BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

BaseHandler.\texttt{add\_parent}(director)

Add a director as parent.

BaseHandler.\texttt{close}()

Remove any parents.

The following attribute and methods should only be used by classes derived from BaseHandler.

\begin{quote}
\textbf{Note:} The convention has been adopted that subclasses defining protocol\_request() or protocol\_response() methods are named *Processor; all others are named *Handler.
\end{quote}

BaseHandler.\texttt{parent}

A valid OpenerDirector, which can be used to open using a different protocol, or handle errors.

BaseHandler.\texttt{default\_open}(req)

This method is not defined in BaseHandler, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent OpenerDirector. It should return a file-like object as described in the return value of the open() of OpenerDirector, or None. It should raise URLError, unless a truly exceptional thing happens
(for example, `MemoryError` should not be mapped to `URLError`).

This method will be called before any protocol-specific open method.

**BaseHandler**. `protocol_open`(`req`)

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler**. `unknown_open`(`req`)

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler**. `http_error_default`(`req`, `fp`, `code`, `msg`, `hdrs`)

This method is *not* defined in `BaseHandler`, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the `OpenerDirector` getting the error, and should not normally be called in other circumstances.

`req` will be a `Request` object, `fp` will be a file-like object with the HTTP error body, `code` will be the three-digit code of the error, `msg`
will be the user-visible explanation of the code and *hdrs* will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of `urlopen()`.

*BaseHandler*. `http_error_nnn(req, fp, code, msg, hdrs)`

*nnn* should be a three-digit HTTP error code. This method is also not defined in *BaseHandler*, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code *nnn* occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for `http_error_default()`.

*BaseHandler*. `protocol_request(req)`

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. The return value should be a *Request* object.

*BaseHandler*. `protocol_response(req, response)`

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. *response* will be
an object implementing the same interface as the return value of `urlopen()`. The return value should implement the same interface as the return value of `urlopen()`.
21.6.4. HTTPRedirectHandler Objects

**Note:** Some HTTP redirections require action from this module's client code. If this is the case, `HTTPError` is raised. See [RFC 2616](https://tools.ietf.org/html/rfc2616) for details of the precise meanings of the various redirection codes.

An `HTTPError` exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected url which is not an HTTP, HTTPS or FTP url.

HTTPRedirectHandler. `redirect_request(req, fp, code, msg, hdrs, newurl)`

Return a `Request` or None in response to a redirect. This is called by the default implementations of the `http_error_30*()` methods when a redirection is received from the server. If a redirection should take place, return a new `Request` to allow `http_error_30*()` to perform the redirect to `newurl`. Otherwise, raise `HTTPError` if no other handler should try to handle this URL, or return None if you can’t but another handler might.

**Note:** The default implementation of this method does not strictly follow [RFC 2616](https://tools.ietf.org/html/rfc2616), which says that 301 and 302 responses to `POST` requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the `POST` to a `GET`, and the default implementation reproduces this behavior.

HTTPRedirectHandler. `http_error_301(req, fp, code, msg, hdrs)`

Redirect to the `Location:` or `URI:` URL. This method is called by
the parent **OpenerDirector** when getting an HTTP 'moved permanently' response.

`HTTPRedirectHandler.http_error_302(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the 'found' response.

`HTTPRedirectHandler.http_error_303(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the 'see other' response.

`HTTPRedirectHandler.http_error_307(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the 'temporary redirect' response.
21.6.5. HTTPCookieProcessor Objects

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor.cookiejar

The http.cookiejar.CookieJar in which cookies are stored.
21.6.6. ProxyHandler Objects

ProxyHandler. **protocol_open**(request)

The **ProxyHandler** will have a method **protocol_open()** for every **protocol** which has a proxy in the **proxies** dictionary given in the constructor. The method will modify requests to go through the proxy, by calling **request.set_proxy()**, and call the next handler in the chain to actually execute the protocol.
21.6.7. HTTPPasswordMgr Objects

These methods are available on HTTPPasswordMgr and HTTPPasswordMgrWithDefaultRealm objects.

HTTPPasswordMgr.add_password(realm, uri, user, passwd)

uri can be either a single URI, or a sequence of URIs. realm, user and passwd must be strings. This causes (user, passwd) to be used as authentication tokens when authentication for realm and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.find_user_password(realm, authuri)

Get user/password for given realm and URI, if any. This method will return (None, None) if there is no matching user/password.

For HTTPPasswordMgrWithDefaultRealm objects, the realm None will be searched if the given realm has no matching user/password.
21.6.8. AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler. **http_error_auth_requed**(*authreq host, req, headers*)

Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) Request object, and *headers* should be the error headers.

*host* is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
21.6.9. HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler. **http_error_401**(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.10. ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler. **http_error_407**(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.11. AbstractDigestAuthHandler Objects

`AbstractDigestAuthHandler.http_error_auth_reqed(authreq, host, req, headers)`

`authreq` should be the name of the header where the information about the realm is included in the request, `host` should be the host to authenticate to, `req` should be the (failed) `Request` object, and `headers` should be the error headers.
21.6.12. HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler. `http_error_401(req, fp, code, msg, hdrs)`

Retry the request with authentication information, if available.
21.6.13. ProxyDigestAuthHandler Objects

Retry the request with authentication information, if available.
21.6.14. HTTPHandler Objects

HTTPHandler. **http_open**(req)

Send an HTTP request, which can be either GET or POST, depending on req.has_data().
21.6.15. HTTPSHandler Objects

HTTPSHandler.\texttt{https\_open}(\textit{req})

Send an HTTPS request, which can be either GET or POST, depending on \textit{req.has\_data}().
21.6.16. FileHandler Objects

FileHandler.\texttt{file\_open}(req)

Open the file locally, if there is no host name, or the host name is 'localhost'.

\textit{Changed in version 3.2:} This method is applicable only for local hostnames. When a remote hostname is given, an \texttt{URLError} is raised.
21.6.17. FTPHandler Objects

FTPHandler. **ftp_open**(req)

Open the FTP file indicated by *req*. The login is always done with empty username and password.
21.6.18. CacheFTPHandler Objects

CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler. **setTimeout**\( (t) \)
Set timeout of connections to \( t \) seconds.

CacheFTPHandler. **setMaxConns**\( (m) \)
Set maximum number of cached connections to \( m \).
21.6.19. UnknownHandler Objects

UnknownHandler. unknown_open()

Raise a URLError exception.
21.6.20. HTTPErrorProcessor Objects

HTTPErrorProcessor. `http_response()`
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the `protocol_error_code()` handler methods, via `OpenerDirector.error()`. Eventually, `HTTPDefaultErrorHandler` will raise an `HTTPError` if no other handler handles the error.

HTTPErrorProcessor. `https_response()`
Process HTTPS error responses.

The behavior is same as `http_response()`.
21.6.21. Examples

This example gets the python.org main page and displays the first 300 bytes of it.

```python
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/
>>> print(f.read(300))
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the http server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, http://www.w3.org/International/O-charset, lists the various ways in which a (X)HTML or a XML document could have specified its encoding information.

As the python.org website uses utf-8 encoding as specified in it's meta tag, we will use the same for decoding the bytes object.

```python
>>> with urllib.request.urlopen('http://www.python.org/
...     print(f.read(100).decode('utf-8'))
...        
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```
It is also possible to achieve the same result without using the context manager approach.

```python
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/
>>> print(f.read(100).decode('utf-8'))
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```python
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/cgi-bin/test.cgi', data=b'This data is passed to stdin of the CGI')
>>> f = urllib.request.urlopen(req)
>>> print(f.read().decode('utf-8'))
Got Data: 'This data is passed to stdin of the CGI'
```

The code for the sample CGI used in the above example is:

```python
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text-plain
Got Data: "%s"' % data)
```

Here is an example of doing a PUT request using `Request`:

```python
import urllib.request
DATA=b'some data'
req = urllib.request.Request(url='http://localhost:8080', method='PUT', data=DATA)
f = urllib.request.urlopen(req)
```
print(f.status)
print(f.reason)

Use of Basic HTTP Authentication:

```python
import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication:
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                           uri='https://mahler:8092/site-updates.py',
                           user='klem',
                           passwd='kadidd!ehopper')

opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urlopen:
urllib.request.install_opener(opener)

urllib.request.urlopen('http://www.example.com/login.html')
```

`build_opener()` provides many handlers by default, including a `ProxyHandler`. By default, `ProxyHandler` uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the `http_proxy` environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default `ProxyHandler` with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with `ProxyBasicAuthHandler`.

```python
proxy_handler = urllib.request.ProxyHandler({'http': proxy_url,'https': proxy_url})
proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password')

opener = urllib.request.build_opener(proxy_handler, proxy_auth_handler)
# This time, rather than install the OpenerDirector, we use it directly:
opener.open('http://www.example.com/login.html')
```
Adding HTTP headers:

Use the headers argument to the Request constructor, or:

```python
import urllib.request
req = urllib.request.Request('http://www.example.com/
req.add_header('Referer', 'http://www.python.org/'))
r = urllib.request.urlopen(req)
```

OpenerDirector automatically adds a User-Agent header to every Request. To change this:

```python
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [(User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/
```

Also, remember that a few standard headers (Content-Length, Content-Type without charset parameter and Host) are added when the Request is passed to urlopen() (or OpenerDirector.open()).

Here is an example session that uses the GET method to retrieve a URL containing parameters:

```python
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'eggs'})
>>> f = urllib.request.urlopen('http://www.musical.com/cgi-bin/query?%s
>>> print(f.read().decode('utf-8'))
```
The following example uses the POST method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```python
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs': 2})
>>> data = data.encode('utf-8')
>>> request = urllib.request.Request("http://requestb.in/xrbl82xr"
>>> request.add_header("Content-Type","application/x-www-form-urlencoded")
>>> f = urllib.request.urlopen(request, data)
>>> print(f.read().decode('utf-8'))
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> f = opener.open("http://www.python.org")
>>> f.read().decode('utf-8')
```

The following example uses no proxies at all, overriding environment settings:

```python
>>> import urllib.request
>>> opener = urllib.request.FancyURLopener({})
>>> f = opener.open("http://www.python.org")
>>> f.read().decode('utf-8')
```
21.6.22. Legacy interface

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

`urllib.request.urlretrieve(url, filename=None, reporthook=None, data=None)`

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple `(filename, headers)` where `filename` is the local file name under which the object can be found, and `headers` is whatever the `info()` method of the object returned by `urlopen()` returned (for a remote object). Exceptions are the same as for `urlopen()`.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```python
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve...
>>> html = open(local_filename)
```
If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a POST request (normally the request type is GET). The `data` argument must be a bytes object in standard `application/x-www-form-urlencoded` format; see the `urllib.parse.urlencode()` function.

`urlretrieve()` will raise `ContentTooShortError` when it detects that the amount of data available was less than the expected amount (which is the size reported by a `Content-Length` header). This can occur, for example, when the download is interrupted.

The `Content-Length` is treated as a lower bound: if there's more data to read, `urlretrieve` reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no `Content-Length` header was supplied, `urlretrieve` can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

`urllib.request.urlcleanup()`

Cleans up temporary files that may have been left behind by previous calls to `urlretrieve()`.

```python
class urllib.request.URLopener(proxies=None, **x509)
```

`Deprecated since version 3.3.`
Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than http:, ftp:, or file:, you probably want to use FancyURLopener.

By default, the URLopener class sends a User-Agent header of urllib/VVV, where VVV is the urllib version number. Applications can define their own User-Agent header by subclassing URLopener or FancyURLopener and setting the class attribute version to an appropriate string value in the subclass definition.

The optional proxies parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is None, in which case environmental proxy settings will be used if present, as discussed in the definition of urlopen(), above.

Additional keyword parameters, collected in x509, may be used for authentication of the client when using the https: scheme. The keywords key_file and cert_file are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an OSError exception if the server returns an error code.

open(fullurl, data=None)
Open fullurl using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, open_unknown() is called. The data argument has the same meaning as the data
argument of \texttt{urlopen()}. 

\textbf{open\_unknown}(\texttt{fullurl, data=\texttt{None}})

Overridable interface to open unknown URL types.

\textbf{retrieve}(\texttt{url, filename=\texttt{None, reporthook=\texttt{None, data=\texttt{None}}}})

Retrieves the contents of \texttt{url} and places it in \texttt{filename}. The return value is a tuple consisting of a local filename and either a \texttt{email.message.Message} object containing the response headers (for remote URLs) or None (for local URLs). The caller must then open and read the contents of \texttt{filename}. If \texttt{filename} is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and \texttt{filename} is not given, the filename is the output of \texttt{tempfile.mktemp()} with a suffix that matches the suffix of the last path component of the input URL. If \texttt{reporthook} is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. \texttt{reporthook} is ignored for local URLs.

If the \texttt{url} uses the \texttt{http:} scheme identifier, the optional \texttt{data} argument may be given to specify a \texttt{POST} request (normally the request type is \texttt{GET}). The \texttt{data} argument must in standard \texttt{application/x-www-form-urlencoded} format; see the \texttt{urllib.parse.urlencode()} function.

\textbf{version}

Variable that specifies the user agent of the opener object.
To get `urllib` to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.

```python
class urllib.request.FancyURLopener(...)
```

*Deprecated since version 3.3.*

FancyURLopener subclasses `URLopener` providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the `Location` header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the `maxtries` attribute, which defaults to 10.

For all other response codes, the method `http_error_default()` is called which you can override in subclasses to handle the error appropriately.

**Note:** According to the letter of RFC 2616, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and `urllib` reproduces this behaviour.

The parameters to the constructor are the same as those for `URLopener`.

**Note:** When performing basic authentication, a `FancyURLopener` instance calls its `prompt_user_password()` method. The default implementation asks the users for the required information on the controlling terminal. A subclass may
override this method to support more appropriate behavior if needed.

The **FancyURLopener** class offers one additional method that should be overloaded to provide the appropriate behavior:

**prompt_user_passwd**(*host*, *realm*)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, *(user, password)*, which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.
21.6.23. `urllib.request` Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, and local files.

- The caching feature of `urlretrive()` has been disabled until someone finds the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can’t be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The `urlopen()` and `urlretrive()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

- The data returned by `urlopen()` or `urlretrive()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `html.parser` to parse it.

- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not
accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing `/` has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the `ftplib` module, subclassing `FancyURLopener`, or changing `_urloperator` to meet your needs.
21.7. **urllib.response** — Response classes used by urllib

The `urllib.response` module defines functions and classes which define a minimal file like interface, including `read()` and `readline()`. The typical response object is an `addinfourl` instance, which defines an `info()` method and that returns headers and a `geturl()` method that returns the url. Functions defined by this module are used internally by the `urllib.request` module.
21.8. **urllib.parse** — Parse URLs into components

**Source code:** Lib/urllib/parse.py

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: file, ftp, gopher, hdl, http, https, imap, mailto, mms, news, nntp, prospero, rsync, rtsp, rtspu, sftp, shttp, sip, sips, snews, svn, svn+ssh, telnet, wais.

The **urllib.parse** module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.
21.8.1. URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

`urllib.parse.urlparse(urlstring, scheme='', allow_fragments=True)`

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the `path` component, which is retained if present. For example:

```
>>> from urllib.parse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in RFC 1808, urlparse recognizes a netloc only if it is properly introduced by ‘//’. Otherwise the input is presumed to be a relative URL and thus to start with a
path component.

```python
>>> from urllib.parse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')
>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/%7Eguido/Python.html', params='', query='', fragment='')
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', query='', fragment='')
```

If the `scheme` argument is specified, it gives the default addressing scheme, to be used only if the URL does not specify one. The default value for this argument is the empty string.

If the `allow_fragments` argument is false, fragment identifiers are not allowed. The default value for this argument is `True`.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>

See section *Structured Parse Results* for more information on the result object.

*Changed in version 3.2:* Added IPv6 URL parsing capabilities.

* Changed in version 3.3: * The fragment is now parsed for all URL schemes (unless `allow_fragment` is false), in accordance with RFC 3986. Previously, a whitelist of schemes that support fragments existed.

```python
urllib.parse.parse_qs(qs, keep_blank_values=False,
                      strict_parsing=False, encoding='utf-8', errors='replace')
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.
The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlencode()` function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

*Changed in version 3.2:* Add `encoding` and `errors` parameters.

```python
er urllib.parse.parse_qsl(qs, keep_blank_values=False, strict_parsing=False, encoding='utf-8', errors='replace')
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a list of name, value pairs.

The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as
accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlencode()` function to convert such lists of pairs into query strings.

*Changed in version 3.2:* Add `encoding` and `errors` parameters.

`urllib.parse.urlunparse(parts)`

Construct a URL from a tuple as returned by `urlparse()`. The `parts` argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a `?` with an empty query; the RFC states that these are equivalent).

`urllib.parse.urlsplit(urlstring, scheme=",", allow_fragments=True)`

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the `path` portion of the URL (see RFC 2396) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Value</td>
<td></td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>-------</td>
<td></td>
</tr>
<tr>
<td>netloc</td>
<td>Network location part</td>
<td>empty string</td>
<td></td>
</tr>
<tr>
<td>path</td>
<td>Hierarchical path</td>
<td>empty string</td>
<td></td>
</tr>
<tr>
<td>query</td>
<td>Query component</td>
<td>empty string</td>
<td></td>
</tr>
<tr>
<td>fragment</td>
<td>Fragment identifier</td>
<td>empty string</td>
<td></td>
</tr>
<tr>
<td>username</td>
<td>User name</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>password</td>
<td>Password</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>hostname</td>
<td>Host name (lower case)</td>
<td>None</td>
<td></td>
</tr>
<tr>
<td>port</td>
<td>Port number as integer, if present</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

See section *Structured Parse Results* for more information on the result object.

**urllib.parse.urlunsplit(parts)**

Combine the elements of a tuple as returned by `urllib.parse.urlsplit()` into a complete URL as a string. The `parts` argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

**urllib.parse.urljoin(base, url, allow_fragments=True)**

Construct a full (“absolute”) URL by combining a “base URL” (base) with another URL (url). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```python
>>> from urllib.parse import urljoin
```
The `allow_fragments` argument has the same meaning and default as for `urlparse()`.

**Note:** If `url` is an absolute URL (that is, starting with `//` or `scheme://`), the `url`'s host name and/or scheme will be present in the result. For example:

```python
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html',
          'http://www.cwi.nl/%7Eguido/FAQ.html')
'http://www.cwi.nl/%7Eguido'
```

If you do not want that behavior, preprocess the `url` with `urlsplit()` and `urlunsplit()`, removing possible `scheme` and `netloc` parts.

**urllib.parse.** `urldefrag(url)`

If `url` contains a fragment identifier, return a modified version of `url` with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in `url`, return `url` unmodified and an empty string.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>url</code></td>
<td>0</td>
<td>URL with no fragment</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>1</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
</tbody>
</table>

See section *Structured Parse Results* for more information on the result object.

*Changed in version 3.2:* Result is a structured object rather than a simple 2-tuple.
21.8.2. Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on bytes and bytearray objects in addition to str objects.

If str data is passed in, the result will also contain only str data. If bytes or bytearray data is passed in, the result will contain only bytes data.

Attempting to mix str data with bytes or bytearray in a single function call will result in a TypeError being raised, while attempting to pass in non-ASCII byte values will trigger UnicodeDecodeError.

To support easier conversion of result objects between str and bytes, all return values from URL parsing functions provide either an encode() method (when the result contains str data) or a decode() method (when the result contains bytes data). The signatures of these methods match those of the corresponding str and bytes methods (except that the default encoding is 'ascii' rather than 'utf-8'). Each produces a value of a corresponding type that contains either bytes data (for encode() methods) or str data (for decode() methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.
The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

*Changed in version 3.2:* URL parsing functions now accept ASCII encoded byte sequences
21.8.3. Structured Parse Results

The result objects from the `urlparse()`, `urlsplit()` and `urldefrag()` functions are subclasses of the `tuple` type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

`urllib.parse.SplitResult.geturl()`

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For `urldefrag()` results, only empty fragment identifiers will be removed. For `urlsplit()` and `urlparse()` results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```python
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/
```

The following classes provide the implementations of the structured
parse results when operating on `str` objects:

```python
class urllib.parse.DefragResult(url, fragment)
```
Concrete class for `urldefrag()` results containing `str` data. The `encode()` method returns a `DefragResultBytes` instance.

*New in version 3.2.*

```python
class urllib.parse.ParseResult(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results containing `str` data. The `encode()` method returns a `ParseResultBytes` instance.

```python
class urllib.parse.SplitResult(scheme, netloc, path, query, fragment)
```
Concrete class for `urlsplit()` results containing `str` data. The `encode()` method returns a `SplitResultBytes` instance.

The following classes provide the implementations of the parse results when operating on `bytes` or `bytearray` objects:

```python
class urllib.parse.DefragResultBytes(url, fragment)
```
Concrete class for `urldefrag()` results containing `bytes` data. The `decode()` method returns a `DefragResult` instance.

