparser** — Parser for robots.txt

13.4. **netrc** — netrc file processing
13.4.1. netrc Objects

13.5. xdrlib — Encode and decode XDR data
   13.5.1. Packer Objects
   13.5.2. Unpacker Objects
   13.5.3. Exceptions

13.6. plistlib — Generate and parse Mac OS X .plist files
   13.6.1. Examples

14. Cryptographic Services
   14.1. hashlib — Secure hashes and message digests
      14.1.1. Key derivation
   14.2. hmac — Keyed-Hashing for Message Authentication
   14.3. md5 — MD5 message digest algorithm
   14.4. sha — SHA-1 message digest algorithm

15. Generic Operating System Services
   15.1. os — Miscellaneous operating system interfaces
      15.1.1. Process Parameters
      15.1.2. File Object Creation
      15.1.3. File Descriptor Operations
         15.1.3.1. open() flag constants
      15.1.4. Files and Directories
      15.1.5. Process Management
      15.1.6. Miscellaneous System Information
      15.1.7. Miscellaneous Functions
   15.2. io — Core tools for working with streams
      15.2.1. Module Interface
      15.2.2. I/O Base Classes
      15.2.3. Raw File I/O
      15.2.4. Buffered Streams
      15.2.5. Text I/O
      15.2.6. Advanced topics
         15.2.6.1. Performance
- 15.2.6.1.1. Binary I/O
- 15.2.6.1.2. Text I/O
  - 15.2.6.2. Multi-threading
  - 15.2.6.3. Reentrancy
- 15.3. time — Time access and conversions
- 15.4. argparse — Parser for command-line options, arguments and sub-commands
  - 15.4.1. Example
    - 15.4.1.1. Creating a parser
    - 15.4.1.2. Adding arguments
    - 15.4.1.3. Parsing arguments
  - 15.4.2. ArgumentParser objects
    - 15.4.2.1. prog
    - 15.4.2.2. usage
    - 15.4.2.3. description
    - 15.4.2.4. epilog
    - 15.4.2.5. parents
    - 15.4.2.6. formatter_class
    - 15.4.2.7. prefix_chars
    - 15.4.2.8. fromfile_prefix_chars
    - 15.4.2.9. argument_default
    - 15.4.2.10. conflict_handler
    - 15.4.2.11. add_help
  - 15.4.3. The add_argument() method
    - 15.4.3.1. name or flags
    - 15.4.3.2. action
    - 15.4.3.3. nargs
    - 15.4.3.4. const
    - 15.4.3.5. default
    - 15.4.3.6. type
    - 15.4.3.7. choices
    - 15.4.3.8. required
    - 15.4.3.9. help
    - 15.4.3.10. metavar
15.4.3.11. dest
15.4.3.12. Action classes

15.4.4. The parse_args() method
15.4.4.1. Option value syntax
15.4.4.2. Invalid arguments
15.4.4.3. Arguments containing -
15.4.4.4. Argument abbreviations (prefix matching)
15.4.4.5. Beyond sys.argv
15.4.4.6. The Namespace object

15.4.5. Other utilities
15.4.5.1. Sub-commands
15.4.5.2. FileType objects
15.4.5.3. Argument groups
15.4.5.4. Mutual exclusion
15.4.5.5. Parser defaults
15.4.5.6. Printing help
15.4.5.7. Partial parsing
15.4.5.8. Customizing file parsing
15.4.5.9. Exiting methods

15.4.6. Upgrading optparse code

15.5. optparse — Parser for command line options

15.5.1. Background
15.5.1.1. Terminology
15.5.1.2. What are options for?
15.5.1.3. What are positional arguments for?

15.5.2. Tutorial
15.5.2.1. Understanding option actions
15.5.2.2. The store action
15.5.2.3. Handling boolean (flag) options
15.5.2.4. Other actions
15.5.2.5. Default values
15.5.2.6. Generating help
15.5.2.6.1. Grouping Options
15.5.2.7. Printing a version string
15.5.2.8. How optparse handles errors
15.5.2.9. Putting it all together

15.5.3. Reference Guide
15.5.3.1. Creating the parser
15.5.3.2. Populating the parser
15.5.3.3. Defining options
15.5.3.4. Option attributes
15.5.3.5. Standard option actions
15.5.3.6. Standard option types
15.5.3.7. Parsing arguments
15.5.3.8. Querying and manipulating your option parser
15.5.3.9. Conflicts between options
15.5.3.10. Cleanup
15.5.3.11. Other methods

15.5.4. Option Callbacks
15.5.4.1. Defining a callback option
15.5.4.2. How callbacks are called
15.5.4.3. Raising errors in a callback
15.5.4.4. Callback example 1: trivial callback
15.5.4.5. Callback example 2: check option order
15.5.4.6. Callback example 3: check option order (generalized)
15.5.4.7. Callback example 4: check arbitrary condition
15.5.4.8. Callback example 5: fixed arguments
15.5.4.9. Callback example 6: variable arguments

15.5.5. Extending optparse
15.5.5.1. Adding new types
15.5.5.2. Adding new actions
15.6. **getopt** — C-style parser for command line options

15.7. **logging** — Logging facility for Python

- 15.7.1. Logger Objects
- 15.7.2. Logging Levels
- 15.7.3. Handler Objects
- 15.7.4. Formatter Objects
- 15.7.5. Filter Objects
- 15.7.6. LogRecord Objects
- 15.7.7. LogRecord attributes
- 15.7.8. LoggerAdapter Objects
- 15.7.9. Thread Safety
- 15.7.10. Module-Level Functions
- 15.7.11. Integration with the warnings module

15.8. **logging.config** — Logging configuration

- 15.8.1. Configuration functions
- 15.8.2. Configuration dictionary schema
  - 15.8.2.1. Dictionary Schema Details
  - 15.8.2.2. Incremental Configuration
  - 15.8.2.3. Object connections
  - 15.8.2.4. User-defined objects
  - 15.8.2.5. Access to external objects
  - 15.8.2.6. Access to internal objects
  - 15.8.2.7. Import resolution and custom importers
- 15.8.3. Configuration file format

15.9. **logging.handlers** — Logging handlers

- 15.9.1. StreamHandler
- 15.9.2. FileHandler
- 15.9.3. NullHandler
- 15.9.4. WatchedFileHandler
- 15.9.5. RotatingFileHandler
- 15.9.6. TimedRotatingFileHandler
- 15.9.7. SocketHandler
- 15.9.8. DatagramHandler
- 15.9.9. SysLogHandler
- 15.9.10. NTEventLogHandler
- 15.9.11. SMTPHandler
- 15.9.12. MemoryHandler
- 15.9.13. HTTPHandler
- 15.10. getpass — Portable password input
- 15.11. curses — Terminal handling for character-cell displays
  - 15.11.1. Functions
  - 15.11.2. Window Objects
  - 15.11.3. Constants
- 15.12. curses.textpad — Text input widget for curses programs
  - 15.12.1. Textbox objects
- 15.13. curses.ascii — Utilities for ASCII characters
- 15.14. curses.panel — A panel stack extension for curses
  - 15.14.1. Functions
  - 15.14.2. Panel Objects
- 15.15. platform — Access to underlying platform's identifying data
  - 15.15.1. Cross Platform
  - 15.15.2. Java Platform
  - 15.15.3. Windows Platform
    - 15.15.3.1. Win95/98 specific
  - 15.15.4. Mac OS Platform
  - 15.15.5. Unix Platforms
- 15.16. errno — Standard errno system symbols
- 15.17. ctypes — A foreign function library for Python
  - 15.17.1. ctypes tutorial
    - 15.17.1.1. Loading dynamic link libraries
    - 15.17.1.2. Accessing functions from loaded
15.17.1.3. Calling functions
15.17.1.4. Fundamental data types
15.17.1.5. Calling functions, continued
15.17.1.6. Calling functions with your own custom data types
15.17.1.7. Specifying the required argument types (function prototypes)
15.17.1.8. Return types
15.17.1.9. Passing pointers (or: passing parameters by reference)
15.17.1.10. Structures and unions
15.17.1.11. Structure/union alignment and byte order
15.17.1.12. Bit fields in structures and unions
15.17.1.13. Arrays
15.17.1.14. Pointers
15.17.1.15. Type conversions
15.17.1.16. Incomplete Types
15.17.1.17. Callback functions
15.17.1.18. Accessing values exported from dlls
15.17.1.19. Surprises
15.17.1.20. Variable-sized data types

15.17.2. ctypes reference
15.17.2.1. Finding shared libraries
15.17.2.2. Loading shared libraries
15.17.2.3. Foreign functions
15.17.2.4. Function prototypes
15.17.2.5. Utility functions
15.17.2.6. Data types
15.17.2.7. Fundamental data types
15.17.2.8. Structured data types
15.17.2.9. Arrays and pointers
16. Optional Operating System Services
   16.1. select — Waiting for I/O completion
       16.1.1. Edge and Level Trigger Polling (epoll) Objects
       16.1.2. Polling Objects
       16.1.3. Kqueue Objects
       16.1.4. Kevent Objects
   16.2. threading — Higher-level threading interface
       16.2.1. Thread Objects
       16.2.2. Lock Objects
       16.2.3. RLock Objects
       16.2.4. Condition Objects
       16.2.5. Semaphore Objects
           16.2.5.1. Semaphore Example
       16.2.6. Event Objects
       16.2.7. Timer Objects
       16.2.8. Using locks, conditions, and semaphores in the with statement
       16.2.9. Importing in threaded code
   16.3. thread — Multiple threads of control
   16.4. dummy_threading — Drop-in replacement for the threading module
   16.5. dummy_thread — Drop-in replacement for the thread module
   16.6. multiprocessing — Process-based “threading” interface
       16.6.1. Introduction
           16.6.1.1. The Process class
           16.6.1.2. Exchanging objects between processes
           16.6.1.3. Synchronization between processes
           16.6.1.4. Sharing state between processes
           16.6.1.5. Using a pool of workers
16.6.2. Reference
  16.6.2.1. Process and exceptions
  16.6.2.2. Pipes and Queues
  16.6.2.3. Miscellaneous
  16.6.2.4. Connection Objects
  16.6.2.5. Synchronization primitives
  16.6.2.6. Shared ctypes Objects
    16.6.2.6.1. The multiprocessing.sharedctypes module
  16.6.2.7. Managers
    16.6.2.7.1. Customized managers
    16.6.2.7.2. Using a remote manager
  16.6.2.8. Proxy Objects
    16.6.2.8.1. Cleanup
  16.6.2.9. Process Pools
  16.6.2.10. Listeners and Clients
    16.6.2.10.1. Address Formats
  16.6.2.11. Authentication keys
  16.6.2.12. Logging
  16.6.2.13. The multiprocessing dummy module
16.6.3. Programming guidelines
  16.6.3.1. All platforms
  16.6.3.2. Windows
16.6.4. Examples
16.7. mmap — Memory-mapped file support
16.8. readline — GNU readline interface
  16.8.1. Init file
  16.8.2. Line buffer
  16.8.3. History file
  16.8.4. History list
  16.8.5. Startup hooks
  16.8.6. Completion
  16.8.7. Example
16.9. r1completer — Completion function for GNU readline
   16.9.1. Completer Objects

17. Interprocess Communication and Networking
   17.1. subprocess — Subprocess management
      17.1.1. Using the subprocess Module
         17.1.1.1. Frequently Used Arguments
         17.1.1.2. Popen Constructor
         17.1.1.3. Exceptions
         17.1.1.4. Security
      17.1.2. Popen Objects
      17.1.3. Windows Popen Helpers
         17.1.3.1. Constants
      17.1.4. Replacing Older Functions with the subprocess Module
         17.1.4.1. Replacing /bin/sh shell backquote
         17.1.4.2. Replacing shell pipeline
         17.1.4.3. Replacing os.system()
         17.1.4.4. Replacing the os.spawn family
         17.1.4.5. Replacing os.popen(), os.popen2(), os.popen3()
         17.1.4.6. Replacing functions from the open2 module
      17.1.5. Notes
         17.1.5.1. Converting an argument sequence to a string on Windows
   17.2. socket — Low-level networking interface
      17.2.1. Socket Objects
      17.2.2. Example
   17.3. ssl — TLS/SSL wrapper for socket objects
      17.3.1. Functions, Constants, and Exceptions
         17.3.1.1. Socket creation
         17.3.1.2. Context creation
- 17.3.1.3. Random generation
- 17.3.1.4. Certificate handling
- 17.3.1.5. Constants
- 17.3.2. SSL Sockets
- 17.3.3. SSL Contexts
- 17.3.4. Certificates
  - 17.3.4.1. Certificate chains
  - 17.3.4.2. CA certificates
  - 17.3.4.3. Combined key and certificate
  - 17.3.4.4. Self-signed certificates
- 17.3.5. Examples
  - 17.3.5.1. Testing for SSL support
  - 17.3.5.2. Client-side operation
  - 17.3.5.3. Server-side operation
- 17.3.6. Notes on non-blocking sockets
- 17.3.7. Security considerations
  - 17.3.7.1. Best defaults
  - 17.3.7.2. Manual settings
    - 17.3.7.2.1. Verifying certificates
    - 17.3.7.2.2. Protocol versions
    - 17.3.7.2.3. Cipher selection
  - 17.3.7.3. Multi-processing
- 17.4. signal — Set handlers for asynchronous events
  - 17.4.1. Example
- 17.5. popen2 — Subprocesses with accessible I/O streams
  - 17.5.1. Popen3 and Popen4 Objects
  - 17.5.2. Flow Control Issues
- 17.6. asyncore — Asynchronous socket handler
  - 17.6.1. asyncore Example basic HTTP client
  - 17.6.2. asyncore Example basic echo server
- 17.7. asynchat — Asynchronous socket command/response handler
  - 17.7.1. asynchat - Auxiliary Classes
17.7.2. asynchat Example

18. Internet Data Handling
- 18.1. email — An email and MIME handling package
  - 18.1.1. email.message: Representing an email message
  - 18.1.2. email.parser: Parsing email messages
    - 18.1.2.1. FeedParser API
    - 18.1.2.2. Parser class API
    - 18.1.2.3. Additional notes
  - 18.1.3. email.generator: Generating MIME documents
  - 18.1.4. email.mime: Creating email and MIME objects from scratch
  - 18.1.5. email.header: Internationalized headers
  - 18.1.6. email.charset: Representing character sets
  - 18.1.7. email.encoders: Encoders
  - 18.1.8. email.errors: Exception and Defect classes
  - 18.1.9. email.utils: Miscellaneous utilities
  - 18.1.10. email.iterators: Iterators
  - 18.1.11. email: Examples
  - 18.1.12. Package History
  - 18.1.13. Differences from mimelib
- 18.2. json — JSON encoder and decoder
  - 18.2.1. Basic Usage
  - 18.2.2. Encoders and Decoders
  - 18.2.3. Standard Compliance and Interoperability
    - 18.2.3.1. Character Encodings
    - 18.2.3.2. Infinite and NaN Number Values
    - 18.2.3.3. Repeated Names Within an Object
    - 18.2.3.4. Top-level Non-Object, Non-Array Values
18.2.3.5. Implementation Limitations

18.3. mailcap — Mailcap file handling

18.4. mailbox — Manipulate mailboxes in various formats
  - 18.4.1. Mailbox objects
    - 18.4.1.1. Maildir
    - 18.4.1.2. mbox
    - 18.4.1.3. MH
    - 18.4.1.4. Babyl
    - 18.4.1.5. MMDF
  - 18.4.2. Message objects
    - 18.4.2.1. MaildirMessage
    - 18.4.2.2. mboxMessage
    - 18.4.2.3. MHMessage
    - 18.4.2.4. BabylMessage
    - 18.4.2.5. MMDFMessage
  - 18.4.3. Exceptions
  - 18.4.4. Deprecated classes and methods
  - 18.4.5. Examples

18.5. mhlib — Access to MH mailboxes
  - 18.5.1. MH Objects
  - 18.5.2. Folder Objects
  - 18.5.3. Message Objects

18.6. mimeutils — Tools for parsing MIME messages
  - 18.6.1. Additional Methods of Message Objects

18.7. mimetypes — Map filenames to MIME types
  - 18.7.1. MimeTypes Objects

18.8. MimeWriter — Generic MIME file writer
  - 18.8.1. MimeWriter Objects

18.9. mimify — MIME processing of mail messages

18.10. multifile — Support for files containing distinct parts
18.10.1. MultiFile Objects
18.10.2. MultiFile Example

18.11. rfc822 — Parse RFC 2822 mail headers
   18.11.1. Message Objects
   18.11.2. AddressList Objects

18.12. base64 — RFC 3548: Base16, Base32, Base64 Data Encodings

18.13. binhex — Encode and decode binhex4 files
   18.13.1. Notes

18.14. binascii — Convert between binary and ASCII

18.15. quopri — Encode and decode MIME quoted-printable data

18.16. uu — Encode and decode uuencode files

19. Structured Markup Processing Tools
   19.1. HTMLParser — Simple HTML and XHTML parser
      19.1.1. Example HTML Parser Application
      19.1.2. HTMLParser Methods
      19.1.3. Examples
   19.2. sgmllib — Simple SGML parser
   19.3. htmllib — A parser for HTML documents
      19.3.1. HTMLParser Objects
   19.4. htmlentitydefs — Definitions of HTML general entities
   19.5. XML Processing Modules
   19.6. XML vulnerabilities
      19.6.1. defused packages
   19.7. xml.etree.ElementTree — The ElementTree XML API
      19.7.1. Tutorial
         19.7.1.1. XML tree and elements
         19.7.1.2. Parsing XML
         19.7.1.3. Finding interesting elements
         19.7.1.4. Modifying an XML File
- 19.7.1.5. Building XML documents
- 19.7.1.6. Parsing XML with Namespaces
- 19.7.1.7. Additional resources
- 19.7.2. XPath support
  - 19.7.2.1. Example
  - 19.7.2.2. Supported XPath syntax
- 19.7.3. Reference
  - 19.7.3.1. Functions
  - 19.7.3.2. Element Objects
  - 19.7.3.3. ElementTree Objects
  - 19.7.3.4. QName Objects
  - 19.7.3.5. TreeBuilder Objects
  - 19.7.3.6. XMLParser Objects
- 19.8. `xml.dom` — The Document Object Model API
  - 19.8.1. Module Contents
  - 19.8.2. Objects in the DOM
    - 19.8.2.1. DOMImplementation Objects
    - 19.8.2.2. Node Objects
    - 19.8.2.3. NodeList Objects
    - 19.8.2.4. DocumentType Objects
    - 19.8.2.5. Document Objects
    - 19.8.2.6. Element Objects
    - 19.8.2.7. Attr Objects
    - 19.8.2.8. NamedNodeMap Objects
    - 19.8.2.9. Comment Objects
    - 19.8.2.10. Text and CDATASection Objects
    - 19.8.2.11. ProcessingInstruction Objects
    - 19.8.2.12. Exceptions
  - 19.8.3. Conformance
    - 19.8.3.1. Type Mapping
    - 19.8.3.2. Accessor Methods
- 19.9. `xml.dom.minidom` — Minimal DOM implementation
  - 19.9.1. DOM Objects
  - 19.9.2. DOM Example
- 19.9.3. minidom and the DOM standard
- 19.10. xml.dom.pulldom — Support for building partial DOM trees
  - 19.10.1. DOMEventStream Objects
- 19.11. xml.sax — Support for SAX2 parsers
  - 19.11.1. SAXException Objects
- 19.12. xml.sax.handler — Base classes for SAX handlers
  - 19.12.1. ContentHandler Objects
  - 19.12.2. DTDHandler Objects
  - 19.12.3. EntityResolver Objects
  - 19.12.4. ErrorHandler Objects
- 19.13. xml.sax.saxutils — SAX Utilities
  - 19.14.1. XMLReader Objects
  - 19.14.2. IncrementalParser Objects
  - 19.14.3. Locator Objects
  - 19.14.4. InputSource Objects
  - 19.14.5. The Attributes Interface
  - 19.14.6. The AttributesNS Interface
- 19.15. xml.parsers.expat — Fast XML parsing using Expat
  - 19.15.1. XMLParser Objects
  - 19.15.2. ExpatError Exceptions
  - 19.15.3. Example
  - 19.15.4. Content Model Descriptions
  - 19.15.5. Expat error constants

- 20. Internet Protocols and Support
  - 20.1. webbrowser — Convenient Web-browser controller
    - 20.1.1. Browser Controller Objects
  - 20.2. cgi — Common Gateway Interface support
    - 20.2.1. Introduction
20.2.2. Using the cgi module
20.2.3. Higher Level Interface
20.2.4. Old classes
20.2.5. Functions
20.2.6. Caring about security
20.2.7. Installing your CGI script on a Unix system
20.2.8. Testing your CGI script
20.2.9. Debugging CGI scripts
20.2.10. Common problems and solutions

20.3. cgitb — Traceback manager for CGI scripts

20.4. wsgiref — WSGI Utilities and Reference Implementation
   20.4.1. wsgiref.util — WSGI environment utilities
   20.4.2. wsgiref.headers — WSGI response header tools
   20.4.3. wsgiref.simple_server — a simple WSGI HTTP server
   20.4.4. wsgiref.validate — WSGI conformance checker
   20.4.5. wsgiref.handlers — server/gateway base classes
   20.4.6. Examples

20.5. urllib — Open arbitrary resources by URL
   20.5.1. High-level interface
   20.5.2. Utility functions
   20.5.3. URL Opener objects
   20.5.4. urllib Restrictions
   20.5.5. Examples

20.6. urllib2 — extensible library for opening URLs
   20.6.1. Request Objects
   20.6.2. OpenerDirector Objects
   20.6.3. BaseHandler Objects
   20.6.4. HTTPRedirectHandler Objects
- 20.6.5. HTTPCookieProcessor Objects
- 20.6.6. ProxyHandler Objects
- 20.6.7. HTTPPasswordMgr Objects
- 20.6.8. AbstractBasicAuthHandler Objects
- 20.6.9. HTTPBasicAuthHandler Objects
- 20.6.10. ProxyBasicAuthHandler Objects
- 20.6.11. AbstractDigestAuthHandler Objects
- 20.6.12. HTTPDigestAuthHandler Objects
- 20.6.13. ProxyDigestAuthHandler Objects
- 20.6.14. HTTPHandler Objects
- 20.6.15. HTTPSHandler Objects
- 20.6.16. FileHandler Objects
- 20.6.17. FTPHandler Objects
- 20.6.18. CacheFTPHandler Objects
- 20.6.19. UnknownHandler Objects
- 20.6.20. HTTPErrorProcessor Objects
- 20.6.21. Examples

- 20.7. httpplib — HTTP protocol client
  - 20.7.1. HTTPConnection Objects
  - 20.7.2. HTTPResponse Objects
  - 20.7.3. Examples

- 20.8. ftplib — FTP protocol client
  - 20.8.1. FTP Objects
  - 20.8.2. FTP_TLS Objects

- 20.9. poplib — POP3 protocol client
  - 20.9.1. POP3 Objects
  - 20.9.2. POP3 Example

- 20.10. imaplib — IMAP4 protocol client
  - 20.10.1. IMAP4 Objects
  - 20.10.2. IMAP4 Example

- 20.11. nntplib — NNTP protocol client
  - 20.11.1. NNTP Objects

- 20.12. smtplib — SMTP protocol client
20.12.1. SMTP Objects
20.12.2. SMTP Example

20.13. smtpd — SMTP Server
- 20.13.1. SMPTServer Objects
- 20.13.2. DebuggingServer Objects
- 20.13.3. PureProxy Objects
- 20.13.4. MailmanProxy Objects

20.14. telnetlib — Telnet client
- 20.14.1. Telnet Objects
- 20.14.2. Telnet Example

20.15. uuid — UUID objects according to RFC 4122
- 20.15.1. Example

20.16. urlparse — Parse URLs into components
- 20.16.1. Results of urlparse() and urlsplit()

20.17. SocketServer — A framework for network servers
- 20.17.1. Server Creation Notes
- 20.17.2. Server Objects
- 20.17.3. Request Handler Objects
- 20.17.4. Examples
  - 20.17.4.1. SocketServer.TCPServer Example
  - 20.17.4.2. SocketServer.UDPServer Example
  - 20.17.4.3. Asynchronous Mixins

20.18. BaseHTTPServer — Basic HTTP server
- 20.18.1. More examples

20.19. SimpleHTTPServer — Simple HTTP request handler

20.20. CGIHTTPServer — CGI-capable HTTP request handler

20.21. cookielib — Cookie handling for HTTP clients
- 20.21.2. FileCookieJar subclasses and cooperation with web browsers
- 20.21.3. CookiePolicy Objects
- 20.21.4. DefaultCookiePolicy Objects
- 20.21.5. Cookie Objects
- 20.21.6. Examples

- 20.22. **Cookie** — HTTP state management
  - 20.22.1. Cookie Objects
  - 20.22.2. Morsel Objects
  - 20.22.3. Example