*New in version 3.2.*

```python
class urllib.parse.ParseResultBytes(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results containing `bytes` data. The `decode()` method returns a `ParseResult` instance.

*New in version 3.2.*
class urllib.parse.SplitResultBytes(scheme, netloc, path, query, fragment)

Concrete class for urllsplit() results containing bytes data. The decode() method returns a SplitResult instance.

New in version 3.2.
21.8.4. URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

urllib.parse.quote(string, safe='/', encoding=None, errors=None)

Replace special characters in string using the %xx escape. Letters, digits, and the characters '.-' are never quoted. By default, this function is intended for quoting the path section of URL. The optional safe parameter specifies additional ASCII characters that should not be quoted — its default value is '/'.

string may be either a str or a bytes.

The optional encoding and errors parameters specify how to deal with non-ASCII characters, as accepted by the str.encode() method. encoding defaults to 'utf-8'. errors defaults to 'strict', meaning unsupported characters raise a UnicodeEncodeError. encoding and errors must not be supplied if string is a bytes, or a TypeError is raised.

Note that quote(string, safe, encoding, errors) is equivalent to quote_from_bytes(string.encode(encoding, errors), safe).
Example: `quote('/El Niño/')` yields `'/El%20Ni%C3%B1o/'`.

`urllib.parse.quote_plus(string, safe='', encoding=None, errors=None)`

Like `quote()`, but also replace spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in `safe`. It also does not have `safe` default to `'/'`.

Example: `quote_plus('/El Niño/')` yields `'/%2FE1+Ni%C3%B1o%2F'`.

`urllib.parse.quote_from_bytes(bytes, safe='/' )`

Like `quote()`, but accepts a `bytes` object rather than a `str`, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields `a%26%EF`.

`urllib.parse.unquote(string, encoding='utf-8', errors='replace')`

Replace `%xx` escapes by their single-character equivalent. The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

`string` must be a `str`.

`encoding` defaults to `'utf-8'`. `errors` defaults to `'replace'`, meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields `'/El Niño/'`.
urllib.parse.unquote_plus(string, encoding='utf-8', errors='replace')

Like unquote(), but also replace plus signs by spaces, as required for unquoting HTML form values.

string must be a str.

Example: unquote_plus('/El+Ni%C3%B1o/') yields '/El Niño/'.

urllib.parse.unquote_to_bytes(string)

Replace %xx escapes by their single-octet equivalent, and return a bytes object.

string may be either a str or a bytes.

If it is a str, unescaped non-ASCII characters in string are encoded into UTF-8 bytes.

Example: unquote_to_bytes('a%26%EF') yields b'a&\xef'.

urllib.parse.urlencode(query, doseq=False, safe='', encoding=None, errors=None)

Convert a mapping object or a sequence of two-element tuples, which may either be a str or a bytes, to a “percent-encoded” string. If the resultant string is to be used as a data for POST operation with urlopen() function, then it should be properly encoded to bytes, otherwise it would result in a TypeError.

The resulting string is a series of key=value pairs separated by '&' characters, where both key and value are quoted using quote_plus() above. When a sequence of two-element tuples is used as the query argument, the first element of each tuple is a key
and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter doseq is evaluates to True, individual key=value pairs separated by ' & ' are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

When query parameter is a str, the safe, encoding and error parameters are passed down to quote_plus() for encoding.

To reverse this encoding process, parse_qs() and parse_qsl() are provided in this module to parse query strings into Python data structures.

Refer to urllib examples to find out how urllencode method can be used for generating query string for a URL or data for POST.

Changed in version 3.2: Query parameter supports bytes and string objects.

See also:

**RFC 3986** - Uniform Resource Identifiers

This is the current standard (STD66). Any changes to urllib.parse module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732** - Format for Literal IPv6 Addresses in URL's.

This specifies the parsing requirements of IPv6 URLs.

**RFC 2396** - Uniform Resource Identifiers (URI): Generic Syntax

Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource
Locators (URLs).

**RFC 2368 - The mailto URL scheme.**
Parsing requirements for mailto url schemes.

**RFC 1808 - Relative Uniform Resource Locators**
This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 1738 - Uniform Resource Locators (URL)**
This specifies the formal syntax and semantics of absolute URLs.
21.9. `urllib.error` — Exception classes raised by `urllib.request`

The `urllib.error` module defines the exception classes for exceptions raised by `urllib.request`. The base exception class is `URLError`.

The following exceptions are raised by `urllib.error` as appropriate:

`exception urllib.error.URLError`

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `OSError`.

`reason`

The reason for this error. It can be a message string or another exception instance.

*Changed in version 3.3:* `URLError` has been made a subclass of `OSError` instead of `IOError`.

`exception urllib.error.HTTPError`

Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

`code`
An HTTP status code as defined in RFC 2616. This numeric value corresponds to a value found in the dictionary of codes as found in `http.server.BaseHTTPRequestHandler.responses`.

**reason**

This is usually a string explaining the reason for this error.

**exception** `urllib.error.ContentTooShortError(msg, content)`

This exception is raised when the `urlretrieve()` function detects that the amount of the downloaded data is less than the expected amount (given by the `Content-Length` header). The `content` attribute stores the downloaded (and supposedly truncated) data.
This module provides a single class, `RobotFileParser`, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see [http://www.robotstxt.org/orig.html](http://www.robotstxt.org/orig.html).

```python
class urllib.robotparser.RobotFileParser(url='')
```

This class provides methods to read, parse and answer questions about the `robots.txt` file at `url`.

- `set_url(url)`
  Sets the URL referring to a `robots.txt` file.

- `read()`
  Reads the `robots.txt` URL and feeds it to the parser.

- `parse(lines)`
  Parses the lines argument.

- `can_fetch(useragent, url)`
  Returns True if the `useragent` is allowed to fetch the `url` according to the rules contained in the parsed `robots.txt` file.

- `mtime()`
  Returns the time the `robots.txt` file was last fetched. This is useful for long-running web spiders that need to check for new
**robots.txt** files periodically.

**modified()**

Sets the time the **robots.txt** file was last fetched to the current time.

The following example demonstrates basic use of the RobotFileParser class.

```python
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/"")
True
```
21.11. http — HTTP modules

http is a package that collects several modules for working with the HyperText Transfer Protocol:

- **http.client** is a low-level HTTP protocol client; for high-level URL opening use **urllib.request**
- **http.server** contains basic HTTP server classes based on **socketserver**
- **http.cookies** has utilities for implementing state management with cookies
- **http.cookiejar** provides persistence of cookies
This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib.request` uses it to handle URLs that use HTTP and HTTPS.

**Note:** HTTPS support is only available if Python was compiled with SSL support (through the `ssl` module).

The module provides the following classes:

```python
class http.client.HTTPConnection(host, port=None[, strict][, timeout], source_address=None)
```

An `HTTPConnection` instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional `timeout` parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional `source_address` parameter may be a tuple of a (host, port) to use as the source address the HTTP connection is made from.

For example, the following calls all create instances that connect to
the server at the same host and port:

```python
>>> h1 = http.client.HTTPConnection('www.cwi.nl')
>>> h2 = http.client.HTTPConnection('www.cwi.nl:80')
>>> h3 = http.client.HTTPConnection('www.cwi.nl',
... source_address=None,
... check_hostname=None)
```

*Changed in version 3.2:* `source_address` was added.

*Deprecated since version 3.2, will be removed in version 3.4:* The `strict` parameter is deprecated. HTTP 0.9-style “Simple Responses” are not supported anymore.

```python
class http.client.HTTPSConnection(host, port=None,
key_file=None, cert_file=None[, strict][, timeout],
source_address=None, *, context=None,
check_hostname=None)
```

A subclass of `HTTPConnection` that uses SSL for communication with secure servers. Default port is 443. If `context` is specified, it must be a `ssl.SSLContext` instance describing the various SSL options. If `context` is specified and has a `verify_mode` of either `CERT_OPTIONAL` or `CERT_REQUIRED`, then by default `host` is matched against the host name(s) allowed by the server's certificate. If you want to change that behaviour, you can explicitly set `check_hostname` to False.

`key_file` and `cert_file` are deprecated, please use `ssl.SSLContext.load_cert_chain()` instead.

If you access arbitrary hosts on the Internet, it is recommended to require certificate checking and feed the `context` with a set of trusted CA certificates:
context = ssl.create_default_context(ssl.PROTOCOL_TLSv1)
context.verify_mode = ssl.CERT_REQUIRED
context.load_verify_locations('/etc/pki/tls/certs/ca-bundle.crt')

http.client.HTTPSConnection('svn.python.org', 443, context=context)

**Changed in version 3.2:** source_address, context and check_hostname were added.

**Changed in version 3.2:** This class now supports HTTPS virtual hosts if possible (that is, if `ssl.HAS_SNI` is true).

**Deprecated since version 3.2, will be removed in version 3.4:** The strict parameter is deprecated. HTTP 0.9-style “Simple Responses” are not supported anymore.

```python
class http.client.HTTPResponse(sock, debuglevel=0[, strict],
method=None, url=None)
```

Class whose instances are returned upon successful connection. Not instantiated directly by user.

**Deprecated since version 3.2, will be removed in version 3.4:** The strict parameter is deprecated. HTTP 0.9-style “Simple Responses” are not supported anymore.

The following exceptions are raised as appropriate:

**exception** http.client.HTTPException

The base class of the other exceptions in this module. It is a subclass of Exception.

**exception** http.client.NotConnected

A subclass of HTTPException.
exception http.client.**InvalidURL**
A subclass of **HTTPException**, raised if a port is given and is either non-numeric or empty.

exception http.client.**UnknownProtocol**
A subclass of **HTTPException**.

exception http.client.**UnknownTransferEncoding**
A subclass of **HTTPException**.

exception http.client.**UnimplementedFileMode**
A subclass of **HTTPException**.

exception http.client.**IncompleteRead**
A subclass of **HTTPException**.

exception http.client.**ImproperConnectionState**
A subclass of **HTTPException**.

exception http.client.**CannotSendRequest**
A subclass of **ImproperConnectionState**.

exception http.client.**CannotSendHeader**
A subclass of **ImproperConnectionState**.

exception http.client.**ResponseNotReady**
A subclass of **ImproperConnectionState**.

exception http.client.**BadStatusLine**
A subclass of **HTTPException**. Raised if a server responds with a HTTP status code that we don’t understand.

The constants defined in this module are:
http.client.HTTP_PORT

The default port for the HTTP protocol (always 80).

http.client.HTTPS_PORT

The default port for the HTTPS protocol (always 443).

and also the following constants for integer status codes:

Changed in version 3.3: Added codes 428, 429, 431 and 511 from RFC 6585.

http.client.responses

This dictionary maps the HTTP 1.1 status codes to the W3C names.

Example:

http.client.responses[http.client.NOT_FOUND] is
'Not Found'.
21.12.1. HTTPConnection Objects

HTTPConnection instances have the following methods:

HTTPConnection.**request**(method, url, body=None, headers={})

This will send a request to the server using the HTTP request method `method` and the selector `url`. If the `body` argument is present, it should be string or bytes object of data to send after the headers are finished. Strings are encoded as ISO-8859-1, the default charset for HTTP. To use other encodings, pass a bytes object. The Content-Length header is set to the length of the string.

The `body` may also be an open *file object*, in which case the contents of the file is sent; this file object should support `fileno()` and `read()` methods. The header Content-Length is automatically set to the length of the file as reported by stat. The `body` argument may also be an iterable and Content-Length header should be explicitly provided when the body is an iterable.

The `headers` argument should be a mapping of extra HTTP headers to send with the request.

*New in version 3.2:* `body` can now be an iterable.

HTTPConnection.**getresponse**()

Should be called after a request is sent to get the response from the server. Returns an HTTPResponse instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

HTTPConnection.**set_debuglevel**(level)
Set the debugging level. The default debug level is 0, meaning no debugging output is printed. Any value greater than 0 will cause all currently defined debug output to be printed to stdout. The `debuglevel` is passed to any new `HTTPRequest` objects that are created.

*New in version 3.1.*

**HTTPConnection.** `set_tunnel(host, port=None, headers=None)`

Set the host and the port for HTTP Connect Tunnelling. Normally used when it is required to a HTTPS Connection through a proxy server.

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

*New in version 3.2.*

**HTTPConnection.** `connect()`

Connect to the server specified when the object was created.

**HTTPConnection.** `close()`

Close the connection to the server.

As an alternative to using the `request()` method described above, you can also send your request step by step, by using the four functions below.

**HTTPConnection.** `putrequest(request, selector, skip_host=False, skip_accept_encoding=False)`

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the `request` string, the `selector` string, and the HTTP version (HTTP/1.1). To
disable automatic sending of Host: or Accept-Encoding: headers (for example to accept additional content encodings), specify skip_host or skip_accept_encoding with non-False values.

HTTPConnection.putheader(header, argument[,...])
Send an RFC 822-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(message_body=None)
Send a blank line to the server, signalling the end of the headers. The optional message_body argument can be used to pass a message body associated with the request. The message body will be sent in the same packet as the message headers if it is string, otherwise it is sent in a separate packet.

HTTPConnection.send(data)
Send data to the server. This should be used directly only after the endheaders() method has been called and before getresponse() is called.
21.12.2. HTTPResponse Objects

An HTTPResponse instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

HTTPResponse.read([amt])
Reads and returns the response body, or up to the next amt bytes.

HTTPResponse.readinto(b)
Reads up to the next len(b) bytes of the response body into the buffer b. Returns the number of bytes read.

New in version 3.3.

HTTPResponse.getheader(name, default=None)
Return the value of the header name, or default if there is no header matching name. If there is more than one header with the name name, return all of the values joined by ‘,’. If ‘default’ is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.getheaders()
Return a list of (header, value) tuples.

HTTPResponse.fileno()
Return the fileno of the underlying socket.

HTTPResponse.msg
A http.client.HTTPMessage instance containing the response headers. http.client.HTTPMessage is a subclass of
email.message.Message.

HTTPResponse.version
  HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.status
  Status code returned by server.

HTTPResponse.reason
  Reason phrase returned by server.

HTTPResponse.debuglevel
  A debugging hook. If debuglevel is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse.closed
  Is True if the stream is closed.
21.12.3. Examples

Here is an example session that uses the GET method:

```python
>>> import http.client
>>> conn = http.client.HTTPConnection("www.python.org")
>>> conn.request("GET", "/index.html")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire contents.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/index.html")
>>> r1 = conn.getresponse()
>>> while not r1.closed:
...    print(r1.read(200))  # 200 bytes
...\b"<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
...# Example of an invalid request
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the HEAD method. Note that the HEAD method never returns any data.

```python
>>> import http.client
>>> conn = http.client.HTTPConnection("www.python.org")
>>> conn.request("HEAD", "/index.html")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
```
Here is an example session that shows how to **POST** requests:

```python
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524})
>>> headers = {
    'Content-type': 'application/x-www-form-urlencoded',
    'Accept': 'text/plain'}
>>> conn = http.client.HTTPConnection('bugs.python.org')
>>> conn.request('POST', '', params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="http://bugs.python.org/issue12524">http://bugs.python.org/issue12524</a>'
>>> conn.close()
```

Client side HTTP **PUT** requests are very similar to **POST** requests. The difference lies only on the server side where HTTP server will allow resources to be created via **PUT** request. It should be noted that custom HTTP methods +are also handled in `urllib.request.Request` by sending the appropriate +method attribute. Here is an example session that shows how to do **PUT** request using `http.client`:

```python
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/foobar
```
>>> import http.client

>>> BODY = "***filecontents***

>>> conn = http.client.HTTPConnection("localhost", &

>>> conn.request("PUT", "/file", BODY)

>>> response = conn.getresponse()

>>> print(response.status, response.reason)

200, OK
21.12.4. HTTPMessage Objects

An `http.client.HTTPMessage` instance holds the headers from an HTTP response. It is implemented using the `email.message.Message` class.

ftplib — FTP protocol client

Source code: Lib/ftplib.py

This module defines the class FTP and a few related items. The FTP class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other ftp servers. It is also used by the module urllib.request to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here's a sample session using the ftplib module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')  # connect to host
>>> ftp.login()                 # user anonymous
'230 Login successful.'
>>> ftp.cwd('debian')          # change into "debian" directory
>>> ftp.retrlines('LIST')      # list directory contents
-rw-rw-r--  1 1176  1176 1063 Jun 15 10:18 README...
... 
-dwrxr-sr-x  5 1176  1176 4096 Dec 19 2000 pool
-dwrxr-sr-x  4 1176  1176 4096 Nov 17 2008 project
-dwrxr-xr-x  3 1176  1176 4096 Oct 10 2012 tools
'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb'))
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:
class ftplib.**FTP**(host='', user='', passwd='', acct='', timeout=None, source_address=None)

Return a new instance of the **FTP** class. When *host* is given, the method call `connect(host)` is made. When *user* is given, additionally the method call `login(user, passwd, acct)` is made (where *passwd* and *acct* default to the empty string when not given). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). *source_address* is a 2-tuple (**host**, **port**) for the socket to bind to as its source address before connecting.

**FTP** class supports the **with** statement. Here is a sample on how using it:

```python
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...    ftp.login()
...    ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
  dr-xr-xr-x  9 ftp     ftp    154 May  6
  dr-xr-xr-x  9 ftp     ftp    154 May  6
  dr-xr-xr-x  5 ftp     ftp    4096 May  6
  dr-xr-xr-x  3 ftp     ftp     18 Jul 10
>>>```

*Changed in version 3.2:* Support for the **with** statement was added.

*Changed in version 3.3:* **source_address** parameter was added.

class ftplib.**FTP_TLS**(host='', user='', passwd='', acct='',

```
keyfile=None, certfile=None, context=None, timeout=None, source_address=None)

A FTP subclass which adds TLS support to FTP as described in RFC 4217. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the prot_p() method. keyfile and certfile are optional – they can contain a PEM formatted private key and certificate chain file name for the SSL connection. context parameter is a ssl.SSLContext object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. source_address is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

New in version 3.2.

Changed in version 3.3: source_address parameter was added.

Here’s a sample session using the FTP_TLS class:

```python
>>> from ftplib import FTP_TLS
>>> ftpts = FTP_TLS('ftp.python.org')
>>> ftpts.login()  # login anonymously before securing control channel
>>> ftpts.prot_p() # switch to secure data connection
>>> ftpts.retrlines('LIST')  # list directory content
```

```

drwxr-xr-x  3 root    wheel    1024 Jan  3
```
exception ftplib.error_reply
   Exception raised when an unexpected reply is received from the server.

exception ftplib.error_temp
   Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

exception ftplib.error_perm
   Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

exception ftplib.error_proto
   Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

ftplib.all_errors
   The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as OSError.

See also:

Module netrc
   Parser for the .netrc file format. The file .netrc is typically
used by FTP clients to load user authentication information before prompting the user.

The file `Tools/scripts/ftpmirror.py` in the Python source distribution is a script that can mirror FTP sites, or portions thereof, using the `ftplib` module. It can be used as an extended example that applies this module.
21.13.1. FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by lines for the text version or binary for the binary version.

FTP instances have the following methods:

FTP. `set_debuglevel(level)`

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

FTP. `connect(host='', port=0, timeout=None, source_address=None)`

Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt. If no `timeout` is passed, the global default timeout setting will be used. `source_address` is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

*Changed in version 3.3: source_address parameter was added.*
FTP. `getwelcome()`

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP. `login(user='anonymous', passwd='', acct='')`

Log in as the given `user`. The `passwd` and `acct` parameters are optional and default to the empty string. If no `user` is specified, it defaults to 'anonymous'. If `user` is 'anonymous', the default `passwd` is 'anonymous@'. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The `acct` parameter supplies “accounting information”; few systems implement this.

FTP. `abort()`

Abort a file transfer that is in progress. Using this does not always work, but it’s worth a try.

FTP. `sendcmd(cmd)`

Send a simple command string to the server and return the response string.

FTP. `voidcmd(cmd)`

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise `error_reply` otherwise.

FTP. `retrbinary(cmd, callback, blocksize=8192, rest=None)`

Retrieve a file in binary transfer mode. `cmd` should be an
appropriate RETR command: 'RETR filename'. The callback function is called for each block of data received, with a single string argument giving the data block. The optional blocksize argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to callback). A reasonable default is chosen. rest means the same thing as in the transfercmd() method.

FTP. **retrlines**(cmd, callback=None)

Retrieve a file or directory listing in ASCII transfer mode. cmd should be an appropriate RETR command (see retrbinary()) or a command such as LIST or NLST (usually just the string 'LIST'). LIST retrieves a list of files and information about those files. NLST retrieves a list of file names. The callback function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default callback prints the line to sys.stdout.

FTP. **set_pasv**(boolean)

Enable “passive” mode if boolean is true, other disable passive mode. Passive mode is on by default.

FTP. **storbinary**(cmd, file, blocksize=8192, callback=None, rest=None)

Store a file in binary transfer mode. cmd should be an appropriate STOR command: "STOR filename". file is a file object (opened in binary mode) which is read until EOF using its read() method in blocks of size blocksize to provide the data to be stored. The blocksize argument defaults to 8192. callback is an optional single parameter callable that is called on each block of data after it is
sent. rest means the same thing as in the transfercmd() method.