- 20.23. **xmlrpclib** — XML-RPC client access
  - 20.23.1. ServerProxy Objects
  - 20.23.2. Boolean Objects
  - 20.23.3. DateTime Objects
  - 20.23.4. Binary Objects
  - 20.23.5. Fault Objects
  - 20.23.6. ProtocolError Objects
  - 20.23.7. MultiCall Objects
  - 20.23.8. Convenience Functions
  - 20.23.9. Example of Client Usage
  - 20.23.10. Example of Client and Server Usage

- 20.24. **SimpleXMLRPCServer** — Basic XML-RPC server
  - 20.24.1. SimpleXMLRPCServer Objects
    - 20.24.1.1. SimpleXMLRPCServer Example
  - 20.24.2. CGIXMLRPCRequestHandler

- 20.25. **DocXMLRPCServer** — Self-documenting XML-RPC server
  - 20.25.1. DocXMLRPCServer Objects
  - 20.25.2. DocCGIXMLRPCRequestHandler

- 21. Multimedia Services
  - 21.1. **audioop** — Manipulate raw audio data
  - 21.2. **imageop** — Manipulate raw image data
  - 21.3. **aifc** — Read and write AIFF and AIFC files
  - 21.4. **sunau** — Read and write Sun AU files
    - 21.4.1. AU_read Objects
- 21.4.2. AU_write Objects
- 21.5. wave — Read and write WAV files
  - 21.5.1. Wave_read Objects
  - 21.5.2. Wave_write Objects
- 21.6. chunk — Read IFF chunked data
- 21.7. colorsys — Conversions between color systems
- 21.8. imghdr — Determine the type of an image
- 21.9. sndhdr — Determine type of sound file
- 21.10. ossaudiodev — Access to OSS-compatible audio devices
  - 21.10.1. Audio Device Objects
  - 21.10.2. Mixer Device Objects

22. Internationalization
- 22.1. gettext — Multilingual internationalization services
  - 22.1.1. GNU gettext API
  - 22.1.2. Class-based API
    - 22.1.2.1. The NullTranslations class
    - 22.1.2.2. The GNUTranslations class
    - 22.1.2.3. Solaris message catalog support
    - 22.1.2.4. The Catalog constructor
  - 22.1.3. Internationalizing your programs and modules
    - 22.1.3.1. Localizing your module
    - 22.1.3.2. Localizing your application
    - 22.1.3.3. Changing languages on the fly
    - 22.1.3.4. Deferred translations
    - 22.1.3.5. gettext() vs. lgettext()
  - 22.1.4. Acknowledgements
- 22.2. locale — Internationalization services
  - 22.2.1. Background, details, hints, tips and caveats
  - 22.2.2. For extension writers and programs that
embed Python

- 22.2.3. Access to message catalogs

- 23. Program Frameworks
  - 23.1. cmd — Support for line-oriented command interpreters
    - 23.1.1. Cmd Objects
  - 23.2. shlex — Simple lexical analysis
    - 23.2.1. shlex Objects
    - 23.2.2. Parsing Rules

- 24. Graphical User Interfaces with Tk
  - 24.1. Tkinter — Python interface to Tcl/Tk
    - 24.1.1. Tkinter Modules
    - 24.1.2. Tkinter Life Preserver
      - 24.1.2.1. How To Use This Section
      - 24.1.2.2. A Simple Hello World Program
    - 24.1.3. A (Very) Quick Look at Tcl/Tk
    - 24.1.4. Mapping Basic Tk into Tkinter
    - 24.1.5. How Tk and Tkinter are Related
    - 24.1.6. Handy Reference
      - 24.1.6.1. Setting Options
      - 24.1.6.2. The Packer
      - 24.1.6.3. Packer Options
      - 24.1.6.4. Coupling Widget Variables
      - 24.1.6.5. The Window Manager
      - 24.1.6.6. Tk Option Data Types
      - 24.1.6.7. Bindings and Events
      - 24.1.6.8. The index Parameter
      - 24.1.6.9. Images
    - 24.1.7. File Handlers
  - 24.2. ttk — Tk themed widgets
    - 24.2.1. Using Ttk
    - 24.2.2. Ttk Widgets
    - 24.2.3. Widget
      - 24.2.3.1. Standard Options
- 24.2.3.2. Scrollable Widget Options
- 24.2.3.3. Label Options
- 24.2.3.4. Compatibility Options
- 24.2.3.5. Widget States
- 24.2.3.6. ttk.Widget

- 24.2.4. Combobox
  - 24.2.4.1. Options
  - 24.2.4.2. Virtual events
  - 24.2.4.3. ttk.Combobox

- 24.2.5. Notebook
  - 24.2.5.1. Options
  - 24.2.5.2. Tab Options
  - 24.2.5.3. Tab Identifiers
  - 24.2.5.4. Virtual Events
  - 24.2.5.5. ttk.Notebook

- 24.2.6. Progressbar
  - 24.2.6.1. Options
  - 24.2.6.2. ttk.Progressbar

- 24.2.7. Separator
  - 24.2.7.1. Options

- 24.2.8. Sizegrip
  - 24.2.8.1. Platform-specific notes
  - 24.2.8.2. Bugs

- 24.2.9. Treeview
  - 24.2.9.1. Options
  - 24.2.9.2. Item Options
  - 24.2.9.3. Tag Options
  - 24.2.9.4. Column Identifiers
  - 24.2.9.5. Virtual Events
  - 24.2.9.6. ttk.Treeview

- 24.2.10. Ttk Styling
  - 24.2.10.1. Layouts

- 24.3. Tix — Extension widgets for Tk
  - 24.3.1. Using Tix
24.3.2. Tix Widgets
   - 24.3.2.1. Basic Widgets
   - 24.3.2.2. File Selectors
   - 24.3.2.3. Hierarchical ListBox
   - 24.3.2.4. Tabular ListBox
   - 24.3.2.5. Manager Widgets
   - 24.3.2.6. Image Types
   - 24.3.2.7. Miscellaneous Widgets
   - 24.3.2.8. Form Geometry Manager

24.3.3. Tix Commands

24.4. ScrolledText — Scrolled Text Widget

24.5. turtle — Turtle graphics for Tk
   - 24.5.1. Introduction
   - 24.5.2. Overview over available Turtle and Screen methods
     - 24.5.2.1. Turtle methods
     - 24.5.2.2. Methods of TurtleScreen/Screen
   - 24.5.3. Methods of RawTurtle/Turtle and corresponding functions
     - 24.5.3.1. Turtle motion
     - 24.5.3.2. Tell Turtle’s state
     - 24.5.3.3. Settings for measurement
     - 24.5.3.4. Pen control
       - 24.5.3.4.1. Drawing state
       - 24.5.3.4.2. Color control
       - 24.5.3.4.3. Filling
       - 24.5.3.4.4. More drawing control
     - 24.5.3.5. Turtle state
       - 24.5.3.5.1. Visibility
       - 24.5.3.5.2. Appearance
     - 24.5.3.6. Using events
     - 24.5.3.7. Special Turtle methods
     - 24.5.3.8. Excursus about the use of compound shapes
24.5.4. Methods of TurtleScreen/Screen and corresponding functions
   - 24.5.4.1. Window control
   - 24.5.4.2. Animation control
   - 24.5.4.3. Using screen events
   - 24.5.4.4. Settings and special methods
   - 24.5.4.5. Methods specific to Screen, not inherited from TurtleScreen

24.5.5. The public classes of the module turtle

24.5.6. Help and configuration
   - 24.5.6.1. How to use help
   - 24.5.6.2. Translation of docstrings into different languages
   - 24.5.6.3. How to configure Screen and Turtles

24.5.7. Demo scripts

24.6. IDLE
   - 24.6.1. Menus
     - 24.6.1.1. File menu (Shell and Editor)
     - 24.6.1.2. Edit menu (Shell and Editor)
     - 24.6.1.3. Format menu (Editor window only)
     - 24.6.1.4. Run menu (Editor window only)
     - 24.6.1.5. Shell menu (Shell window only)
     - 24.6.1.6. Debug menu (Shell window only)
     - 24.6.1.7. Options menu (Shell and Editor)
     - 24.6.1.8. Window menu (Shell and Editor)
     - 24.6.1.9. Help menu (Shell and Editor)
     - 24.6.1.10. Context Menus
   - 24.6.2. Editing and navigation
     - 24.6.2.1. Automatic indentation
     - 24.6.2.2. Completions
     - 24.6.2.3. Calltips
     - 24.6.2.4. Python Shell window
     - 24.6.2.5. Text colors
   - 24.6.3. Startup and code execution
24.6.3.1. Command line usage
24.6.3.2. IDLE-console differences
24.6.3.3. Running without a subprocess
24.6.4. Help and preferences
   24.6.4.1. Additional help sources
   24.6.4.2. Setting preferences
   24.6.4.3. Extensions

24.7. Other Graphical User Interface Packages

25. Development Tools
   25.1. pydoc — Documentation generator and online help system
   25.2. doctest — Test interactive Python examples
      25.2.1. Simple Usage: Checking Examples in Docstrings
      25.2.2. Simple Usage: Checking Examples in a Text File
      25.2.3. How It Works
         25.2.3.1. Which Docstrings Are Examined?
         25.2.3.2. How are Docstring Examples Recognized?
         25.2.3.3. What’s the Execution Context?
         25.2.3.4. What About Exceptions?
         25.2.3.5. Option Flags
         25.2.3.6. Directives
         25.2.3.7. Warnings
      25.2.4. Basic API
      25.2.5. Unittest API
      25.2.6. Advanced API
         25.2.6.1. DocTest Objects
         25.2.6.2. Example Objects
         25.2.6.3. DocTestFinder objects
         25.2.6.4. DocTestParser objects
         25.2.6.5. DocTestRunner objects
         25.2.6.6. OutputChecker objects
- 25.2.7. Debugging
- 25.2.8. Soapbox
- 25.3. `unittest` — Unit testing framework
  - 25.3.1. Basic example
  - 25.3.2. Command-Line Interface
    - 25.3.2.1. Command-line options
  - 25.3.3. Test Discovery
  - 25.3.4. Organizing test code
  - 25.3.5. Re-using old test code
  - 25.3.6. Skipping tests and expected failures
  - 25.3.7. Classes and functions
    - 25.3.7.1. Test cases
      - 25.3.7.1.1. Deprecated aliases
    - 25.3.7.2. Grouping tests
    - 25.3.7.3. Loading and running tests
      - 25.3.7.3.1. load_tests Protocol
  - 25.3.8. Class and Module Fixtures
    - 25.3.8.1. setUpClass and tearDownClass
    - 25.3.8.2. setUpModule and tearDownModule
  - 25.3.9. Signal Handling
- 25.4. `2to3` - Automated Python 2 to 3 code translation
  - 25.4.1. Using 2to3
  - 25.4.2. Fixers
  - 25.4.3. `lib2to3` - 2to3’s library
- 25.5. `test` — Regression tests package for Python
  - 25.5.1. Writing Unit Tests for the test package
  - 25.5.2. Running tests using the command-line interface
- 25.6. `test.test_support` — Utility functions for tests
- 26. Debugging and Profiling
  - 26.1. `bdb` — Debugger framework
  - 26.2. `pdb` — The Python Debugger
  - 26.3. Debugger Commands
- 28.1. `sys` — System-specific parameters and functions
- 28.2. `sysconfig` — Provide access to Python's configuration information
  - 28.2.1. Configuration variables
  - 28.2.2. Installation paths
  - 28.2.3. Other functions
- 28.3. `__builtin__` — Built-in objects
- 28.4. `future_builtins` — Python 3 builtins
- 28.5. `__main__` — Top-level script environment
- 28.6. `warnings` — Warning control
  - 28.6.1. Warning Categories
  - 28.6.2. The Warnings Filter
    - 28.6.2.1. Default Warning Filters
  - 28.6.3. Temporarily Suppressing Warnings
  - 28.6.4. Testing Warnings
  - 28.6.5. Updating Code For New Versions of Python
  - 28.6.6. Available Functions
  - 28.6.7. Available Context Managers
- 28.7. `contextlib` — Utilities for `with`-statement contexts
- 28.8. `abc` — Abstract Base Classes
- 28.9. `atexit` — Exit handlers
  - 28.9.1. `atexit` Example
- 28.10. `traceback` — Print or retrieve a stack traceback
  - 28.10.1. Traceback Examples
- 28.11. `__future__` — Future statement definitions
- 28.12. `gc` — Garbage Collector interface
- 28.13. `inspect` — Inspect live objects
  - 28.13.1. Types and members
  - 28.13.2. Retrieving source code
  - 28.13.3. Classes and functions
  - 28.13.4. The interpreter stack
28.14. **site** — Site-specific configuration hook
28.15. **user** — User-specific configuration hook
28.16. **fpectl** — Floating point exception control
   - 28.16.1. Example
   - 28.16.2. Limitations and other considerations

- **29. Custom Python Interpreters**
  - 29.1. **code** — Interpreter base classes
    - 29.1.1. Interactive Interpreter Objects
    - 29.1.2. Interactive Console Objects
  - 29.2. **codeop** — Compile Python code

- **30. Restricted Execution**
  - 30.1. **reexec** — Restricted execution framework
    - 30.1.1. RExec Objects
    - 30.1.2. Defining restricted environments
    - 30.1.3. An example
  - 30.2. **Bastion** — Restricting access to objects

- **31. Importing Modules**
  - 31.1. **imp** — Access the `import` internals
    - 31.1.1. Examples
  - 31.2. **importlib** — Convenience wrappers for `__import__()`
  - 31.3. **imputil** — Import utilities
    - 31.3.1. Examples
  - 31.4. **zipimport** — Import modules from Zip archives
    - 31.4.1. zipimporter Objects
    - 31.4.2. Examples
  - 31.5. **pkgutil** — Package extension utility
  - 31.6. **modulefinder** — Find modules used by a script
    - 31.6.1. Example usage of `ModuleFinder`
  - 31.7. **runpy** — Locating and executing Python modules

- **32. Python Language Services**
  - 32.1. **parser** — Access Python parse trees
32.1. Creating ST Objects
32.1.2. Converting ST Objects
32.1.3. Queries on ST Objects
32.1.4. Exceptions and Error Handling
32.1.5. ST Objects
32.1.6. Example: Emulation of \texttt{compile()}

32.2. \texttt{ast} — Abstract Syntax Trees
   32.2.1. Node classes
   32.2.2. Abstract Grammar
   32.2.3. \texttt{ast} Helpers

32.3. \texttt{symtable} — Access to the compiler’s symbol tables
   32.3.1. Generating Symbol Tables
   32.3.2. Examining Symbol Tables

32.4. \texttt{symbol} — Constants used with Python parse trees
32.5. \texttt{token} — Constants used with Python parse trees
32.6. \texttt{keyword} — Testing for Python keywords
32.7. \texttt{tokenize} — Tokenizer for Python source
32.8. \texttt{tabnanny} — Detection of ambiguous indentation
32.9. \texttt{pyclbr} — Python class browser support
   32.9.1. Class Objects
   32.9.2. Function Objects
32.10. \texttt{py_compile} — Compile Python source files
32.11. \texttt{compileall} — Byte-compile Python libraries
   32.11.1. Command-line use
   32.11.2. Public functions
32.12. \texttt{dis} — Disassembler for Python bytecode
   32.12.1. Python Bytecode Instructions
32.13. \texttt{pickletools} — Tools for pickle developers

33. Python compiler package
   33.1. The basic interface
   33.2. Limitations
33.3. Python Abstract Syntax
   - 33.3.1. AST Nodes
   - 33.3.2. Assignment nodes
   - 33.3.3. Examples

33.4. Using Visitors to Walk ASTs

33.5. Bytecode Generation

34. Miscellaneous Services
   - 34.1. formatter — Generic output formatting
     - 34.1.1. The Formatter Interface
     - 34.1.2. Formatter Implementations
     - 34.1.3. The Writer Interface
     - 34.1.4. Writer Implementations

35. MS Windows Specific Services
   - 35.1. msilib — Read and write Microsoft Installer files
     - 35.1.1. Database Objects
     - 35.1.2. View Objects
     - 35.1.3. Summary Information Objects
     - 35.1.4. Record Objects
     - 35.1.5. Errors
     - 35.1.6. CAB Objects
     - 35.1.7. Directory Objects
     - 35.1.8. Features
     - 35.1.9. GUI classes
     - 35.1.10. Precomputed tables

   - 35.2. msvcrt – Useful routines from the MS VC++ runtime
     - 35.2.1. File Operations
     - 35.2.2. Console I/O
     - 35.2.3. Other Functions

   - 35.3. _winreg – Windows registry access
     - 35.3.1. Constants
       - 35.3.1.1. HKEY_* Constants
       - 35.3.1.2. Access Rights
         - 35.3.1.2.1. 64-bit Specific
35.3.1.3. Value Types
35.3.2. Registry Handle Objects
35.4. **winsound** — Sound-playing interface for Windows

36. **Unix Specific Services**
   - 36.1. **posix** — The most common POSIX system calls
     - 36.1.1. Large File Support
     - 36.1.2. Notable Module Contents
   - 36.2. **pwd** — The password database
   - 36.3. **spwd** — The shadow password database
   - 36.4. **grp** — The group database
   - 36.5. **crypt** — Function to check Unix passwords
   - 36.6. **dl** — Call C functions in shared objects
     - 36.6.1. DI Objects
   - 36.7. **termios** — POSIX style tty control
     - 36.7.1. Example
   - 36.8. **tty** — Terminal control functions
   - 36.9. **pty** — Pseudo-terminal utilities
   - 36.10. **fcntl** — The `fcntl` and `ioctl` system calls
   - 36.11. **pipes** — Interface to shell pipelines
     - 36.11.1. Template Objects
   - 36.12. **posixfile** — File-like objects with locking support
   - 36.13. **resource** — Resource usage information
     - 36.13.1. Resource Limits
     - 36.13.2. Resource Usage
   - 36.14. **nis** — Interface to Sun’s NIS (Yellow Pages)
   - 36.15. **syslog** — Unix syslog library routines
     - 36.15.1. Examples
       - 36.15.1.1. Simple example
   - 36.16. **commands** — Utilities for running commands

37. **Mac OS X specific services**
   - 37.1. **ic** — Access to the Mac OS X Internet Config
37.1.1. IC Objects

37.2. MacOS — Access to Mac OS interpreter features

37.3. macostools — Convenience routines for file manipulation

37.4. findertools — The finder's Apple Events interface

37.5. EasyDialogs — Basic Macintosh dialogs
  - 37.5.1. ProgressBar Objects

37.6. FrameWork — Interactive application framework
  - 37.6.1. Application Objects
  - 37.6.2. Window Objects
  - 37.6.3. ControlsWindow Object
  - 37.6.4. ScrolledWindow Object
  - 37.6.5. DialogWindow Objects

37.7. autoGIL — Global Interpreter Lock handling in event loops

37.8. Mac OS Toolbox Modules
  - 37.8.1. Carbon.AE — Apple Events
  - 37.8.2. Carbon.AH — Apple Help
  - 37.8.3. Carbon.App — Appearance Manager
  - 37.8.4. Carbon.Appearance — Appearance Manager constants
  - 37.8.5. Carbon.CF — Core Foundation
  - 37.8.6. Carbon.CG — Core Graphics
  - 37.8.7. Carbon.CarbonEvt — Carbon Event Manager
  - 37.8.9. Carbon.Cm — Component Manager
  - 37.8.10. Carbon.Components — Component Manager constants
  - 37.8.11. Carbon.ControlAccessor — Control
Manager accessor

- 37.8.12. `Carbon.Controls` — Control Manager constants
- 37.8.13. `Carbon.CoreFoundation` — CoreFoundation constants
- 37.8.15. `Carbon.Ctl` — Control Manager
- 37.8.16. `Carbon.Dials` — Dialog Manager constants
- 37.8.17. `Carbon.Dlg` — Dialog Manager
- 37.8.18. `Carbon.Drag` — Drag and Drop Manager
- 37.8.19. `Carbon.Dragconst` — Drag and Drop Manager constants
- 37.8.20. `Carbon.Events` — Event Manager constants
- 37.8.22. `Carbon.File` — File Manager
- 37.8.23. `Carbon.Files` — File Manager constants
- 37.8.24. `Carbon.Fm` — Font Manager
- 37.8.25. `Carbon.Folder` — Folder Manager
- 37.8.27. `Carbon.Fonts` — Font Manager constants
- 37.8.28. `Carbon.Help` — Help Manager
- 37.8.29. `Carbon.IBCarbon` — Carbon InterfaceBuilder
- 37.8.30. `Carbon.IBCarbonRuntime` — Carbon InterfaceBuilder constants
- 37.8.31. `Carbon.Icn` — Carbon Icon Manager
- 37.8.32. `Carbon.Icons` — Carbon Icon Manager constants
37.8.33. **Carbon.Launch** — Carbon Launch Services
37.8.34. **Carbon.LaunchServices** — Carbon Launch Services constants
37.8.35. **Carbon.List** — List Manager
37.8.36. **Carbon.Lists** — List Manager constants
37.8.37. **Carbon.MacHelp** — Help Manager constants
37.8.38. **Carbon.MediaDescr** — Parsers and generators for Quicktime Media descriptors
37.8.39. **Carbon.Menu** — Menu Manager
37.8.40. **Carbon.Menus** — Menu Manager constants
37.8.41. **Carbon.Mlte** — MultiLingual Text Editor
37.8.42. **Carbon.OSA** — Carbon OSA Interface
37.8.43. **Carbon.OSAconst** — Carbon OSA Interface constants
37.8.44. **Carbon.QDOffscreen** — QuickDraw Offscreen constants
37.8.45. **Carbon.Qd** — QuickDraw
37.8.46. **Carbon.Qdoffs** — QuickDraw Offscreen
37.8.47. **Carbon.Qt** — QuickTime
37.8.48. **Carbon.QuickDraw** — QuickDraw constants
37.8.49. **Carbon.QuickTime** — QuickTime constants
37.8.50. **Carbon.Res** — Resource Manager and Handles
37.8.51. **Carbon.Resources** — Resource Manager and Handles constants
37.8.52. **Carbon.Scrap** — Scrap Manager
37.8.53. **Carbon.Snd** — Sound Manager
- 37.8.54. **Carbon.Sound** — Sound Manager constants
- 37.8.55. **Carbon.TE** — TextEdit
- 37.8.56. **Carbon.TextEdit** — TextEdit constants
- 37.8.57. **Carbon.Win** — Window Manager
- 37.8.58. **Carbon.Windows** — Window Manager constants
- 37.9. **ColorPicker** — Color selection dialog

38. MacPython OSA Modules
- 38.1. **gensuitemodule** — Generate OSA stub packages
- 38.2. **aetools** — OSA client support
- 38.3. **aepack** — Conversion between Python variables and AppleEvent data containers
- 38.4. **aetypes** — AppleEvent objects
- 38.5. **MiniAEFrame** — Open Scripting Architecture server support
  - 38.5.1. AEServer Objects

39. SGI IRIX Specific Services
- 39.1. **a1** — Audio functions on the SGI
  - 39.1.1. Configuration Objects
  - 39.1.2. Port Objects
- 39.2. **AL** — Constants used with the **a1** module
- 39.3. **cd** — CD-ROM access on SGI systems
  - 39.3.1. Player Objects
  - 39.3.2. Parser Objects
- 39.4. **f1** — FORMS library for graphical user interfaces
  - 39.4.1. Functions Defined in Module **f1**
  - 39.4.2. Form Objects
  - 39.4.3. FORMS Objects
- 39.5. **FL** — Constants used with the **f1** module
- 39.6. **f1p** — Functions for loading stored FORMS designs
39.7. fm — *Font Manager* interface
39.8. gl — *Graphics Library* interface
39.9. DEVICE — Constants used with the *gl* module
39.10. GL — Constants used with the *gl* module
39.11. imgfile — Support for SGI imglib files
39.12. jpeg — Read and write JPEG files

- 40. SunOS Specific Services
  - 40.1. sunaudiodev — Access to Sun audio hardware
    - 40.1.1. Audio Device Objects
  - 40.2. SUNAUDIODEV — Constants used with *sunaudiodev*

- 41. Undocumented Modules
  - 41.1. Miscellaneous useful utilities
  - 41.2. Platform specific modules
  - 41.3. Multimedia
  - 41.4. Undocumented Mac OS modules
    - 41.4.1. applesingle — Apple Single decoder
    - 41.4.2. buildtools — Helper module for BuildApplet and Friends
    - 41.4.3. cfmfile — Code Fragment Resource module
    - 41.4.4. icopen — Internet Config replacement for open()
    - 41.4.5. macerrors — Mac OS Errors
    - 41.4.6. macresource — Locate script resources
    - 41.4.7. Nav — NavServices calls
    - 41.4.8. PixMapWrapper — Wrapper for PixMap objects
    - 41.4.9. videoreader — Read QuickTime movies
    - 41.4.10. W — Widgets built on FrameWork

- 41.5. Obsolete
- 41.6. SGI-specific Extension modules

- Extending and Embedding the Python Interpreter
1. Extending Python with C or C++
   1.1. A Simple Example
   1.2. Intermezzo: Errors and Exceptions
   1.3. Back to the Example
   1.4. The Module's Method Table and Initialization Function
   1.5. Compilation and Linkage
   1.6. Calling Python Functions from C
   1.7. Extracting Parameters in Extension Functions
   1.8. Keyword Parameters for Extension Functions
   1.9. Building Arbitrary Values
   1.10. Reference Counts
      1.10.1. Reference Counting in Python
      1.10.2. Ownership Rules
      1.10.3. Thin Ice
      1.10.4. NULL Pointers
   1.11. Writing Extensions in C++
   1.12. Providing a C API for an Extension Module

2. Defining New Types
   2.1. The Basics
      2.1.1. Adding data and methods to the Basic example
      2.1.2. Providing finer control over data attributes
      2.1.3. Supporting cyclic garbage collection
      2.1.4. Subclassing other types
   2.2. Type Methods
      2.2.1. Finalization and De-allocation
      2.2.2. Object Presentation
      2.2.3. Attribute Management
         2.2.3.1. Generic Attribute Management
         2.2.3.2. Type-specific Attribute Management
      2.2.4. Object Comparison
      2.2.5. Abstract Protocol Support
      2.2.6. Weak Reference Support

10. API Reference
10.1. distutils.core — Core Distutils functionality

The `distutils.core` module is the only module that needs to be installed to use the Distutils. It provides the `setup()` (which is called from the setup script). Indirectly provides the `distutils.dist.Distribution` and `distutils.cmd.Command` class.