Changed in version 3.2: rest parameter added.

FTP. storlines(cmd, file, callback=None)
Store a file in ASCII transfer mode. cmd should be an appropriate STOR command (see storbinary()). Lines are read until EOF from the file object file (opened in binary mode) using its readline() method to provide the data to be stored. callback is an optional single parameter callable that is called on each line after it is sent.

FTP. transfercmd(cmd, rest=None)
Initiate a transfer over the data connection. If the transfer is active, send a EPRT or PORT command and the transfer command specified by cmd, and accept the connection. If the server is passive, send a EPSV or PASV command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional rest is given, a REST command is sent to the server, passing rest as an argument. rest is usually a byte offset into the requested file, telling the server to restart sending the file’s bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that rest be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The transfercmd() method, therefore, converts rest to a string, but no check is performed on the string’s contents. If the server does not recognize the REST command, an error_reply exception will be raised. If this happens, simply call transfercmd() without a rest argument.
FTP.\texttt{nttransfercmd}(cmd, rest=None)

Like \texttt{transfercmd()}, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, None will be returned as the expected size. \texttt{cmd} and \texttt{rest} means the same thing as in \texttt{transfercmd()}.

FTP.\texttt{mlsd}(path="", facts=[])

List a directory in a standardized format by using MLSD command \texttt{(RFC 3659)}. If \texttt{path} is omitted the current directory is assumed. \texttt{facts} is a list of strings representing the type of information desired (e.g. ["type", "size", "perm"]). Return a generator object yielding a tuple of two elements for every file found in path. First element is the file name, the second one is a dictionary containing facts about the file name. Content of this dictionary might be limited by the \texttt{facts} argument but server is not guaranteed to return all requested facts.

\textit{New in version 3.3.}

FTP.\texttt{nlst}(argument[,...])

Return a list of file names as returned by the NLST command. The optional \texttt{argument} is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the NLST command.

\textcolor{red}{\textit{Deprecated since version 3.3: use mlsd()} instead.}

FTP.\texttt{dir}(argument[,...])

Produce a directory listing as returned by the LIST command, printing it to standard output. The optional \texttt{argument} is a directory to list (default is the current server directory). Multiple arguments
can be used to pass non-standard options to the LIST command. If the last argument is a function, it is used as a callback function as for retrlines(); the default prints to sys.stdout. This method returns None.

Deprecated since version 3.3: use mlsd() instead.

**FTP. rename(fromname, toname)**

Rename file fromname on the server to toname.

**FTP. delete(filename)**

Remove the file named filename from the server. If successful, returns the text of the response, otherwise raises error_perm on permission errors or error_reply on other errors.

**FTP. cwd(pathname)**

Set the current directory on the server.

**FTP. mkd(pathname)**

Create a new directory on the server.

**FTP. pwd()**

Return the pathname of the current directory on the server.

**FTP. rmd(dirname)**

Remove the directory named dirname on the server.

**FTP. size(filename)**

Request the size of the file named filename on the server. On success, the size of the file is returned as an integer, otherwise None is returned. Note that the SIZE command is not standardized, but is supported by many common server
implementations.

**FTP.quit()**

Send a QUIT command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception if the server responds with an error to the QUIT command. This implies a call to the `close()` method which renders the FTP instance useless for subsequent calls (see below).

**FTP.close()**

Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to `quit()`. After this call the FTP instance should not be used any more (after a call to `close()` or `quit()` you cannot reopen the connection by issuing another `login()` method).
21.13.2. FTP_TLS Objects

FTP_TLS class inherits from FTP, defining these additional objects:

FTP_TLS.*ssl_version*

The SSL version to use (defaults to TLSv1).

FTP_TLS.*auth(*)

Set up secure control connection by using TLS or SSL, depending on what specified in ssl_version() attribute.

FTP_TLS.*ccc(*)

Revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports.

*New in version 3.3.*

FTP_TLS.*prot_p(*)

Set up secure data connection.

FTP_TLS.*prot_c(*)

Set up clear text data connection.
21.14. **poplib — POP3 protocol client**

**Source code:** [Lib/poplib.py](#)

This module defines a class, `POP3`, which encapsulates a connection to a POP3 server and implements the protocol as defined in [RFC 1725](#). The `POP3` class supports both the minimal and optional command sets. Additionally, this module provides a class `POP3_SSL`, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

The `poplib` module provides two classes:

```python
class poplib.POP3(host, port=POP3_PORT[, timeout])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

```python
class poplib.POP3_SSL(host, port=POP3_SSL_PORT, keyfile=None, certfile=None, timeout=None, context=None)
```
This is a subclass of **POP3** that connects to the server over an SSL encrypted socket. If *port* is not specified, 995, the standard POP3-over-SSL port is used. *keyfile* and *certfile* are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection. *timeout* works as in the **POP3** constructor. *context* parameter is a `ssl.SSLContext` object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure.

*Changed in version 3.2:* *context* parameter added.

One exception is defined as an attribute of the **poplib** module:

**exception** `poplib.error_proto`

Exception raised on any errors from this module (errors from **socket** module are not caught). The reason for the exception is passed to the constructor as a string.

**See also:**

**Module imaplib**

The standard Python IMAP module.

**Frequently Asked Questions About Fetchmail**

The FAQ for the **fetchmail** POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.
21.14.1. POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An POP3 instance has the following methods:

POP3.set_debuglevel(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

POP3.getwelcome()
Returns the greeting string sent by the POP3 server.

POP3.user(username)
Send user command, response should indicate that a password is required.

POP3.pass_(password)
Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until quit() is called.

POP3.apop(user, secret)
Use the more secure APOP authentication to log into the POP3 server.

POP3.rpop(user)
Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

**POP3.** *stat()*

Get mailbox status. The result is a tuple of 2 integers: (message count, mailbox size).

**POP3.** *list([which]*)

Request message list, result is in the form (response, ['mesg_num octets', ...], octets). If *which* is set, it is the message to list.

**POP3.** *retr(which)*

Retrieve whole message number *which*, and set its seen flag. Result is in form (response, ['line', ...], octets).

**POP3.** *dele(which)*

Flag message number *which* for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

**POP3.** *rset()*

Remove any deletion marks for the mailbox.

**POP3.** *noop()*

Do nothing. Might be used as a keep-alive.

**POP3.** *quit()*

Signoff: commit changes, unlock mailbox, drop connection.

**POP3.** *top(which, howmuch)*
Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form (response, ['line', ...], octets).

The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

**POP3.** `uidl(which=None)`

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form *response mesgnum uid*, otherwise result is list (response, ['mesgnum uid', ...], octets).

Instances of **POP3_SSL** have no additional methods. The interface of this subclass is identical to its parent.
21.14.2. POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib
M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list())[1]
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.
This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in RFC 2060. It is backward compatible with IMAP4 (RFC 1730) servers, but note that the STATUS command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class:

```python
class imaplib.IMAP4(host='', port=IMAP4_PORT)
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If `host` is not specified, `'.'` (the local host) is used. If `port` is omitted, the standard IMAP4 port (143) is used.

Three exceptions are defined as attributes of the `IMAP4` class:

```python
exception IMAP4.error
```

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

```python
exception IMAP4.abort
```

IMAP4 server errors cause this exception to be raised. This is a
sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

**exception IMAP4.**readonly

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of `IMAP4.error`. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There’s also a subclass for secure connections:

```python
class imaplib.IMAP4_SSL(host='', port=IMAP4_SSL_PORT, keyfile=None, certfile=None, ssl_context=None)
```

This is a subclass derived from `IMAP4` that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If `host` is not specified, `'.'` (the local host) is used. If `port` is omitted, the standard IMAP4-over-SSL port (993) is used. `keyfile` and `certfile` are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection. `ssl_context` parameter is a `ssl.SSLContext` object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Note that the `keyfile/certfile` parameters are mutually exclusive with `ssl_context`, a `ValueError` is raised if `keyfile/certfile` is provided along with `ssl_context`.

*Changed in version 3.3: ssl_context parameter added.*

The second subclass allows for connections created by a child process:

```python
class imaplib.IMAP4_stream(command)
```
This is a subclass derived from `IMAP4` that connects to the stdin/stdout file descriptors created by passing `command` to `subprocess.Popen()`.

The following utility functions are defined:

`imaplib.Internaldate2tuple(datestr)`

Parse an IMAP4 `INTERNALDATE` string and return corresponding local time. The return value is a `time.struct_time` tuple or None if the string has wrong format.

`imaplib.Int2AP(num)`

Converts an integer into a string representation using characters from the set `[A .. P]`.

`imaplib.ParseFlags(flagstr)`

Converts an IMAP4 `FLAGS` response to a tuple of individual flags.

`imaplib.Time2Internaldate(date_time)`

Convert `date_time` to an IMAP4 `INTERNALDATE` representation. The return value is a string in the form: "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The `date_time` argument can be a number (int or float) representing seconds since epoch (as returned by `time.time()`), a 9-tuple representing local time an instance of `time.struct_time` (as returned by `time.localtime()`), an aware instance of `datetime.datetime`, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an EXPUNGE command performs deletions the remaining messages are renumbered. So it is highly advisable to use
UIIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

See also: Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the University of Washington’s IMAP Information Center (http://www.washington.edu/imap/).
21.15.1. IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn’t enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'\Deleted').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: ‘literal’ value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3, 6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:*').

An IMAP4 instance has the following methods:

IMAP4. **append**(mailbox, flags, date_time, message)

Append message to named mailbox.
**IMAP4. authenticate** *(mechanism, authobject)*

Authenticate command — requires response processing.

*mechanism* specifies which authentication mechanism is to be used - it should appear in the instance variable *capabilities* in the form *AUTH=mechanism*.

*authobject* must be a callable object:

```python
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be *bytes*. It should return *bytes data* that will be base64 encoded and sent to the server. It should return *None* if the client abort response * should be sent instead.

**IMAP4. check()**

Checkpoint mailbox on server.

**IMAP4. close()**

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before *LOGOUT*.

**IMAP4. copy** *(message_set, new_mailbox)*

Copy *message_set* messages onto end of *new_mailbox*.

**IMAP4. create** *(mailbox)*

Create new mailbox named *mailbox*.

**IMAP4. delete** *(mailbox)*

Delete old mailbox named *mailbox*. 
**IMAP4. `deleteacl(mailbox, who)`**
Delete the ACLs (remove any rights) set for who on mailbox.

**IMAP4. `expunge()`**
Permanently remove deleted items from selected mailbox. Generates an EXPUNGE response for each deleted message. Returned data contains a list of EXPUNGE message numbers in order received.

**IMAP4. `fetch(message_set, message_parts)`**
Fetch (parts of) messages. `message_parts` should be a string of message part names enclosed within parentheses, eg: "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

**IMAP4. `getacl(mailbox)`**
Get the ACLs for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. `getannotation(mailbox, entry, attribute)`**
Retrieve the specified ANNOTATIONs for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. `getquota(root)`**
Get the quota `root`'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `getquotaroot(mailbox)`**
Get the list of quota roots for the named `mailbox`. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `list([directory[, pattern]])`**
List mailbox names in directory matching pattern. directory defaults to the top-level mail folder, and pattern defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4. login**(user, password)
Identify the client using a plaintext password. The password will be quoted.

**IMAP4. login_cram_md5**(user, password)
Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server CAPABILITY response includes the phrase AUTH=CRAM-MD5.

**IMAP4. logout()**
Shutdown connection to server. Returns server BYE response.

**IMAP4. lsub**(directory='""", pattern='*')
List subscribed mailbox names in directory matching pattern. directory defaults to the top level directory and pattern defaults to match any mailbox. Returned data are tuples of message part envelope and data.

**IMAP4. myrights**(mailbox)
Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

**IMAP4. namespace()**
Returns IMAP namespaces as defined in RFC2342.

**IMAP4. noop()**
Send NOOP to server.
**IMAP4. open** (*host, port*)

Opens socket to *port* at *host*. This method is implicitly called by the **IMAP4** constructor. The connection objects established by this method will be used in the **IMAP4.read()**, **IMAP4.readline()**, **IMAP4.send()**, and **IMAP4.shutdown()** methods. You may override this method.

**IMAP4. partial** (*message_num, message_part, start, length*)

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4. proxyauth** (*user*)

Assume authentication as *user*. Allows an authorised administrator to proxy into any user’s mailbox.

**IMAP4. read** (*size*)

Reads *size* bytes from the remote server. You may override this method.

**IMAP4. readline** ()

Reads one line from the remote server. You may override this method.

**IMAP4. recent** ()

Prompt server for an update. Returned data is None if no new messages, else value of **RECENT** response.

**IMAP4. rename** (*oldmailbox, newmailbox*)

Rename mailbox named *oldmailbox* to *newmailbox*.

**IMAP4. response** (*code*)

Return data for response *code* if received, or None. Returns the
given code, instead of the usual type.

**IMAP4. search**(charset, criterion[, ...])

Search mailbox for matching messages. `charset` may be `None`, in which case no `CHARSET` will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error.

Example:

```python
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', 'LDJ')
# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

**IMAP4. select**(mailbox='INBOX', readonly=False)

Select a mailbox. Returned data is the count of messages in `mailbox` (EXISTS response). The default `mailbox` is 'INBOX'. If the `readonly` flag is set, modifications to the mailbox are not allowed.

**IMAP4. send**(data)

Sends `data` to the remote server. You may override this method.

**IMAP4. setacl**(mailbox, who, what)

Set an ACL for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. setannotation**(mailbox, entry, attribute[, ...])

Set ANNOTATIONs for `mailbox`. The method is non-standard, but is
supported by the Cyrus server.

**IMAP4. `setquota(root, limits)`**
Set the quota `root`'s resource `limits`. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `shutdown()`**
Close connection established in `open`. This method is implicitly called by `IMAP4.logout()`. You may override this method.

**IMAP4. `socket()`**
Returns socket instance used to connect to server.

**IMAP4. `sort(sort_criteria, charset, search_criterion[, ...])`**
The `sort` command is a variant of `search` with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the `search_criterion` argument(s); a parenthesized list of `sort_criteria`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid sort` command which corresponds to `sort` the way that `uid search` corresponds to `search`. The `sort` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an `IMAP4rev1` extension command.

**IMAP4. `starttls(ssl_context=None)`**
Send a `STARTTLS` command. The `ssl_context` argument is
optional and should be a `ssl.SSLContext` object. This will enable encryption on the IMAP connection.

*New in version 3.2.*

**IMAP4. status** *(mailbox, names)*
Request named status conditions for *mailbox*.

**IMAP4. store** *(message_set, command, flag_list)*
Alters flag dispositions for messages in *mailbox*. *command* is specified by section 6.4.6 of [RFC 2060](https://tools.ietf.org/html/rfc2060) as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of”.SILENT”.

For example, to set the delete flag on all messages:

```python
typ, data = M.search(\None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\\Deleted')
M.expunge()
```

**IMAP4. subscribe** *(mailbox)*
Subscribe to new *mailbox*.

**IMAP4. thread** *(threading_algorithm, charset, search_criterion[, ...]*)
The *thread* command is a variant of *search* with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the *search_criterion* argument(s); a *threading_algorithm*, and the searching *charset*. 

Note that unlike search, the searching charset argument is mandatory. There is also a uid thread command which corresponds to thread the way that uid search corresponds to search. The thread command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

**IMAP4. uid**(command, arg[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

**IMAP4. unsubscribe**(mailbox)

Unsubscribe from old mailbox.

**IMAP4. xatom**(name[, ...])

Allow simple extension commands notified by server in CAPABILITY response.

The following attributes are defined on instances of **IMAP4**:

**IMAP4. PROTOCOL_VERSION**

The most recent supported protocol in the CAPABILITY response from the server.

**IMAP4. debug**

Integer value to control debugging output. The initialize value is
taken from the module variable `Debug`. Values greater than three trace each command.
Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print('Message %s
%s
' % (num, data[0][1]))
M.close()
M.logout()
```
This module defines the class NNTP which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with RFC 3977 as well as the older RFC 977 and RFC 2980.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print('Group', name, 'has', count, 'articles, range', first, '-', last)
Group gmane.comp.python.committers has 1096 articles, range 1 to 1096

>>> resp, overviews = s.overviews((last - 9, last))
>>> for id, over in overviews:
...    print(id, nntplib.decode_header(over['subject'])
... 1087 Re: Commit privileges for Łukasz Langa
1088 Re: 3.2 alpha 2 freeze
1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
```
To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```python
>>> s.quit()
'205 Bye!'
```

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

```python
class nntplib.NNTP(host, port=119, user=None, password=None, readermode=None, usenetrc=False[, timeout])
```

Return a new `NNTP` object, representing a connection to the NNTP server running on host `host`, listening at port `port`. An optional `timeout` can be specified for the socket connection. If the optional `user` and `password` are provided, or if suitable credentials are present in `~/.netrc` and the optional flag `usenetrc` is true, the `AUTHINFO USER` and `AUTHINFO PASS` commands are used to identify and authenticate the user to the server. If the optional flag `readermode` is true, then a `mode reader` command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as `group`. If you get unexpected `NNTPPermanentErrors`, you might need to set `readermode`. `NNTP` class supports the `with` statement to unconditionally consume `socket.error` exceptions and to close
the NNTP connection when done. Here is a sample on how using it:

```python
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.org') as n:
...     n.group('gmane.comp.python.committers')
... ('211 1755 1 1755 gmane.comp.python.committers',
```

*Changed in version 3.2:* `usenetrc` is now False by default.

*Changed in version 3.3:* Support for the `with` statement was added.

```python
class nntplib.NNTP_SSL(host, port=563, user=None, password=None, ssl_context=None, readermode=None, usenetrc=False[, timeout])
```

Return a new `NNTP_SSL` object, representing an encrypted connection to the NNTP server running on host `host`, listening at port `port`. `NNTP_SSL` objects have the same methods as `NNTP` objects. If `port` is omitted, port 563 (NNTPS) is used. `ssl_context` is also optional, and is a `SSLContext` object. All other parameters behave the same as for `NNTP`.

Note that SSL-on-563 is discouraged per RFC 4642, in favor of STARTTLS as described below. However, some servers only support the former.

*New in version 3.2.*

```python
exception nntplib.NNTPError
```

Derived from the standard exception `Exception`, this is the base
class for all exceptions raised by the `nntplib` module. Instances of this class have the following attribute:

**response**

The response of the server if available, as a `str` object.

*exception nntplib.NNTPReplyError*

Exception raised when an unexpected reply is received from the server.

*exception nntplib.NNTPTemporaryError*

Exception raised when a response code in the range 400–499 is received.

*exception nntplib.NNTPPermanentError*

Exception raised when a response code in the range 500–599 is received.

*exception nntplib.NNTPProtocolError*

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

*exception nntplib.NNTPDataError*

Exception raised when there is some error in the response data.
21.16.1. NNTP Objects

When connected, **NNTP** and **NNTP_SSL** objects support the following methods and attributes.

### 21.16.1.1. Attributes

**NNTP**. **nntp_version**

An integer representing the version of the NNTP protocol supported by the server. In practice, this should be 2 for servers advertising **RFC 3977** compliance and 1 for others.

*New in version 3.2.*

**NNTP**. **nntp_implementation**

A string describing the software name and version of the NNTP server, or **None** if not advertised by the server.

*New in version 3.2.*

### 21.16.1.2. Methods

The *response* that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument *file*. When the *file* argument is supplied, it must be either a *file object* opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the
server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

Changed in version 3.2: Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

NNTP. **quit()**

Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

NNTP. **getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

NNTP. **getcapabilities()**

Return the RFC 3977 capabilities advertised by the server, as a dict instance mapping capability names to (possibly empty) lists of values. On legacy servers which don’t understand the CAPABILITIES command, an empty dictionary is returned instead.

```python
>>> s = NNTP('news.gmane.org')
>>> 'POST' in s.getcapabilities()
True
```

*New in version 3.2.*

NNTP. **login**(*user=None, password=None, usenetrc=True*)

Send AUTHINFO commands with the user name and password. If
user and password are None and usenetrc is True, credentials from ~/.netrc will be used if possible.

Unless intentionally delayed, login is normally performed during the NNTP object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set user or password when creating the object, and must set usenetrc to False.

New in version 3.2.

NNTP.starttls(ssl_context=None)
Send a STARTTLS command. The ssl_context argument is optional and should be a ssl.SSLContext object. This will enable encryption on the NNTP connection.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a NNTP object initialization. See NNTP.login() for information on suppressing this behavior.

New in version 3.2.

NNTP.newgroups(date, *, file=None)
Send a NEWGROUPS command. The date argument should be a datetime.date or datetime.datetime object. Return a pair (response, groups) where groups is a list representing the groups that are new since the given date. If file is supplied, though, then groups will be empty.