**distutils.core.** `setup(arguments)`

The basic do-everything function that does most everything you could ever ask for from a Distutils method.

The setup function takes a large number of arguments. These are laid out in the following table.

<table>
<thead>
<tr>
<th>argument name</th>
<th>value</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name</code></td>
<td>The name of the package</td>
<td>a string</td>
</tr>
<tr>
<td><code>version</code></td>
<td>The version number of the package; see <code>distutils.version</code></td>
<td>a string</td>
</tr>
<tr>
<td><code>description</code></td>
<td>A single line describing the package</td>
<td>a string</td>
</tr>
<tr>
<td><code>long_description</code></td>
<td>Longer description of the package</td>
<td>a string</td>
</tr>
<tr>
<td><code>author</code></td>
<td>The name of the package author</td>
<td>a string</td>
</tr>
<tr>
<td><code>author_email</code></td>
<td>The email address of the package author</td>
<td>a string</td>
</tr>
<tr>
<td></td>
<td>The name of the current maintainer,</td>
<td></td>
</tr>
<tr>
<td><strong>maintainer</strong></td>
<td>if different from the author. Note that if the maintainer is provided, distutils will use it as the author in <strong>PKG-INFO</strong></td>
<td>a string</td>
</tr>
<tr>
<td><strong>maintainer_email</strong></td>
<td>The email address of the current maintainer, if different from the author</td>
<td>a string</td>
</tr>
<tr>
<td><strong>url</strong></td>
<td>A URL for the package (homepage)</td>
<td>a string</td>
</tr>
<tr>
<td><strong>download_url</strong></td>
<td>A URL to download the package</td>
<td>a string</td>
</tr>
<tr>
<td><strong>packages</strong></td>
<td>A list of Python packages that distutils will manipulate</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>py_modules</strong></td>
<td>A list of Python modules that distutils will manipulate</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>scripts</strong></td>
<td>A list of standalone script files to be built and installed</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>ext_modules</strong></td>
<td>A list of Python extensions to be built</td>
<td>a list of instances of <code>distutils.core.Extension</code></td>
</tr>
<tr>
<td><strong>classifiers</strong></td>
<td>A list of categories for the package</td>
<td>a list of strings; valid classifiers are listed on PyPI.</td>
</tr>
<tr>
<td><strong>distclass</strong></td>
<td>the <code>Distribution</code> class to use</td>
<td>a subclass of <code>distutils.core.Distribution</code></td>
</tr>
</tbody>
</table>
The name of the setup.py script - defaults to sys.argv[0]

Arguments to supply to the setup script

default options for the setup script

The license for the package

Descriptive metadata, see PEP 314

A mapping of command names to Command subclasses

A list of data files to install

A mapping of package to directory names

The name of the setup.py script - defaults to sys.argv[0]

Arguments to supply to the setup script

default options for the setup script

The license for the package

Descriptive metadata, see PEP 314

A mapping of command names to Command subclasses

A list of data files to install

A mapping of package to directory names

Run a setup script in a somewhat controlled environment, and return the distutils.dist.Distribution instance that drives things. This is useful if you need to find out the distribution metadata (passed as keyword args from script to setup()), or the contents of the config files or command-line.

script_name is a file that will be run with execfile() sys.argv[0]
will be replaced with \textit{script} for the duration of the call. \textit{script\_args} is a list of strings; if supplied, \texttt{sys.argv[1:]} will be replaced by \textit{script\_args} for the duration of the call.

\textit{stop\_after} tells \texttt{setup()} when to stop processing; possible values:

<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{init}</td>
<td>Stop after the \texttt{Distribution} instance has been created and populated with the keyword arguments to \texttt{setup()}</td>
</tr>
<tr>
<td>\textit{config}</td>
<td>Stop after config files have been parsed (and their data stored in the \texttt{Distribution} instance)</td>
</tr>
<tr>
<td>\textit{commandline}</td>
<td>Stop after the command-line (\texttt{sys.argv[1:]} or \textit{script_args}) have been parsed (and the data stored in the \texttt{Distribution} instance.)</td>
</tr>
<tr>
<td>\textit{run}</td>
<td>Stop after all commands have been run (the same as if \texttt{setup()} had been called in the usual way). This is the default value.</td>
</tr>
</tbody>
</table>

In addition, the \texttt{distutils.core} module exposed a number of classes that live elsewhere.

- \texttt{Extension} from \texttt{distutils.extension}
- \texttt{Command} from \texttt{distutils.cmd}
- \texttt{Distribution} from \texttt{distutils.dist}

A short description of each of these follows, but see the relevant module for the full reference.

\texttt{class} \texttt{distutils.core.Extension}

The Extension class describes a single C or C++ extension module in a setup script. It accepts the following keyword arguments in its constructor

<table>
<thead>
<tr>
<th>argument name</th>
<th>value</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td>the full name of the extension, including any packages — <em>not</em> a filename or pathname, but Python dotted name</td>
<td>a string</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>sources</strong></td>
<td>list of source filenames, relative to the distribution root (where the setup script lives), in Unix form (slash-separated) for portability. Source files may be C, C++, SWIG (.i), platform-specific resource files, or whatever else is recognized by the <code>build_ext</code> command as source for a Python extension.</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>include_dirs</strong></td>
<td>list of directories to search for C/C++ header files (in Unix form for portability)</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>define_macros</strong></td>
<td>list of macros to define; each macro is defined using a 2-tuple <code>(name, value)</code>, where <code>value</code> is either the string to define it to or <code>None</code> to define it without a particular value (equivalent of <code>#define FOO</code> in source or <code>-DFOO</code> on Unix C compiler command line)</td>
<td>a list of tuples</td>
</tr>
<tr>
<td><strong>undef_macros</strong></td>
<td>list of macros to</td>
<td>a list of strings</td>
</tr>
<tr>
<td><strong>variable</strong></td>
<td><strong>description</strong></td>
<td><strong>type</strong></td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td><code>library_dirs</code></td>
<td>list of directories to search for C/C++ libraries at link time</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>libraries</code></td>
<td>list of library names (not filenames or paths) to link against</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>runtime_library_dirs</code></td>
<td>list of directories to search for C/C++ libraries at run time (for shared extensions, this is when the extension is loaded)</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>extra_objects</code></td>
<td>list of extra files to link with (eg. object files not implied by ‘sources’, static library that must be explicitly specified, binary resource files, etc.)</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>extra_compile_args</code></td>
<td>any extra platform- and compiler-specific information to use when compiling the source files in ‘sources’. For platforms and compilers where a command line makes sense, this is typically a list of command-line arguments, but for other platforms it could be anything.</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>extra_link_args</code></td>
<td>any extra platform- and compiler-specific information to use when linking object files</td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
<td>Type</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>extra_link_args</code></td>
<td>together to create the extension (or to create a new static Python interpreter). Similar interpretation as for ‘extra_compile_args’.</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>export_symbols</code></td>
<td>list of symbols to be exported from a shared extension. Not used on all platforms, and not generally necessary for Python extensions, which typically export exactly one symbol: init + extension_name.</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>depends</code></td>
<td>list of files that the extension depends on</td>
<td>a list of strings</td>
</tr>
<tr>
<td><code>language</code></td>
<td>extension language (i.e. 'c', 'c++', 'objc'). Will be detected from the source extensions if not provided.</td>
<td>a string</td>
</tr>
</tbody>
</table>

**class distutils.core.Distribution**

A `Distribution` describes how to build, install and package up a Python software package.

See the `setup()` function for a list of keyword arguments accepted by the Distribution constructor. `setup()` creates a Distribution instance.

**class distutils.core.Command**

A `Command` class (or rather, an instance of one of its subclasses) implement a single distutils command.
10.2. distutils.ccompiler — CCompiler base class

This module provides the abstract base class for the `CCompiler` classes. A `CCompiler` instance can be used for all the compile and link steps needed to build a single project. Methods are provided to set options for the compiler — macro definitions, include directories, link path, libraries and the like.

This module provides the following functions.

**distutils.ccompiler.**

- **gen_lib_options**(compiler, library_dirs, runtime_library_dirs, libraries)
  Generate linker options for searching library directories and linking with specific libraries. `libraries` and `library_dirs` are, respectively, lists of library names (not filenames!) and search directories. Returns a list of command-line options suitable for use with some compiler (depending on the two format strings passed in).

- **gen_preprocess_options**(macros, include_dirs)
  Generate C pre-processor options (`-D`, `-U`, `-I`) as used by at least two types of compilers: the typical Unix compiler and Visual C++. `macros` is the usual thing, a list of 1- or 2-tuples, where `(name,)` means undefine (`-U`) macro `name`, and `(name, value)` means define (`-D`) macro `name` to `value`. `include_dirs` is just a list of directory names to be added to the header file search path (`-I`). Returns a list of command-line options suitable for either Unix compilers or Visual C++.

- **get_default_compiler**(osname, platform)
  Determine the default compiler to use for the given platform.
osname should be one of the standard Python OS names (i.e. the ones returned by os.name) and platform the common value returned by sys.platform for the platform in question.

The default values are os.name and sys.platform in case the parameters are not given.

distutils.ccompiler.new_compiler(plat=None, compiler=None, verbose=0, dry_run=0, force=0)

Factory function to generate an instance of some CCompiler subclass for the supplied platform/compiler combination. plat defaults to os.name (eg. 'posix', 'nt'), and compiler defaults to the default compiler for that platform. Currently only 'posix' and 'nt' are supported, and the default compilers are “traditional Unix interface” (UnixCCompiler class) and Visual C++ (MSVCCompiler class). Note that it’s perfectly possible to ask for a Unix compiler object under Windows, and a Microsoft compiler object under Unix—if you supply a value for compiler, plat is ignored.

distutils.ccompiler.show_compilers()

Print list of available compilers (used by the --help-compiler options to build, build_ext, build_clib).

class distutils.ccompiler.CCompiler([verbose=0, dry_run=0, force=0])

The abstract base class CCompiler defines the interface that must be implemented by real compiler classes. The class also has some utility methods used by several compiler classes.

The basic idea behind a compiler abstraction class is that each instance can be used for all the compile/link steps in building a single project. Thus, attributes common to all of those compile and link steps — include directories, macros to define, libraries to
link against, etc. — are attributes of the compiler instance. To allow for variability in how individual files are treated, most of those attributes may be varied on a per-compilation or per-link basis.

The constructor for each subclass creates an instance of the Compiler object. Flags are verbose (show verbose output), dry_run (don’t actually execute the steps) and force (rebuild everything, regardless of dependencies). All of these flags default to 0 (off). Note that you probably don’t want to instantiate CCompiler or one of its subclasses directly - use the distutils.CCompiler.new_compiler() factory function instead.

The following methods allow you to manually alter compiler options for the instance of the Compiler class.

add_include_dir(dir)
Add dir to the list of directories that will be searched for header files. The compiler is instructed to search directories in the order in which they are supplied by successive calls to add_include_dir().

set_include_dirs(dirs)
Set the list of directories that will be searched to dirs (a list of strings). Overrides any preceding calls to add_include_dir(); subsequent calls to add_include_dir() add to the list passed to set_include_dirs(). This does not affect any list of standard include directories that the compiler may search by default.

add_library(libname)
Add libname to the list of libraries that will be included in all links driven by this compiler object. Note that libname should *not* be the name of a file containing a library, but the name
of the library itself: the actual filename will be inferred by the linker, the compiler, or the compiler class (depending on the platform).

The linker will be instructed to link against libraries in the order they were supplied to `add_library()` and/or `set_libraries()`. It is perfectly valid to duplicate library names; the linker will be instructed to link against libraries as many times as they are mentioned.

**set_libraries(libnames)**
Set the list of libraries to be included in all links driven by this compiler object to `libnames` (a list of strings). This does not affect any standard system libraries that the linker may include by default.

**add_library_dir(dir)**
Add `dir` to the list of directories that will be searched for libraries specified to `add_library()` and `set_libraries()`. The linker will be instructed to search for libraries in the order they are supplied to `add_library_dir()` and/or `set_library_dirs()`.

**set_library_dirs(dirs)**
Set the list of library search directories to `dirs` (a list of strings). This does not affect any standard library search path that the linker may search by default.

**add_runtime_library_dir(dir)**
Add `dir` to the list of directories that will be searched for shared libraries at runtime.

**set_runtime_library_dirs(dirs)**
Set the list of directories to search for shared libraries at runtime to `dirs` (a list of strings). This does not affect any
standard search path that the runtime linker may search by default.

**define_macro**(name[, value=None])
Define a preprocessor macro for all compilations driven by this compiler object. The optional parameter *value* should be a string; if it is not supplied, then the macro will be defined without an explicit value and the exact outcome depends on the compiler used.

**undefine_macro**(name)
Undefine a preprocessor macro for all compilations driven by this compiler object. If the same macro is defined by **define_macro()** and undefined by **undefine_macro()** the last call takes precedence (including multiple redefinitions or undefinitions). If the macro is redefined/undefined on a per-compilation basis (ie. in the call to **compile()**), then that takes precedence.

**add_link_object**(object)
Add *object* to the list of object files (or analogues, such as explicitly named library files or the output of “resource compilers”) to be included in every link driven by this compiler object.

**set_link_objects**(objects)
Set the list of object files (or analogues) to be included in every link to *objects*. This does not affect any standard object files that the linker may include by default (such as system libraries).

The following methods implement methods for autodetection of compiler options, providing some functionality similar to GNU **autoconf**.
detect_language(sources)
Detect the language of a given file, or list of files. Uses the instance attributes language_map (a dictionary), and language_order (a list) to do the job.

find_library_file(dirs, lib[, debug=0])
Search the specified list of directories for a static or shared library file lib and return the full path to that file. If debug is true, look for a debugging version (if that makes sense on the current platform). Return None if lib wasn’t found in any of the specified directories.

has_function(funcname[, includes=None, include_dirs=None, libraries=None, library_dirs=None])
Return a boolean indicating whether funcname is supported on the current platform. The optional arguments can be used to augment the compilation environment by providing additional include files and paths and libraries and paths.

library_dir_option(dir)
Return the compiler option to add dir to the list of directories searched for libraries.

library_option(lib)
Return the compiler option to add lib to the list of libraries linked into the shared library or executable.

runtime_library_dir_option(dir)
Return the compiler option to add dir to the list of directories searched for runtime libraries.

set_executables(**args)
Define the executables (and options for them) that will be run to perform the various stages of compilation. The exact set of
executables that may be specified here depends on the compiler class (via the ‘executables’ class attribute), but most will have:

<table>
<thead>
<tr>
<th>attribute</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compiler</td>
<td>the C/C++ compiler</td>
</tr>
<tr>
<td>linker_so</td>
<td>linker used to create shared objects and libraries</td>
</tr>
<tr>
<td>linker_exe</td>
<td>linker used to create binary executables</td>
</tr>
<tr>
<td>archiver</td>
<td>static library creator</td>
</tr>
</tbody>
</table>

On platforms with a command-line (Unix, DOS/Windows), each of these is a string that will be split into executable name and (optional) list of arguments. (Splitting the string is done similarly to how Unix shells operate: words are delimited by spaces, but quotes and backslashes can override this. See `distutils.util.split_quoted()`.)

The following methods invoke stages in the build process.

```python
compile(sources[, output_dir=None, macros=None, include_dirs=None, debug=0, extra_preargs=None, extra_postargs=None, depends=None])
```

Compile one or more source files. Generates object files (e.g. transforms a `.c` file to a `.o` file.)

`sources` must be a list of filenames, most likely C/C++ files, but in reality anything that can be handled by a particular compiler and compiler class (eg. `MSVCCompiler` can handle resource files in `sources`). Return a list of object filenames, one per source filename in `sources`. Depending on the implementation, not all source files will necessarily be compiled, but all corresponding object filenames will be returned.
If `output_dir` is given, object files will be put under it, while retaining their original path component. That is, `foo/bar.c` normally compiles to `foo/bar.o` (for a Unix implementation); if `output_dir` is `build`, then it would compile to `build/foo/bar.o`.

`macros`, if given, must be a list of macro definitions. A macro definition is either a `(name, value)` 2-tuple or a `(name,)` 1-tuple. The former defines a macro; if the value is `None`, the macro is defined without an explicit value. The 1-tuple case undefines a macro. Later definitions/redefinitions/undefinitions take precedence.

`include_dirs`, if given, must be a list of strings, the directories to add to the default include file search path for this compilation only.

`debug` is a boolean; if true, the compiler will be instructed to output debug symbols in (or alongside) the object file(s).

`extra_preargs` and `extra_postargs` are implementation-dependent. On platforms that have the notion of a command-line (e.g. Unix, DOS/Windows), they are most likely lists of strings: extra command-line arguments to prepend/append to the compiler command line. On other platforms, consult the implementation class documentation. In any event, they are intended as an escape hatch for those occasions when the abstract compiler framework doesn’t cut the mustard.

`depends`, if given, is a list of filenames that all targets depend on. If a source file is older than any file in depends, then the source file will be recompiled. This supports dependency tracking, but only at a coarse granularity.

Raises `CompileError` on failure.
create_static_lib(objects, output_libname[, output_dir=None, debug=0, target_lang=None])

Link a bunch of stuff together to create a static library file. The “bunch of stuff” consists of the list of object files supplied as objects, the extra object files supplied to add_link_object() and/or set_link_objects(), the libraries supplied to add_library() and/or set_libraries(), and the libraries supplied as libraries (if any).

output_libname should be a library name, not a filename; the filename will be inferred from the library name. output_dir is the directory where the library file will be put.

debug is a boolean; if true, debugging information will be included in the library (note that on most platforms, it is the compile step where this matters: the debug flag is included here just for consistency).

target_lang is the target language for which the given objects are being compiled. This allows specific linkage time treatment of certain languages.

 Raises LibError on failure.

link(target_desc, objects, output_filename[, output_dir=None, libraries=None, library_dirs=None, runtime_library_dirs=None, export_symbols=None, debug=0, extra_preargs=None, extra_postargs=None, build_temp=None, target_lang=None])

Link a bunch of stuff together to create an executable or shared library file.

The “bunch of stuff” consists of the list of object files supplied as objects. output_filename should be a filename. If output_dir is supplied, output_filename is relative to it (i.e.
**output_filename** can provide directory components if needed).

**libraries** is a list of libraries to link against. These are library names, not filenames, since they're translated into filenames in a platform-specific way (eg. *foo* becomes *libfoo.a* on Unix and *foo.lib* on DOS/Windows). However, they can include a directory component, which means the linker will look in that specific directory rather than searching all the normal locations.

**library_dirs**, if supplied, should be a list of directories to search for libraries that were specified as bare library names (ie. no directory component). These are on top of the system default and those supplied to *add_library_dir()* and/or *set_library_dirs()*.

**runtime_library_dirs** is a list of directories that will be embedded into the shared library and used to search for other shared libraries that *it* depends on at run-time. (This may only be relevant on Unix.)

**export_symbols** is a list of symbols that the shared library will export. (This appears to be relevant only on Windows.)

**debug** is as for *compile()* and *create_static_lib()*, with the slight distinction that it actually matters on most platforms (as opposed to *create_static_lib()* , which includes a **debug** flag mostly for form's sake).

**extra_preargs** and **extra_postargs** are as for *compile()* (except of course that they supply command-line arguments for the particular linker being used).

**target_lang** is the target language for which the given objects are being compiled. This allows specific linkage time treatment of certain languages.
Raises `LinkError` on failure.

```python
link_executable(objects, output_progname[, output_dir=None, libraries=None, library_dirs=None, runtime_library_dirs=None, debug=0, extra_preargs=None, extra_postargs=None, target_lang=None])
```

Link an executable. `output_progname` is the name of the file executable, while `objects` are a list of object filenames to link in. Other arguments are as for the `link()` method.

```python
link_shared_lib(objects, output_libname[, output_dir=None, libraries=None, library_dirs=None, runtime_library_dirs=None, export_symbols=None, debug=0, extra_preargs=None, extra_postargs=None, build_temp=None, target_lang=None])
```

Link a shared library. `output_libname` is the name of the output library, while `objects` is a list of object filenames to link in. Other arguments are as for the `link()` method.

```python
link_shared_object(objects, output_filename[, output_dir=None, libraries=None, library_dirs=None, runtime_library_dirs=None, export_symbols=None, debug=0, extra_preargs=None, extra_postargs=None, build_temp=None, target_lang=None])
```

Link a shared object. `output_filename` is the name of the shared object that will be created, while `objects` is a list of object filenames to link in. Other arguments are as for the `link()` method.

```python
preprocess(source[, output_file=None, macros=None, include_dirs=None, extra_preargs=None, extra_postargs=None])
```

Preprocess a single C/C++ source file, named in `source`. Output will be written to file named `output_file`, or `stdout` if
output_file not supplied. macros is a list of macro definitions as for compile(), which will augment the macros set with define_macro() and undefine_macro(). include_dirs is a list of directory names that will be added to the default list, in the same way as add_include_dir().

 Raises PreprocessError on failure.

The following utility methods are defined by the CCompiler class, for use by the various concrete subclasses.

 executable_filename(basename[, strip_dir=0, output_dir=''])
 Returns the filename of the executable for the given basename. Typically for non-Windows platforms this is the same as the basename, while Windows will get a .exe added.

 library_filename(libname[, lib_type='static', strip_dir=0, output_dir=''])
 Returns the filename for the given library name on the current platform. On Unix a library with lib_type of 'static' will typically be of the form liblibname.a, while a lib_type of 'dynamic' will be of the form liblibname.so.

 object_filenames(source_filenames[, strip_dir=0, output_dir=''])
 Returns the name of the object files for the given source files. source_filenames should be a list of filenames.

 shared_object_filename(basename[, strip_dir=0, output_dir=''])
 Returns the name of a shared object file for the given file name basename.
execute(func, args[, msg=None, level=1])
Invokes distutils.util.execute(). This method invokes a Python function func with the given arguments args, after logging and taking into account the dry_run flag.

spawn(cmd)
Invokes distutils.util.spawn(). This invokes an external process to run the given command.

mkpath(name[, mode=511])
Invokes distutils.dir_util.mkpath(). This creates a directory and any missing ancestor directories.

move_file(src, dst)
Invokes distutils.file_util.move_file(). Renames src to dst.

announce(msg[, level=1])
Write a message using distutils.log.debug().

warn(msg)
Write a warning message msg to standard error.

download_file(msg)
If the debug flag is set on this CCompiler instance, print msg to standard output, otherwise do nothing.
This module provides the `UnixCCompiler` class, a subclass of `CCompiler` that handles the typical Unix-style command-line C compiler:

- macros defined with `-Dname[=value]`
- macros undefined with `-Uname`
- include search directories specified with `-Idir`
- libraries specified with `-llib`
- library search directories specified with `-Ldir`
- compile handled by `cc` (or similar) executable with `-c` option: compiles `.c` to `.o`
- link static library handled by `ar` command (possibly with `ranlib`)
- link shared library handled by `cc -shared`
This module provides `MSVCCCompiler`, an implementation of the abstract `CCompiler` class for Microsoft Visual Studio. Typically, extension modules need to be compiled with the same compiler that was used to compile Python. For Python 2.3 and earlier, the compiler was Visual Studio 6. For Python 2.4 and 2.5, the compiler is Visual Studio .NET 2003. The AMD64 and Itanium binaries are created using the Platform SDK.