```python
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today() - timedelta(days=1))
>>> len(groups)
```
NNTP. `newnews(group, date, *, file=None)`

Send a NEWNEWS command. Here, `group` is a group name or `'*'`, and `date` has the same meaning as for `newgroups()`. Return a pair `(response, articles)` where `articles` is a list of message ids.

This command is frequently disabled by NNTP server administrators.

NNTP. `list(group_pattern=None, *, file=None)`

Send a LIST or LIST ACTIVE command. Return a pair `(response, list)` where `list` is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string `group_pattern`. Each tuple has the form `(group, last, first, flag)`, where `group` is a group name, `last` and `first` are the last and first article numbers, and `flag` usually takes one of these values:

- `y`: Local postings and articles from peers are allowed.
- `m`: The group is moderated and all postings must be approved.
- `n`: No local postings are allowed, only articles from peers.
- `j`: Articles from peers are filed in the junk group instead.
- `x`: No local postings, and articles from peers are ignored.
- `=foo.bar`: Articles are filed in the `foo.bar` group instead.

If `flag` has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if
group_pattern is not specified. It is best to cache the results offline unless you really need to refresh them.

*Changed in version 3.2: group_pattern was added.*

**NNTP.** **descriptions** *(grouppattern)*

Send a LIST NEWSGROUPS command, where grouppattern is a wildmat string as specified in **RFC 3977** (it’s essentially the same as DOS or UNIX shell wildcard strings). Return a pair *(response, descriptions)*, where descriptions is a dictionary mapping group names to textual descriptions.

```python
>>> resp, descs = s.descriptions('gmane.comp.python.*
>>> len(descs)
295
>>> descs.popitem()
('gmane.comp.python.bio.general', 'BioPython discussion list (Moderated)')
```

**NNTP.** **description** *(group)*

Get a description for a single group group. If more than one group matches (if ‘group’ is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use **descriptions()**.

**NNTP.** **group** *(name)*

Send a GROUP command, where name is the group name. The group is selected as the current group, if it exists. Return a tuple *(response, count, first, last, name)* where count is the (estimated) number of articles in the group, first is the first article number in the group, last is the last article number in the
group, and *name* is the group name.

**NNTP.** over(*message_spec*, *, file=None*)

Send a *0VER* command, or a *X0VER* command on legacy servers. *message_spec* can be either a string representing a message id, or a *(first, last)* tuple of numbers indicating a range of articles in the current group, or a *(first, None)* tuple indicating a range of articles starting from *first* to the last article in the current group, or *None* to select the current article in the current group.

Return a pair *(response, overviews)*. *overviews* is a list of *(article_number, overview)* tuples, one for each article selected by *message_spec*. Each *overview* is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with "::"). The following items are guaranteed to be present by the NNTP specification:

- the *subject*, *from*, *date*, *message-id* and *references* headers
- the *:bytes* metadata: the number of bytes in the entire raw article (including headers and body)
- the *:lines* metadata: the number of lines in the article body

The value of each item is either a string, or *None* if not present.

It is advisable to use the *decode_header()* function on header values when they may contain non-ASCII characters:

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel')
>>> resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
```
New in version 3.2.

NNTP. `help(*, file=\text{None})`

Send a `HELP` command. Return a pair `(response, list)` where `list` is a list of help strings.

NNTP. `stat(message_spec=\text{None})`

Send a `STAT` command, where `message_spec` is either a message id (enclosed in '<' and '>') or an article number in the current group. If `message_spec` is omitted or `\text{None}`, the current article in the current group is considered. Return a triple `(response, number, id)` where `number` is the article number and `id` is the message id.

NNTP. `next()`

Send a `NEXT` command. Return as for `\text{stat()}`.

NNTP. `last()`
Send a LAST command. Return as for stat().

NNTP.article(message_spec=None, *, file=None)

Send an ARTICLE command, where message_spec has the same meaning as for stat(). Return a tuple (response, info) where info is a namedtuple with three attributes number, message_id and lines (in that order). number is the article number in the group (or 0 if the information is not available), message_id the message id as a string, and lines a list of lines (without terminating newlines) comprising the raw message including headers and body.

>>> resp, info = s.article('<20030112190404.GE29873@epoch.metaslash.com>"
>>> info.number
0
>>> info.message_id
'<20030112190404.GE29873@epoch.metaslash.com>"
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[-3:]
[b'There is a patch for 2.3 as well as 2.2.', b''

NNTP.head(message_spec=None, *, file=None)

Same as article(), but sends a HEAD command. The lines returned (or written to file) will only contain the message headers, not the body.

NNTP.body(message_spec=None, *, file=None)

Same as article(), but sends a BODY command. The lines
returned (or written to file) will only contain the message body, not the headers.

NNTP. **post**(data)
Post an article using the POST command. The *data* argument is either a *file object* opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The **post()** method automatically escapes lines beginning with . and appends the termination line.

If the method succeeds, the server’s response is returned. If the server refuses posting, a **NNTPReplyError** is raised.

NNTP. **ihave**(message_id, data)
Send an **IHAVE** command. *message_id* is the id of the message to send to the server (enclosed in '<' and '>'). The *data* parameter and the return value are the same as for **post()**.

NNTP. **date**()
Return a pair (response, date). *date* is a datetime object containing the current date and time of the server.

NNTP. **slave**()
Send a **SLAVE** command. Return the server’s response.

NNTP. **set_debuglevel**(level)
Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output,
logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in RFC 2980. Some of them have been superseded by newer commands in RFC 3977.

NNTP. **xhdr**(*hdr*, *str*, *, file=None*)

Send an XHDR command. The *hdr* argument is a header keyword, e.g. 'subject'. The *str* argument should have the form 'first-last' where first and last are the first and last article numbers to search. Return a pair (response, list), where list is a list of pairs (id, text), where id is an article number (as a string) and text is the text of the requested header for that article. If the file parameter is supplied, then the output of the XHDR command is stored in a file. If file is a string, then the method will open a file with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

NNTP. **xover**(*start*, *end*, *, file=None*)

Send an XOVER command. start and end are article numbers delimiting the range of articles to select. The return value is the same as for over(). It is recommended to use over() instead, since it will automatically use the newer OVER command if available.

NNTP. **xpath**(*id*)

Return a pair (resp, path), where path is the directory path to the article with message ID id. Most of the time, this extension is not enabled by NNTP server administrators.
Deprecated since version 3.3: The XPATH extension is not actively used.
21.16.2. Utility functions

The module also defines the following utility function:

```python
ntplib.decode_header(header_str)
```

Decode a header value, un-escaping any escaped non-ASCII characters. `header_str` must be a `str` object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

```python
>>> decode_header("Some subject")
'Some subject'
'Débuter en Python'
>>> decode_header("Re: =?UTF-8?B?cHJvYmzDqG1lIG1hdHJpY2U=?=
'Re: problème de matrice'
```
21.17. `smtplib` — SMTP protocol client

**Source code:** Lib/smtplib.py

The `smtplib` module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult RFC 821 (Simple Mail Transfer Protocol) and RFC 1869 (SMTP Service Extensions).

```python
class smtplib.SMTP(host='', port=0, local_hostname=None, timeout=None, source_address=None):
```

A `SMTP` instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the `SMTP connect()` method is called with those parameters during initialization. If specified, `local_hostname` is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using `socket.getfqdn()`. If the `connect()` call returns anything other than a success code, an `SMTPConnectError` is raised. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The optional `source_address` parameter allows to bind to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple (host, port), for the socket to bind to as its
source address before connecting. If omitted (or if host or port are '' and/or 0 respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/connect, sendmail(), and quit() methods. An example is included below.

The SMTP class supports the with statement. When used like this, the SMTP QUIT command is issued automatically when the with statement exits. E.g.:

```python
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...    smtp.noop()
...
(250, b'Ok')
>>>  
```

*Changed in version 3.3:* Support for the with statement was added.

*Changed in version 3.3:* source_address argument was added.

class smtplib.SMTP_SSL(host=", port=0, local_hostname=None,
keyfile=None, certfile=None[, timeout], context=None,
source_address=None)

A SMTP_SSL instance behaves exactly the same as instances of SMTP. SMTP_SSL should be used for situations where SSL is required from the beginning of the connection and using starttls() is not appropriate. If host is not specified, the local host is used. If port is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments local_hostname and source_address have the same meaning as they do in the SMTP
class. keyfile and certfile are also optional, and can contain a PEM formatted private key and certificate chain file for the SSL connection. context also optional, can contain a SSLContext, and is an alternative to keyfile and certfile; If it is specified both keyfile and certfile must be None. The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The optional source_address parameter allows to bind to some specific source address in a machine with multiple network interfaces, and/or to some specific source tcp port. It takes a 2-tuple (host, port), for the socket to bind to as its source address before connecting. If omitted (or if host or port are '' and/or 0 respectively) the OS default behavior will be used.

Changed in version 3.3: context was added.

Changed in version 3.3: source_address argument was added.

class smtplib.LMTP(host='', port=LMTP_PORT,
local_hostname=None, source_address=None)

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It's common to use Unix sockets for LMTP, so our connect() method must support that as well as a regular host:port server. The optional arguments local_hostname and source_address have the same meaning as they do in the SMTP class. To specify a Unix socket, you must use an absolute path for host, starting with a '/'.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don't support or require any authentication, but your mileage might vary.

A nice selection of exceptions is defined as well:
exception smtplib.SMTPException

The base exception class for all the other exceptions provided by this module.

exception smtplib.SMTPServerDisconnected

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the SMTP instance before connecting it to a server.

exception smtplib.SMTPResponseException

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the smtp_code attribute of the error, and the smtp_error attribute is set to the error message.

exception smtplib.SMTPSenderRefused

Sender address refused. In addition to the attributes set by on all SMTPResponseException exceptions, this sets ‘sender’ to the string that the SMTP server refused.

exception smtplib.SMTPRecipientsRefused

All recipient addresses refused. The errors for each recipient are accessible through the attribute recipients, which is a dictionary of exactly the same sort as SMTP.sendmail() returns.

exception smtplib.SMTPDataError

The SMTP server refused to accept the message data.

exception smtplib.SMTPConnectError

Error occurred during establishment of a connection with the server.
exception smtplib.SMTPHeloError
The server refused our HELO message.

exception smtplib.SMTPAuthenticationError
SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

See also:

**RFC 821 - Simple Mail Transfer Protocol**
Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869 - SMTP Service Extensions**
Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
21.17.1. SMTP Objects

An SMTP instance has the following methods:

**SMTP. set_debuglevel**(level)
Set the debug output level. A true value for level results in debug messages for connection and for all messages sent to and received from the server.

**SMTP. docmd**(cmd, args='')
Send a command cmd to the server. The optional argument args is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, **SMTPServerDisconnected** will be raised.

**SMTP. connect**(host='localhost', port=0)
Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (':') followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.
SMTP. **helo**(name="")

Identify yourself to the SMTP server using HELO. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the `helo_resp` attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

SMTP. **ehlo**(name="")

Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by `has_extn()`. Also sets several informational attributes: the message returned by the server is stored as the `ehlo_resp` attribute, `does_esmtp` is set to true or false depending on whether the server supports ESMTP, and `esmtp_features` will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

SMTP. **ehlo_or_helo_if_needed()**

This method call `ehlo()` and or `helo()` if there has been no previous EHLO or HELO command this session. It tries ESMTP EHLO first.

SMTPHeloError

The server didn’t reply properly to the HELO greeting.
**SMTP.** has_extn(name)

Return `True` if `name` is in the set of SMTP service extensions returned by the server, `False` otherwise. Case is ignored.

**SMTP.** verify(address)

Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

**Note:** Many sites disable SMTP VRFY in order to foil spammers.

**SMTP.** login(user, password)

Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTPAuthenticationError**

The server didn’t accept the username/password combination.

**SMTPException**

No suitable authentication method was found.

**SMTP.** starttls(keyfile=None, certfile=None, context=None)

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call `ehlo()` again.
If `keyfile` and `certfile` are provided, these are passed to the `socket` module's `ssl()` function.

Optional `context` parameter is a `ssl.SSLContext` object; This is an alternative to using a keyfile and a certfile and if specified both `keyfile` and `certfile` should be None.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

**SMTPHeloError**

The server didn’t reply properly to the `HELO` greeting.

**SMTPException**

The server does not support the STARTTLS extension.

**RuntimeError**

SSL/TLS support is not available to your Python interpreter.

*Changed in version 3.3: context was added.*

**SMTP.** `sendmail(from_addr, to_addrs, msg, mail_options=[], rcpt_options=[])`

Send mail. The required arguments are an RFC 822 from-address string, a list of RFC 822 to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmimetic`) to be used in `MAIL FROM` commands as `mail_options`. ESMTP options (such as DSN commands) that should be used with all `RCPT` commands can be passed as `rcpt_options`. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message.)
**Note:** The `from_addr` and `to_addrs` parameters are used to construct the message envelope used by the transport agents. `sendmail` does not modify the message headers in any way.

`msg` may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone `\r` and `\n` characters are converted to `\r\n` characters. A byte string is not modified.

If there has been no previous `EHL0` or `HELO` command this session, this method tries ESMTP `EHL0` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHL0` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

This method may raise the following exceptions:

**SMTPRecipientsRefused**

All recipients were refused. Nobody got the mail. The `recipients` attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**SMTPHeloError**

The server didn’t reply properly to the `HELO` greeting.
SMTPSenderRefused
The server didn't accept the from_addr.

SMTPDataError
The server replied with an unexpected error code (other than a refusal of a recipient).

Unless otherwise noted, the connection will be open even after an exception is raised.

Changed in version 3.2: msg may be a byte string.

**SMTP. send_message** *(msg, from_addr=None, to_addrs=None, mail_options=[], rcpt_options=[])*

This is a convenience method for calling sendmail() with the message represented by an email.message.Message object. The arguments have the same meaning as for sendmail(), except that msg is a Message object.

If from_addr is None or to_addrs is None, send_message fills those arguments with addresses extracted from the headers of msg as specified in RFC 2822: from_addr is set to the Sender field if it is present, and otherwise to the From field. to_addresses combines the values (if any) of the To, Cc, and Bcc fields from msg. If exactly one set of Resent-* headers appear in the message, the regular headers are ignored and the Resent-* headers are used instead. If the message contains more than one set of Resent-* headers, a ValueError is raised, since there is no way to unambiguously detect the most recent set of Resent-headers.

send_message serializes msg using BytesGenerator with \r\n as the linesep, and calls sendmail() to transmit the
resulting message. Regardless of the values of `from_addr` and `to_addrs`, `send_message` does not transmit any `Bcc` or `Resent-Bcc` headers that may appear in `msg`.

*New in version 3.2.*

**SMTP.** `quit()`

Terminate the SMTP session and close the connection. Return the result of the SMTP `QUIT` command.

Low-level methods corresponding to the standard SMTP/ESMTP commands `HELP`, `RSET`, `NOOP`, `MAIL`, `RCPT`, and `DATA` are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
21.17.2. SMTP Example

This example prompts the user for addresses needed in the message envelope (‘To’ and ‘From’ addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn’t do any processing of the RFC 822 headers. In particular, the ‘To’ and ‘From’ addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows)\\n"
# Add the From: and To: headers at the start!
msg = ("From: %s\r\nTo: %s\r\n\r
" % (fromaddr, ','.join(toaddrs)))

while True:
    try:
        line = input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print("Message length is", len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
```
server.quit()

**Note:** In general, you will want to use the `email` package’s features to construct an email message, which you can then send via `send_message()`; see *email: Examples*. 
This module offers several classes to implement SMTP (email) servers.

Several server implementations are present; one is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

Additionally the SMTPChannel may be extended to implement very specific interaction behaviour with SMTP clients.

The code supports RFC 5321, plus the RFC 1870 SIZE extension.
21.18.1. SMTPServer Objects

class smtplib.SMTPServer(localaddr, remoteaddr, 
data_size_limit=33554432)

Create a new SMTPServer object, which binds to local address localaddr. It will treat remoteaddr as an upstream SMTP relayer. It inherits from asyncore.dispatcher, and so will insert itself into asyncore's event loop on instantiation.

data_size_limit specifies the maximum number of bytes that will be accepted in a DATA command. A value of None or 0 means no limit.

process_message(peer, mailfrom, rcpttos, data)

Raise NotImplementedException exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as remoteaddr will be available as the _remoteaddr attribute. peer is the remote host's address, mailfrom is the envelope originator, rcpttos are the envelope recipients and data is a string containing the contents of the e-mail (which should be in RFC 2822 format).

channel_class

Override this in subclasses to use a custom SMTPChannel for managing SMTP clients.
21.18.2. DebuggingServer Objects

class smtplib.**DebuggingServer**(localaddr, remoteaddr)

Create a new debugging server. Arguments are as per **SMTPServer**. Messages will be discarded, and printed on stdout.
21.18.3. PureProxy Objects

class smtpd.PureProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.4. MailmanProxy Objects

class smtqd. **MailmanProxy**(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per **SMTPServer**. Everything will be relayed to remoteaddr, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.5. SMTPChannel Objects

class smtplib.SMTPChannel(server, conn, addr)

Create a new SMTPChannel object which manages the communication between the server and a single SMTP client.

To use a custom SMTPChannel implementation you need to override the SMTPServer.channel_class of your SMTPServer.

The SMTPChannel has the following instance variables:

smtp_server
  Holds the SMTPServer that spawned this channel.

c_conn
  Holds the socket object connecting to the client.

addr
  Holds the address of the client, the second value returned by socket.accept

received_lines
  Holds a list of the line strings (decoded using UTF-8) received from the client. The lines have their \r\n line ending translated to \n.

smtp_state
  Holds the current state of the channel. This will be either COMMAND initially and then DATA after the client sends a “DATA” line.
**seen_greeting**

Holds a string containing the greeting sent by the client in its “HELO”.

**mailfrom**

Holds a string containing the address identified in the “MAIL FROM:” line from the client.

**rcpttos**

Holds a list of strings containing the addresses identified in the “RCPT TO:” lines from the client.

**received_data**

Holds a string containing all of the data sent by the client during the DATA state, up to but not including the terminating "\r\n.\r\n".

**fqdn**

Holds the fully-qualified domain name of the server as returned by `socket.getfqdn()`.

**peer**

Holds the name of the client peer as returned by `conn.getpeername()` where `conn` is `conn`.

The **SMTPChannel** operates by invoking methods named `smtp_<command>` upon reception of a command line from the client. Built into the base **SMTPChannel** class are methods for handling the following commands (and responding to them appropriately):

<table>
<thead>
<tr>
<th>Command</th>
<th>Action taken</th>
</tr>
</thead>
</table>

---
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HELO</td>
<td>Accepts the greeting from the client and stores it in <code>seen_greeting</code>. Sets server to base command mode.</td>
</tr>
<tr>
<td>EHLO</td>
<td>Accepts the greeting from the client and stores it in <code>seen_greeting</code>. Sets server to extended command mode.</td>
</tr>
<tr>
<td>NOOP</td>
<td>Takes no action.</td>
</tr>
<tr>
<td>QUIT</td>
<td>Closes the connection cleanly.</td>
</tr>
<tr>
<td>MAIL</td>
<td>Accepts the “MAIL FROM:” syntax and stores the supplied address as <code>mailfrom</code>. In extended command mode, accepts the RFC 1870 SIZE attribute and responds appropriately based on the value of <code>data_size_limit</code>.</td>
</tr>
<tr>
<td>RCPT</td>
<td>Accepts the “RCPT TO:” syntax and stores the supplied addresses in the <code>rcpttos</code> list.</td>
</tr>
<tr>
<td>RSET</td>
<td>Resets the <code>mailfrom</code>, <code>rcpttos</code>, and <code>received_data</code>, but not the greeting.</td>
</tr>
</tbody>
</table>
| DATA    | Sets the internal state to DATA and stores remaining lines from the client in `received_data` until the terminator '
.\r\n' is received. |
| HELP    | Returns minimal information on command syntax |
| VRFY    | Returns code 252 (the server doesn't know if the address is valid) |
| EXPN    | Reports that the command is not implemented. |
The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

class telnetlib.Telnet(host=None, port=0[, timeout])

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor, to, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).
Do not reopen an already connected instance.

This class has many \texttt{read_*()} methods. Note that some of them raise \texttt{EOFError} when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

\begin{quote}
\textbf{See also:}
\end{quote}

\begin{quote}
\textbf{RFC 854 - Telnet Protocol Specification}

Definition of the Telnet protocol.
\end{quote}
21.19.1. Telnet Objects

Telnet instances have the following methods:

*Telnet*. `read_until(expected, timeout=None)`

Read until a given byte string, `expected`, is encountered or until `timeout` seconds have passed.

When no match is found, return whatever is available instead, possibly empty bytes. Raise `EOFError` if the connection is closed and no cooked data is available.

*Telnet*. `read_all()`

Read all data until EOF as bytes; block until connection closed.

*Telnet*. `read_some()`

Read at least one byte of cooked data unless EOF is hit. Return `b''` if EOF is hit. Block if no data is immediately available.

*Telnet*. `read_very_eager()`

Read everything that can be without blocking in I/O (eager).

Raise `EOFError` if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

*Telnet*. `read_eager()`

Read readily available data.

Raise `EOFError` if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
**Telnet.read_lazy()**
Process and return data already in the queues (lazy).

Raise `EOFError` if connection closed and no data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

**Telnet.read_very_lazy()**
Return any data available in the cooked queue (very lazy).

Raise `EOFError` if connection closed and no data available. Return `b''` if no cooked data available otherwise. This method never blocks.

**Telnet.read_sb_data()**
Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

**Telnet.open(host, port=0[, timeout])**
Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

**Telnet.msg(msg, *args)**
Print a debug message when the debug level is \( \geq 0 \). If extra arguments are present, they are substituted in the message using the standard string formatting operator.
Telnet. **set_debuglevel**(debuglevel)
Set the debug level. The higher the value of `debuglevel`, the more debug output you get (on `sys.stdout`).

Telnet. **close**()
Close the connection.

Telnet. **get_socket**()
Return the socket object used internally.

Telnet. **fileno**()
Return the file descriptor of the socket object used internally.

Telnet. **write**(buffer)
Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise **OSError** if the connection is closed.

*Changed in version 3.3:* This method used to raise `socket.error`, which is now an alias of **OSError**.

Telnet. **interact**()
Interaction function, emulates a very dumb Telnet client.

Telnet. **mt_interact**()
Multithreaded version of **interact**().

Telnet. **expect**(list, timeout=None)
Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (`regex objects`) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block
indefinitely.

Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, data)` where `data` is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

**Telnet**. `set_option_negotiation_callback(callback)`

Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.
21.19.2. Telnet Example

A simple example illustrating typical use:

```python
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()
	n = telnetlib.Telnet(HOST)
	n.read_until(b"login: ")
	n.write(user.encode('ascii') + b"\n")

if password:
    t.read_until(b"Password: ")
    t.write(password.encode('ascii') + b"\n")
	n.write(b"ls\n")
	n.write(b"exit\n")

print(t.read_all().decode('ascii'))
```
21.20. `uuid` — UUID objects according to RFC 4122

This module provides immutable `UUID` objects (the `UUID` class) and the functions `uuid1()`, `uuid3()`, `uuid4()`, `uuid5()` for generating version 1, 3, 4, and 5 UUIDs as specified in RFC 4122.

If all you want is a unique ID, you should probably call `uuid1()` or `uuid4()`. Note that `uuid1()` may compromise privacy since it creates a UUID containing the computer's network address. `uuid4()` creates a random UUID.

```python
class uuid.UUID(hex=None, bytes=None, bytes_le=None, fields=None, int=None, version=None)
```

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the `bytes` argument, a string of 16 bytes in little-endian order as the `bytes_le` argument, a tuple of six integers (32-bit `time_low`, 16-bit `time_mid`, 16-bit `time_hi_version`, 8-bit `clock_seq_hi_variant`, 8-bit `clock_seq_low`, 48-bit `node`) as the `fields` argument, or a single 128-bit integer as the `int` argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```python
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes=b'\x12\x34\x56\x78'*4)
UUID(bytes_le=b'\x78\x56\x34\x12\x34\x12\x78\x56'
b'\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x
Exactly one of hex, bytes, bytes_le, fields, or int must be given. The version argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given hex, bytes, bytes_le, fields, or int.

UUID instances have these read-only attributes:

**UUID.** bytes

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.** bytes_le

The UUID as a 16-byte string (with time_low, time_mid, and time_hi_version in little-endian byte order).

**UUID.** fields

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>time_low</td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td>time_mid</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>time_hi_version</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_hi_variant</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_low</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>node</td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td>time</td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td>clock_seq</td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>
**UUID.hex**

The UUID as a 32-character hexadecimal string.

**UUID.int**

The UUID as a 128-bit integer.

**UUID.urn**

The UUID as a URN as specified in RFC 4122.

**UUID.variant**

The UUID variant, which determines the internal layout of the UUID. This will be one of the integer constants `RESERVED_NCS`, `RFC_4122`, `RESERVED_MICROSOFT`, or `RESERVED_FUTURE`.

**UUID.version**

The UUID version number (1 through 5, meaningful only when the variant is `RFC_4122`).

The `uuid` module defines the following functions:

**uuid.getnode()**

Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

**uuid.uuid1(node=None, clock_seq=None)**

Generate a UUID from a host ID, sequence number, and the current time. If `node` is not given, `getnode()` is used to obtain the
hardware address. If clock_seq is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

**uuid.uuid3(namespace, name)**
Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

**uuid.uuid4()**
Generate a random UUID.

**uuid.uuid5(namespace, name)**
Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The **uuid** module defines the following namespace identifiers for use with **uuid3()** or **uuid5()**.

**uuid.NAMESPACE_DNS**
When this namespace is specified, the name string is a fully-qualified domain name.

**uuid.NAMESPACE_URL**
When this namespace is specified, the name string is a URL.

**uuid.NAMESPACE_OID**
When this namespace is specified, the name string is an ISO OID.

**uuid.NAMESPACE_X500**
When this namespace is specified, the name string is an X.500 DN in DER or a text output format.

The **uuid** module defines the following constants for the possible values of the variant attribute:
uuid. **RESERVED_NCS**
   Reserved for NCS compatibility.

uuid. **RFC_4122**
   Specifies the UUID layout given in RFC 4122.

uuid. **RESERVED_MICROSOFT**
   Reserved for Microsoft compatibility.

uuid. **RESERVED_FUTURE**
   Reserved for future definition.

---

**See also:**

**RFC 4122** - A Universally Unique IDentifier (UUID) URN Namespace
   This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
21.20.1. Example

Here are some examples of typical usage of the `uuid` module:

```python
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace URL
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace URL
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r'

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
```

**Source code:** `Lib/socketserver.py`

The `socketserver` module simplifies the task of writing network servers.

There are four basic server classes: TCPServer uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. UDPServer uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The more infrequently used UnixStreamServer and UnixDatagramServer classes are similar, but use Unix domain sockets; they're not available on non-Unix platforms. For more details on network programming, consult a book such as W. Richard Steven's *UNIX Network Programming* or Ralph Davis's *Win32 Network Programming*.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the ForkingMixIn and ThreadingMixIn mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a
request handler class by subclassing the BaseRequestHandler class and overriding its handle() method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server's address and the request handler class. Finally, call the handle_request() or serve_forever() method of the server object to process one or many requests.

When inheriting from ThreadingMixIn for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The ThreadingMixIn class defines an attribute daemon_threads, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is False, meaning that Python will not exit until all threads created by ThreadingMixIn have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.
21.21.1. Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+-------------+      +-------------------+
| BaseServer  |------>| TCPServer         |
+-------------+      +-------------------+
|              |------>| UnixStreamServer |
+-------------+      +-------------------+
|              |------>| UDPServer         |
+-------------+      +-------------------+
```

Note that UnixDatagramServer derives from UDPServer, not from UnixStreamServer — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

Forking and threading versions of each type of server can be created using the ForkingMixIn and ThreadingMixIn mix-in classes. For instance, a threading UDP server class is created as follows:

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer):
```

The mix-in class must come first, since it overrides a method defined in UDPServer. Setting the various attributes also change the behavior of the underlying server mechanism.
To implement a service, you must derive a class from BaseRequestHandler and redefine its handle() method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses StreamRequestHandler or DatagramRequestHandler.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class handle() method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor fork() (or where these are too expensive or inappropriate for the service) is to maintain
an explicit table of partially finished requests and to use `select()` to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See `asyncore` for another way to manage this.
21.21.2. Server Objects

class socketserver.BaseServer

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses.

BaseServer.fileno()

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to select.select(), to allow monitoring multiple servers in the same process.

BaseServer.handle_request()

Process a single request. This function calls the following methods in order: get_request(), verify_request(), and process_request(). If the user-provided handle() method of the handler class raises an exception, the server's handle_error() method will be called. If no request is received within self.timeout seconds, handle_timeout() will be called and handle_request() will return.

BaseServer.serve_forever(poll_interval=0.5)

Handle requests until an explicit shutdown() request. Poll for shutdown every poll_interval seconds. Ignores self.timeout. It also calls service_actions(), which may be used by a subclass or mixin to provide actions specific to a given service. For example, the ForkingMixIn class uses service_actions() to clean up zombie child processes.

Changed in version 3.3: Added service_actions call to the
serve_forever method.

**BaseServer.service_actions()**

This is called in the `serve_forever()` loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

*New in version 3.3.*

**BaseServer.shutdown()**

Tell the `serve_forever()` loop to stop and wait until it does.

**BaseServer.address_family**

The family of protocols to which the server’s socket belongs. Common examples are `socket.AF_INET` and `socket.AF_UNIX`.

**BaseServer.RequestHandlerClass**

The user-provided request handler class; an instance of this class is created for each request.

**BaseServer.server_address**

The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the socket module for details. For Internet protocols, this is a tuple containing a string giving the address, and an integer port number: (`'127.0.0.1'`, `80`), for example.

**BaseServer.socket**

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:
BaseServer.**allow_reuse_address**

Whether the server will allow the reuse of an address. This defaults to **False**, and can be set in subclasses to change the policy.

BaseServer.**request_queue_size**

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to **request_queue_size** requests. Once the queue is full, further requests from clients will get a “Connection denied” error. The default value is usually 5, but this can be overridden by subclasses.

BaseServer.**socket_type**

The type of socket used by the server; **socket.SOCK_STREAM** and **socket.SOCK_DGRAM** are two common values.

BaseServer.**timeout**

Timeout duration, measured in seconds, or **None** if no timeout is desired. If **handle_request()** receives no incoming requests within the timeout period, the **handle_timeout()** method is called.

There are various server methods that can be overridden by subclasses of base server classes like **TCPServer**; these methods aren’t useful to external users of the server object.

BaseServer.**finish_request()**

Actually processes the request by instantiating **RequestHandlerClass** and calling its **handle()** method.

BaseServer.**get_request()**

Must accept a request from the socket, and return a 2-tuple
containing the new socket object to be used to communicate with the client, and the client’s address.

**BaseServer.** `handle_error(request, client_address)`

This function is called if the `RequestHandlerClass`'s handle() method raises an exception. The default action is to print the traceback to standard output and continue handling further requests.

**BaseServer.** `handle_timeout()`

This function is called when the `timeout` attribute has been set to a value other than `None` and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**BaseServer.** `process_request(request, client_address)`

Calls `finish_request()` to create an instance of the `RequestHandlerClass`. If desired, this function can create a new process or thread to handle the request; the `ForkingMixIn` and `ThreadingMixIn` classes do this.

**BaseServer.** `server_activate()`

Called by the server’s constructor to activate the server. The default behavior just `listen()`s to the server’s socket. May be overridden.

**BaseServer.** `server_bind()`

Called by the server’s constructor to bind the socket to the desired address. May be overridden.

**BaseServer.** `verify_request(request, client_address)`
Must return a Boolean value; if the value is `True`, the request will be processed, and if it's `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`. 
21.21.3. RequestHandler Objects

The request handler class must define a new handle() method, and can override any of the following methods. A new instance is created for each request.

RequestHandler. **finish()**

Called after the handle() method to perform any clean-up actions required. The default implementation does nothing. If setup() raises an exception, this function will not be called.

RequestHandler. **handle()**

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as self.request; the client address as self.client_address; and the server instance as self.server, in case it needs access to per-server information.

The type of self.request is different for datagram or stream services. For stream services, self.request is a socket object; for datagram services, self.request is a pair of string and socket. However, this can be hidden by using the request handler subclasses StreamRequestHandler or DatagramRequestHandler, which override the setup() and finish() methods, and provide self.rfile and self.wfile attributes. self.rfile and self.wfile can be read or written, respectively, to get the request data or return data to the client.

RequestHandler. **setup()**

Called before the handle() method to perform any initialization
actions required. The default implementation does nothing.
21.21.4. Examples

21.21.4.1. socketserver.TCPServer Example

This is the server side:

```python
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    """
    The RequestHandler class for our server.

    It is instantiated once per connection to the server, and must
    override the handle() method to implement communication with
    the client.
    """

def handle(self):
    # self.request is the TCP socket connected to the client
    self.data = self.request.recv(1024).strip()
    print("{} wrote:").format(self.client_address)
    print(self.data)
    # just send back the same data, but upper-cased
    self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    server = socketserver.TCPServer((HOST, PORT), MyTCPHandler)

    # Activate the server; this will keep running until you interrupt the program with Ctrl-C
    server.serve_forever()
```
An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```python
class MyTCPHandler(socketserver.StreamRequestHandler):
    def handle(self):
        # self.rfile is a file-like object created by the handler;
        # we can now use e.g. readline() instead of
        self.data = self.rfile.readline().strip()
        print("{}	wrote:".format(self.client_address))
        print(self.data)
        # Likewise, self.wfile is a file-like object
        # to the client
        self.wfile.write(self.data.upper())
```

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `sendall()` call.

This is the client side:

```python
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

try:
    # Connect to server and send data
    sock.connect((HOST, PORT))
```
sock.sendall(bytes(data + "\n", "utf-8"))

# Receive data from the server and shut down
received = str(sock.recv(1024), "utf-8")

finally:
    sock.close()

print("Sent: \{\}".format(data))
print("Received: \{\}".format(received))

The output of the example should look something like this:

Server:

$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'

Client:

$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE

21.21.4.2. socketserver.UDPServer Example

This is the server side:

```python
import socketserver
```
class MyUDPHandler(socketserver.BaseRequestHandler):
    ""
    This class works similar to the TCP handler class.
    self.request consists of a pair of data and client socket,
    there is no connection the client address must be given
    when sending data back via sendto().
    ""

def handle(self):
    data = self.request[0].strip()
    socket = self.request[1]
    print('{} wrote:'.format(self.client_address))
    print(data)
    socket.sendto(data.upper(), self.client_address)

if __name__ == '__main__':
    HOST, PORT = "localhost", 9999
    server = socketserver.UDPServer((HOST, PORT), MyUDPHandler)
    server.serve_forever()

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " " .join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has
# Instead, data is directly sent to the recipient via
sock.sendto(bytes(data + "\n", "utf-8"), (HOST, PORT))
received = str(sock.recv(1024), "utf-8")
```
print("Sent: \{\}").format(data))
print("Received: \{\}").format(received)

The output of the example should look exactly like for the TCP server example.

21.21.4.3. Asynchronous Mixins

To build asynchronous handlers, use the ThreadingMixIn and ForkingMixIn classes.

An example for the ThreadingMixIn class:

```python
import socket
import threading
import socketserver

class ThreadedTCPRequestHandler(socketserver.BaseRequestHandler):
    def handle(self):
        data = str(self.request.recv(1024), 'ascii')
        cur_thread = threading.current_thread()
        response = bytes("{}: {}".format(cur_thread, self.request.sendall(response))

class ThreadedTCPServer(socketserver.ThreadingMixIn, pass

def client(ip, port, message):
    sock = socket.socket(socket.AF_INET, socket.SOCK
    sock.connect((ip, port))
    try:
        sock.sendall(bytes(message, 'ascii'))
        response = str(sock.recv(1024), 'ascii')
```
```
print("Received: {}".format(response))
finally:
    sock.close()

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    ip, port = server.server_address

    # Start a thread with the server -- that thread
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)
    server_thread.daemon = True
    server_thread.start()
    print("Server loop running in thread:", server_thread)

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()
```

The output of the example should look something like this:

```
$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3
```

The `ForkingMixIn` class is used in the same way, except that the server will spawn a new process for each request.
This module defines classes for implementing HTTP servers (Web servers).

One class, `HTTPServer`, is a `socketserver.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=HTTPServer, handler_class=BaseHTTPRequestHandler, server_address = ('', 8000)):
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

```python
class http.server.HTTPServer(server_address, RequestHandlerClass):
    This class builds on the TCPServer class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler's server instance variable.
```

The `HTTPServer` must be given a `RequestHandlerClass` on instantiation, of which this module provides three different variants:

```python
class http.server.BaseHTTPRequestHandler(request, client_address, server)
```
This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). `BaseHTTPRequestHandler` provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method SPAM, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

`BaseHTTPRequestHandler` has the following instance variables:

- **client_address**
  Contains a tuple of the form `(host, port)` referring to the client's address.

- **server**
  Contains the server instance.

- **command**
  Contains the command (request type). For example, `'GET'`.

- **path**
  Contains the request path.

- **request_version**
  Contains the version string from the request. For example, `'HTTP/1.0'`. 
headers
Hold an instance of the class specified by the MessageClass class variable. This instance parses and manages the headers in the HTTP request.

rfile
Contains an input stream, positioned at the start of the optional input data.

wfile
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream.

BaseHTTPRequestHandler has the following class variables:

server_version
Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.

sys_version
Contains the Python system version, in a form usable by the version_string method and the server_version class variable. For example, 'Python/1.4'.

ersor_message_format
Specifies a format string for building an error response to the client. It uses parenthesized, keyed format specifiers, so the format operand must be a dictionary. The code key should be an integer, specifying the numeric HTTP error code value. message should be a string containing a (detailed) error
message of what occurred, and explain should be an explanation of the error code number. Default message and explain values can found in the responses class variable.

**error_content_type**

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

**protocol_version**

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server must then include an accurate Content-Length header (using send_header()) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

**MessageClass**

Specifies an `email.message.Message`-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to `http.client.HTTPMessage`.

**responses**

This variable contains a mapping of error code integers to two-element tuples containing a short and long message. For example, `{code: (shortmessage, longmessage)}`. The shortmessage is usually used as the message key in an error response, and longmessage as the explain key (see the error_message_format class variable).

A `BaseHTTPRequestHandler` instance has the following methods:
**handle()**

Calls `handle_one_request()` once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate `do_*()` methods.

**handle_one_request()**

This method will parse and dispatch the request to the appropriate `do_*()` method. You should never need to override it.

**handle_expect_100()**

When a HTTP/1.1 compliant server receives a `Expect: 100-continue` request header it responds back with a `100 Continue` followed by `200 OK` headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can chose to send `417 Expectation Failed` as a response header and return `False`.

*New in version 3.2.*

**send_error(code, message=None)**

Sends and logs a complete error reply to the client. The numeric `code` specifies the HTTP error code, with `message` as optional, more specific text. A complete set of headers is sent, followed by text composed using the `error_message_format` class variable.

**send_response(code, message=None)**

Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the
internal buffer, followed by Server and Date headers. The values for these two headers are picked up from the version_string() and date_time_string() methods, respectively. If the server does not intend to send any other headers using the send_header() method, then send_response() should be followed by a end_headers() call.

*Changed in version 3.3:* Headers are stored to an internal buffer and end_headers() needs to be called explicitly.

**send_header**(keyword, value)

Adds the HTTP header to an internal buffer which will be written to the output stream when either end_headers() or flush_headers() is invoked. keyword should specify the header keyword, with value specifying its value. Note that, after the send_header calls are done, end_headers() MUST BE called in order to complete the operation.

*Changed in version 3.2:* Headers are stored in an internal buffer.

**send_response_only**(code, message=None)

Sends the response header only, used for the purposes when 100 Continue response is sent by the server to the client. The headers not buffered and sent directly the output stream. If the message is not specified, the HTTP message corresponding the response code is sent.

*New in version 3.2.*

**end_headers()**
Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls `flush_headers()`.

*Changed in version 3.2:* The buffered headers are written to the output stream.

**flush_headers()**

Finally send the headers to the output stream and flush the internal headers buffer.

*New in version 3.3.*

**log_request**(*code='-', size='-')

Logs an accepted (successful) request. `code` should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the `size` parameter.

**log_error**(...)

Logs an error when a request cannot be fulfilled. By default, it passes the message to `log_message()`, so it takes the same arguments (`format` and additional values).

**log_message**(*format, ...*)

Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The `format` argument is a standard printf-style format string, where the additional arguments to `log_message()` are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

**version_string()**

Returns the server software’s version string. This is a
combination of the server_version and sys_version class variables.

**date_time_string**(timestamp=None)

Returns the date and time given by timestamp (which must be None or in the format returned by time.time()), formatted for a message header. If timestamp is omitted, it uses the current date and time.

The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.

**log_date_time_string()**

Returns the current date and time, formatted for logging.

**address_string()**

Returns the client address.

*Changed in version 3.3:* Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

class http.server.SimpleHTTPRequestHandler(request, client_address, server)

This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class BaseHTTPRequestHandler. This class implements the do_GET() and do_HEAD() functions.

The following are defined as class-level attributes of SimpleHTTPRequestHandler:
**server_version**

This will be "SimpleHTTP/" + __version__, where __version__ is defined at the module level.

**extensions_map**

A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be application/octet-stream. The mapping is used case-insensitively, and so should contain only lower-cased keys.

The SimpleHTTPRequestHandler class defines the following methods:

**do_HEAD()**

This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the do_GET() method for a more complete explanation of the possible headers.

**do_GET()**

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named index.html or index.htm (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the list_directory() method. This method uses os.listdir() to scan the directory, and returns a 404 error response if the listdir() fails.

If the request was mapped to a file, it is opened and the
contents are returned. Any OSError exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the guess_type() method, which in turn uses the extensions_map variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file’s MIME type starts with text/ the file is opened in text mode; otherwise binary mode is used.

For example usage, see the implementation of the test() function invocation in the http.server module.

The SimpleHTTPRequestHandler class can be used in the following manner in order to create a very basic webserver serving files relative to the current directory.