`MSVCCCompiler` will normally choose the right compiler, linker etc. on its own. To override this choice, the environment variables `DISTUTILS_USE_SDK` and `MSSdk` must be both set. `MSSdk` indicates that the current environment has been setup by the SDK’s `SetEnv.Cmd` script, or that the environment variables had been registered when the SDK was installed; `DISTUTILS_USE_SDK` indicates that the distutils user has made an explicit choice to override the compiler selection by `MSVCCCompiler`. 
This module provides `BorlandCCompiler`, a subclass of the abstract `CCompiler` class for the Borland C++ compiler.
This module provides the `CygwinCCompiler` class, a subclass of `UnixCCompiler` that handles the Cygwin port of the GNU C compiler to Windows. It also contains the `Mingw32CCompiler` class which handles the mingw32 port of GCC (same as cygwin in no-cygwin mode).
This module provides the EMXCCCompiler class, a subclass of UnixCCCompiler that handles the EMX port of the GNU C compiler to OS/2.
This module provides a few functions for creating archive files, such as tarballs or zipfiles.

```
from distutils.archive_util import make_archive, make_tarball, make_zipfile
```

### `make_archive(base_name, format[, root_dir=None, base_dir=None, verbose=0, dry_run=0])`

Create an archive file (eg. *zip* or *tar*). `base_name` is the name of the file to create, minus any format-specific extension; `format` is the archive format: one of *zip*, *tar*, *ztar*, or *gztar*. `root_dir` is a directory that will be the root directory of the archive; ie. we typically `chdir` into `root_dir` before creating the archive. `base_dir` is the directory where we start archiving from; ie. `base_dir` will be the common prefix of all files and directories in the archive. `root_dir` and `base_dir` both default to the current directory. Returns the name of the archive file.

### `make_tarball(base_name, base_dir[, compress='gzip', verbose=0, dry_run=0])`

Create an (optional compressed) archive as a tar file from all files in and under `base_dir`. `compress` must be *gzip* (the default), *compress*, *bzip2*, or None. Both *tar* and the compression utility named by `compress` must be on the default program search path, so this is probably Unix-specific. The output tar file will be named `base_dir.tar`, possibly plus the appropriate compression extension (*.gz*, *.bz2* or *.Z*). Return the output filename.

### `make_zipfile(base_name, base_dir[, compress=None, verbose=0, dry_run=0])`

Create a zip archive file from all files in and under `base_dir`. `compress` is the file compression utility to use (None or *gzip*, *compress*, *bzip2*, or None). Returns the filename of the archive file.
Create a zip file from all files in and under `base_dir`. The output zip file will be named `base_name + .zip`. Uses either the `zipfile` Python module (if available) or the InfoZIP `zip` utility (if installed and found on the default search path). If neither tool is available, raises `DistutilsExecError`. Returns the name of the output zip file.
10.9. distutils.dep_util — Dependency checking

This module provides functions for performing simple, timestamp-based dependency of files and groups of files; also, functions based entirely on such timestamp dependency analysis.

**distutils.dep_util.newer(source, target)**

Return true if *source* exists and is more recently modified than *target*, or if *source* exists and *target* doesn't. Return false if both exist and *target* is the same age or newer than *source*. Raise **DistutilsFileError** if *source* does not exist.

**distutils.dep_util.newer_pairwise(sources, targets)**

Walk two filename lists in parallel, testing if each source is newer than its corresponding target. Return a pair of lists (*sources*, *targets*) where source is newer than target, according to the semantics of **newer()**.

**distutils.dep_util.newer_group(sources, target[, missing='error'])**

Return true if *target* is out-of-date with respect to any file listed in *sources* In other words, if *target* exists and is newer than every file in *sources*, return false; otherwise return true. **missing** controls what we do when a source file is missing; the default ('error') is to blow up with an **OSError** from inside **os.stat()**; if it is 'ignore', we silently drop any missing source files; if it is 'newer', any missing source files make us assume that *target* is out-of-date (this is handy in “dry-run” mode: it'll make you pretend to carry out commands that wouldn't work because inputs are missing, but that doesn’t matter because you’re not actually going to run the commands).
This module provides functions for operating on directories and trees of directories.

```python
distutils.dir_util.mkpath(name[, mode=0777, verbose=0, dry_run=0])
```

Create a directory and any missing ancestor directories. If the directory already exists (or if `name` is the empty string, which means the current directory, which of course exists), then do nothing. Raise `DistutilsFileError` if unable to create some directory along the way (e.g. some sub-path exists, but is a file rather than a directory). If `verbose` is true, print a one-line summary of each `mkdir` to stdout. Return the list of directories actually created.

```python
distutils.dir_util.create_tree(base_dir, files[, mode=0777, verbose=0, dry_run=0])
```

Create all the empty directories under `base_dir` needed to put `files` there. `base_dir` is just the name of a directory which doesn’t necessarily exist yet; `files` is a list of filenames to be interpreted relative to `base_dir`. `base_dir` + the directory portion of every file in `files` will be created if it doesn’t already exist. `mode`, `verbose` and `dry_run` flags are as for `mkpath()`.

```python
distutils.dir_util.copy_tree(src, dst[, preserve_mode=1, preserve_times=1, preservesymlinks=0, update=0, verbose=0, dry_run=0])
```

Copy an entire directory tree `src` to a new location `dst`. Both `src` and `dst` must be directory names. If `src` is not a directory, raise
**DistutilsFileError.** If *dst* does not exist, it is created with *mkpath()*.

The end result of the copy is that every file in *src* is copied to *dst*, and directories under *src* are recursively copied to *dst*. Return the list of files that were copied or might have been copied, using their output name. The return value is unaffected by *update* or *dry_run*: it is simply the list of all files under *src*, with the names changed to be under *dst*.

*preserve_mode* and *preserve_times* are the same as for *distutils.file_util.copy_file()*; note that they only apply to regular files, not to directories. If *preserve_symlinks* is true, symlinks will be copied as symlinks (on platforms that support them!); otherwise (the default), the destination of the symlink will be copied. *update* and *verbose* are the same as for *copy_file()*.

Files in *src* that begin with `.nfs` are skipped (more information on these files is available in answer D2 of the [NFS FAQ page](https://example.com)).

*Changed in version 2.7.4:* NFS files are ignored.

```python
distutils.dir_util.remove_tree(directory[, verbose=0, dry_run=0])
```

Recursively remove *directory* and all files and directories underneath it. Any errors are ignored (apart from being reported to *sys.stdout* if *verbose* is true).
10.11. distutils.file_util — Single file operations

This module contains some utility functions for operating on individual files.

```
distutils.file_util.copy_file(src, dst[, preserve_mode=1, preserve_times=1, update=0, link=None, verbose=0, dry_run=0])
```

Copy file `src` to `dst`. If `dst` is a directory, then `src` is copied there with the same name; otherwise, it must be a filename. (If the file exists, it will be ruthlessly clobbered.) If `preserve_mode` is true (the default), the file's mode (type and permission bits, or whatever is analogous on the current platform) is copied. If `preserve_times` is true (the default), the last-modified and last-access times are copied as well. If `update` is true, `src` will only be copied if `dst` does not exist, or if `dst` does exist but is older than `src`.

`link` allows you to make hard links (using `os.link()`) or symbolic links (using `os.symlink()`) instead of copying: set it to 'hard' or 'sym'; if it is `None` (the default), files are copied. Don't set `link` on systems that don't support it: `copy_file()` doesn't check if hard or symbolic linking is available. It uses `_copy_file_contents()` to copy file contents.

Return a tuple `(dest_name, copied): dest_name` is the actual name of the output file, and `copied` is true if the file was copied (or would have been copied, if `dry_run` true).

```
distutils.file_util.move_file(src, dst[, verbose, dry_run])
```

Move file `src` to `dst`. If `dst` is a directory, the file will be moved into it with the same name; otherwise, `src` is just renamed to `dst`. 
Returns the new full name of the file.

**Warning:** Handles cross-device moves on Unix using `copy_file()`. What about other systems?

distutils.file_util.\texttt{write\_file}(filename, contents)

Create a file called \textit{filename} and write \textit{contents} (a sequence of strings without line terminators) to it.
This module contains other assorted bits and pieces that don't fit into any other utility module.

\texttt{distutils.util.get\_platform()}

Return a string that identifies the current platform. This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by \texttt{os.uname()})\texttt{), although the exact information included depends on the OS; eg. for IRIX the architecture isn’t particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn’t particularly important.

Examples of returned values:

- \texttt{linux-i586}
- \texttt{linux-alpha}
- \texttt{solaris-2.6-sun4u}
- \texttt{irix-5.3}
- \texttt{irix64-6.2}

For non-POSIX platforms, currently just returns \texttt{sys.platform}.

For Mac OS X systems the OS version reflects the minimal version on which binaries will run (that is, the value of \texttt{MACOSX\_DEPLOYMENT\_TARGET} during the build of Python), not the OS version of the current system.

For universal binary builds on Mac OS X the architecture value reflects the universal binary status instead of the architecture of
the current processor. For 32-bit universal binaries the architecture is fat, for 64-bit universal binaries the architecture is fat64, and for 4-way universal binaries the architecture is universal. Starting from Python 2.7 and Python 3.2 the architecture fat3 is used for a 3-way universal build (ppc, i386, x86_64) and intel is used for a universal build with the i386 and x86_64 architectures.

Examples of returned values on Mac OS X:

- macosx-10.3-ppc
- macosx-10.3-fat
- macosx-10.5-universal
- macosx-10.6-intel

```
# convert_path

distutils.util.convert_path(pathname)
```

Return ‘pathname’ as a name that will work on the native filesystem, i.e. split it on ‘/’ and put it back together again using the current directory separator. Needed because filenames in the setup script are always supplied in Unix style, and have to be converted to the local convention before we can actually use them in the filesystem. Raises ValueError on non-Unix-ish systems if pathname either starts or ends with a slash.

```
# change_root

distutils.util.change_root(new_root, pathname)
```

Return pathname with new_root prepended. If pathname is relative, this is equivalent to os.path.join(new_root, pathname). Otherwise, it requires making pathname relative and then joining the two, which is tricky on DOS/Windows.

```
# check_environ

distutils.util.check_environ()
```

Ensure that ‘os.environ’ has all the environment variables we guarantee that users can use in config files, command-line options, etc. Currently this includes:
- **HOME** - user’s home directory (Unix only)
- **PLAT** - description of the current platform, including hardware and OS (see `get_platform()`)

```python
distutils.util.subst_vars(s, local_vars)
```
Perform shell/Perl-style variable substitution on s. Every occurrence of $ followed by a name is considered a variable, and variable is substituted by the value found in the `local_vars` dictionary, or in `os.environ` if it’s not in `local_vars`. `os.environ` is first checked/augmented to guarantee that it contains certain values: see `check_environ()`. Raise `ValueError` for any variables not found in either `local_vars` or `os.environ`.

Note that this is not a fully-fledged string interpolation function. A valid $variable can consist only of upper and lower case letters, numbers and an underscore. No { } or ( ) style quoting is available.

```python
distutils.util.split_quoted(s)
```
Split a string up according to Unix shell-like rules for quotes and backslashes. In short: words are delimited by spaces, as long as those spaces are not escaped by a backslash, or inside a quoted string. Single and double quotes are equivalent, and the quote characters can be backslash-escaped. The backslash is stripped from any two-character escape sequence, leaving only the escaped character. The quote characters are stripped from any quoted string. Returns a list of words.

```python
distutils.util.execute(func, args[, msg=None, verbose=0, dry_run=0])
```
Perform some action that affects the outside world (for instance, writing to the filesystem). Such actions are special because they are disabled by the `dry_run` flag. This method takes care of all
that bureaucracy for you; all you have to do is supply the function to call and an argument tuple for it (to embody the “external action” being performed), and an optional message to print.

**distutils.util.strtobool(val)**

Convert a string representation of truth to true (1) or false (0).

True values are `y`, `yes`, `t`, `true`, `on` and 1; false values are `n`, `no`, `f`, `false`, `off` and 0. Raises `ValueError` if `val` is anything else.

**distutils.util.byte_compile(py_files[, optimize=0, force=0, prefix=None, base_dir=None, verbose=1, dry_run=0, direct=None])**

Byte-compile a collection of Python source files to either `.pyc` or `.pyo` files in the same directory. `py_files` is a list of files to compile; any files that don’t end in `.py` are silently skipped. `optimize` must be one of the following:

- 0 - don’t optimize (generate `.pyc`)
- 1 - normal optimization (like `python -O`)
- 2 - extra optimization (like `python -OO`)

If `force` is true, all files are recompiled regardless of timestamps.

The source filename encoded in each bytecode file defaults to the filenames listed in `py_files`; you can modify these with `prefix` and `basedir`. `prefix` is a string that will be stripped off of each source filename, and `base_dir` is a directory name that will be prepended (after `prefix` is stripped). You can supply either or both (or neither) of `prefix` and `base_dir`, as you wish.

If `dry_run` is true, doesn’t actually do anything that would affect the filesystem.

Byte-compilation is either done directly in this interpreter process with the standard `py_compile` module, or indirectly by writing a
temporary script and executing it. Normally, you should let byte_compile() figure out to use direct compilation or not (see the source for details). The direct flag is used by the script generated in indirect mode; unless you know what you’re doing, leave it set to None.

distutils.util/rfc822_escape(header)
Return a version of header escaped for inclusion in an RFC 822 header, by ensuring there are 8 spaces space after each newline. Note that it does no other modification of the string.
This module provides the `Distribution` class, which represents the module distribution being built/installed/distributed.
This module provides the `Extension` class, used to describe C/C++ extension modules in setup scripts.
This module provides the DEBUG flag.
Provides exceptions used by the Distutils modules. Note that Distutils modules may raise standard exceptions; in particular, SystemExit is usually raised for errors that are obviously the end-user's fault (e.g. bad command-line arguments).

This module is safe to use in `from ... import *` mode; it only exports symbols whose names start with `Distutils` and end with `Error`. 
This module provides a wrapper around the standard `getopt` module that provides the following additional features:

- short and long options are tied together
- options have help strings, so `fancy_getopt()` could potentially create a complete usage summary
- options set attributes of a passed-in object
- boolean options can have “negative aliases” — eg. if `--quiet` is the “negative alias” of `--verbose`, then `--quiet` on the command line sets `verbose` to false.

**distutils.fancy_getopt**

`fancy_getopt(options, negative_opt, object, args)`

Wrapper function. `options` is a list of `(long_option, short_option, help_string)` 3-tuples as described in the constructor for `FancyGetopt`. `negative_opt` should be a dictionary mapping option names to option names, both the key and value should be in the `options` list. `object` is an object which will be used to store values (see the `getopt()` method of the `FancyGetopt` class). `args` is the argument list. Will use `sys.argv[1:]` if you pass `None` as `args`.

`wrap_text(text, width)`

Wraps `text` to less than `width` wide.

**class distutils.fancy_getopt.FancyGetopt([option_table=None])**

The `option_table` is a list of 3-tuples: `(long_option, short_option, help_string)`
If an option takes an argument, its *long_option* should have '=' appended; *short_option* should just be a single character, no ':' in any case. *short_option* should be *None* if a *long_option* doesn't have a corresponding *short_option*. All option tuples must have long options.

The **FancyGetopt** class provides the following methods:

**FancyGetopt**. **getopt**([*args=None, object=None]*)

Parse command-line options in *args*. Store as attributes on *object*.

If *args* is *None* or not supplied, uses `sys.argv[1:]`. If *object* is *None* or not supplied, creates a new *OptionDummy* instance, stores option values there, and returns a tuple (*args, object*). If *object* is supplied, it is modified in place and **getopt()** just returns *args*; in both cases, the returned *args* is a modified copy of the passed-in *args* list, which is left untouched.

**FancyGetopt**. **get_option_order**()

Returns the list of (*option, value*) tuples processed by the previous run of **getopt()**. Raises **RuntimeError** if **getopt()** hasn't been called yet.

**FancyGetopt**. **generate_help**([*header=None]*)

Generate help text (a list of strings, one per suggested line of output) from the option table for this **FancyGetopt** object.

If supplied, prints the supplied *header* at the top of the help.
This module provides the `FileList` class, used for poking about the filesystem and building lists of files.
10.19. distutils.log — Simple PEP 282-style logging
This module provides the `spawn()` function, a front-end to various platform-specific functions for launching another program in a subprocess. Also provides `find_executable()` to search the path for a given executable name.
10.21. distutils.sysconfig — System configuration information

The `distutils.sysconfig` module provides access to Python's low-level configuration information. The specific configuration variables available depend heavily on the platform and configuration. The specific variables depend on the build process for the specific version of Python being run; the variables are those found in the Makefile and configuration header that are installed with Python on Unix systems. The configuration header is called `pyconfig.h` for Python versions starting with 2.2, and `config.h` for earlier versions of Python.

Some additional functions are provided which perform some useful manipulations for other parts of the distutils package.

- **distutils.sysconfig.PREFIX**
  The result of `os.path.normpath(sys.prefix)`.

- **distutils.sysconfig.EXEC_PREFIX**
  The result of `os.path.normpath(sys.exec_prefix)`.

- **distutils.sysconfig.get_config_var(name)**
  Return the value of a single variable. This is equivalent to `get_config_vars().get(name)`.

- **distutils.sysconfig.get_config_vars(...)**
  Return a set of variable definitions. If there are no arguments, this returns a dictionary mapping names of configuration variables to values. If arguments are provided, they should be strings, and the return value will be a sequence giving the associated values. If a given name does not have a corresponding value, `None` will be included for that variable.
distutils.sysconfig.get_config_h_filename()
Return the full path name of the configuration header. For Unix, this will be the header generated by the configure script; for other platforms the header will have been supplied directly by the Python source distribution. The file is a platform-specific text file.

distutils.sysconfig.get_makefile_filename()
Return the full path name of the Makefile used to build Python. For Unix, this will be a file generated by the configure script; the meaning for other platforms will vary. The file is a platform-specific text file, if it exists. This function is only useful on POSIX platforms.

distutils.sysconfig.get_python_inc([plat_specific, prefix])
Return the directory for either the general or platform-dependent C include files. If plat_specific is true, the platform-dependent include directory is returned; if false or omitted, the platform-independent directory is returned. If prefix is given, it is used as either the prefix instead of PREFIX, or as the exec-prefix instead of EXEC_PREFIX if plat_specific is true.

distutils.sysconfig.get_python_lib([plat_specific, standard_lib, prefix])
Return the directory for either the general or platform-dependent library installation. If plat_specific is true, the platform-dependent include directory is returned; if false or omitted, the platform-independent directory is returned. If prefix is given, it is used as either the prefix instead of PREFIX, or as the exec-prefix instead of EXEC_PREFIX if plat_specific is true. If standard_lib is true, the directory for the standard library is returned rather than the directory for the installation of third-party extensions.
The following function is only intended for use within the `distutils` package.

`distutils.sysconfig.customize_compiler(compiler)`

Do any platform-specific customization of a `distutils.ccompiler.CCompiler` instance.

This function is only needed on Unix at this time, but should be called consistently to support forward-compatibility. It inserts the information that varies across Unix flavors and is stored in Python’s `Makefile`. This information includes the selected compiler, compiler and linker options, and the extension used by the linker for shared objects.

This function is even more special-purpose, and should only be used from Python’s own build procedures.

`distutils.sysconfig.set_python_build()`

Inform the `distutils.sysconfig` module that it is being used as part of the build process for Python. This changes a lot of relative locations for files, allowing them to be located in the build area rather than in an installed Python.
This module provides the `TextFile` class, which gives an interface to text files that (optionally) takes care of stripping comments, ignoring blank lines, and joining lines with backslashes.

```python
class distutils.text_file.TextFile([filename=None, file=None, **options])
```

This class provides a file-like object that takes care of all the things you commonly want to do when processing a text file that has some line-by-line syntax: strip comments (as long as `#` is your comment character), skip blank lines, join adjacent lines by escaping the newline (ie. backslash at end of line), strip leading and/or trailing whitespace. All of these are optional and independently controllable.

The class provides a `warn()` method so you can generate warning messages that report physical line number, even if the logical line in question spans multiple physical lines. Also provides `unreadline()` for implementing line-at-a-time lookahead.

`TextFile` instances are create with either `filename`, `file`, or both. `RuntimeError` is raised if both are `None`. `filename` should be a string, and `file` a file object (or something that provides `readline()` and `close()` methods). It is recommended that you supply at least `filename`, so that `TextFile` can include it in warning messages. If `file` is not supplied, `TextFile` creates its own using the `open()` built-in function.

The options are all boolean, and affect the values returned by
### readline()

<table>
<thead>
<tr>
<th>option name</th>
<th>description</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>strip_comments</td>
<td>strip from ' #' to end-of-line, as well as any whitespace leading up to the ' #':—unless it is escaped by a backslash</td>
<td>true</td>
</tr>
<tr>
<td>lstrip_ws</td>
<td>strip leading whitespace from each line before returning it</td>
<td>false</td>
</tr>
<tr>
<td>rstrip_ws</td>
<td>strip trailing whitespace (including line terminator!) from each line before returning it.</td>
<td>true</td>
</tr>
<tr>
<td>skip_blanks</td>
<td>skip lines that are empty <em>after</em> stripping comments and whitespace. (If both lstrip_ws and rstrip_ws are false, then some lines may consist of solely whitespace: these will <em>not</em> be skipped, even if skip_blanks is true.)</td>
<td>true</td>
</tr>
<tr>
<td>join_lines</td>
<td>if a backslash is the last non-newline character on a line after stripping comments and whitespace, join the following line to it to form one logical line; if N consecutive lines end with a backslash, then N+1 physical lines will be joined to form one logical line.</td>
<td>false</td>
</tr>
<tr>
<td>collapse_join</td>
<td>strip leading whitespace from lines that are joined to their predecessor; only matters if (join_lines and not lstrip_ws)</td>
<td>false</td>
</tr>
</tbody>
</table>

Note that since rstrip_ws can strip the trailing newline, the semantics of `readline()` must differ from those of the built-in file object's `readline()` method! In particular, `readline()` returns
None for end-of-file: an empty string might just be a blank line (or an all-whitespace line), if rstrip_ws is true but skip_blanks is not.

open(filename)
Open a new file filename. This overrides any file or filename constructor arguments.

close()
Close the current file and forget everything we know about it (including the filename and the current line number).

warn(msg[, line=None])
Print (to stderr) a warning message tied to the current logical line in the current file. If the current logical line in the file spans multiple physical lines, the warning refers to the whole range, such as "lines 3-5". If line is supplied, it overrides the current line number; it may be a list or tuple to indicate a range of physical lines, or an integer for a single physical line.

readline()
Read and return a single logical line from the current file (or from an internal buffer if lines have previously been “unread” with unreadline()). If the join_lines option is true, this may involve reading multiple physical lines concatenated into a single string. Updates the current line number, so calling warn() after readline() emits a warning about the physical line(s) just read. Returns None on end-of-file, since the empty string can occur if rstrip_ws is true but strip_blanks is not.

readlines()
Read and return the list of all logical lines remaining in the current file. This updates the current line number to the last line of the file.
unreadline(line)

Push line (a string) onto an internal buffer that will be checked by future readline() calls. Handy for implementing a parser with line-at-a-time lookahead. Note that lines that are “unread” with unreadline() are not subsequently re-cleansed (whitespace stripped, or whatever) when read with readline(). If multiple calls are made to unreadline() before a call to readline(), the lines will be returned most in most recent first order.
10.23. *distutils.version* — Version number classes
This module supplies the abstract base class `Command`.

```
class distutils.cmd.Command(dist)
```

Abstract base class for defining command classes, the “worker bees” of the Distutils. A useful analogy for command classes is to think of them as subroutines with local variables called `options`. The options are declared in `initialize_options()` and defined (given their final values) in `finalize_options()`, both of which must be defined by every command class. The distinction between the two is necessary because option values might come from the outside world (command line, config file, ...), and any options dependent on other options must be computed after these outside influences have been processed — hence `finalize_options()`. The body of the subroutine, where it does all its work based on the values of its options, is the `run()` method, which must also be implemented by every command class.

The class constructor takes a single argument `dist`, a `Distribution` instance.
10.25. Creating a new Distutils command

This section outlines the steps to create a new Distutils command.

A new command lives in a module in the `distutils.command` package. There is a sample template in that directory called `command_template`. Copy this file to a new module with the same name as the new command you're implementing. This module should implement a class with the same name as the module (and the command). So, for instance, to create the command `peel_banana` (so that users can run `setup.py peel_banana`), you'd copy `command_template` to `distutils/command/peel_banana.py`, then edit it so that it's implementing the class `peel_banana`, a subclass of `distutils.cmd.Command`.

Subclasses of `Command` must define the following methods.

`Command.initialize_options()`
Set default values for all the options that this command supports. Note that these defaults may be overridden by other commands, by the setup script, by config files, or by the command-line. Thus, this is not the place to code dependencies between options; generally, `initialize_options()` implementations are just a bunch of `self.foo = None` assignments.

`Command.finalize_options()`
Set final values for all the options that this command supports. This is always called as late as possible, i.e. after any option assignments from the command-line or from other commands have been done. Thus, this is the place to code option dependencies: if `foo` depends on `bar`, then it is safe to set `foo` from `bar` as long as `foo` still has the same value it was assigned
in `initialize_options()`.

**Command. run()**

A command's raison d'être: carry out the action it exists to perform, controlled by the options initialized in `initialize_options()`, customized by other commands, the setup script, the command-line, and config files, and finalized in `finalize_options()`. All terminal output and filesystem interaction should be done by `run()`.