```python
import http.server
import socketserver

PORT = 8000

Handler = http.server.SimpleHTTPRequestHandler

httpd = socketserver.TCPServer(('', PORT), Handler)

print("serving at port", PORT)
httpd.serve_forever()
```
http.server can also be invoked directly using the -m switch of the interpreter with a port number argument. Similar to the previous example, this serves files relative to the current directory.

```python
python -m http.server 8000
```

class http.server.CGIHTTPRequestHandler(request, client_address, server)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in SimpleHTTPRequestHandler.

**Note:** CGI scripts run by the CGIHTTPRequestHandler class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The do_GET() and do_HEAD() functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the cgi_directories path.

The CGIHTTPRequestHandler defines the following data member:

**cgi_directories**

This defaults to ['/cgi-bin', '/htbin'] and describes
directories to treat as containing CGI scripts.

The CGIHTTPRequestHandler defines the following method:

```python
def do_POST()
```

This method serves the 'POST' request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

CGIHTTPRequestHandler can be enabled in the command line by passing the --cgi option:

```bash
python -m http.server --cgi 8000
```
21.23. **http.cookies** — HTTP state management

**Source code:** Lib/http/cookies.py

The `http.cookies` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](https://www.rfc-editor.org/rfc/rfc2109) and [RFC 2068](https://www.rfc-editor.org/rfc/rfc2068) specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters, string.digits` and `!#$%&'*+-.^_` denote the set of valid characters allowed by this module in Cookie name (as key).

*Changed in version 3.3:* Allowed `:` as a valid Cookie name character.

**Note:** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

```python
exception http.cookies.CookieError

Exception failing because of [RFC 2109](https://www.rfc-editor.org/rfc/rfc2109) invalidity: incorrect
```
attributes, incorrect Set-Cookie header, etc.

```python
class http.cookies.BaseCookie([input])
```

This class is a dictionary-like object whose keys are strings and whose values are `Morsel` instances. Note that upon setting a key to a value, the value is first converted to a `Morsel` containing the key and the value.

If `input` is given, it is passed to the `load()` method.

```python
class http.cookies.SimpleCookie([input])
```

This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

**See also:**

**Module** [http.cookiejar](http://example.com/http.cookiejar)

HTTP cookie handling for web clients. The [http.cookiejar](http://example.com/http.cookiejar) and [http.cookies](http://example.com/http.cookies) modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**

This is the state management specification implemented by this module.
21.23.1. Cookie Objects

BaseCookie.\texttt{value\_decode(val)}

Return a decoded value from a string representation. Return value can be any type. This method does nothing in \texttt{BaseCookie} — it exists so it can be overridden.

BaseCookie.\texttt{value\_encode(val)}

Return an encoded value. \texttt{val} can be any type, but return value must be a string. This method does nothing in \texttt{BaseCookie} — it exists so it can be overridden.

In general, it should be the case that \texttt{value\_encode()} and \texttt{value\_decode()} are inverses on the range of \texttt{value\_decode}.

BaseCookie.\texttt{output(attrs=None, header='Set-Cookie:', sep='\r\n')}\texttt{output()} method. \texttt{sep} is used to join the headers together, and is by default the combination '\r\n' (CRLF).

BaseCookie.\texttt{js\_output(attrs=None)}

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for \texttt{attrs} is the same as in \texttt{output()}.

BaseCookie.\texttt{load(rawdata)}

If \texttt{rawdata} is a string, parse it as an \texttt{HTTP\_COOKIE} and add the values found there as \texttt{Morsels}. If it is a dictionary, it is equivalent
for k, v in rawdata.items():
    cookie[k] = v
21.23.2. Morsel Objects

class http.cookies.Morsel

Abstract a key/value pair, which has some RFC 2109 attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

- expires
- path
- comment
- domain
- max-age
- secure
- version
- httponly

The attribute httponly specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive.

Morsel.value

The value of the cookie.

Morsel.coded_value

The encoded value of the cookie — this is what should be sent.

Morsel.key

The name of the cookie.
Morsel.set(key, value, coded_value)
    Set the key, value and coded_value attributes.

Morsel.isReservedKey(K)
    Whether K is a member of the set of keys of a Morsel.

Morsel.output(attrs=None, header='Set-Cookie:')
    Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless attr is given, in which case it should be a list of attributes to use. header is by default "Set-Cookie:"

Morsel.js_output(attrs=None)
    Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

    The meaning for attrs is the same as in output().

Morsel.OutputString(attrs=None)
    Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

    The meaning for attrs is the same as in output().
21.23.3. Example

The following example demonstrates how to use the `http.cookies` module.

```python
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C)  # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output())  # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]['path'] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger")  # load from
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
>>> C.load('keebler="E=everybody; L="Loves"; fudge')
>>> print(C)
Set-Cookie: keebler=E=everybody; L="Loves"; fudge
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]['path'] = "/"
>>> print(C)
```
```python
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'
>>> C = cookies.SimpleCookie()
>>> C["number"] = 7  # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
>>> C["string"].value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
```
The `http.cookiejar` module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – cookies – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by [RFC 2965](https://www.rfc-editor.org/rfc/rfc2965) are handled. RFC 2965 handling is switched off by default. [RFC 2109](https://www.rfc-editor.org/rfc/rfc2109) cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the 'policy' in effect. Note that the great majority of cookies on the Internet are Netscape cookies. `http.cookiejar` attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the max-age and port cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in Set-Cookie and Set-Cookie2 headers (eg. domain and expires) are conventionally referred to as attributes. To distinguish them from Python attributes, the documentation for this module uses the term `cookie-attribute` instead.

The module defines the following exception:
exception http.cookiejar.LoadError

Instances of FileCookieJar raise this exception on failure to load cookies from a file. LoadError is a subclass of OSError.

Changed in version 3.3: LoadError was made a subclass of OSError instead of IOError.

The following classes are provided:

class http.cookiejar.CookieJar(policy=None)

policy is an object implementing the CookiePolicy interface.

The CookieJar class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. CookieJar instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

class http.cookiejar.FileCookieJar(filename, delayload=None, policy=None)

policy is an object implementing the CookiePolicy interface. For the other arguments, see the documentation for the corresponding attributes.

A CookieJar which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are NOT loaded from the named file until either the load() or revert() method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.

class http.cookiejar.CookiePolicy

This class is responsible for deciding whether each cookie should be accepted from / returned to the server.
class http.cookiejar.DefaultCookiePolicy(
    blocked_domains=None,
    allowed_domains=None,
    netscape=True,
    rfc2965=False,
    rfc2109_as_netscape=None,
    hide_cookie2=False,
    strict_domain=False,
    strict_rfc2965_unverifiable=True,
    strict_ns_unverifiable=False,
    strict_ns_domain=DefaultCookiePolicy.DomainLiberal,
    strict_ns_set_initial_dollar=False,
    strict_ns_set_path=False
)

Constructor arguments should be passed as keyword arguments only. `blocked_domains` is a sequence of domain names that we never accept cookies from, nor return cookies to. `allowed_domains` if not `None`, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for `CookiePolicy` and `DefaultCookiePolicy` objects.

`DefaultCookiePolicy` implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (i.e. cookies received in a `Set-Cookie` header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or `rfc2109_as_netscape` is `True`, RFC 2109 cookies are 'downgraded' by the `CookieJar` instance to Netscape cookies, by setting the version attribute of the `Cookie` instance to 0. `DefaultCookiePolicy` also provides some parameters to allow some fine-tuning of policy.

class http.cookiejar.Cookie

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of `http.cookiejar` construct their own `Cookie` instances. Instead, if necessary, call `make_cookies()` on a `CookieJar` instance.
See also:

**Module urllib.request**
URL opening with automatic cookie handling.

**Module http.cookies**
HTTP cookie classes, principally useful for server-side code. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

**http://wp.netscape.com/newsref/std/cookie_spec.html**
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and `http.cookiejar`) only bears a passing resemblance to the one sketched out in `cookie_spec.html`.

**RFC 2109 - HTTP State Management Mechanism**
Obsoleted by RFC 2965. Uses `Set-Cookie` with version=1.

**RFC 2965 - HTTP State Management Mechanism**
The Netscape protocol with the bugs fixed. Uses `Set-Cookie2` in place of `Set-Cookie`. Not widely used.

**http://kristol.org/cookie/errata.html**
Unfinished errata to RFC 2965.

**RFC 2964 - Use of HTTP State Management**

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.\texttt{add\_cookie\_header}(\texttt{request})

Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar's CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The request object (usually a urllib.request.Request instance) must support the methods get\_full\_url(), get\_host(), get\_type(), unverifiable(), has\_header(), get\_header(), header\_items(), add\_unredirected\_header() and origin\_req\_host attribute as documented by urllib.request.

\textit{Changed in version 3.3.}

CookieJar.\texttt{extract\_cookies}(\texttt{response}, \texttt{request})

Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-Cookie2 headers in the response argument, and store cookies as appropriate (subject to the CookiePolicy.set\_ok() method's
approval).

The response object (usually the result of a call to urllib.request.urlopen(), or similar) should support an info() method, which returns a email.message.Message instance.

The request object (usually a urllib.request.Request instance) must support the methods get_full_url(), get_host(), unverifiable(), and origin_req_host attribute, as documented by urllib.request. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

*Changed in version 3.3.*

CookieJar.set_policy(policy)
Set the CookiePolicy instance to be used.

CookieJar.make_cookies(response, request)
Return sequence of Cookie objects extracted from response object.

See the documentation for extract_cookies() for the interfaces required of the response and request arguments.

CookieJar.set_cookie_if_ok(cookie, request)
Set a Cookie if policy says it’s OK to do so.

CookieJar.set_cookie(cookie)
Set a Cookie, without checking with policy to see whether or not it should be set.
CookieJar. **clear**([*domain*, *path*, *name]*)

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that *domain* will be removed. If given two arguments, cookies belonging to the specified *domain* and URL *path* are removed. If given three arguments, then the cookie with the specified *domain*, *path* and *name* is removed.

 Raises **KeyError** if no matching cookie exists.

CookieJar. **clear_session_cookies**()

Discard all session cookies.

Discards all contained cookies that have a true discard attribute (usually because they had either no max-age or expires cookie-attribute, or an explicit discard cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the save() method won’t save session cookies anyway, unless you ask otherwise by passing a true *ignore_discard* argument.

**FileCookieJar** implements the following additional methods:

FileCookieJar. **save**(filename=None, ignore_discard=False, ignore_expires=False)

Save cookies to a file.

This base class raises **NotImplementedError**. Subclasses may leave this method unimplemented.
filename is the name of file in which to save cookies. If filename is not specified, self.filename is used (whose default is the value passed to the constructor, if any); if self.filename is None, ValueError is raised.

ignore_discard: save even cookies set to be discarded. ignore_expires: save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the load() or revert() methods.

FileCookieJar.load(filename=None, ignore_discard=False, ignore_expires=False)
Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for save().

The named file must be in the format understood by the class, or LoadError will be raised. Also, OSError may be raised, for example if the file does not exist.

Changed in version 3.3: IOError used to be raised, it is now an alias of OSError.

FileCookieJar.revert(filename=None, ignore_discard=False, ignore_expires=False)
Clear all cookies and reload cookies from a saved file.

revert() can raise the same exceptions as load(). If there is a failure, the object's state will not be altered.
FileCookieJar instances have the following public attributes:

FileCookieJar. **filename**
Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar. **delayload**
If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A CookieJar object may ignore it. None of the FileCookieJar classes included in the standard library lazily loads cookies.
21.24.2. FileCookieJar subclasses and cooperation with web browsers

The following `CookieJar` subclasses are provided for reading and writing:

```python
class http.cookiejar.MozillaCookieJar(filename, delayload=None, policy=None)
```

A `FileCookieJar` that can load from and save cookies to disk in the Mozilla `cookies.txt` file format (which is also used by the Lynx and Netscape browsers).

**Note:** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as `port`.

**Warning:** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

```python
class http.cookiejar.LWPCookieJar(filename, delayload=None, policy=None)
```

A `FileCookieJar` that can load from and save cookies to disk in format compatible with the libwww-perl library's `Set-Cookie3` file format. This is convenient if you want to store cookies in a human-readable file.
21.24.3. CookiePolicy Objects

Objects implementing the CookiePolicy interface have the following methods:

CookiePolicy.set_ok(cookie, request)
   Return boolean value indicating whether cookie should be accepted from server.

   cookie is a Cookie instance. request is an object implementing the interface defined by the documentation for CookieJar.extract_cookies().

CookiePolicy.return_ok(cookie, request)
   Return boolean value indicating whether cookie should be returned to server.

   cookie is a Cookie instance. request is an object implementing the interface defined by the documentation for CookieJar.add_cookie_header().

CookiePolicy.domain_return_ok(domain, request)
   Return false if cookies should not be returned, given cookie domain.

   This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from domain_return_ok() and path_return_ok() leaves all the work to return_ok().

   If domain_return_ok() returns true for the cookie domain, path_return_ok() is called for the cookie path. Otherwise,
path_return_ok() and return_ok() are never called for that cookie domain. If path_return_ok() returns true, return_ok() is called with the Cookie object itself for a full check. Otherwise, return_ok() is never called for that cookie path.

Note that domain_return_ok() is called for every cookie domain, not just for the request domain. For example, the function might be called with both ".example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for path_return_ok().

The request argument is as documented for return_ok().

CookiePolicy.path_return_ok(path, request)
Return false if cookies should not be returned, given cookie path.

See the documentation for domain_return_ok().

In addition to implementing the methods above, implementations of the CookiePolicy interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy.netscape
Implement Netscape protocol.

CookiePolicy.rfc2965
Implement RFC 2965 protocol.

CookiePolicy.hide_cookie2
Don't add Cookie2 header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).
The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of the methods above. `CookiePolicy` itself may be used as a ‘null policy’ to allow setting and receiving any and all cookies (this is unlikely to be useful).
21.24.4. DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import http.cookiejar
class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the `CookiePolicy` interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the `blocked_domains` constructor argument, and `blocked_domains()` and `set_blocked_domains()` methods (and the corresponding argument and methods for `allowed_domains`). If you set a whitelist,
you can turn it off again by setting it to None.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.blocked_domains()

Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.set_blocked_domains(blocked_domains)

Set the sequence of blocked domains.

DefaultCookiePolicy.is_blocked(domain)

Return whether domain is on the blacklist for setting or receiving cookies.

DefaultCookiePolicy.allowed_domains()

Return None, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.set_allowed_domains(allowed_domains)

Set the sequence of allowed domains, or None.
DefaultCookiePolicy.\texttt{is\_not\_allowed}(domain)

Return whether \textit{domain} is not on the whitelist for setting or receiving cookies.

\textbf{DefaultCookiePolicy} instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

\textbf{DefaultCookiePolicy.} \texttt{rfc2109\_as\_netscape}

If true, request that the \texttt{CookieJar} instance downgrade RFC 2109 cookies (i.e. cookies received in a \texttt{Set-Cookie} header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the \texttt{Cookie} instance to 0. The default value is \texttt{None}, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

General strictness switches:

\textbf{DefaultCookiePolicy.} \texttt{strict\_domain}

Don’t allow sites to set two-component domains with country-code top-level domains like \texttt{.co.uk}, \texttt{.gov.uk}, \texttt{.co.nz} etc. This is far from perfect and isn’t guaranteed to work!

RFC 2965 protocol strictness switches:

\textbf{DefaultCookiePolicy.} \texttt{strict\_rfc2965\_unverifiable}

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are \textit{never} blocked on the basis of verifiability.

Netscape protocol strictness switches:
DefaultCookiePolicy. **strict_ns_unverifiable**

apply RFC 2965 rules on unverifiable transactions even to Netscape cookies

DefaultCookiePolicy. **strict_ns_domain**

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

DefaultCookiePolicy. **strict_ns_set_initial_dollar**

Ignore cookies in Set-Cookie: headers that have names starting with '$'.

DefaultCookiePolicy. **strict_ns_set_path**

Don’t allow setting cookies whose path doesn’t path-match request URI.

**strict_ns_domain** is a collection of flags. Its value is constructed by or-ing together (for example, DomainStrictNoDots|DomainStrictNonDomain means both flags are set).

DefaultCookiePolicy. **DomainStrictNoDots**

When setting cookies, the ‘host prefix’ must not contain a dot (eg. www.foo.bar.com can’t set a cookie for .bar.com, because www.foo contains a dot).

DefaultCookiePolicy. **DomainStrictNonDomain**

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. spam.example.com won’t be returned cookies from example.com that had no domain cookie-attribute).

DefaultCookiePolicy. **DomainRFC2965Match**
When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

**DefaultCookiePolicy. DomainLiberal**

Equivalent to 0 (i.e. all of the above Netscape domain strictness flags switched off).

**DefaultCookiePolicy. DomainStrict**

Equivalent to `DomainStrictNoDots|DomainStrictNonDomain`. 
21.24.5. Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by http.cookiejar from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie.version

Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that http.cookiejar may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie.name

Cookie name (a string).

Cookie.value

Cookie value (a string), or None.

Cookie.port

String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie.path
Cookie path (a string, eg. '/acme/rocket_launchers').

Cookie. **secure**
True if cookie should only be returned over a secure connection.

Cookie. **expires**
Integer expiry date in seconds since epoch, or None. See also the **is_expired()** method.

Cookie. **discard**
True if this is a session cookie.

Cookie. **comment**
String comment from the server explaining the function of this cookie, or None.

Cookie. **comment_url**
URL linking to a comment from the server explaining the function of this cookie, or None.

Cookie. **rfc2109**
True if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a Set-Cookie header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because http.cookiejar may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie. **port_specified**
True if a port or set of ports was explicitly specified by the server (in the Set-Cookie / Set-Cookie2 header).

Cookie. **domain_specified**
True if a domain was explicitly specified by the server.
Cookie. **domain_initial_dot**

True if the domain explicitly specified by the server began with a dot ('.').

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

Cookie. **has_nonstandard_attr**(name)

Return true if cookie has the named cookie-attribute.

Cookie. **get_nonstandard_attr**(name, default=None)

If cookie has the named cookie-attribute, return its value. Otherwise, return default.

Cookie. **set_nonstandard_attr**(name, value)

Set the value of the named cookie-attribute.

The Cookie class also defines the following method:

Cookie. **is_expired**(now=None)

True if cookie has passed the time at which the server requested it should expire. If now is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
21.24.6. Examples

The first example shows the most common usage of `http.cookiejar`:

```python
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.
     r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".nets
opener = urllib.request.build_opener(urllib.request.
r = opener.open("http://example.com/")
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```python
import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolicy,
    policy = DefaultCookiePolicy(
        rfc2965=True, strict_ns_domain=Policy.DomainStri
        blocked_domains=["ads.net", ".ads.net"]
    cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.
```
```python
r = opener.open("http://example.com/")
```
21.25. xmlrpc — XMLRPC server and client modules

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data.

`xmlrpc` is a package that collects server and client modules implementing XML-RPC. The modules are:

- `xmlrpc.client`
- `xmlrpc.server`
XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

**Warning:** The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

class xmlrpc.client.ServerProxy(uri, transport=None, encoding=None, verbose=False, allow_none=False, use_datetime=False, use_builtin_types=False)

*Changed in version 3.3:* The `use_builtin_types` flag was added.

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal `SafeTransport` instance for https: URLs and an internal HTTP `Transport` instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a
debugging flag. If `allow_none` is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a `TypeError`. This is a commonly-used extension to the XML-RPC specification, but isn’t supported by all clients and servers; see [http://ontosys.com/xml-rpc/extensions.php](http://ontosys.com/xml-rpc/extensions.php) for a description. The `use_builtin_types` flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default. `datetime.datetime` and `bytes` objects may be passed to calls.

The obsolete `use_datetime` flag is similar to `use_builtin_types` but it applies only to date/time values.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: `http://user:pass@host:port/path`. The `user:pass` portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

`ServerProxy` instance methods take Python basic types and objects as arguments and return Python basic types and classes. Types that are conformable (e.g. that can be marshalled through
XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>The <code>True</code> and <code>False</code> constants</td>
</tr>
<tr>
<td>integers</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>floating-point numbers</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>strings</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>arrays</td>
<td>Any Python sequence type containing conformable elements. Arrays are returned as lists</td>
</tr>
<tr>
<td>structures</td>
<td>A Python dictionary. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.</td>
</tr>
<tr>
<td>dates</td>
<td>In seconds since the epoch. Pass in an instance of the DateTime class or a <code>datetime.datetime</code> instance.</td>
</tr>
<tr>
<td>binary data</td>
<td>Pass in an instance of the Binary wrapper class or a <code>bytes</code> instance.</td>
</tr>
</tbody>
</table>

This is the full set of data types supported by XML-RPC. Method calls may also raise a special Fault instance, used to signal XML-RPC server errors, or ProtocolError used to signal an error in the HTTP/HTTPS transport layer. Both Fault and ProtocolError derive from a base class called Error. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.
When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it’s the caller’s responsibility to ensure that the string is free of characters that aren’t allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn’t well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use the `bytes` class or the class: `Binary` wrapper class described below.

Server is retained as an alias for `ServerProxy` for backwards compatibility. New code should use `ServerProxy`.

See also:

**XML-RPC HOWTO**
A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

**XML-RPC Introspection**
Describes the XML-RPC protocol extension for introspection.

**XML-RPC Specification**
The official specification.

**Unofficial XML-RPC Errata**
Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best practices’ to use when designing your own XML-RPC implementations.”

A ServerProxy instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a Fault or ProtocolError object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved system attribute:

ServerProxy.system.listMethods()

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

ServerProxy.system.methodSignature(name)

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.

If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

ServerProxy.system.methodHelp(name)

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

A working example follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
def is_even(n):
    return n%2 == 0
server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client
print("3 is even: %s" % str(proxy.is_even(3)))
print("100 is even: %s" % str(proxy.is_even(100)))
```
21.26.2. DateTime Objects

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a `datetime.datetime` instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

DateTime. **decode**(string)

Accept a string as the instance’s new time value.

DateTime. **encode**(out)

Write the XML-RPC encoding of this DateTime item to the `out` stream object.

It also supports certain of Python’s built-in operators through rich comparison and `__repr__()` methods.

A working example follows. The server code:

```python
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:
import xmlrpc.client
import datetime

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, 
print("Today: %s" % converted.strftime("%d.%m.%Y, %H:%M")"))
21.26.3. Binary Objects

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

**Binary.data**

The binary data encapsulated by the Binary instance. The data is provided as a bytes object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

**Binary.decode**(bytes)

Accept a base64 bytes object and decode it as the instance's new data.

**Binary.encode**(out)

Write the XML-RPC base 64 encoding of this binary item to the out stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python's built-in operators through `__eq__() and __ne__() methods.

Example usage of the binary objects. We're going to transfer an image over XMLRPC:

```python
from xmlrpc.server import SimpleXMLRPCServer
```
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')
server.serve_forever()

The client gets the image and saves it to a file:

```python
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/"
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
```
21.26.4. Fault Objects

A Fault object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

**Fault. faultCode**
A string indicating the fault type.

**Fault. faultString**
A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a Fault by returning a complex type object. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a complex number
def add(x, y):
    return x+y+0j

server = SimpleXMLRPCServer(('localhost', 8000))
print("Listening on port 8000...")
server.register_function(add, 'add')

server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client

try:
```
proxy.add(2, 5)
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
21.26.5. ProtocolError Objects

A ProtocolError object describes a protocol error in the underlying transport layer (such as a 404 ‘not found’ error if the server named by the URI does not exist). It has the following attributes:

```python
ProtocolError.url
```

The URI or URL that triggered the error.

```python
ProtocolError.errcode
```

The error code.

```python
ProtocolError.errmsg
```

The error message or diagnostic string.

```python
ProtocolError.headers
```

A dict containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we’re going to intentionally cause a ProtocolError by providing an invalid URI:

```
import xmlrpc.client

# create a ServerProxy with an URI that doesn't respond
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
    print("URL: %s" % err.url)
    print("HTTP/HTTPS headers: %s" % err.headers)
    print("Error code: %d" % err.errcode)
```
print("Error message: %s" % err.errmsg)
21.26.6. MultiCall Objects

The **MultiCall** object provides a way to encapsulate multiple calls to a remote server into a single request [1].

```python
class xmlrpc.client.MultiCall(server)
    Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.
```

A usage example of this class follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y

def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer("localhost", 8000)
print("Listening on port 8000...")
server.register_multicall_functions()
```
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()

The client code for the preceding server:

```python
import xmlrpc.client

multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```
21.26.7. Convenience Functions

```python
xmlrpc.client.dumps(params, methodname=None, methodresponse=None, encoding=None, allow_none=False)
```

Convert `params` into an XML-RPC request. or into a response if `methodresponse` is true. `params` can be either a tuple of arguments or an instance of the Fault exception class. If `methodresponse` is true, only a single value can be returned, meaning that `params` must be of length 1. `encoding`, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python’s `None` value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for `allow_none`.

```python
xmlrpc.client.loads(data, use_datetime=False, use_builtin_types=False)
```

Convert an XML-RPC request or response into Python objects, a (params, methodname). `params` is a tuple of argument; `methodname` is a string, or None if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a Fault exception. The `use_builtin_types` flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default.

The obsolete `use_datetime` flag is similar to `use_builtin_types` but it applies only to date/time values.

*Changed in version 3.3:* The `use_builtin_types` flag was added.
# simple test program (from the XML-RPC specification)

```python
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000")  # local
server = ServerProxy("http://betty.userland.com")

print(server)

try:
    print(server.examples.getStateName(41))
except Error as v:
    print("ERROR", v)
```

To access an XML-RPC server through a proxy, you need to define a custom transport. The following example shows how:

```python
import xmlrpc.client, http.client

class ProxiedTransport(xmlrpc.client.Transport):
    def set_proxy(self, proxy):
        self.proxy = proxy
    def make_connection(self, host):
        self.realhost = host
        h = http.client.HTTP(self.proxy)
        return h
    def send_request(self, connection, handler, request_body):
        connection.putrequest("POST", 'http://%s%s'
    def send_host(self, connection, host):
        connection.putheader('Host', self.realhost)

p = ProxiedTransport()
p.set_proxy('proxy-server:8080')
```
server = xmlrpc.client.Server('http://time.xmlrpc.com
print(server.currentTime.getCurrentTime())
21.26.9. Example of Client and Server Usage

See *SimpleXMLRPCServer Example*.

Footnotes

[1] This approach has been first presented in a discussion on xmlrpc.com.
21.27. `xmlrpc.server` — Basic XML-RPC servers

**Source code:** `Lib/xmlrpc/server.py`

The `xmlrpc.server` module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using `SimpleXMLRPCServer`, or embedded in a CGI environment, using `CGIXMLRPCRequestHandler`.

**Warning:** The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

```python
class xmlrpc.server.SimpleXMLRPCServer(addr,
requestHandler=SimpleXMLRPCRequestHandler, logRequests=True,
allow_none=False, encoding=None, bind_and_activate=True,
use_builtin_types=False)
```

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The `requestHandler` parameter should be a factory for request handler instances; it defaults to `SimpleXMLRPCRequestHandler`. The `addr` and `requestHandler` parameters are passed to the `socketserver.TCPServer` constructor. If `logRequests` is true (the default), requests will be logged; setting this parameter to false will turn off logging. The `allow_none` and `encoding` parameters are passed on to `xmlrpc.client` and control the XML-RPC responses that will be returned from the server. The `bind_and_activate` parameter
controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

```python
class xmlrpc.server.CGIXMLRPCRequestHandler(allow_none=False, encoding=None, use_builtin_types=False)
```

Create a new instance to handle XML-RPC requests in a CGI environment. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

```python
class xmlrpc.server.SimpleXMLRPCRequestHandler
```

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the logRequests parameter to the SimpleXMLRPCServer constructor parameter is honored.
21.27.1. SimpleXMLRPCServer Objects

The SimpleXMLRPCServer class is based on socketserver.TCPServer and provides a means of creating simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.register_function(function, name=None)

Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

SimpleXMLRPCServer.register_instance(instance, allow_dotted_names=False)

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request. Its API is def _dispatch(self, method, params) (note that params does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as func(*params), expanding the parameter list. The return value from _dispatch() is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method.

If the optional allow_dotted_names argument is true and the instance does not have a _dispatch() method, then if the requested method name contains periods, each component of the
method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the `allow_dotted_names` option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

`SimpleXMLRPCServer.register_introspection_functions`
 Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

`SimpleXMLRPCServer.register_multicall_functions`
 Registers the XML-RPC multicall function `system.multicall`.

`SimpleXMLRPCRequestHandler.rpc_paths`
 An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 “no such page” HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

### 21.27.1.1. SimpleXMLRPCServer Example

Server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler
```
The following client code will call the methods made available by the preceding server:

```python
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2, 3))  # Returns 2**3 = 8
```
print(s.add(2,3))  # Returns 5
print(s.mul(5,2))  # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())
21.27.2. CGI XMLRPCRequestHandler

The CGI XMLRPCRequestHandler class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.register_function(function, name=None)

Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

CGIXMLRPCRequestHandler.register_instance(instance)

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.register_introspection_functions

Register the XML-RPC introspection functions system.listMethods, system.methodHelp and system.methodSignature.
CGIXMLRPCRequestHandler. `register_multicall_function`:
Register the XML-RPC multicall function `system.multicall`.

CGIXMLRPCRequestHandler. `handle_request(request_text=None)`:
Handle a XML-RPC request. If `request_text` is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

```python
class MyFuncs:
    def mul(self, x, y):
        return x * y
```

```python
handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x, y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```
21.27.3. Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using `DocXMLRPCServer`, or embedded in a CGI environment, using `DocCGIXMLRPCRequestHandler`.

```python
class xmlrpc.server.DocXMLRPCServer(addr, requestHandler=DocXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=True)
```

Create a new server instance. All parameters have the same meaning as for `SimpleXMLRPCServer`; `requestHandler` defaults to `DocXMLRPCRequestHandler`.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```python
class xmlrpc.server.DocCGIXMLRPCRequestHandler
```

Create a new instance to handle XML-RPC requests in a CGI environment.

```python
class xmlrpc.server.DocXMLRPCRequestHandler
```

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the `logRequests` parameter to the `DocXMLRPCServer` constructor parameter is honored.
21.27.4. DocXMLRPCServer Objects

The DocXMLRPCServer class is derived from SimpleXMLRPCServer and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.set_server_title(server_title)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocXMLRPCServer.set_server_name(server_name)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocXMLRPCServer.set_server_documentation(server_doc)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.27.5. DocCGIXMLRPCRequestHandler

The `DocCGIXMLRPCRequestHandler` class is derived from `CGIXMLRPCRequestHandler` and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

`DocCGIXMLRPCRequestHandler.set_server_title(server_title)`
Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

`DocCGIXMLRPCRequestHandler.set_server_name(server_name)`
Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

`DocCGIXMLRPCRequestHandler.set_server_documentation(description)`
Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.28. ipaddress — IPv4/IPv6 manipulation library

Source code: Lib/ipaddress.py

**Note:** The ipaddress module has been included in the standard library on a *provisional basis*. Backwards incompatible changes (up to and including removal of the package) may occur if deemed necessary by the core developers.

The ipaddress module provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference - for an overview and introduction, see *An introduction to the ipaddress module*.

*New in version 3.3.*
21.28.1. Convenience factory functions

The `ipaddress` module provides factory functions to conveniently create IP addresses, networks and interfaces:

```python
ipaddress.ip_address(address)
```

Return an `IPv4Address` or `IPv6Address` object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than $2^{32}$ will be considered to be IPv4 by default. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address.

```python
>>> ipaddress.ip_address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

```python
ipaddress.ip_network(address, strict=True)
```

Return an `IPv4Network` or `IPv6Network` object depending on the IP address passed as argument. `address` is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than $2^{32}$ will be considered to be IPv4 by default. `strict` is passed to `IPv4Network` or `IPv6Network` constructor. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```python
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

```python
ipaddress.ip_interface(address)
```

Return an `IPv4Interface` or `IPv6Interface` object depending
on the IP address passed as argument. address is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than $2^{**32}$ will be considered to be IPv4 by default. A ValueError is raised if address does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don’t know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.
21.28.2. IP Addresses

21.28.2.1. Address objects

The IPv4Address and IPv6Address objects share a lot of common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by IPv4Address objects, in order to make it easier to write code that handles both IP versions correctly.

class ipaddress.IPv4Address(address)

Construct an IPv4 address. An AddressValueError is raised if address is not a valid IPv4 address.

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0-255, separated by dots (e.g. 192.168.0.1). Each integer represents an octet (byte) in the address. Leading zeroes are tolerated only for values less then 8 (as there is no ambiguity between the decimal and octal interpretations of such strings).
2. An integer that fits into 32 bits.
3. An integer packed into a bytes object of length 4 (most significant octet first).

```python
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\xC0\xA8\x00\x01')
IPv4Address('192.168.0.1')
version```
The appropriate version number: 4 for IPv4, 6 for IPv6.

**max_prefixlen**
The total number of bits in the address representation for this version: 32 for IPv4, 128 for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

**compressed**

**exploded**
The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

**packed**
The binary representation of this address - a `bytes` object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

**is_multicast**
True if the address is reserved for multicast use. See RFC 3171 (for IPv4) or RFC 2373 (for IPv6).

**is_private**
True if the address is allocated for private networks. See RFC
1918 (for IPv4) or RFC 4193 (for IPv6).

**is_unspecified**
True if the address is unspecified. See RFC 5375 (for IPv4) or RFC 2373 (for IPv6).

**is_reserved**
True if the address is otherwise IETF reserved.

**is_loopback**
True if this is a loopback address. See RFC 3330 (for IPv4) or RFC 2373 (for IPv6).

**is_link_local**
True if the address is reserved for link-local usage. See RFC 3927.

```python
class ipaddress.IPv6Address(address)
```
Construct an IPv6 address. An `AddressValueError` is raised if `address` is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an *exploded* (longhand) notation. The string can also be *compressed* (shorthand notation) by various means. See RFC 4291 for details. For example, "0000:0000:0000:0000:0000:0abc:0007:0def" can be compressed to "::abc:7:def".
2. An integer that fits into 128 bits.
3. An integer packed into a `bytes` object of length 16, big-endian.
The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by `str(addr)` for IPv6 addresses.

The long form of the address representation, with all leading zeroes and groups consisting entirely of zeroes included.

Refer to the corresponding attribute documentation in `IPv4Address`

True if the address is reserved for site-local usage. Note that
the site-local address space has been deprecated by RFC 3879. Use is_private to test if this address is in the space of unique local addresses as defined by RFC 4193.

**ipv4_mapped**
For addresses that appear to be IPv4 mapped addresses (starting with ::FFFF/96), this property will report the embedded IPv4 address. For any other address, this property will be None.

**sixtofour**
For addresses that appear to be 6to4 addresses (starting with 2002::/16) as defined by RFC 3056, this property will report the embedded IPv4 address. For any other address, this property will be None.

**teredo**
For addresses that appear to be Teredo addresses (starting with 2001::/32) as defined by RFC 4380, this property will report the embedded (server, client) IP address pair. For any other address, this property will be None.

### 21.28.2.2. Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is handled using the `str()` and `int()` builtin functions:

```python
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
```
21.28.2.3. Operators

Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.2.3.1. Comparison operators

Address objects can be compared with the usual set of comparison operators. Some examples:

```python
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
```

21.28.2.3.2. Arithmetic operators

Integers can be added to or subtracted from address objects. Some examples:

```python
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32) is not permitted as an IPv4 address
21.28.3. IP Network definitions

The IPv4Network and IPv6Network objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a mask and a network address, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask 255.255.255.0 and the network address 192.168.1.0 consists of IP addresses in the inclusive range 192.168.1.0 to 192.168.1.255.

21.28.3.1. Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A prefix /<nbets> is a notation that denotes how many high-order bits are set in the network mask. A net mask is an IP address with some number of high-order bits set. Thus the prefix /24 is equivalent to the net mask 255.255.255.0 in IPv4, or ffff:ff00:: in IPv6. In addition, a host mask is the logical inverse of a net mask, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to /24 in IPv4 is 0.0.0.255.

21.28.3.2. Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement additional attributes. All of these are common between IPv4Network and IPv6Network, so to avoid duplication they are only documented for IPv4Network.
class ipaddress.IPv4Network(address, strict=True)

Construct an IPv4 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a prefix, or a string representation of an IPv4 address. If it's the latter, the mask is interpreted as a net mask if it starts with a non-zero field, or as a host mask if it starts with a zero field. If no mask is provided, it's considered to be /32.

For example, the following address specifications are equivalent:

- \texttt{192.168.1.0/24},
- \texttt{192.168.1.0/255.255.255.0}
- \texttt{192.168.1.0/0.0.0.255}.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being address and the mask being /32.

3. An integer packed into a bytes object of length 4, big-endian. The interpretation is similar to an integer address.

An AddressValueError is raised if address is not a valid IPv4 address. A NetmaskValueError is raised if the mask is not valid for an IPv4 address.

If strict is True and host bits are set in the supplied address, then ValueError is raised. Otherwise, the host bits are masked out to determine the appropriate network address.
Unless stated otherwise, all network methods accepting other network/address objects will raise `TypeError` if the argument’s IP version is incompatible to `self` version.

**version**

**max_prefixlen**

Refer to the corresponding attribute documentation in `IPv4Address`.

**is_multicast**

**is_private**

**is_unspecified**

**is_reserved**

**is_loopback**

**is_link_local**

These attributes are true for the network as a whole if they are true for both the network address and the broadcast address.

**network_address**

The network address for the network. The network address and the prefix length together uniquely define a network.

**broadcast_address**

The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

**host mask**

The host mask, as a string.
with_prefixlen

compressed

exploded
A string representation of the network, with the mask in prefix notation.

with_prefixlen and compressed are always the same as str(network). exploded uses the exploded form the network address.

with_netmask
A string representation of the network, with the mask in net mask notation.

with_hostmask
A string representation of the network, with the mask in host mask notation.

num_addresses
The total number of addresses in the network.

prefixlen
Length of the network prefix, in bits.

hosts()
Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address.

```python
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2.2'), IPv4Address('192.0.2.3'), IPv4Address('192.0.2.4'), IPv4Address('192.0.2.5'), IPv4Address('192.0.2.6'), IPv4Address('192.0.2.7'), IPv4Address('192.0.2.8'), IPv4Address('192.0.2.9'), IPv4Address('192.0.2.10'), IPv4Address('192.0.2.11'), IPv4Address('192.0.2.12'), IPv4Address('192.0.2.13'), IPv4Address('192.0.2.14'), IPv4Address('192.0.2.15')]
```
overlaps(other)
True if this network is partly or wholly contained in other or other is wholly contained in this network.

address_exclude(network)
Computes the network definitions resulting from removing the given network from this one. Returns an iterator of network objects. Raises ValueError if network is not completely contained in this network.

>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.0.2.4/30'), IPv4Network('192.0.2.2/31'), IPv4Network('192.0.2.0/32')]

subnets(prefixlen_diff=1, new_prefix=None)
The subnets that join to make the current network definition, depending on the argument values. prefixlen_diff is the amount our prefix length should be increased by. new_prefix is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of prefixlen_diff and new_prefix must be set. Returns an iterator of network objects.

>>> list(ip_network('192.0.2.0/24').subnets())
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=1))
[IPv4Network('192.0.2.0/26'), IPv4Network('192.0.2.64/26'), IPv4Network('192.0.2.128/26'), IPv4Network('192.0.2.192/26')]
supernet\( (\text{prefixlen}_\text{diff}=1, \text{new}_\text{prefix} = \text{None}) \)

The supernet containing this network definition, depending on the argument values. \text{prefixlen}_\text{diff} is the amount our prefix length should be decreased by. \text{new}_\text{prefix} is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of \text{prefixlen}_\text{diff} and \text{new}_\text{prefix} must be set. Returns a single network object.

\[
>>> \text{ip\_network('192.0.2.0/24').supernet()}
IPv4Network('192.0.2.0/23')
\]

\[
>>> \text{ip\_network('192.0.2.0/24').supernet(prefixlen\_diff=1)}
IPv4Network('192.0.0.0/22')
\]

\[
>>> \text{ip\_network('192.0.2.0/24').supernet(new\_prefix=IPv4Network('192.0.0.0/20'))}
\]

compare_networks\( (\text{other}) \)

Compare this network to \text{other}. In this comparison only the network addresses are considered; host bits aren't. Returns either \(-1\), \(0\) or \(1\).

\[
>>> \text{ip\_network('192.0.2.1/32').compare\_networks(ip\_network('192.0.2.1/32'))}
-1
\]
class ipaddress.IPv6Network(address, strict=True)

Construct an IPv6 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a prefix, or a string representation of an IPv6 address. If it's the latter, the mask is interpreted as a net mask. If no mask is provided, it's considered to be /128.

   For example, the following address specifications are equivalent: 2001:db00::0/24 and 2001:db00::0/ffff:ff00::.

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being address and the mask being /128.

3. An integer packed into a bytes object of length 16, bit-endian. The interpretation is similar to an integer address.

An AddressValueError is raised if address is not a valid IPv6 address. A NetmaskValueError is raised if the mask is not valid for an IPv6 address.

If strict is True and host bits are set in the supplied address, then ValueError is raised. Otherwise, the host bits are masked out to
determine the appropriate network address.

is_site_local

These attribute is true for the network as a whole if it is true for both the network address and the broadcast address

21.28.3.3. Operators

Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.3.3.1. Logical operators

Network objects can be compared with the usual set of logical operators, similarly to address objects.