**Command. sub_commands**

`sub_commands` formalizes the notion of a “family” of commands, e.g. install as the parent with sub-commands `install_lib`, `install_headers`, etc. The parent of a family of commands defines `sub_commands` as a class attribute; it's a list of 2-tuples `(command_name, predicate)`, with `command_name` a string and `predicate` a function, a string or `None`. `predicate` is a method of the parent command that determines whether the corresponding command is applicable in the current situation. (E.g. `install_headers` is only applicable if we have any C header files to install.) If `predicate` is `None`, that command is always applicable.

`sub_commands` is usually defined at the end of a class, because predicates can be methods of the class, so they must already have been defined. The canonical example is the `install` command.
10.26. distutils.command — Individual Distutils commands
10.27. distutils.command.bdist — Build a binary installer
10.28. distutils.command.bdist_packager —
Abstract base class for packagers
10.30. distutils.command.bdist_msi — Build a Microsoft Installer binary package

```python
class distutils.command.bdist_msi.bdist_msi

Builds a Windows Installer (.msi) binary package.

In most cases, the bdist_msi installer is a better choice than the bdist_wininst installer, because it provides better support for Win64 platforms, allows administrators to perform non-interactive installations, and allows installation through group policies.
```
10.31. distutils.command.bdist_rpm — Build a binary distribution as a Redhat RPM and SRPM
10.32. distutils.command.bdist_wininst — Build a Windows installer
10.33. distutils.command.sdist — Build a source distribution
distutils.command.build — Build all files of a package
10.35. distutils.command.build_clib — Build any C libraries in a package
distutils.command.build_ext — Build any extensions in a package
10.37. distutils.command.build_py — Build the .py/.pyc files of a package
10.38. distutils.command.build_scripts — Build the scripts of a package
This command removes the temporary files created by `build` and its subcommands, like intermediary compiled object files. With the `--all` option, the complete build directory will be removed.

Extension modules built in place will not be cleaned, as they are not in the build directory.
10.40. distutils.command.config — Perform package configuration
10.41. distutils.command.install — Install a package
10.42. distutils.command.install_data —
Install data files from a package
Install C/C++ header files from a package
10.44. distutils.command.install_lib — Install library files from a package
The `register` command registers the package with the Python Package Index. This is described in more detail in PEP 301.
The `check` command performs some tests on the meta-data of a package. For example, it verifies that all required meta-data are provided as the arguments passed to the `setup()` function.
Installing Python Modules (Legacy version)

Author: Greg Ward

Installing Python Modules
The up to date module installation documentations

This document describes the Python Distribution Utilities (“Distutils”) from the end-user’s point-of-view, describing how to extend the capabilities of a standard Python installation by building and installing third-party Python modules and extensions.

Note: This guide only covers the basic tools for building and distributing extensions that are provided as part of this version of Python. Third party tools offer easier to use and more secure alternatives. Refer to the quick recommendations section in the Python Packaging User Guide for more information.
Introduction

Although Python's extensive standard library covers many programming needs, there often comes a time when you need to add some new functionality to your Python installation in the form of third-party modules. This might be necessary to support your own programming, or to support an application that you want to use and that happens to be written in Python.

In the past, there has been little support for adding third-party modules to an existing Python installation. With the introduction of the Python Distribution Utilities (Distutils for short) in Python 2.0, this changed.

This document is aimed primarily at the people who need to install third-party Python modules: end-users and system administrators who just need to get some Python application running, and existing Python programmers who want to add some new goodies to their toolbox. You don't need to know Python to read this document; there will be some brief forays into using Python's interactive mode to explore your installation, but that's it. If you're looking for information on how to distribute your own Python modules so that others may use them, see the Distributing Python Modules (Legacy version) manual. Debugging the setup script may also be of interest.

Best case: trivial installation

In the best case, someone will have prepared a special version of the module distribution you want to install that is targeted specifically at your platform and is installed just like any other software on your platform. For example, the module developer might make an executable installer available for Windows users, an RPM package for users of RPM-based Linux systems (Red Hat, SuSE, Mandrake,
and many others), a Debian package for users of Debian-based Linux systems, and so forth.

In that case, you would download the installer appropriate to your platform and do the obvious thing with it: run it if it’s an executable installer, `rpm --install` it if it’s an RPM, etc. You don’t need to run Python or a setup script, you don’t need to compile anything—you might not even need to read any instructions (although it’s always a good idea to do so anyway).

Of course, things will not always be that easy. You might be interested in a module distribution that doesn’t have an easy-to-use installer for your platform. In that case, you’ll have to start with the source distribution released by the module’s author/maintainer. Installing from a source distribution is not too hard, as long as the modules are packaged in the standard way. The bulk of this document is about building and installing modules from standard source distributions.

### The new standard: Distutils

If you download a module source distribution, you can tell pretty quickly if it was packaged and distributed in the standard way, i.e. using the Distutils. First, the distribution’s name and version number will be featured prominently in the name of the downloaded archive, e.g. `foo-1.0.tar.gz` or `widget-0.9.7.zip`. Next, the archive will unpack into a similarly-named directory: `foo-1.0` or `widget-0.9.7`. Additionally, the distribution will contain a setup script `setup.py`, and a file named `README.txt` or possibly just `README`, which should explain that building and installing the module distribution is a simple matter of running one command from a terminal:

```
python setup.py install
```
For Windows, this command should be run from a command prompt window (Start ▶ Accessories):

```
setup.py install
```

If all these things are true, then you already know how to build and install the modules you’ve just downloaded: Run the command above. Unless you need to install things in a non-standard way or customize the build process, you don’t really need this manual. Or rather, the above command is everything you need to get out of this manual.
Standard Build and Install

As described in section The new standard: Distutils, building and installing a module distribution using the Distutils is usually one simple command to run from a terminal:

```
python setup.py install
```

Platform variations

You should always run the setup command from the distribution root directory, i.e. the top-level subdirectory that the module source distribution unpacks into. For example, if you've just downloaded a module source distribution `foo-1.0.tar.gz` onto a Unix system, the normal thing to do is:

```
gunzip -c foo-1.0.tar.gz | tar xf -  # unpacks into directory
cd foo-1.0
python setup.py install
```

On Windows, you’d probably download `foo-1.0.zip`. If you downloaded the archive file to `C:\Temp`, then it would unpack into `C:\Temp\foo-1.0`; you can use either an archive manipulator with a graphical user interface (such as WinZip) or a command-line tool (such as `unzip` or `pkunzip`) to unpack the archive. Then, open a command prompt window and run:

```
cd c:\Temp\foo-1.0
python setup.py install
```

Splitting the job up

Running `setup.py install` builds and installs all modules in one run.
If you prefer to work incrementally—especially useful if you want to customize the build process, or if things are going wrong—you can use the setup script to do one thing at a time. This is particularly helpful when the build and install will be done by different users—for example, you might want to build a module distribution and hand it off to a system administrator for installation (or do it yourself, with super-user privileges).

For example, you can build everything in one step, and then install everything in a second step, by invoking the setup script twice:

```bash
python setup.py build
python setup.py install
```

If you do this, you will notice that running the `install` command first runs the `build` command, which—in this case—quickly notices that it has nothing to do, since everything in the `build` directory is up-to-date.

You may not need this ability to break things down often if all you do is install modules downloaded off the ‘net, but it’s very handy for more advanced tasks. If you get into distributing your own Python modules and extensions, you’ll run lots of individual Distutils commands on their own.

---

**How building works**

As implied above, the `build` command is responsible for putting the files to install into a *build directory*. By default, this is `build` under the distribution root; if you’re excessively concerned with speed, or want to keep the source tree pristine, you can change the build directory with the `--build-base` option. For example:

```bash
python setup.py build --build-base=/path/to/pybuild/foo-1.0
```
(Or you could do this permanently with a directive in your system or personal Distutils configuration file; see section Distutils Configuration Files.) Normally, this isn't necessary.

The default layout for the build tree is as follows:

```plaintext
--- build/ --- lib/
or
--- build/ --- lib.<plat>/
    temp.<plat>/
```

where `<plat>` expands to a brief description of the current OS/hardware platform and Python version. The first form, with just a `lib` directory, is used for “pure module distributions”—that is, module distributions that include only pure Python modules. If a module distribution contains any extensions (modules written in C/C++), then the second form, with two `<plat>` directories, is used. In that case, the `temp.<plat>` directory holds temporary files generated by the compile/link process that don't actually get installed. In either case, the `lib` (or `lib.<plat>`) directory contains all Python modules (pure Python and extensions) that will be installed.

In the future, more directories will be added to handle Python scripts, documentation, binary executables, and whatever else is needed to handle the job of installing Python modules and applications.

## How installation works

After the `build` command runs (whether you run it explicitly, or the `install` command does it for you), the work of the `install` command is relatively simple: all it has to do is copy everything under `build/lib` (or `build/lib.<plat>`) to your chosen installation directory.

If you don’t choose an installation directory—i.e., if you just run `setup.py install`—then the `install` command installs to the standard
location for third-party Python modules. This location varies by
platform and by how you built/installed Python itself. On Unix (and
Mac OS X, which is also Unix-based), it also depends on whether
the module distribution being installed is pure Python or contains
extensions (“non-pure”):

<table>
<thead>
<tr>
<th>Platform</th>
<th>Standard installation location</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unix (pure)</td>
<td><code>prefix/lib/pythonX.Y/site-packages</code></td>
<td><code>/usr/local/lib/pythonX.Y/site-packages</code></td>
</tr>
<tr>
<td>Unix (non-pure)</td>
<td><code>exec-prefix/lib/pythonX.Y/site-packages</code></td>
<td><code>/usr/local/lib/pythonX.Y/site-packages</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>prefix\Lib\site-packages</code></td>
<td><code>C:\PythonXY\Lib\site-packages</code></td>
</tr>
</tbody>
</table>

Notes:

1. Most Linux distributions include Python as a standard part of the
system, so `prefix` and `exec-prefix` are usually both `/usr` on
Linux. If you build Python yourself on Linux (or any Unix-like
system), the default `prefix` and `exec-prefix` are `/usr/local`.
2. The default installation directory on Windows was `C:\Program
Files\Python` under Python 1.6a1, 1.5.2, and earlier.

`prefix` and `exec-prefix` stand for the directories that Python is
installed to, and where it finds its libraries at run-time. They are
always the same under Windows, and very often the same under
Unix and Mac OS X. You can find out what your Python installation
uses for `prefix` and `exec-prefix` by running Python in interactive
mode and typing a few simple commands. Under Unix, just type
`python` at the shell prompt. Under Windows, choose Start › Programs › Python X.Y › Python (command line). Once the
interpreter is started, you type Python code at the prompt. For
example, on my Linux system, I type the three Python statements
shown below, and get the output as shown, to find out my `prefix` and `exec-prefix`:

```
Python 2.4 (#26, Aug 7 2004, 17:19:02)
Type "help", "copyright", "credits" or "license" for more information.
>>> import sys
>>> sys.prefix
'/usr'
>>> sys.exec_prefix
'/usr'
```

A few other placeholders are used in this document: `x.y` stands for the version of Python, for example 2.7; `distname` will be replaced by the name of the module distribution being installed. Dots and capitalization are important in the paths; for example, a value that uses `python2.7` on UNIX will typically use `Python27` on Windows.

If you don’t want to install modules to the standard location, or if you don’t have permission to write there, then you need to read about alternate installations in section Alternate Installation. If you want to customize your installation directories more heavily, see section Custom Installation on custom installations.
Alternate Installation

Often, it is necessary or desirable to install modules to a location other than the standard location for third-party Python modules. For example, on a Unix system you might not have permission to write to the standard third-party module directory. Or you might wish to try out a module before making it a standard part of your local Python installation. This is especially true when upgrading a distribution already present: you want to make sure your existing base of scripts still works with the new version before actually upgrading.

The Distutils install command is designed to make installing module distributions to an alternate location simple and painless. The basic idea is that you supply a base directory for the installation, and the install command picks a set of directories (called an installation scheme) under this base directory in which to install files. The details differ across platforms, so read whichever of the following sections applies to you.

Note that the various alternate installation schemes are mutually exclusive: you can pass --user, or --home, or --prefix and --exec-prefix, or --install-base and --install-platbase, but you can’t mix from these groups.

Alternate installation: the user scheme

This scheme is designed to be the most convenient solution for users that don’t have write permission to the global site-packages directory or don’t want to install into it. It is enabled with a simple option:

```
python setup.py install --user
```
Files will be installed into subdirectories of `site.USER_BASE` (written as `userbase` hereafter). This scheme installs pure Python modules and extension modules in the same location (also known as `site.USER_SITE`). Here are the values for UNIX, including Mac OS X:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Installation directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>modules</td>
<td><code>userbase/lib/pythonX.Y/site-packages</code></td>
</tr>
<tr>
<td>scripts</td>
<td><code>userbase/bin</code></td>
</tr>
<tr>
<td>data</td>
<td><code>userbase</code></td>
</tr>
<tr>
<td>C headers</td>
<td><code>userbase/include/pythonX.Y/distname</code></td>
</tr>
</tbody>
</table>

And here are the values used on Windows:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Installation directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>modules</td>
<td><code>userbase\PythonXY\site-packages</code></td>
</tr>
<tr>
<td>scripts</td>
<td><code>userbase\Scripts</code></td>
</tr>
<tr>
<td>data</td>
<td><code>userbase</code></td>
</tr>
<tr>
<td>C headers</td>
<td><code>userbase\PythonXY\Include\distname</code></td>
</tr>
</tbody>
</table>

The advantage of using this scheme compared to the other ones described below is that the user site-packages directory is under normal conditions always included in `sys.path` (see `site` for more information), which means that there is no additional step to perform after running the `setup.py` script to finalize the installation.

The `build_ext` command also has a `--user` option to add `userbase/include` to the compiler search path for header files and `userbase/lib` to the compiler search path for libraries as well as to the runtime search path for shared C libraries (rpath).

### Alternate installation: the home scheme

The idea behind the “home scheme” is that you build and maintain a
personal stash of Python modules. This scheme’s name is derived from the idea of a “home” directory on Unix, since it’s not unusual for a Unix user to make their home directory have a layout similar to /usr/ or /usr/local/. This scheme can be used by anyone, regardless of the operating system they are installing for.

Installing a new module distribution is as simple as

```python
python setup.py install --home=<dir>
```

where you can supply any directory you like for the --home option. On Unix, lazy typists can just type a tilde (~); the install command will expand this to your home directory:

```python
python setup.py install --home=~
```

To make Python find the distributions installed with this scheme, you may have to modify Python’s search path or edit sitecustomize (see site) to call site.addsitedir() or edit sys.path.

The --home option defines the installation base directory. Files are installed to the following directories under the installation base as follows:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Installation directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>modules</td>
<td>home/lib/python</td>
</tr>
<tr>
<td>scripts</td>
<td>home/bin</td>
</tr>
<tr>
<td>data</td>
<td>home</td>
</tr>
<tr>
<td>C headers</td>
<td>home/include/python/distname</td>
</tr>
</tbody>
</table>

(Mentally replace slashes with backslashes if you're on Windows.)

*Changed in version 2.4:* The --home option used to be supported only on Unix.
**Alternate installation: Unix (the prefix scheme)**

The “prefix scheme” is useful when you wish to use one Python installation to perform the build/install (i.e., to run the setup script), but install modules into the third-party module directory of a different Python installation (or something that looks like a different Python installation). If this sounds a trifle unusual, it is—that’s why the user and home schemes come before. However, there are at least two known cases where the prefix scheme will be useful.

First, consider that many Linux distributions put Python in `/usr`, rather than the more traditional `/usr/local`. This is entirely appropriate, since in those cases Python is part of “the system” rather than a local add-on. However, if you are installing Python modules from source, you probably want them to go in `/usr/local/lib/python2.X` rather than `/usr/lib/python2.X`. This can be done with

```
/usr/bin/python setup.py install --prefix=/usr/local
```

Another possibility is a network filesystem where the name used to write to a remote directory is different from the name used to read it: for example, the Python interpreter accessed as `/usr/local/bin/python` might search for modules in `/usr/local/lib/python2.X`, but those modules would have to be installed to, say, `/mnt/@server/export/lib/python2.X`. This could be done with

```
/usr/local/bin/python setup.py install --prefix=/mnt/@server/export
```

In either case, the `--prefix` option defines the installation base, and the `--exec-prefix` option defines the platform-specific installation base, which is used for platform-specific files. (Currently, this just
means non-pure module distributions, but could be expanded to C libraries, binary executables, etc.) If --exec-prefix is not supplied, it defaults to --prefix. Files are installed as follows:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Installation directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Python modules</td>
<td>prefix/lib/pythonX.Y/site-packages</td>
</tr>
<tr>
<td>extension modules</td>
<td>exec-prefix/lib/pythonX.Y/site-packages</td>
</tr>
<tr>
<td>scripts</td>
<td>prefix/bin</td>
</tr>
<tr>
<td>data</td>
<td>prefix</td>
</tr>
<tr>
<td>C headers</td>
<td>prefix/include/pythonX.Y/distname</td>
</tr>
</tbody>
</table>

There is no requirement that --prefix or --exec-prefix actually point to an alternate Python installation; if the directories listed above do not already exist, they are created at installation time.

Incidentally, the real reason the prefix scheme is important is simply that a standard Unix installation uses the prefix scheme, but with --prefix and --exec-prefix supplied by Python itself as sys.prefix and sys.exec_prefix. Thus, you might think you’ll never use the prefix scheme, but every time you run python setup.py install without any other options, you’re using it.

Note that installing extensions to an alternate Python installation has no effect on how those extensions are built: in particular, the Python header files (Python.h and friends) installed with the Python interpreter used to run the setup script will be used in compiling extensions. It is your responsibility to ensure that the interpreter used to run extensions installed in this way is compatible with the interpreter used to build them. The best way to do this is to ensure that the two interpreters are the same version of Python (possibly different builds, or possibly copies of the same build). (Of course, if your --prefix and --exec-prefix don’t even point to an alternate
Python installation, this is immaterial.)

**Alternate installation: Windows (the prefix scheme)**

Windows has no concept of a user's home directory, and since the standard Python installation under Windows is simpler than under Unix, the `--prefix` option has traditionally been used to install additional packages in separate locations on Windows.

```
python setup.py install --prefix="\Temp\Python"
```

to install modules to the `\Temp\Python` directory on the current drive.

The installation base is defined by the `--prefix` option; the `--exec-prefix` option is not supported under Windows, which means that pure Python modules and extension modules are installed into the same location. Files are installed as follows:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Installation directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>modules</td>
<td><code>prefix\Lib\site-packages</code></td>
</tr>
<tr>
<td>scripts</td>
<td><code>prefix\Scripts</code></td>
</tr>
<tr>
<td>data</td>
<td><code>prefix</code></td>
</tr>
<tr>
<td>C headers</td>
<td><code>prefix\Include\distname</code></td>
</tr>
</tbody>
</table>
Custom Installation

Sometimes, the alternate installation schemes described in section Alternate Installation just don’t do what you want. You might want to tweak just one or two directories while keeping everything under the same base directory, or you might want to completely redefine the installation scheme. In either case, you’re creating a custom installation scheme.

To create a custom installation scheme, you start with one of the alternate schemes and override some of the installation directories used for the various types of files, using these options:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Override option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Python modules</td>
<td>--install-purelib</td>
</tr>
<tr>
<td>extension modules</td>
<td>--install-platlib</td>
</tr>
<tr>
<td>all modules</td>
<td>--install-lib</td>
</tr>
<tr>
<td>scripts</td>
<td>--install-scripts</td>
</tr>
<tr>
<td>data</td>
<td>--install-data</td>
</tr>
<tr>
<td>C headers</td>
<td>--install-headers</td>
</tr>
</tbody>
</table>

These override options can be relative, absolute, or explicitly defined in terms of one of the installation base directories. (There are two installation base directories, and they are normally the same—they only differ when you use the Unix “prefix scheme” and supply different --prefix and --exec-prefix options; using --install-lib will override values computed or given for --install-purelib and --install-platlib, and is recommended for schemes that don’t make a difference between Python and extension modules.)

For example, say you’re installing a module distribution to your home directory under Unix—but you want scripts to go in ~/scripts rather than ~/bin. As you might expect, you can override this directory with
the --install-scripts option; in this case, it makes most sense to supply a relative path, which will be interpreted relative to the installation base directory (your home directory, in this case):

```bash
python setup.py install --home=~ --install-scripts=scripts
```

Another Unix example: suppose your Python installation was built and installed with a prefix of `/usr/local/python`, so under a standard installation scripts will wind up in `/usr/local/python/bin`. If you want them in `/usr/local/bin` instead, you would supply this absolute directory for the --install-scripts option:

```bash
python setup.py install --install-scripts=/usr/local/bin
```

(This performs an installation using the “prefix scheme,” where the prefix is whatever your Python interpreter was installed with—`/usr/local/python` in this case.)

If you maintain Python on Windows, you might want third-party modules to live in a subdirectory of `prefix`, rather than right in `prefix` itself. This is almost as easy as customizing the script installation directory —you just have to remember that there are two types of modules to worry about, Python and extension modules, which can conveniently be both controlled by one option:

```bash
python setup.py install --install-lib=Site
```

The specified installation directory is relative to `prefix`. Of course, you also have to ensure that this directory is in Python's module search path, such as by putting a `.pth` file in a site directory (see `site`). See section Modifying Python's Search Path to find out how to modify Python’s search path.

If you want to define an entire installation scheme, you just have to
supply all of the installation directory options. The recommended way to do this is to supply relative paths; for example, if you want to maintain all Python module-related files under `python` in your home directory, and you want a separate directory for each platform that you use your home directory from, you might define the following installation scheme:

```bash
python setup.py install --home=~/ 
  --install-purelib=python/lib 
  --install-platlib=python/lib.$PLAT 
  --install-scripts=python/scripts 
  --install-data=python/data
```

or, equivalently,

```bash
python setup.py install --home=~/python 
  --install-purelib=lib 
  --install-platlib='lib.$PLAT' 
  --install-scripts=scripts 
  --install-data=data
```

`$PLAT` is not (necessarily) an environment variable—it will be expanded by the Distutils as it parses your command line options, just as it does when parsing your configuration file(s).

Obviously, specifying the entire installation scheme every time you install a new module distribution would be very tedious. Thus, you can put these options into your Distutils config file (see section Distutils Configuration Files):

```
[install]
install-base=$HOME
install-purelib=python/lib
install-platlib=python/lib.$PLAT
install-scripts=python/scripts
install-data=python/data
```

or, equivalently,
Note that these two are not equivalent if you supply a different installation base directory when you run the setup script. For example,

```
python setup.py install --install-base=/tmp
```

would install pure modules to `/tmp/python/lib` in the first case, and to `/tmp/lib` in the second case. (For the second case, you probably want to supply an installation base of `/tmp/python`.)

You probably noticed the use of `$HOME` and `$PLAT` in the sample configuration file input. These are Distutils configuration variables, which bear a strong resemblance to environment variables. In fact, you can use environment variables in config files on platforms that have such a notion but the Distutils additionally define a few extra variables that may not be in your environment, such as `$PLAT`. (And of course, on systems that don't have environment variables, such as Mac OS 9, the configuration variables supplied by the Distutils are the only ones you can use.) See section Distutils Configuration Files for details.

## Modifying Python’s Search Path

When the Python interpreter executes an `import` statement, it searches for both Python code and extension modules along a search path. A default value for the path is configured into the Python binary when the interpreter is built. You can determine the path by importing the `sys` module and printing the value of `sys.path`.
The null string in `sys.path` represents the current working directory.

The expected convention for locally installed packages is to put them in the `.../site-packages/` directory, but you may want to install Python modules into some arbitrary directory. For example, your site may have a convention of keeping all software related to the web server under `/www`. Add-on Python modules might then belong in `/www/python`, and in order to import them, this directory must be added to `sys.path`. There are several different ways to add the directory.

The most convenient way is to add a path configuration file to a directory that’s already on Python’s path, usually to the `.../site-packages/` directory. Path configuration files have an extension of `.pth`, and each line must contain a single path that will be appended to `sys.path`. (Because the new paths are appended to `sys.path`, modules in the added directories will not override standard modules. This means you can’t use this mechanism for installing fixed versions of standard modules.)

Paths can be absolute or relative, in which case they’re relative to the directory containing the `.pth` file. See the documentation of the `site` module for more information.

A slightly less convenient way is to edit the `site.py` file in Python’s
standard library, and modify `sys.path`. `site.py` is automatically imported when the Python interpreter is executed, unless the `-s` switch is supplied to suppress this behaviour. So you could simply edit `site.py` and add two lines to it:

```python
import sys
sys.path.append('/www/python/')
```

However, if you reinstall the same major version of Python (perhaps when upgrading from 2.2 to 2.2.2, for example) `site.py` will be overwritten by the stock version. You’d have to remember that it was modified and save a copy before doing the installation.

There are two environment variables that can modify `sys.path`. `PYTHONHOME` sets an alternate value for the prefix of the Python installation. For example, if `PYTHONHOME` is set to `/www/python`, the search path will be set to `['', '/www/python/lib/pythonX.Y/', '/www/python/lib/pythonX.Y/plat-linux2', ...]`.

The `PYTHONPATH` variable can be set to a list of paths that will be added to the beginning of `sys.path`. For example, if `PYTHONPATH` is set to `/www/python:/opt/py`, the search path will begin with `['/www/python', '/opt/py']`. (Note that directories must exist in order to be added to `sys.path`; the `site` module removes paths that don’t exist.)

Finally, `sys.path` is just a regular Python list, so any Python application can modify it by adding or removing entries.
Distutils Configuration Files

As mentioned above, you can use Distutils configuration files to record personal or site preferences for any Distutils options. That is, any option to any command can be stored in one of two or three (depending on your platform) configuration files, which will be consulted before the command-line is parsed. This means that configuration files will override default values, and the command-line will in turn override configuration files. Furthermore, if multiple configuration files apply, values from “earlier” files are overridden by “later” files.

Location and names of config files

The names and locations of the configuration files vary slightly across platforms. On Unix and Mac OS X, the three configuration files (in the order they are processed) are:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Location and filename</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>system</td>
<td><code>prefix/lib/pythonver/distutils/distutils.cfg</code></td>
<td>(1)</td>
</tr>
<tr>
<td>personal</td>
<td><code>~/.pydistutils.cfg</code></td>
<td>(2)</td>
</tr>
<tr>
<td>local</td>
<td><code>setup.cfg</code></td>
<td>(3)</td>
</tr>
</tbody>
</table>

And on Windows, the configuration files are:

<table>
<thead>
<tr>
<th>Type of file</th>
<th>Location and filename</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>system</td>
<td><code>prefix\Lib\distutils\distutils.cfg</code></td>
<td>(4)</td>
</tr>
<tr>
<td>personal</td>
<td><code>%HOME%\pydistutils.cfg</code></td>
<td>(5)</td>
</tr>
<tr>
<td>local</td>
<td><code>setup.cfg</code></td>
<td>(3)</td>
</tr>
</tbody>
</table>

On all platforms, the “personal” file can be temporarily disabled by passing the `--no-user-cfg` option.
Notes:

1. Strictly speaking, the system-wide configuration file lives in the directory where the Distutils are installed; under Python 1.6 and later on Unix, this is as shown. For Python 1.5.2, the Distutils will normally be installed to \texttt{prefix/lib/python1.5/site-packages/distutils}, so the system configuration file should be put there under Python 1.5.2.

2. On Unix, if the \texttt{HOME} environment variable is not defined, the user’s home directory will be determined with the \texttt{getpwuid()} function from the standard \texttt{pwd} module. This is done by the \texttt{os.path.expanduser()} function used by Distutils.

3. I.e., in the current directory (usually the location of the setup script).

4. (See also note (1).) Under Python 1.6 and later, Python’s default “installation prefix” is \texttt{C:\Python}, so the system configuration file is normally \texttt{C:\Python\Lib\distutils\distutils.cfg}. Under Python 1.5.2, the default prefix was \texttt{C:\Program Files\Python}, and the Distutils were not part of the standard library—so the system configuration file would be \texttt{C:\Program Files\Python\distutils\distutils.cfg} in a standard Python 1.5.2 installation under Windows.

5. On Windows, if the \texttt{HOME} environment variable is not defined, \texttt{USERPROFILE} then \texttt{HOMEDRIVE} and \texttt{HOMEPATH} will be tried. This is done by the \texttt{os.path.expanduser()} function used by Distutils.

\section*{Syntax of config files}

The Distutils configuration files all have the same syntax. The config files are grouped into sections. There is one section for each Distutils command, plus a \texttt{global} section for global options that affect every command. Each section consists of one option per line, specified as
option=value.

For example, the following is a complete config file that just forces all commands to run quietly by default:

```
[global]
verbose=0
```

If this is installed as the system config file, it will affect all processing of any Python module distribution by any user on the current system. If it is installed as your personal config file (on systems that support them), it will affect only module distributions processed by you. And if it is used as the `setup.cfg` for a particular module distribution, it affects only that distribution.

You could override the default “build base” directory and make the `build*` commands always forcibly rebuild all files with the following:

```
[build]
build-base=blib
force=1
```

which corresponds to the command-line arguments

```
python setup.py build --build-base=blib --force
```

except that including the `build` command on the command-line means that command will be run. Including a particular command in config files has no such implication; it only means that if the command is run, the options in the config file will apply. (Or if other commands that derive values from it are run, they will use the values in the config file.)

You can find out the complete list of options for any command using the `--help` option, e.g.:
Python setup.py build --help

and you can find out the complete list of global options by using --help without a command:

Python setup.py --help

See also the “Reference” section of the “Distributing Python Modules” manual.
Building Extensions: Tips and Tricks

Whenever possible, the Distutils try to use the configuration information made available by the Python interpreter used to run the setup.py script. For example, the same compiler and linker flags used to compile Python will also be used for compiling extensions. Usually this will work well, but in complicated situations this might be inappropriate. This section discusses how to override the usual Distutils behaviour.

Tweaking compiler/linker flags

Compiling a Python extension written in C or C++ will sometimes require specifying custom flags for the compiler and linker in order to use a particular library or produce a special kind of object code. This is especially true if the extension hasn't been tested on your platform, or if you're trying to cross-compile Python.

In the most general case, the extension author might have foreseen that compiling the extensions would be complicated, and provided a Setup file for you to edit. This will likely only be done if the module distribution contains many separate extension modules, or if they often require elaborate sets of compiler flags in order to work.

A setup file, if present, is parsed in order to get a list of extensions to build. Each line in a Setup describes a single module. Lines have the following structure:

```plaintext
module ... [sourcefile ...] [cpparg ...] [library ...]
```

Let's examine each of the fields in turn.

- **module** is the name of the extension module to be built, and
should be a valid Python identifier. You can’t just change this in order to rename a module (edits to the source code would also be needed), so this should be left alone.

- **sourcefile** is anything that’s likely to be a source code file, at least judging by the filename. Filenames ending in `.c` are assumed to be written in C, filenames ending in `.c`, `.cc`, and `.cpp` are assumed to be C++, and filenames ending in `.m` or `.mm` are assumed to be in Objective C.
- **cpparg** is an argument for the C preprocessor, and is anything starting with `-I`, `-D`, `-U` or `-c`.
- **library** is anything ending in `.a` or beginning with `-l` or `-L`.

If a particular platform requires a special library on your platform, you can add it by editing the Setup file and running `python setup.py build`. For example, if the module defined by the line

```python
foo foomodule.c
```

must be linked with the math library `libm.a` on your platform, simply add `-lm` to the line:

```python
foo foomodule.c -lm
```

Arbitrary switches intended for the compiler or the linker can be supplied with the `-Xcompiler arg` and `-Xlinker arg` options:

```python
foo foomodule.c -Xcompiler -o32 -Xlinker -shared -lm
```

The next option after `-Xcompiler` and `-Xlinker` will be appended to the proper command line, so in the above example the compiler will be passed the `-o32` option, and the linker will be passed `-shared`. If a compiler option requires an argument, you’ll have to supply multiple `-Xcompiler` options; for example, to pass `-x c++` the Setup file would have to contain `-Xcompiler -x -Xcompiler c++`. 
Compiler flags can also be supplied through setting the `CFLAGS` environment variable. If set, the contents of `CFLAGS` will be added to the compiler flags specified in the `Setup` file.

Using non-Microsoft compilers on Windows

Borland/CodeGear C++

This subsection describes the necessary steps to use Distutils with the Borland C++ compiler version 5.5. First you have to know that Borland's object file format (OMF) is different from the format used by the Python version you can download from the Python or ActiveState Web site. (Python is built with Microsoft Visual C++, which uses COFF as the object file format.) For this reason you have to convert Python's library `python25.lib` into the Borland format. You can do this as follows:

```
coff2omf python25.lib python25_bcpp.lib
```

The `coff2omf` program comes with the Borland compiler. The file `python25.lib` is in the `Libs` directory of your Python installation. If your extension uses other libraries (`zlib, ...`) you have to convert them too.

The converted files have to reside in the same directories as the normal libraries.

How does Distutils manage to use these libraries with their changed names? If the extension needs a library (eg. `foo`) Distutils checks first if it finds a library with suffix `_bcpp` (eg. `foo_bcpp.lib`) and then uses this library. In the case it doesn't find such a special library it uses the default name (`foo.lib`).[1]

To let Distutils compile your extension with Borland C++ you now
have to type:

```plaintext
python setup.py build --compiler=bcpp
```

If you want to use the Borland C++ compiler as the default, you could specify this in your personal or system-wide configuration file for Distutils (see section Distutils Configuration Files.)

**See also:**

  Information about the free C++ compiler from Borland, including links to the download pages.

- **Creating Python Extensions Using Borland's Free Compiler**
  Document describing how to use Borland's free command-line C++ compiler to build Python.

**GNU C / Cygwin / MinGW**

This section describes the necessary steps to use Distutils with the GNU C/C++ compilers in their Cygwin and MinGW distributions. [2]

For a Python interpreter that was built with Cygwin, everything should work without any of these following steps.

Not all extensions can be built with MinGW or Cygwin, but many can. Extensions most likely to not work are those that use C++ or depend on Microsoft Visual C extensions.

To let Distutils compile your extension with Cygwin you have to type:

```plaintext
python setup.py build --compiler=cygwin
```

and for Cygwin in no-cygwin mode [3] or for MinGW type:

```plaintext
python setup.py build --compiler=mingw32
```
If you want to use any of these options/compilers as default, you should consider writing it in your personal or system-wide configuration file for Distutils (see section Distutils Configuration Files.)

**Older Versions of Python and MinGW**

The following instructions only apply if you’re using a version of Python inferior to 2.4.1 with a MinGW inferior to 3.0.0 (with binutils-2.13.90-20030111-1).

These compilers require some special libraries. This task is more complex than for Borland’s C++, because there is no program to convert the library. First you have to create a list of symbols which the Python DLL exports. (You can find a good program for this task at https://sourceforge.net/projects/mingw/files/MinGW/Extension/pexports/)

```
pexports python25.dll >python25.def
```

The location of an installed `python25.dll` will depend on the installation options and the version and language of Windows. In a “just for me” installation, it will appear in the root of the installation directory. In a shared installation, it will be located in the system directory.

Then you can create from these information an import library for gcc.

```
/cygwin/bin/dlltool --dllname python25.dll --def python25.def -l
```

The resulting library has to be placed in the same directory as `python25.lib`. (Should be the `libs` directory under your Python installation directory.)
If your extension uses other libraries (zlib,...) you might have to convert them too. The converted files have to reside in the same directories as the normal libraries do.

Building Python modules on MS Windows platform with MinGW
   Information about building the required libraries for the MinGW environment.

Footnotes

[1] This also means you could replace all existing COFF-libraries with OMF-libraries of the same name.
[3] Then you have no POSIX emulation available, but you also don't need cygwin1.dll.
This document describes the Python Distribution Utilities (“Distutils”) from the module developer’s point of view, describing how to use the Distutils to make Python modules and extensions easily available to a wider audience with very little overhead for build/release/install mechanics.

**Note:** This guide only covers the basic tools for building and distributing extensions that are provided as part of this version of Python. Third party tools offer easier to use and more secure alternatives. Refer to the quick recommendations section in the Python Packaging User Guide for more information.

- 10.28. distutils.command.bdist_packager — Abstract base class for packagers
- 10.29. distutils.command.bdist_dumb — Build a “dumb” installer
- 10.30. distutils.command.bdist_msi — Build a Microsoft Installer binary package
- 10.31. distutils.command.bdist_rpm — Build a binary distribution as a Redhat RPM and SRPM
- 10.32. distutils.command.bdist_wininst — Build a Windows installer
- 10.33. distutils.command.sdist — Build a source distribution
- 10.34. distutils.command.build — Build all files of a package
- 10.35. distutils.command.build_clib — Build any C libraries in a package
- 10.36. distutils.command.build_ext — Build any extensions in a package
- 10.37. distutils.command.build_py — Build the .py/.pyc files of a package
- 10.38. distutils.command.build_scripts — Build the scripts of a package
- 10.39. distutils.command.clean — Clean a package build area
- 10.40. distutils.command.config — Perform package configuration
- 10.41. distutils.command.install — Install a package
- 10.42. distutils.command.install_data — Install data files from a package
- 10.43. distutils.command.install_headers — Install C/C++ header files from a package
- 10.44. distutils.command.install_lib — Install library files from a package
- 10.45. distutils.command.install_scripts — Install script files from a package
- 10.46. distutils.command.register — Register a module
with the Python Package Index

- 10.47. distutils.command.check — Check the meta-data of a package
8. Extending Distutils

Distutils can be extended in various ways. Most extensions take the form of new commands or replacements for existing commands. New commands may be written to support new types of platform-specific packaging, for example, while replacements for existing commands may be made to modify details of how the command operates on a package.

Most extensions of the distutils are made within `setup.py` scripts that want to modify existing commands; many simply add a few file extensions that should be copied into packages in addition to `.py` files as a convenience.

Most distutils command implementations are subclasses of the `distutils.cmd.Command` class. New commands may directly inherit from `Command`, while replacements often derive from `Command` indirectly, directly subclassing the command they are replacing. Commands are required to derive from `Command`.
8.1. Integrating new commands

There are different ways to integrate new command implementations into distutils. The most difficult is to lobby for the inclusion of the new features in distutils itself, and wait for (and require) a version of Python that provides that support. This is really hard for many reasons.

The most common, and possibly the most reasonable for most needs, is to include the new implementations with your setup.py script, and cause the distutils.core.setup() function use them:

```python
from distutils.command.build_py import build_py as _build_py
from distutils.core import setup

class build_py(_build_py):
    #"""Specialized Python source builder."""

        # implement whatever needs to be different...

setup(cmdclass={'build_py': build_py},
     ...
)
```

This approach is most valuable if the new implementations must be used to use a particular package, as everyone interested in the package will need to have the new command implementation.

Beginning with Python 2.4, a third option is available, intended to allow new commands to be added which can support existing setup.py scripts without requiring modifications to the Python installation. This is expected to allow third-party extensions to provide support for additional packaging systems, but the commands can be used for anything distutils commands can be used for. A new configuration option, command_packages (command-line option --command-packages), can be used to specify additional packages to be
searched for modules implementing commands. Like all distutils options, this can be specified on the command line or in a configuration file. This option can only be set in the [global] section of a configuration file, or before any commands on the command line. If set in a configuration file, it can be overridden from the command line; setting it to an empty string on the command line causes the default to be used. This should never be set in a configuration file provided with a package.

This new option can be used to add any number of packages to the list of packages searched for command implementations; multiple package names should be separated by commas. When not specified, the search is only performed in the distutils.command package. When setup.py is run with the option --command-packages distcmds,buildcmds, however, the packages distutils.command, distcmds, and buildcmds will be searched in that order. New commands are expected to be implemented in modules of the same name as the command by classes sharing the same name. Given the example command line option above, the command bdist_openpkg could be implemented by the class distcmds.bdist_openpkg.bdist_openpkg or buildcmds.bdist_openpkg.bdist_openpkg.
8.2. Adding new distribution types

Commands that create distributions (files in the \texttt{dist/} directory) need to add \texttt{(command, filename)} pairs to \texttt{self.distribution.dist_files} so that \texttt{upload} can upload it to PyPI. The \texttt{filename} in the pair contains no path information, only the name of the file itself. In dry-run mode, pairs should still be added to represent what would have been created.

9. Command Reference
9.1. Installing modules: the **install** command family

The install command ensures that the build commands have been run and then runs the subcommands `install_lib`, `install_data` and `install_scripts`.

### 9.1.1. `install_data`

This command installs all data files provided with the distribution.

### 9.1.2. `install_scripts`

This command installs all (Python) scripts in the distribution.
3. Writing the Setup Configuration File

Often, it's not possible to write down everything needed to build a distribution \textit{a priori}: you may need to get some information from the user, or from the user's system, in order to proceed. As long as that information is fairly simple—a list of directories to search for C header files or libraries, for example—then providing a configuration file, \texttt{setup.cfg}, for users to edit is a cheap and easy way to solicit it. Configuration files also let you provide default values for any command option, which the installer can then override either on the command-line or by editing the config file.

The setup configuration file is a useful middle-ground between the setup script—which, ideally, would be opaque to installers—\cite{[1]}—and the command-line to the setup script, which is outside of your control and entirely up to the installer. In fact, \texttt{setup.cfg} (and any other Distutils configuration files present on the target system) are processed after the contents of the setup script, but before the command-line. This has several useful consequences:

- installers can override some of what you put in \texttt{setup.py} by editing \texttt{setup.cfg}
- you can provide non-standard defaults for options that are not easily set in \texttt{setup.py}
- installers can override anything in \texttt{setup.cfg} using the command-line options to \texttt{setup.py}

The basic syntax of the configuration file is simple:

```
[command]
option=value
...
```
where command is one of the Distutils commands (e.g. `build_py`, `install`), and option is one of the options that command supports. Any number of options can be supplied for each command, and any number of command sections can be included in the file. Blank lines are ignored, as are comments, which run from a `#` character until the end of the line. Long option values can be split across multiple lines simply by indenting the continuation lines.

You can find out the list of options supported by a particular command with the universal `--help` option, e.g.

```bash
> python setup.py --help build_ext
[...]
Options for 'build_ext' command:
   --build-lib (-b) directory for compiled extension modules
   --build-temp (-t) directory for temporary files (build by-
                     ignoring build-lib and put compiled extens
                     source directory alongside your pure Pyt
   --inplace (-i) ignore build-lib and put compiled extens
   --include-dirs (-I) list of directories to search for header
   --define (-D) C preprocessor macros to define
   --undef (-U) C preprocessor macros to undefine
   --swig-opts list of SWIG command line options
[...]
```

Note that an option spelled `--foo-bar` on the command-line is spelled `foo_bar` in configuration files.

For example, say you want your extensions to be built “in-place”—that is, you have an extension `pkg.ext`, and you want the compiled extension file (`ext.so` on Unix, say) to be put in the same source directory as your pure Python modules `pkg.mod1` and `pkg.mod2`. You can always use the `--inplace` option on the command-line to ensure this:

```bash
python setup.py build_ext --inplace
```

But this requires that you always specify the `build_ext` command
explicitly, and remember to provide --inplace. An easier way is to "set and forget" this option, by encoding it in setup.cfg, the configuration file for this distribution:

```ini
[build_ext]
inplace=1
```

This will affect all builds of this module distribution, whether or not you explicitly specify build_ext. If you include setup.cfg in your source distribution, it will also affect end-user builds—which is probably a bad idea for this option, since always building extensions in-place would break installation of the module distribution. In certain peculiar cases, though, modules are built right in their installation directory, so this is conceivably a useful ability. (Distributing extensions that expect to be built in their installation directory is almost always a bad idea, though.)

Another example: certain commands take a lot of options that don’t change from run to run; for example, bdist_rpm needs to know everything required to generate a “spec” file for creating an RPM distribution. Some of this information comes from the setup script, and some is automatically generated by the Distutils (such as the list of files installed). But some of it has to be supplied as options to bdist_rpm, which would be very tedious to do on the command-line for every run. Hence, here is a snippet from the Distutils’ own setup.cfg:

```ini
[bdist_rpm]
release = 1
packager = Greg Ward <gward@python.net>
doc_files = CHANGEs.txt
          README.txt
          USAGE.txt
doc/
    examples/
```
Note that the `doc_files` option is simply a whitespace-separated string split across multiple lines for readability.

**See also:**

**Syntax of config files** in “Installing Python Modules”

More information on the configuration files is available in the manual for system administrators.

**Footnotes**

[1] This ideal probably won't be achieved until auto-configuration is fully supported by the Distutils.
Distributing Python Modules (Legacy version) »
2. Writing the Setup Script

The setup script is the centre of all activity in building, distributing, and installing modules using the Distutils. The main purpose of the setup script is to describe your module distribution to the Distutils, so that the various commands that operate on your modules do the right thing. As we saw in section A Simple Example above, the setup script consists mainly of a call to setup(), and most information supplied to the Distutils by the module developer is supplied as keyword arguments to setup().

Here's a slightly more involved example, which we'll follow for the next couple of sections: the Distutils' own setup script. (Keep in mind that although the Distutils are included with Python 1.6 and later, they also have an independent existence so that Python 1.5.2 users can use them to install other module distributions. The Distutils' own setup script, shown here, is used to install the package into Python 1.5.2.)

```python
#!/usr/bin/env python

from distutils.core import setup

setup(name='Distutils',
      version='1.0',
      description='Python Distribution Utilities',
      author='Greg Ward',
      author_email='gward@python.net',
      url='https://www.python.org/sigs/distutils-sig/',
      packages=['distutils', 'distutils.command'],
)
```

There are only two differences between this and the trivial one-file distribution presented in section A Simple Example: more metadata, and the specification of pure Python modules by package, rather than by module. This is important since the Distutils consist of a
couple of dozen modules split into (so far) two packages; an explicit list of every module would be tedious to generate and difficult to maintain. For more information on the additional meta-data, see section Additional meta-data.

Note that any pathnames (files or directories) supplied in the setup script should be written using the Unix convention, i.e. slash-separated. The Distutils will take care of converting this platform-neutral representation into whatever is appropriate on your current platform before actually using the pathname. This makes your setup script portable across operating systems, which of course is one of the major goals of the Distutils. In this spirit, all pathnames in this document are slash-separated.

This, of course, only applies to pathnames given to Distutils functions. If you, for example, use standard Python functions such as `glob.glob()` or `os.listdir()` to specify files, you should be careful to write portable code instead of hardcoding path separators:

```python
import os

glob.glob(os.path.join('mydir', 'subdir', '*.html'))
os.listdir(os.path.join('mydir', 'subdir'))
```
2.1. Listing whole packages

The `packages` option tells the Distutils to process (build, distribute, install, etc.) all pure Python modules found in each package mentioned in the `packages` list. In order to do this, of course, there has to be a correspondence between package names and directories in the filesystem. The default correspondence is the most obvious one, i.e. package `distutils` is found in the directory `distutils` relative to the distribution root. Thus, when you say `packages = ['foo']` in your setup script, you are promising that the Distutils will find a file `foo/__init__.py` (which might be spelled differently on your system, but you get the idea) relative to the directory where your setup script lives. If you break this promise, the Distutils will issue a warning but still process the broken package anyway.

If you use a different convention to lay out your source directory, that's no problem: you just have to supply the `package_dir` option to tell the Distutils about your convention. For example, say you keep all Python source under `lib`, so that modules in the “root package” (i.e., not in any package at all) are in `lib`, modules in the `foo` package are in `lib/foo`, and so forth. Then you would put

```python
package_dir = {'': 'lib'}
```

in your setup script. The keys to this dictionary are package names, and an empty package name stands for the root package. The values are directory names relative to your distribution root. In this case, when you say `packages = ['foo']`, you are promising that the file `lib/foo/__init__.py` exists.

Another possible convention is to put the `foo` package right in `lib`,
the foo.bar package in lib/bar, etc. This would be written in the setup script as

```python
package_dir = {'foo': 'lib'}
```

A package: dir entry in the package_dir dictionary implicitly applies to all packages below package, so the foo.bar case is automatically handled here. In this example, having `packages = ['foo', 'foo.bar']` tells the Distutils to look for `lib/__init__.py` and `lib/bar/__init__.py`. (Keep in mind that although package_dir applies recursively, you must explicitly list all packages in packages: the Distutils will not recursively scan your source tree looking for any directory with an __init__.py file.)
2.2. Listing individual modules

For a small module distribution, you might prefer to list all modules rather than listing packages—especially the case of a single module that goes in the “root package” (i.e., no package at all). This simplest case was shown in section A Simple Example; here is a slightly more involved example:

```python
py_modules = ['mod1', 'pkg.mod2']
```

This describes two modules, one of them in the “root” package, the other in the `pkg` package. Again, the default package/directory layout implies that these two modules can be found in `mod1.py` and `pkg/mod2.py`, and that `pkg/__init__.py` exists as well. And again, you can override the package/directory correspondence using the `package_dir` option.
2.3. Describing extension modules

Just as writing Python extension modules is a bit more complicated than writing pure Python modules, describing them to the Distutils is a bit more complicated. Unlike pure modules, it's not enough just to list modules or packages and expect the Distutils to go out and find the right files; you have to specify the extension name, source file(s), and any compile/link requirements (include directories, libraries to link with, etc.).

All of this is done through another keyword argument to `setup()`, the `ext_modules` option. `ext_modules` is just a list of `Extension` instances, each of which describes a single extension module. Suppose your distribution includes a single extension, called `foo` and implemented by `foo.c`. If no additional instructions to the compiler/linker are needed, describing this extension is quite simple:

```python
Extension('foo', ['foo.c'])
```

The `Extension` class can be imported from `distutils.core` along with `setup()`. Thus, the setup script for a module distribution that contains only this one extension and nothing else might be:

```python
from distutils.core import setup, Extension
setup(name='foo',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

The `Extension` class (actually, the underlying extension-building machinery implemented by the `build_ext` command) supports a great deal of flexibility in describing Python extensions, which is explained in the following sections.
2.3.1. Extension names and packages

The first argument to the `Extension` constructor is always the name of the extension, including any package names. For example,

```python
Extension('foo', ['src/foo1.c', 'src/foo2.c'])
```

describes an extension that lives in the root package, while

```python
Extension('pkg.foo', ['src/foo1.c', 'src/foo2.c'])
```

describes the same extension in the `pkg` package. The source files and resulting object code are identical in both cases; the only difference is where in the filesystem (and therefore where in Python’s namespace hierarchy) the resulting extension lives.

If you have a number of extensions all in the same package (or all under the same base package), use the `ext_package` keyword argument to `setup()`. For example,

```python
setup(...,
    ext_package='pkg',
    ext_modules=[Extension('foo', ['foo.c']),
                 Extension('subpkg.bar', ['bar.c'])],
)
```

will compile `foo.c` to the extension `pkg.foo`, and `bar.c` to `pkg.subpkg.bar`.

2.3.2. Extension source files

The second argument to the `Extension` constructor is a list of source files. Since the Distutils currently only support C, C++, and Objective-C extensions, these are normally C/C++/Objective-C source files. (Be sure to use appropriate extensions to distinguish
C++ source files: .cc and .cpp seem to be recognized by both Unix and Windows compilers.)

However, you can also include SWIG interface (.i) files in the list; the build_ext command knows how to deal with SWIG extensions: it will run SWIG on the interface file and compile the resulting C/C++ file into your extension.

This warning notwithstanding, options to SWIG can be currently passed like this:

```python
setup(...,
    ext_modules=[Extension('_foo', ['foo.i'],
                             swig_opts=['-modern', '-I../include'],
                             py_modules=['foo'],
    )
```

Or on the commandline like this:

```
> python setup.py build_ext --swig-opts="-modern -I../include"
```

On some platforms, you can include non-source files that are processed by the compiler and included in your extension. Currently, this just means Windows message text (.mc) files and resource definition (.rc) files for Visual C++. These will be compiled to binary resource (.res) files and linked into the executable.

### 2.3.3. Preprocessor options

Three optional arguments to `Extension` will help if you need to specify include directories to search or preprocessor macros to define/undefine: `include_dirs`, `define_macros`, and `undef_macros`.

For example, if your extension requires header files in the `include` directory under your distribution root, use the `include_dirs` option:
You can specify absolute directories there; if you know that your extension will only be built on Unix systems with X11R6 installed to \texttt{/usr}, you can get away with

Extension(\texttt{\'foo\', ['foo.c'], include_dirs=[\texttt{\'/usr/include/X11\']})

You should avoid this sort of non-portable usage if you plan to distribute your code: it's probably better to write C code like

\texttt{\#include <X11/Xlib.h>}

If you need to include header files from some other Python extension, you can take advantage of the fact that header files are installed in a consistent way by the Distutils \texttt{install\_headers} command. For example, the Numerical Python header files are installed (on a standard Unix installation) to \texttt{/usr/local/include/python1.5/Numerical}. (The exact location will differ according to your platform and Python installation.) Since the Python include directory—\texttt{/usr/local/include/python1.5} in this case—is always included in the search path when building Python extensions, the best approach is to write C code like

\texttt{\#include <Numerical/arrayobject.h>}

If you must put the \texttt{Numerical} include directory right into your header search path, though, you can find that directory using the Distutils \texttt{distutils.sysconfig} module:

\texttt{from distutils.sysconfig import get\textunderscore python\textunderscore inc
inicdir = os.path.join(get\textunderscore python\textunderscore inc(plat\textunderscore specific=1), \texttt{\'Numerical\'})
setup(\ldots,
     Extension(\ldots, include\textunderscore dirs=[inicdir]),
    )}
Even though this is quite portable—it will work on any Python installation, regardless of platform—it’s probably easier to just write your C code in the sensible way.

You can define and undefine pre-processor macros with the `define_macros` and `undef_macros` options. `define Macros` takes a list of `(name, value)` tuples, where `name` is the name of the macro to define (a string) and `value` is its value: either a string or `None`. (Defining a macro `FOO` to `None` is the equivalent of a bare `#define FOO` in your C source: with most compilers, this sets `FOO` to the string `1`.)

`undef Macros` is just a list of macros to redefine.

For example:

```python
Extension(...,
    define_macros=[('NDEBUG', '1'),
                  ('HAVE_STRFTIME', None)],
    undef_macros=['HAVE_FOO', 'HAVE_BAR'])
```

is the equivalent of having this at the top of every C source file:

```c
#define NDEBUG 1
#define HAVE_STRFTIME
#undef HAVE_FOO
#undef HAVE_BAR
```

### 2.3.4. Library options

You can also specify the libraries to link against when building your extension, and the directories to search for those libraries. The `libraries` option is a list of libraries to link against, `library_dirs` is a list of directories to search for libraries at link-time, and `runtime_library_dirs` is a list of directories to search for shared (dynamically loaded) libraries at run-time.

For example, if you need to link against libraries known to be in the
standard library search path on target systems

```python
Extension(...,
    libraries=['gdbm', 'readline'])
```

If you need to link with libraries in a non-standard location, you'll have to include the location in `library_dirs`:

```python
Extension(...,
    library_dirs=['/usr/X11R6/lib'],
    libraries=['X11', 'Xt'])
```

(Again, this sort of non-portable construct should be avoided if you intend to distribute your code.)

### 2.3.5. Other options

There are still some other options which can be used to handle special cases.

The `extra_objects` option is a list of object files to be passed to the linker. These files must not have extensions, as the default extension for the compiler is used.

`extra_compile_args` and `extra_link_args` can be used to specify additional command line options for the respective compiler and linker command lines.

`export_symbols` is only useful on Windows. It can contain a list of symbols (functions or variables) to be exported. This option is not needed when building compiled extensions: Distutils will automatically add `initmodule` to the list of exported symbols.

The `depends` option is a list of files that the extension depends on (for example header files). The build command will call the compiler on the sources to rebuild extension if any on this files has been modified.
since the previous build.
2.4. Relationships between Distributions and Packages

A distribution may relate to packages in three specific ways:

1. It can require packages or modules.
2. It can provide packages or modules.
3. It can obsolete packages or modules.

These relationships can be specified using keyword arguments to the `distutils.core.setup()` function.

Dependencies on other Python modules and packages can be specified by supplying the `requires` keyword argument to `setup()`. The value must be a list of strings. Each string specifies a package that is required, and optionally what versions are sufficient.

To specify that any version of a module or package is required, the string should consist entirely of the module or package name. Examples include `mymodule` and `xml.parsers.expat`.

If specific versions are required, a sequence of qualifiers can be supplied in parentheses. Each qualifier may consist of a comparison operator and a version number. The accepted comparison operators are:

```
<   >   ==
<=  >=  !=
```

These can be combined by using multiple qualifiers separated by commas (and optional whitespace). In this case, all of the qualifiers must be matched; a logical AND is used to combine the evaluations.

Let’s look at a bunch of examples:
<table>
<thead>
<tr>
<th>Requires Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>==1.0</td>
<td>Only version 1.0 is compatible</td>
</tr>
<tr>
<td>&gt;1.0, !=1.5.1, &lt;2.0</td>
<td>Any version after 1.0 and before 2.0 is compatible, except 1.5.1</td>
</tr>
</tbody>
</table>

Now that we can specify dependencies, we also need to be able to specify what we provide that other distributions can require. This is done using the `provides` keyword argument to `setup()`. The value for this keyword is a list of strings, each of which names a Python module or package, and optionally identifies the version. If the version is not specified, it is assumed to match that of the distribution.

Some examples:

<table>
<thead>
<tr>
<th>Provides Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>mypkg</td>
<td>Provide mypkg, using the distribution version</td>
</tr>
<tr>
<td>mypkg (1.1)</td>
<td>Provide mypkg version 1.1, regardless of the distribution version</td>
</tr>
</tbody>
</table>

A package can declare that it obsoletes other packages using the `obsoletes` keyword argument. The value for this is similar to that of the `requires` keyword: a list of strings giving module or package specifiers. Each specifier consists of a module or package name optionally followed by one or more version qualifiers. Version qualifiers are given in parentheses after the module or package name.

The versions identified by the qualifiers are those that are obsoleted by the distribution being described. If no qualifiers are given, all versions of the named module or package are understood to be obsoleted.
2.5. Installing Scripts

So far we have been dealing with pure and non-pure Python modules, which are usually not run by themselves but imported by scripts.

Scripts are files containing Python source code, intended to be started from the command line. Scripts don’t require Distutils to do anything very complicated. The only clever feature is that if the first line of the script starts with `#!` and contains the word “python”, the Distutils will adjust the first line to refer to the current interpreter location. By default, it is replaced with the current interpreter location. The **--executable** (or `-e`) option will allow the interpreter path to be explicitly overridden.

The `scripts` option simply is a list of files to be handled in this way. From the PyXML setup script:

```python
setup(...,
      scripts=['scripts/xmlproc_parse', 'scripts/xmlproc_val'])
```

*Changed in version 2.7:* All the scripts will also be added to the MANIFEST file if no template is provided. See Specifying the files to distribute.
2.6. Installing Package Data

Often, additional files need to be installed into a package. These files are often data that’s closely related to the package’s implementation, or text files containing documentation that might be of interest to programmers using the package. These files are called *package data*.

Package data can be added to packages using the `package_data` keyword argument to the `setup()` function. The value must be a mapping from package name to a list of relative path names that should be copied into the package. The paths are interpreted as relative to the directory containing the package (information from the `package_dir` mapping is used if appropriate); that is, the files are expected to be part of the package in the source directories. They may contain glob patterns as well.

The path names may contain directory portions; any necessary directories will be created in the installation.

For example, if a package should contain a subdirectory with several data files, the files can be arranged like this in the source tree:

```plaintext
setup.py
src/
  mypkg/
    __init__.py
    module.py
  data/
    tables.dat
    spoons.dat
    forks.dat
```

The corresponding call to `setup()` might be:

```python
setup(...,
```
New in version 2.4.

Changed in version 2.7: All the files that match `package_data` will be added to the `MANIFEST` file if no template is provided. See Specifying the files to distribute.
The `data_files` option can be used to specify additional files needed by the module distribution: configuration files, message catalogs, data files, anything which doesn’t fit in the previous categories.

`data_files` specifies a sequence of `(directory, files)` pairs in the following way:

```python
setup(...,
    data_files=[('bitmaps', ['bm/b1.gif', 'bm/b2.gif'])),
           ('config', ['cfg/data.cfg'])),
           ('etc/init.d', ['init-script']))
)
```

Note that you can specify the directory names where the data files will be installed, but you cannot rename the data files themselves.

Each `(directory, files)` pair in the sequence specifies the installation directory and the files to install there. If `directory` is a relative path, it is interpreted relative to the installation prefix (Python’s `sys.prefix` for pure-Python packages, `sys.exec_prefix` for packages that contain extension modules). Each file name in `files` is interpreted relative to the `setup.py` script at the top of the package source distribution. No directory information from `files` is used to determine the final location of the installed file; only the name of the file is used.

You can specify the `data_files` options as a simple sequence of files without specifying a target directory, but this is not recommended, and the `install` command will print a warning in this case. To install data files directly in the target directory, an empty string should be given as the directory.

*Changed in version 2.7:* All the files that match `data_files` will be
added to the MANIFEST file if no template is provided. See Specifying the files to distribute.
2.8. Additional meta-data

The setup script may include additional meta-data beyond the name and version. This information includes:

<table>
<thead>
<tr>
<th>Meta-Data</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name of the package</td>
<td>short string</td>
<td>(1)</td>
</tr>
<tr>
<td>version</td>
<td>version of this release</td>
<td>short string</td>
<td>(1)(2)</td>
</tr>
<tr>
<td>author</td>
<td>package author’s name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>author_email</td>
<td>email address of the package author</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer</td>
<td>package maintainer’s name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer_email</td>
<td>email address of the package maintainer</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>url</td>
<td>home page for the package</td>
<td>URL</td>
<td>(1)</td>
</tr>
<tr>
<td>description</td>
<td>short, summary description of the package</td>
<td>short string</td>
<td></td>
</tr>
<tr>
<td>long_description</td>
<td>longer description of the package</td>
<td>long string</td>
<td>(5)</td>
</tr>
<tr>
<td>download_url</td>
<td>location where the package may be downloaded</td>
<td>URL</td>
<td>(4)</td>
</tr>
<tr>
<td>classifiers</td>
<td>a list of classifiers</td>
<td>list of strings</td>
<td>(4)</td>
</tr>
<tr>
<td>platforms</td>
<td>a list of platforms</td>
<td>list of strings</td>
<td></td>
</tr>
<tr>
<td>license</td>
<td>license for the package</td>
<td>short string</td>
<td>(6)</td>
</tr>
</tbody>
</table>

Notes:

1. These fields are required.
2. It is recommended that versions take the form
Encoding the version information is an art in itself. Python packages generally adhere to the version format *major.minor[.patch][sub]*. The major number is 0 for initial, experimental releases of software. It is incremented for releases that represent major milestones in a package. The minor number is incremented when important new features are added to the package. The patch number increments when bug-fix releases are made. Additional trailing version information is sometimes used to indicate sub-releases. These are “a1,a2,...,aN” (for alpha releases, where functionality and API may
change), “b1,b2,...,bN” (for beta releases, which only fix bugs) and “pr1,pr2,...,prN” (for final pre-release release testing). Some examples:

0.1.0
   the first, experimental release of a package

1.0.1a2
   the second alpha release of the first patch version of 1.0

classifiers are specified in a Python list:

```
setup(...,
   classifiers=[
      'Development Status :: 4 - Beta',
      'Environment :: Console',
      'Environment :: Web Environment',
      'Intended Audience :: End Users/Desktop',
      'Intended Audience :: Developers',
      'Intended Audience :: System Administrators',
      'License :: OSI Approved :: Python Software Foundation',
      'Operating System :: MacOS :: MacOS X',
      'Operating System :: Microsoft :: Windows',
      'Operating System :: POSIX',
      'Programming Language :: Python',
      'Topic :: Communications :: Email',
      'Topic :: Office/Business',
      'Topic :: Software Development :: Bug Tracking',
   ],
)
```

If you wish to include classifiers in your `setup.py` file and also wish to remain backwards-compatible with Python releases prior to 2.2.3, then you can include the following code fragment in your `setup.py` before the `setup()` call.

```
# patch distutils if it can't cope with the "classifiers" or
# "download_url" keywords
from sys import version
if version < '2.2.3':

```
from distutils.dist import DistributionMetadata
DistributionMetadata.classifiers = None
DistributionMetadata.download_url = None
2.9. Debugging the setup script

Sometimes things go wrong, and the setup script doesn't do what the developer wants.

Distutils catches any exceptions when running the setup script, and print a simple error message before the script is terminated. The motivation for this behaviour is to not confuse administrators who don't know much about Python and are trying to install a package. If they get a big long traceback from deep inside the guts of Distutils, they may think the package or the Python installation is broken because they don't read all the way down to the bottom and see that it's a permission problem.

On the other hand, this doesn’t help the developer to find the cause of the failure. For this purpose, the DISTUTILS_DEBUG environment variable can be set to anything except an empty string, and distutils will now print detailed information about what it is doing, dump the full traceback when an exception occurs, and print the whole command line when an external program (like a C compiler) fails.
1. An Introduction to Distutils

This document covers using the Distutils to distribute your Python modules, concentrating on the role of developer/distributor: if you're looking for information on installing Python modules, you should refer to the Installing Python Modules (Legacy version) chapter.
1.1. Concepts & Terminology

Using the Distutils is quite simple, both for module developers and for users/administrators installing third-party modules. As a developer, your responsibilities (apart from writing solid, well-documented and well-tested code, of course!) are:

- write a setup script (`setup.py` by convention)
- (optional) write a setup configuration file
- create a source distribution
- (optional) create one or more built (binary) distributions

Each of these tasks is covered in this document.

Not all module developers have access to a multitude of platforms, so it's not always feasible to expect them to create a multitude of built distributions. It is hoped that a class of intermediaries, called packagers, will arise to address this need. Packagers will take source distributions released by module developers, build them on one or more platforms, and release the resulting built distributions. Thus, users on the most popular platforms will be able to install most popular Python module distributions in the most natural way for their platform, without having to run a single setup script or compile a line of code.
1.2. A Simple Example

The setup script is usually quite simple, although since it's written in Python, there are no arbitrary limits to what you can do with it, though you should be careful about putting arbitrarily expensive operations in your setup script. Unlike, say, Autoconf-style configure scripts, the setup script may be run multiple times in the course of building and installing your module distribution.

If all you want to do is distribute a module called foo, contained in a file foo.py, then your setup script can be as simple as this:

```python
from distutils.core import setup
setup(
    name='foo',
    version='1.0',
    py_modules=['foo'],
)
```

Some observations:

- most information that you supply to the Distutils is supplied as keyword arguments to the setup() function
- those keyword arguments fall into two categories: package metadata (name, version number) and information about what's in the package (a list of pure Python modules, in this case)
- modules are specified by module name, not filename (the same will hold true for packages and extensions)
- it's recommended that you supply a little more metadata, in particular your name, email address and a URL for the project (see section Writing the Setup Script for an example)

To create a source distribution for this module, you would create a setup script, setup.py, containing the above code, and run this command from a terminal:
python setup.py sdist

For Windows, open a command prompt windows (Start ➤ Accessories) and change the command to:

    setup.py sdist

`sdist` will create an archive file (e.g., tarball on Unix, ZIP file on Windows) containing your setup script `setup.py`, and your module `foo.py`. The archive file will be named `foo-1.0.tar.gz` (or `.zip`), and will unpack into a directory `foo-1.0`.

If an end-user wishes to install your `foo` module, all she has to do is download `foo-1.0.tar.gz` (or `.zip`), unpack it, and—from the `foo-1.0` directory—run

    python setup.py install

which will ultimately copy `foo.py` to the appropriate directory for third-party modules in their Python installation.

This simple example demonstrates some fundamental concepts of the Distutils. First, both developers and installers have the same basic user interface, i.e. the setup script. The difference is which Distutils `commands` they use: the `sdist` command is almost exclusively for module developers, while `install` is more often for installers (although most developers will want to install their own code occasionally).

If you want to make things really easy for your users, you can create one or more built distributions for them. For instance, if you are running on a Windows machine, and want to make things easy for other Windows users, you can create an executable installer (the most appropriate type of built distribution for this platform) with the `bdist_wininst` command. For example:
```bash
python setup.py bdist_wininst
```

will create an executable installer, `foo-1.0.win32.exe`, in the current directory.

Other useful built distribution formats are RPM, implemented by the `bdist_rpm` command, Solaris `pkgtool (bdist/pkgtool)`, and HP-UX `swinstall (bdist/sdux)`. For example, the following command will create an RPM file called `foo-1.0.noarch.rpm`:

```bash
python setup.py bdist_rpm
```

(The `bdist_rpm` command uses the `rpm` executable, therefore this has to be run on an RPM-based system such as Red Hat Linux, SuSE Linux, or Mandrake Linux.)

You can find out what distribution formats are available at any time by running

```bash
python setup.py bdist --help-formats
```
1.3. General Python terminology

If you’re reading this document, you probably have a good idea of what modules, extensions, and so forth are. Nevertheless, just to be sure that everyone is operating from a common starting point, we offer the following glossary of common Python terms:

module
  the basic unit of code reusability in Python: a block of code imported by some other code. Three types of modules concern us here: pure Python modules, extension modules, and packages.

pure Python module
  a module written in Python and contained in a single .py file (and possibly associated .pyc and/or .pyo files). Sometimes referred to as a “pure module.”

extension module
  a module written in the low-level language of the Python implementation: C/C++ for Python, Java for Jython. Typically contained in a single dynamically loadable pre-compiled file, e.g. a shared object (.so) file for Python extensions on Unix, a DLL (given the .pyd extension) for Python extensions on Windows, or a Java class file for Jython extensions. (Note that currently, the Distutils only handles C/C++ extensions for Python.)

package
  a module that contains other modules; typically contained in a directory in the filesystem and distinguished from other directories by the presence of a file __init__.py.

root package
  the root of the hierarchy of packages. (This isn’t really a package, since it doesn’t have an __init__.py file. But we have to call it
something.) The vast majority of the standard library is in the root package, as are many small, standalone third-party modules that don’t belong to a larger module collection. Unlike regular packages, modules in the root package can be found in many directories: in fact, every directory listed in `sys.path` contributes modules to the root package.
1.4. Distutils-specific terminology

The following terms apply more specifically to the domain of distributing Python modules using the Distutils:

module distribution
   a collection of Python modules distributed together as a single downloadable resource and meant to be installed *en masse*. Examples of some well-known module distributions are Numeric Python, PyXML, PIL (the Python Imaging Library), or mxBase. (This would be called a *package*, except that term is already taken in the Python context: a single module distribution may contain zero, one, or many Python packages.)

pure module distribution
   a module distribution that contains only pure Python modules and packages. Sometimes referred to as a “pure distribution.”

non-pure module distribution
   a module distribution that contains at least one extension module. Sometimes referred to as a “non-pure distribution.”

distribution root
   the top-level directory of your source tree (or source distribution); the directory where `setup.py` exists. Generally `setup.py` will be run from this directory.
4. Creating a Source Distribution

As shown in section A Simple Example, you use the `sdist` command to create a source distribution. In the simplest case,

```
python setup.py sdist
```

(assuming you haven't specified any `sdist` options in the setup script or config file), `sdist` creates the archive of the default format for the current platform. The default format is a gzip'ed tar file (.tar.gz) on Unix, and ZIP file on Windows.

You can specify as many formats as you like using the `--formats` option, for example:

```
python setup.py sdist --formats=gztar,zip
```

to create a gzipped tarball and a zip file. The available formats are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>gztar</td>
<td>gzip'ed tar file (.tar.gz)</td>
<td>(2)</td>
</tr>
<tr>
<td>bztar</td>
<td>bzip2'ed tar file (.tar.bz2)</td>
<td></td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.z)</td>
<td>(4)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. default on Windows
2. default on Unix
3. requires either external `zip` utility or `zipfile` module (part of the standard Python library since Python 1.6)
4. requires the `compress` program.
When using any tar format (gztar, bztar, ztar or tar) under Unix, you can specify the owner and group names that will be set for each member of the archive.

For example, if you want all files of the archive to be owned by root:

```bash
python setup.py sdist --owner=root --group=root
```
4.1. Specifying the files to distribute

If you don’t supply an explicit list of files (or instructions on how to generate one), the `sdist` command puts a minimal default set into the source distribution:

- all Python source files implied by the `py_modules` and `packages` options
- all C source files mentioned in the `ext_modules` or `libraries` options
- scripts identified by the `scripts` option See Installing Scripts.
- anything that looks like a test script: `test/test*.py` (currently, the Distutils don’t do anything with test scripts except include them in source distributions, but in the future there will be a standard for testing Python module distributions)
- `README.txt` (or `README`), `setup.py` (or whatever you called your setup script), and `setup.cfg`
- all files that matches the `package_data` metadata. See Installing Package Data.
- all files that matches the `data_files` metadata. See Installing Additional Files.

Sometimes this is enough, but usually you will want to specify additional files to distribute. The typical way to do this is to write a *manifest template*, called `MANIFEST.in` by default. The manifest template is just a list of instructions for how to generate your manifest file, `MANIFEST`, which is the exact list of files to include in your source distribution. The `sdist` command processes this template and generates a manifest based on its instructions and what it finds in the filesystem.

If you prefer to roll your own manifest file, the format is simple: one
filename per line, regular files (or symlinks to them) only. If you do supply your own MANIFEST, you must specify everything: the default set of files described above does not apply in this case.

*Changed in version 2.7:* An existing generated MANIFEST will be regenerated without sdist comparing its modification time to the one of MANIFEST.in or setup.py.

*Changed in version 2.7.1:* MANIFEST files start with a comment indicating they are generated. Files without this comment are not overwritten or removed.

*Changed in version 2.7.3:* sdist will read a MANIFEST file if no MANIFEST.in exists, like it did before 2.7.

See The MANIFEST.in template section for a syntax reference.
4.2. Manifest-related options

The normal course of operations for the `sdist` command is as follows:

- if the manifest file (MANIFEST by default) exists and the first line does not have a comment indicating it is generated from MANIFEST.in, then it is used as is, unaltered
- if the manifest file doesn’t exist or has been previously automatically generated, read `MANIFEST.in` and create the manifest
- if neither MANIFEST nor MANIFEST.in exist, create a manifest with just the default file set
- use the list of files now in MANIFEST (either just generated or read in) to create the source distribution archive(s)

There are a couple of options that modify this behaviour. First, use the `--no-defaults` and `--no-prune` to disable the standard “include” and “exclude” sets.

Second, you might just want to (re)generate the manifest, but not create a source distribution:

```
python setup.py sdist --manifest-only
```

-o is a shortcut for `--manifest-only`. 
4.3. The MANIFEST.in template

A `MANIFEST.in` file can be added in a project to define the list of files to include in the distribution built by the `sdist` command.

When `sdist` is run, it will look for the `MANIFEST.in` file and interpret it to generate the `MANIFEST` file that contains the list of files that will be included in the package.

This mechanism can be used when the default list of files is not enough. (See Specifying the files to distribute).

4.3.1. Principle

The manifest template has one command per line, where each command specifies a set of files to include or exclude from the source distribution. For an example, let's look at the Distutils' own manifest template:

```
include *.txt
recursive-include examples *.txt *.py
prune examples/sample?/build
```

The meanings should be fairly clear: include all files in the distribution root matching `*.txt`, all files anywhere under the `examples` directory matching `*.txt` or `*.py`, and exclude all directories matching `examples/sample?/build`. All of this is done after the standard include set, so you can exclude files from the standard set with explicit instructions in the manifest template. (Or, you can use the `--no-defaults` option to disable the standard set entirely.)

The order of commands in the manifest template matters: initially, we have the list of default files as described above, and each command
in the template adds to or removes from that list of files. Once we have fully processed the manifest template, we remove files that should not be included in the source distribution:

- all files in the Distutils “build” tree (default build/)
- all files in directories named RCS, CVS, .svn, .hg, .git, .bzr or _darcs

Now we have our complete list of files, which is written to the manifest for future reference, and then used to build the source distribution archive(s).

You can disable the default set of included files with the --no-defaults option, and you can disable the standard exclude set with --no-prune.

Following the Distutils’ own manifest template, let’s trace how the sdist command builds the list of files to include in the Distutils source distribution:

1. include all Python source files in the distutils and distutils/command subdirectories (because packages corresponding to those two directories were mentioned in the packages option in the setup script—see section Writing the Setup Script)
2. include README.txt, setup.py, and setup.cfg (standard files)
3. include test/test*.py (standard files)
4. include *.txt in the distribution root (this will find README.txt a second time, but such redundancies are weeded out later)
5. include anything matching *.txt or *.py in the sub-tree under examples,
6. exclude all files in the sub-trees starting at directories matching examples/sample?/build—this may exclude files included by the
previous two steps, so it's important that the `prune` command in the manifest template comes after the `recursive-include` command

7. exclude the entire build tree, and any `RCS`, `CVS`, `.svn`, `.hg`, `.git`, `.bzr` and `_darcs` directories

Just like in the setup script, file and directory names in the manifest template should always be slash-separated; the Distutils will take care of converting them to the standard representation on your platform. That way, the manifest template is portable across operating systems.

### 4.3.2. Commands

The manifest template commands are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>include pat1 pat2 ...</code></td>
<td>include all files matching any of the listed patterns</td>
</tr>
<tr>
<td><code>exclude pat1 pat2 ...</code></td>
<td>exclude all files matching any of the listed patterns</td>
</tr>
<tr>
<td><code>recursive-include dir pat1 pat2 ...</code></td>
<td>include all files under <code>dir</code> matching any of the listed patterns</td>
</tr>
<tr>
<td><code>recursive-exclude dir pat1 pat2 ...</code></td>
<td>exclude all files under <code>dir</code> matching any of the listed patterns</td>
</tr>
<tr>
<td><code>global-include pat1 pat2 ...</code></td>
<td>include all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td><code>global-exclude pat1 pat2 ...</code></td>
<td>exclude all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td><code>prune dir</code></td>
<td>exclude all files under <code>dir</code></td>
</tr>
<tr>
<td><code>graft dir</code></td>
<td>include all files under <code>dir</code></td>
</tr>
</tbody>
</table>
The patterns here are Unix-style “glob” patterns: * matches any sequence of regular filename characters, ? matches any single regular filename character, and [range] matches any of the characters in range (e.g., a-z, a-zA-Z, a-f0-9_). The definition of “regular filename character” is platform-specific: on Unix it is anything except slash; on Windows anything except backslash or colon.
5. Creating Built Distributions

A “built distribution” is what you’re probably used to thinking of either as a “binary package” or an “installer” (depending on your background). It’s not necessarily binary, though, because it might contain only Python source code and/or byte-code; and we don’t call it a package, because that word is already spoken for in Python. (And “installer” is a term specific to the world of mainstream desktop systems.)

A built distribution is how you make life as easy as possible for installers of your module distribution: for users of RPM-based Linux systems, it’s a binary RPM; for Windows users, it’s an executable installer; for Debian-based Linux users, it’s a Debian package; and so forth. Obviously, no one person will be able to create built distributions for every platform under the sun, so the Distutils are designed to enable module developers to concentrate on their specialty—writing code and creating source distributions—while an intermediary species called packagers springs up to turn source distributions into built distributions for as many platforms as there are packagers.

Of course, the module developer could be his own packager; or the packager could be a volunteer “out there” somewhere who has access to a platform which the original developer does not; or it could be software periodically grabbing new source distributions and turning them into built distributions for as many platforms as the software has access to. Regardless of who they are, a packager uses the setup script and the bdist command family to generate built distributions.

As a simple example, if I run the following command in the Distutils source tree:
then the Distutils builds my module distribution (the Distutils itself in this case), does a “fake” installation (also in the build directory), and creates the default type of built distribution for my platform. The default format for built distributions is a “dumb” tar file on Unix, and a simple executable installer on Windows. (That tar file is considered “dumb” because it has to be unpacked in a specific location to work.)

Thus, the above command on a Unix system creates Distutils-1.0.plat.tar.gz; unpacking this tarball from the right place installs the Distutils just as though you had downloaded the source distribution and run python setup.py install. (The “right place” is either the root of the filesystem or Python’s prefix directory, depending on the options given to the bdist_dumb command; the default is to make dumb distributions relative to prefix.)

Obviously, for pure Python distributions, this isn’t any simpler than just running python setup.py install—but for non-pure distributions, which include extensions that would need to be compiled, it can mean the difference between someone being able to use your extensions or not. And creating “smart” built distributions, such as an RPM package or an executable installer for Windows, is far more convenient for users even if your distribution doesn’t include any extensions.

The bdist command has a --formats option, similar to the sdist command, which you can use to select the types of built distribution to generate: for example,

```
python setup.py bdist --format=zip
```

would, when run on a Unix system, create Distutils-1.0.plat.zip—again, this archive would be unpacked from the root directory to
install the Distutils.

The available formats for built distributions are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>gztar</td>
<td>gzipped tar file (.tar.gz)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.Z)</td>
<td>(3)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td>(3)</td>
</tr>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(2),(4)</td>
</tr>
<tr>
<td>rpm</td>
<td>RPM</td>
<td>(5)</td>
</tr>
<tr>
<td>pkgtool</td>
<td>Solaris pkgtool</td>
<td></td>
</tr>
<tr>
<td>sdux</td>
<td>HP-UX swinstall</td>
<td></td>
</tr>
<tr>
<td>wininst</td>
<td>self-extracting ZIP file for Windows</td>
<td>(4)</td>
</tr>
<tr>
<td>msi</td>
<td>Microsoft Installer.</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. default on Unix
2. default on Windows
3. requires external utilities: tar and possibly one of gzip, bzip2, or compress
4. requires either external zip utility or zipfile module (part of the standard Python library since Python 1.6)
5. requires external rpm utility, version 3.0.4 or better (use rpm --version to find out which version you have)

You don’t have to use the bdist command with the --formats option; you can also use the command that directly implements the format you’re interested in. Some of these bdist “sub-commands” actually generate several similar formats; for instance, the bdist_dumb command generates all the “dumb” archive formats (tar, ztar, gztar, and zip), and bdist_rpm generates both binary and source RPMs. The bdist sub-commands, and the formats generated by each, are:
<table>
<thead>
<tr>
<th>Command</th>
<th>Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>bdist_dumb</td>
<td>tar, ztar, gztar, zip</td>
</tr>
<tr>
<td>bdist_rpm</td>
<td>rpm, srpm</td>
</tr>
<tr>
<td>bdist_wininst</td>
<td>wininst</td>
</tr>
<tr>
<td>bdist_msi</td>
<td>msi</td>
</tr>
</tbody>
</table>

The following sections give details on the individual `bdist_*` commands.
5.1. Creating dumb built distributions
5.2. Creating RPM packages

The RPM format is used by many popular Linux distributions, including Red Hat, SuSE, and Mandrake. If one of these (or any of the other RPM-based Linux distributions) is your usual environment, creating RPM packages for other users of that same distribution is trivial. Depending on the complexity of your module distribution and differences between Linux distributions, you may also be able to create RPMs that work on different RPM-based distributions.

The usual way to create an RPM of your module distribution is to run the **bdist_rpm** command:

```
python setup.py bdist_rpm
```

or the **bdist** command with the **--format** option:

```
python setup.py bdist --format=rpm
```

The former allows you to specify RPM-specific options; the latter allows you to easily specify multiple formats in one run. If you need to do both, you can explicitly specify multiple **bdist_*** commands and their options:

```
python setup.py bdist_rpm --packager="John Doe <jdoe@example.org>
bdist_wininst --target-version="2.0"
```

Creating RPM packages is driven by a `.spec` file, much as using the Distutils is driven by the setup script. To make your life easier, the **bdist_rpm** command normally creates a `.spec` file based on the information you supply in the setup script, on the command line, and in any Distutils configuration files. Various options and sections in the `.spec` file are derived from options in the setup script as follows:
<table>
<thead>
<tr>
<th>RPM <code>.spec</code> file option or section</th>
<th>Distutils setup script option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Summary (in preamble)</td>
<td>description</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Vendor</td>
<td>author and author_email, or — &amp; maintainer and maintainer_email</td>
</tr>
<tr>
<td>Copyright</td>

Additionally, there are many options in `.spec` files that don’t have corresponding options in the setup script. Most of these are handled through options to the `bdist_rpm` command as follows:

<table>

Obviously, supplying even a few of these options on the command-line would be tedious and error-prone, so it’s usually best to put them in the setup configuration file, `setup.cfg`—see section Writing the Setup Configuration File. If you distribute or package many Python
module distributions, you might want to put options that apply to all of them in your personal Distutils configuration file (~/.pydistutils.cfg). If you want to temporarily disable this file, you can pass the --no-user-cfg option to setup.py.

There are three steps to building a binary RPM package, all of which are handled automatically by the Distutils:

1. create a .spec file, which describes the package (analogous to the Distutils setup script; in fact, much of the information in the setup script winds up in the .spec file)
2. create the source RPM
3. create the “binary” RPM (which may or may not contain binary code, depending on whether your module distribution contains Python extensions)

Normally, RPM bundles the last two steps together; when you use the Distutils, all three steps are typically bundled together.

If you wish, you can separate these three steps. You can use the --spec-only option to make bdist_rpm just create the .spec file and exit; in this case, the .spec file will be written to the “distribution directory”—normally dist/, but customizable with the --dist-dir option. (Normally, the .spec file winds up deep in the “build tree,” in a temporary directory created by bdist_rpm.)
5.3. Creating Windows Installers

Executable installers are the natural format for binary distributions on Windows. They display a nice graphical user interface, display some information about the module distribution to be installed taken from the metadata in the setup script, let the user select a few options, and start or cancel the installation.

Since the metadata is taken from the setup script, creating Windows installers is usually as easy as running:

```
python setup.py bdist_wininst
```

or the `bdist` command with the `--formats` option:

```
python setup.py bdist --formats=wininst
```

If you have a pure module distribution (only containing pure Python modules and packages), the resulting installer will be version independent and have a name like `foo-1.0.win32.exe`. These installers can even be created on Unix platforms or Mac OS X.

If you have a non-pure distribution, the extensions can only be created on a Windows platform, and will be Python version dependent. The installer filename will reflect this and now has the form `foo-1.0.win32-py2.0.exe`. You have to create a separate installer for every Python version you want to support.

The installer will try to compile pure modules into bytecode after installation on the target system in normal and optimizing mode. If you don't want this to happen for some reason, you can run the `bdist_wininst` command with the `--no-target-compile` and/or the `--no-target-optimize` option.
By default the installer will display the cool “Python Powered” logo when it is run, but you can also supply your own 152x261 bitmap which must be a Windows .bmp file with the --bitmap option.

The installer will also display a large title on the desktop background window when it is run, which is constructed from the name of your distribution and the version number. This can be changed to another text by using the --title option.

The installer file will be written to the “distribution directory” — normally dist/, but customizable with the --dist-dir option.
5.4. Cross-compiling on Windows

Starting with Python 2.6, distutils is capable of cross-compiling between Windows platforms. In practice, this means that with the correct tools installed, you can use a 32bit version of Windows to create 64bit extensions and vice-versa.

To build for an alternate platform, specify the `--plat-name` option to the build command. Valid values are currently ‘win32’, ‘win-amd64’ and ‘win-ia64’. For example, on a 32bit version of Windows, you could execute:

```bash
python setup.py build --plat-name=win-amd64
```

to build a 64bit version of your extension. The Windows Installers also support this option, so the command:

```bash
python setup.py build --plat-name=win-amd64 bdist_wininst
```

would create a 64bit installation executable on your 32bit version of Windows.

To cross-compile, you must download the Python source code and cross-compile Python itself for the platform you are targeting - it is not possible from a binary installation of Python (as the .lib etc file for other platforms are not included.) In practice, this means the user of a 32 bit operating system will need to use Visual Studio 2008 to open the `PCBuild/PCbuild.sln` solution in the Python source tree and build the “x64” configuration of the ‘pythoncore’ project before cross-compiling extensions is possible.

Note that by default, Visual Studio 2008 does not install 64bit compilers or tools. You may need to reexecute the Visual Studio setup process and select these tools (using Control Panel->
5.4.1. The Postinstallation script

Starting with Python 2.3, a postinstallation script can be specified with the \texttt{--install-script} option. The basename of the script must be specified, and the script filename must also be listed in the scripts argument to the setup function.

This script will be run at installation time on the target system after all the files have been copied, with \texttt{argv[1]} set to \texttt{-install}, and again at uninstallation time before the files are removed with \texttt{argv[1]} set to \texttt{-remove}.

The installation script runs embedded in the windows installer, every output (\texttt{sys.stdout}, \texttt{sys.stderr}) is redirected into a buffer and will be displayed in the GUI after the script has finished.

Some functions especially useful in this context are available as additional built-in functions in the installation script.

\texttt{directory_created(path)}
\texttt{file_created(path)}

These functions should be called when a directory or file is created by the postinstall script at installation time. It will register \texttt{path} with the uninstaller, so that it will be removed when the distribution is uninstalled. To be safe, directories are only removed if they are empty.

\texttt{get_special_folder_path(csidl_string)}

This function can be used to retrieve special folder locations on Windows like the Start Menu or the Desktop. It returns the full path to the folder. \texttt{csidl_string} must be one of the following strings:
If the folder cannot be retrieved, `OSError` is raised.

Which folders are available depends on the exact Windows version, and probably also the configuration. For details refer to Microsoft's documentation of the `SHGetSpecialFolderPath()` function.

```python
createShortcut(target, description, filename[, arguments[, workdir[, iconpath[, iconindex]]]])
```

This function creates a shortcut. `target` is the path to the program to be started by the shortcut. `description` is the description of the shortcut. `filename` is the title of the shortcut that the user will see. `arguments` specifies the command line arguments, if any. `workdir` is the working directory for the program. `iconpath` is the file containing the icon for the shortcut, and `iconindex` is the index of the icon in the file `iconpath`. Again, for details consult the Microsoft documentation for the IShellLink interface.
5.5. Vista User Access Control (UAC)

Starting with Python 2.6, bdist_wininst supports a `--user-access-control` option. The default is `none` (meaning no UAC handling is done), and other valid values are `auto` (meaning prompt for UAC elevation if Python was installed for all users) and `force` (meaning always prompt for elevation).
6. The Python Package Index (PyPI)

The Python Package Index (PyPI) stores meta-data describing distributions packaged with distutils, as well as package data like distribution files if a package author wishes.

Distutils provides the register and upload commands for pushing meta-data and distribution files to PyPI, respectively. See Distutils commands for information on these commands.
6.1. PyPI overview

PyPI lets you submit any number of versions of your distribution to the index. If you alter the meta-data for a particular version, you can submit it again and the index will be updated.

PyPI holds a record for each (name, version) combination submitted. The first user to submit information for a given name is designated the Owner of that name. Changes can be submitted through the register command or through the web interface. Owners can designate other users as Owners or Maintainers. Maintainers can edit the package information, but not designate new Owners or Maintainers.

By default PyPI displays only the newest version of a given package. The web interface lets one change this default behavior and manually select which versions to display and hide.

For each version, PyPI displays a home page. The home page is created from the long_description which can be submitted via the register command. See PyPI package display for more information.
6.2. Distutils commands

Distutils exposes two commands for submitting package data to PyPI: the register command for submitting meta-data to PyPI and the upload command for submitting distribution files. Both commands read configuration data from a special file called a .pypirc file.

6.2.1. The register command

The distutils command register is used to submit your distribution’s meta-data to an index server. It is invoked as follows:

```python
python setup.py register
```

Distutils will respond with the following prompt:

```
running register
We need to know who you are, so please choose either:
  1. use your existing login,
  2. register as a new user,
  3. have the server generate a new password for you (and email)
  4. quit
Your selection [default 1]:
```

Note: if your username and password are saved locally, you will not see this menu. Also, refer to The .pypirc file for how to store your credentials in a .pypirc file.

If you have not registered with PyPI, then you will need to do so now. You should choose option 2, and enter your details as required. Soon after submitting your details, you will receive an email which will be used to confirm your registration.

Once you are registered, you may choose option 1 from the menu. You will be prompted for your PyPI username and password, and
register will then submit your meta-data to the index.

See Additional command options for options to the register command.

6.2.2. The upload command

New in version 2.5.

The distutils command upload pushes the distribution files to PyPI.

The command is invoked immediately after building one or more distribution files. For example, the command

```
python setup.py sdist bdist_wininst upload
```

will cause the source distribution and the Windows installer to be uploaded to PyPI. Note that these will be uploaded even if they are built using an earlier invocation of setup.py, but that only distributions named on the command line for the invocation including the upload command are uploaded.

If a register command was previously called in the same command, and if the password was entered in the prompt, upload will reuse the entered password. This is useful if you do not want to store a password in clear text in a .pypirc file.

You can use the --sign option to tell upload to sign each uploaded file using GPG (GNU Privacy Guard). The gpg program must be available for execution on the system PATH. You can also specify which key to use for signing using the --identity=name option.

See Additional command options for additional options to the upload command.
6.2.3. Additional command options

This section describes options common to both the register and upload commands.

The --repository or -r option lets you specify a PyPI server different from the default. For example:

```
python setup.py sdist bdist_wininst upload -r https://example.com/
```

For convenience, a name can be used in place of the URL when the .pypirc file is configured to do so. For example:

```
python setup.py register -r other
```

See The .pypirc file for more information on defining alternate servers.

The --show-response option displays the full response text from the PyPI server, which is useful when debugging problems with registering and uploading.

6.2.4. The .pypirc file

The register and upload commands both check for the existence of a .pypirc file at the location $HOME/.pypirc. If this file exists, the command uses the username, password, and repository URL configured in the file. The format of a .pypirc file is as follows:

```
[distutils]
index-servers =
  pypi

[pypi]
repository: <repository-url>
```
The *distutils* section defines an *index-servers* variable that lists the name of all sections describing a repository.

Each section describing a repository defines three variables:

- *repository*, that defines the url of the PyPI server. Defaults to https://www.python.org/pypi.

- *username*, which is the registered username on the PyPI server.

- *password*, that will be used to authenticate. If omitted the user will be prompt to type it when needed.

If you want to define another server a new section can be created and listed in the *index-servers* variable:

```bash
[distutils]
index-servers =
    pypi
    other

[pypi]
repository: <repository-url>
username: <username>
password: <password>

[other]
repository: https://example.com/pypi
username: <username>
password: <password>
```

This allows the *register* and *upload* commands to be called with the *--repository* option as described in Additional command options.

Specifically, you might want to add the PyPI Test Repository to your `.pypirc` to facilitate testing before doing your first upload to PyPI.
itself.
6.3. PyPI package display

The `long_description` field plays a special role at PyPI. It is used by the server to display a home page for the registered package.

If you use the `reStructuredText` syntax for this field, PyPI will parse it and display an HTML output for the package home page.

The `long_description` field can be attached to a text file located in the package:

```python
from distutils.core import setup

with open('README.txt') as file:
    long_description = file.read()

setup(name='Distutils',
      long_description=long_description)
```

In that case, `README.txt` is a regular `reStructuredText` text file located in the root of the package besides `setup.py`.

To prevent registering broken `reStructuredText` content, you can use the `rst2html` program that is provided by the `docutils` package and check the `long_description` from the command line:

```bash
$ python setup.py --long-description | rst2html.py > output.html
```

`docutils` will display a warning if there’s something wrong with your syntax. Because PyPI applies additional checks (e.g. by passing `--no-raw` to `rst2html.py` in the command above), being able to run the command above without warnings does not guarantee that PyPI will convert the content successfully.
7. Examples

This chapter provides a number of basic examples to help get started with distutils. Additional information about using distutils can be found in the Distutils Cookbook.

See also:

Distutils Cookbook
Collection of recipes showing how to achieve more control over distutils.
If you're just distributing a couple of modules, especially if they don't live in a particular package, you can specify them individually using the `py_modules` option in the setup script.

In the simplest case, you'll have two files to worry about: a setup script and the single module you're distributing, `foo.py` in this example:

```
<root>/
    setup.py
    foo.py
```

(In all diagrams in this section, `<root>` will refer to the distribution root directory.) A minimal setup script to describe this situation would be:

```
from distutils.core import setup
setup(name='foo',
    version='1.0',
    py_modules=['foo'],
)
```

Note that the name of the distribution is specified independently with the `name` option, and there's no rule that says it has to be the same as the name of the sole module in the distribution (although that's probably a good convention to follow). However, the distribution name is used to generate filenames, so you should stick to letters, digits, underscores, and hyphens.

Since `py_modules` is a list, you can of course specify multiple modules, eg. if you're distributing modules `foo` and `bar`, your setup might look like this:

```
<root>/
```
and the setup script might be

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      py_modules=['foo', 'bar'],
)
```

You can put module source files into another directory, but if you have enough modules to do that, it's probably easier to specify modules by package rather than listing them individually.
7.2. Pure Python distribution (by package)

If you have more than a couple of modules to distribute, especially if they are in multiple packages, it’s probably easier to specify whole packages rather than individual modules. This works even if your modules are not in a package; you can just tell the Distutils to process modules from the root package, and that works the same as any other package (except that you don’t have to have an \_init\_.py file).

The setup script from the last example could also be written as

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=[''],
)
```

(The empty string stands for the root package.)

If those two files are moved into a subdirectory, but remain in the root package, e.g.:

```
<root>/
  setup.py
  src/
     foo.py
     bar.py
```

then you would still specify the root package, but you have to tell the Distutils where source files in the root package live:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'': 'src'},
      packages=[''],
)
```
More typically, though, you will want to distribute multiple modules in the same package (or in sub-packages). For example, if the foo and bar modules belong in package foobar, one way to layout your source tree is

```python
<root/>
    setup.py
    foobar/
        __init__.py
        foo.py
        bar.py
```

This is in fact the default layout expected by the Distutils, and the one that requires the least work to describe in your setup script:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=['foobar'],
)
```

If you want to put modules in directories not named for their package, then you need to use the `package_dir` option again. For example, if the src directory holds modules in the foobar package:

```python
<root/>
    setup.py
    src/
        __init__.py
        foo.py
        bar.py
```

an appropriate setup script would be

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'foobar': 'src'},
      packages=['foobar'],
)
```
Or, you might put modules from your main package right in the distribution root:

```
<root/>

    setup.py
    __init__.py
    foo.py
    bar.py
```

in which case your setup script would be

```
from distutils.core import setup
setup(name='foobar',
       version='1.0',
       package_dir={'foobar': ''},
       packages=['foobar'],
)
```

(The empty string also stands for the current directory.)

If you have sub-packages, they must be explicitly listed in `packages`, but any entries in `package_dir` automatically extend to sub-packages. (In other words, the Distutils does *not* scan your source tree, trying to figure out which directories correspond to Python packages by looking for `__init__.py` files.) Thus, if the default layout grows a sub-package:

```
<root/>

    setup.py
    foobar/

          __init__.py
    foo.py
    bar.py
        subfoo/  
                  __init__.py
    blah.py
```

then the corresponding setup script would be

```
from distutils.core import setup
```
setup(name='foobar',
    version='1.0',
    packages=['foobar', 'foobar.subfoo'],
)
7.3. Single extension module

Extension modules are specified using the `ext_modules` option. `package_dir` has no effect on where extension source files are found; it only affects the source for pure Python modules. The simplest case, a single extension module in a single C source file, is:

```python
<root>/
    setup.py
    foo.c
```

If the `foo` extension belongs in the root package, the setup script for this could be

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

If the extension actually belongs in a package, say `foopkg`, then

With exactly the same source tree layout, this extension can be put in the `foopkg` package simply by changing the name of the extension:

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foopkg.foo', ['foo.c'])],
)
```