21.28.3.3.2. Iteration

Network objects can be iterated to list all the addresses belonging to the network. For iteration, all hosts are returned, including unusable hosts (for usable hosts, use the hosts() method). An example:

```python
>>> for addr in IPv4Network('192.0.2.0/28'):
   ...   addr
```
21.28.3.3.3. Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```python
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/28')
True
>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/28')
False
```
21.28.4. Interface objects

class ipaddress.**IPv4Interface**(address)

Construct an IPv4 interface. The meaning of `address` is as in the constructor of `IPv4Network`, except that arbitrary host addresses are always accepted.

**IPv4Interface** is a subclass of **IPv4Address**, so it inherits all the attributes from that class. In addition, the following attributes are available:

- **ip**
  The address (**IPv4Address**) without network information.

  ```python
  >>> interface = IPv4Interface('192.0.2.5/24')
  >>> interface.ip
  IPv4Address('192.0.2.5')
  ```

- **network**
  The network (**IPv4Network**) this interface belongs to.

  ```python
  >>> interface = IPv4Interface('192.0.2.5/24')
  >>> interface.network
  IPv4Network('192.0.2.0/24')
  ```

- **with_prefixlen**
  A string representation of the interface with the mask in prefix notation.

  ```python
  >>> interface = IPv4Interface('192.0.2.5/24')
  >>> interface.with_prefixlen
  '192.0.2.5/24'
  ```
**with_netmask**
A string representation of the interface with the network as a net mask.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'
```

**with_hostmask**
A string representation of the interface with the network as a host mask.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'
```

**class ipaddress.**IPv6Interface**(address)**
Construct an IPv6 interface. The meaning of *address* is as in the constructor of IPv6Network, except that arbitrary host addresses are always accepted.

`IPv6Interface` is a subclass of `IPv6Address`, so it inherits all the attributes from that class. In addition, the following attributes are available:

- **ip**
- **network**
- **with_prefixlen**
- **with_netmask**
- **with_hostmask**

Refer to the corresponding attribute documentation in
IPv4Interface.
21.28.5. Other Module Level Functions

The module also provides the following module level functions:

`ipaddress.v4_int_to_packed(address)`

Represent an address as 4 packed bytes in network (big-endian) order. `address` is an integer representation of an IPv4 IP address. A `ValueError` is raised if the integer is negative or too large to be an IPv4 IP address.

```python
>>> ipaddress.ip_address(3221225985)
IPv4Address('192.0.2.1')
>>> ipaddress.v4_int_to_packed(3221225985)
b'\xc0\x00\x02\x01'
```

`ipaddress.v6_int_to_packed(address)`

Represent an address as 16 packed bytes in network (big-endian) order. `address` is an integer representation of an IPv6 IP address. A `ValueError` is raised if the integer is negative or too large to be an IPv6 IP address.

`ipaddress.summarize_address_range(first, last)`

Return an iterator of the summarized network range given the first and last IP addresses. `first` is the first `IPv4Address` or `IPv6Address` in the range and `last` is the last `IPv4Address` or `IPv6Address` in the range. A `TypeError` is raised if `first` or `last` are not IP addresses or are not of the same version. A `ValueError` is raised if `last` is not greater than `first` or if `first` address version is not 4 or 6.

```python
>>> [ipaddr for ipaddr in ipaddress.summarize_address_range(ipaddress.IPv4Address('192.0.2.0'),... ipaddress.IPv4Address('192.0.2.255'))]
[IPv4Address('192.0.2.0'), IPv4Address('192.0.2.255')]
```
ipaddress.\texttt{collapse\_addresses}(\textit{addresses})

Return an iterator of the collapsed IPv4Network or IPv6Network objects. \textit{addresses} is an iterator of IPv4Network or IPv6Network objects. A \texttt{TypeError} is raised if \textit{addresses} contains mixed version objects.

```python
>>> [ipaddr for ipaddr in ...
... ipaddress.collapse_addresses([[
...
... ipaddress.IPv4Network('192.0.2.128/25')]])
[IPv4Network('192.0.2.0/24')]
```

ipaddress.\texttt{get\_mixed\_type\_key}(\textit{obj})

Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they're fundamentally different, so the expression:

```python
IPv4Address('192.0.2.0') \leq IPv4Network('192.0.2.0')
```

doesn't make sense. There are some times however, where you may wish to have \texttt{ipaddress} sort these anyway. If you need to do this, you can use this function as the \texttt{key} argument to \texttt{sorted()}.

\textit{obj} is either a network or address object.
21.28.6. Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

```
exception ipaddress.AddressValueError(ValueError)
    Any value error related to the address.

exception ipaddress.NetmaskValueError(ValueError)
    Any value error related to the netmask.
```
22. Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **22.1. audioop** — Manipulate raw audio data
- **22.2. aifc** — Read and write AIFF and AIFC files
- **22.3. sunau** — Read and write Sun AU files
  - **22.3.1. AU_read** Objects
  - **22.3.2. AU_write** Objects
- **22.4. wave** — Read and write WAV files
  - **22.4.1. Wave_read** Objects
  - **22.4.2. Wave_write** Objects
- **22.5. chunk** — Read IFF chunked data
- **22.6. colorsys** — Conversions between color systems
- **22.7. imghdr** — Determine the type of an image
- **22.8. sndhdr** — Determine type of sound file
- **22.9. ossaudiodev** — Access to OSS-compatible audio devices
  - **22.9.1. Audio Device Objects**
  - **22.9.2. Mixer Device Objects**
22.1. audioop — Manipulate raw audio data

The `audioop` module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16 or 32 bits wide, stored in bytes objects. All scalar items are integers, unless specified otherwise.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

- **exception audioop.error**
  - This exception is raised on all errors, such as unknown number of bytes per sample, etc.

- **audioop.add(fragment1, fragment2, width)**
  - Return a fragment which is the addition of the two samples passed as parameters. `width` is the sample width in bytes, either 1, 2 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.

- **audioop.adpcm2lin(adpcmfragment, width, state)**
  - Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of `lin2adpcm()` for details on ADPCM coding. Return a tuple `(sample, newstate)` where the sample
has the width specified in *width*.

**audioop.alaw2lin(fragment, width)**

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

**audioop.avg(fragment, width)**

Return the average over all samples in the fragment.

**audioop.avgpp(fragment, width)**

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

**audioop.bias(fragment, width, bias)**

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

**audioop.cross(fragment, width)**

Return the number of zero crossings in the fragment passed as an argument.

**audioop.findfactor(fragment, reference)**

Return a factor $F$ such that $\text{rms}(\text{add(fragment, mul(reference, -F)))}$ is minimal, i.e., return the factor with which you should multiply *reference* to make it match as well as possible to *fragment*. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to $\text{len(fragment)}$.

**audioop.findfit(fragment, reference)**
Try to match *reference* as well as possible to a portion of *fragment* (which should be the longer fragment). This is (conceptually) done by taking slices out of *fragment*, using `findfactor()` to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple \((\text{offset}, \text{factor})\) where \(\text{offset}\) is the (integer) offset into *fragment* where the optimal match started and \(\text{factor}\) is the (floating-point) factor as per `findfactor()`.

audioop. **findmax**(fragment, length)

Search *fragment* for a slice of length \(\text{length}\) samples (not bytes!) with maximum energy, i.e., return \(i\) for which \(\text{rms}(\text{fragment}[i*2:(i+\text{length})*2])\) is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to \(\text{len}(\text{fragment})\).

audioop. **getsample**(fragment, width, index)

Return the value of sample \(\text{index}\) from the fragment.

audioop. **lin2adpcm**(fragment, width, state)

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

\(\text{state}\) is a tuple containing the state of the coder. The coder returns a tuple \((\text{adpcmfrag}, \text{newstate})\), and the \(\text{newstate}\) should be passed to the next call of `lin2adpcm()`. In the initial call, None can be passed as the state. \(\text{adpcmfrag}\) is the ADPCM coded fragment packed 2 4-bit values per byte.
audioop. `lin2alaw(fragment, width)`

Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop. `lin2lin(fragment, width, newwidth)`

Convert samples between 1-, 2- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```
new_frames = audioop.lin2lin(frames, old_width, new_width)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16 or 32 bit width samples.

audioop. `lin2ulaw(fragment, width)`

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop. `max(fragment, width)`

Return the maximum of the *absolute value* of all samples in a fragment.

audioop. `maxpp(fragment, width)`

Return the maximum peak-peak value in the sound fragment.
audioop.\texttt{minmax}(\textit{fragment, width})

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop.\texttt{mul}(\textit{fragment, width, factor})

Return a fragment that has all samples in the original fragment multiplied by the floating-point value \textit{factor}. Samples are truncated in case of overflow.

audioop.\texttt{ratecv}(\textit{fragment, width, nchannels, inrate, outrate},
\textit{state[, weightA[, weightB]]})

Convert the frame rate of the input fragment.

\textit{state} is a tuple containing the state of the converter. The converter returns a tuple \texttt{(newfragment, newstate)}, and \textit{newstate} should be passed to the next call of \texttt{ratecv()}. The initial call should pass None as the state.

The \textit{weightA} and \textit{weightB} arguments are parameters for a simple digital filter and default to 1 and 0 respectively.

audioop.\texttt{reverse}(\textit{fragment, width})

Reverse the samples in a fragment and returns the modified fragment.

audioop.\texttt{rms}(\textit{fragment, width})

Return the root-mean-square of the fragment, i.e. \texttt{sqrt(sum(S_i^2)/n)}.

This is a measure of the power in an audio signal.

audioop.\texttt{tomono}(\textit{fragment, width, lfactor, rfactor})

Convert a stereo fragment to a mono fragment. The left channel is
multiplied by $lfactor$ and the right channel by $rfactor$ before adding the two channels to give a mono signal.

audioop.\texttt{tostereo}(\texttt{fragment}, \texttt{width}, \texttt{lfactor}, \texttt{rfactor})

Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by $lfactor$ and right channel samples by $rfactor$.

audioop.\texttt{ulaw2lin}(\texttt{fragment}, \texttt{width})

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so $width$ refers only to the sample width of the output fragment here.

Note that operations such as \texttt{mul()} or \texttt{max()} make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:

```python
def mul_stereo(sample, width, lfactor, rfactor):
  lsample = audioop.tomono(sample, width, 1, 0)
  rsample = audioop.tomono(sample, width, 0, 1)
  lsample = audioop.mul(lsample, width, lfactor)
  rsample = audioop.mul(rsample, width, rfactor)
  lsample = audioop.tostereo(lsample, width, 1, 0)
  rsample = audioop.tostereo(rsample, width, 0, 1)
  return audioop.add(lsample, rsample, width)

```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the \textit{initial} state (the one you passed to \texttt{lin2adpcm()})
along to the decoder, not the final state (as returned by the coder). If you want to use `struct.Struct` to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The `find*()` routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

```python
def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)]
    #    out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(outputdata)-len(prefill)-len(out_test)
    outputdata = prefill + audioop.mul(outputdata, 2,
    return audioop.add(inputdata, outputdata, 2)
```
Last updated on Nov 11, 2013. Found a bug?
Created using Sphinx 1.0.7.
22.2. **aifc** — Read and write AIFF and AIFC files

**Source code:** Lib/aifc.py

This module provides support for reading and writing AIFF and AIFC files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

**Note:** Some operations may only work under IRIX; these will raise `ImportError` when attempting to import the cl module, which is only available on IRIX.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of $nchannels \times samplesize$ bytes, and a second's worth of audio consists of $nchannels \times samplesize \times framerate$ bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes ($2^2$), and a second's worth occupies $2^2 \times 44100$ bytes (176,400 bytes).

Module **aifc** defines the following function:

```python
aifc.open(file, mode=None)
```
Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument file is either a string naming a file or a file object. mode must be 'r' or 'rb' when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, file.mode is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use writeframesraw() and setnframes().

Objects returned by open() when a file is opened for reading have the following methods:

**aifc.getnchannels()**
Return the number of audio channels (1 for mono, 2 for stereo).

**aifc.getsampwidth()**
Return the size in bytes of individual samples.

**aifc.getframerate()**
Return the sampling rate (number of audio frames per second).

**aifc.getnframes()**
Return the number of audio frames in the file.

**aifc.getcomptype()**
Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is b'NONE'.

**aifc.getcompname()**
Return a bytes array convertible to a human-readable description
of the type of compression used in the audio file. For AIFF files, the returned value is b'not compressed'.

aifc.getparams()
Return a tuple consisting of all of the above values in the above order.

aifc.getmarkers()
Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

aifc.getmark(id)
Return the tuple as described in getmarkers() for the mark with the given id.

aifc.readframes(nframes)
Read and return the next nframes frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

aifc.rewind()
Rewind the read pointer. The next readframes() will start from the beginning.

aifc.setpos(pos)
Seek to the specified frame number.

aifc.tell()
Return the current frame number.

aifc.close()
Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by `open()` when a file is opened for writing have all the above methods, except for `readframes()` and `setpos()`. In addition the following methods exist. The `get*()` methods can only be called after the corresponding `set*()` methods have been called. Before the first `writeframes()` or `writeframesraw()`, all parameters except for the number of frames must be filled in.

**aifc.aiff()**
Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in `.aiff` in which case the default is an AIFF file.

**aifc.aifc()**
Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in `.aiff` in which case the default is an AIFF file.

**aifc.setnchannels(nchannels)**
Specify the number of channels in the audio file.

**aifc.setsampwidth(width)**
Specify the size in bytes of audio samples.

**aifc.setframerate(rate)**
Specify the sampling frequency in frames per second.

**aifc.setnframes(nframes)**
Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to
support seeking.

**aifc.setcomptype**(type, name)
Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: b'NONE', b'ULAW', b'ALAW', b'G722'.

**aifc.setparams**(nchannels, sampwidth, framerate, comptype, compname)
Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a getparams() call as argument to setparams().

**aifc.setmark**(id, pos, name)
Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before close().

**aifc.tell()**
Return the current write position in the output file. Useful in combination with setmark().

**aifc.writeframes**(data)
Write data to the output file. This method can only be called after the audio file parameters have been set.

**aifc.writeframesraw**(data)
Like writeframes(), except that the header of the audio file is
not updated.

**aifc.close()**

Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.
22.3. **sunau** — Read and write Sun AU files

Source code: Lib/sunau.py

The **sunau** module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules **aifc** and **wave**.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes <code>.snd.</code></td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes).</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The **sunau** module defines the following functions:

sunau. **open**(file, mode)
If file is a string, open the file by that name, otherwise treat it as a seekable file-like object. mode can be any of

'\texttt{r}'
Read only mode.

'\texttt{w}'
Write only mode.

Note that it does not allow read/write files.

A \texttt{mode} of 'r' returns a AU\_read object, while a \texttt{mode} of 'w' or 'wb' returns a AU\_write object.

\texttt{sunau.openfp(file, mode)}
A synonym for \texttt{open()}, maintained for backwards compatibility.

The \texttt{sunau} module defines the following exception:

\texttt{exception sunau.Error}
An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The \texttt{sunau} module defines the following data items:

\texttt{sunau.AUDIO\_FILE\_MAGIC}
An integer every valid Sun AU file begins with, stored in big-endian form. This is the string .\texttt{snd} interpreted as an integer.

\texttt{sunau.AUDIO\_FILE\_ENCODING\_MULAW\_8}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_8}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_16}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_24}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_32}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_ALAW\_8}
Values of the encoding field from the AU header which are supported by this module.

sunau. `AUDIO_FILE_ENCODING_FLOAT`
sunau. `AUDIO_FILE_ENCODING_DOUBLE`
sunau. `AUDIO_FILE_ENCODING_ADPCM_G721`
sunau. `AUDIO_FILE_ENCODING_ADPCM_G722`
sunau. `AUDIO_FILE_ENCODING_ADPCM_G723_3`
sunau. `AUDIO_FILE_ENCODING_ADPCM_G723_5`

Additional known values of the encoding field from the AU header, but which are not supported by this module.
22.3.1. AU_read Objects

AU_read objects, as returned by open() above, have the following methods:

AU_read.close()
    Close the stream, and make the instance unusable. (This is called automatically on deletion.)

AU_read.getnchannels()
    Returns number of audio channels (1 for mono, 2 for stereo).

AU_read.getsampwidth()
    Returns sample width in bytes.

AU_read.getframerate()
    Returns sampling frequency.

AU_read.getnframes()
    Returns number of audio frames.

AU_read.getcomptype()
    Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

AU_read.getcompname()
    Human-readable version of getcomptype(). The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

AU_read.getparams()
    Returns a tuple (nchannels, sampwidth, framerate,
nframes, comptype, compname), equivalent to output of the get*() methods.

AU_read.readframes(n)
Reads and returns at most \( n \) frames of audio, as a string of bytes. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

AU_read.rewind()
Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

AU_read.setpos(pos)
Set the file pointer to the specified position. Only values returned from tell() should be used for pos.

AU_read.tell()
Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the aifc, and don’t do anything interesting.

AU_read.getmarkers()
Returns None.

AU_read.getmark(id)
Raise an error.
22.3.2. AU_write Objects

AU_write objects, as returned by open() above, have the following methods:

AU_write.setnchannels(n)
    Set the number of channels.

AU_write.setsampwidth(n)
    Set the sample width (in bytes.)

AU_write.setframerate(n)
    Set the frame rate.

AU_write.setnframes(n)
    Set the number of frames. This can be later changed, when and if more frames are written.

AU_write.setcomptype(type, name)
    Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

AU_write.setparams(tuple)
    The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

AU_write.tell()
    Return current position in the file, with the same disclaimer for the AU_read.tell() and AU_read.setpos() methods.

AU_write.writeframesraw(data)
Write audio frames, without correcting \textit{nframes}.

\texttt{AU\_write.writeframes(data)}

Write audio frames and make sure \textit{nframes} is correct.

\texttt{AU\_write.close()}

Make sure \textit{nframes} is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling \texttt{writeframes()} or \texttt{writeframesraw()}. 
22.4. **wave** — Read and write WAV files

**Source code:** Lib/wave.py

The `wave` module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The `wave` module defines the following function and exception:

```python
wave.open(file, mode=None)
```

If `file` is a string, open the file by that name, otherwise treat it as a seekable file-like object. `mode` can be any of

- `'r'`, `'rb'`
  - Read only mode.
- `'w'`, `'wb'`
  - Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'r'` or `'rb'` returns a `Wave_read` object, while a `mode` of `'w'` or `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode` (the `b` flag is still added if necessary).

If you pass in a file-like object, the `wave` object will not close it when its `close()` method is called; it is the caller’s responsibility
to close the file object.

wave.openfp(file, mode)

A synonym for open(), maintained for backwards compatibility.

exception wave.Error

An error raised when something is impossible because it violates
the WAV specification or hits an implementation deficiency.
22.4.1. Wave_read Objects

Wave_read objects, as returned by `open()`, have the following methods:

**Wave_read.close()**

Close the stream if it was opened by `wave`, and make the instance unusable. This is called automatically on object collection.

**Wave_read.getnchannels()**

Returns number of audio channels (1 for mono, 2 for stereo).

**Wave_read.getsampwidth()**

Returns sample width in bytes.

**Wave_read.getframerate()**

Returns sampling frequency.

**Wave_read.getnframes()**

Returns number of audio frames.

**Wave_read.getcomptype()**

Returns compression type ('NONE' is the only supported type).

**Wave_read.getcompname()**

Human-readable version of `getcomptype()`. Usually 'not compressed' parallels 'NONE'.

**Wave_read.getparams()**

Returns a tuple `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the
get*() methods.

Wave_read.readframes(n)
Reads and returns at most $n$ frames of audio, as a string of bytes.

Wave_read.rewind()
Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the aifc module, and don’t do anything interesting.

Wave_read.getmarkers()
Returns None.

Wave_read.getmark(id)
Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

Wave_read.setpos(pos)
Set the file pointer to the specified position.

Wave_read.tell()
Return current file pointer position.
22.4.2. Wave_write Objects

Wave_write objects, as returned by open(), have the following methods:

Wave_write.close()
  Make sure nframes is correct, and close the file if it was opened by wave. This method is called upon object collection.

Wave_write.setnchannels(n)
  Set the number of channels.

Wave_write.setsampwidth(n)
  Set the sample width to n bytes.

Wave_write.setframerate(n)
  Set the frame rate to n.

  Changed in version 3.2: A non-integral input to this method is rounded to the nearest integer.

Wave_write.setnframes(n)
  Set the number of frames to n. This will be changed later if more frames are written.

Wave_write.setcomptype(type, name)
  Set the compression type and description. At the moment, only compression type NONE is supported, meaning no compression.

Wave_write.setparams(tuple)
  The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the
set*() methods. Sets all parameters.

Wave_write.tell()

Return current position in the file, with the same disclaimer for the Wave_read.tell() and Wave_read.setpos() methods.

Wave_write.writeframesraw(data)

Write audio frames, without correcting nframes.

Wave_write.writeframes(data)

Write audio frames and make sure nframes is correct.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw(), and any attempt to do so will raise wave.Error.
22.5. chunk — Read IFF chunked data

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>n</td>
<td>Data bytes, where n is the size given in the preceding field</td>
</tr>
<tr>
<td>8 + n</td>
<td>0 or 1</td>
<td>Pad byte needed if n is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the Chunk class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with a EOFError exception.
class chunk. **Chunk**(file, align=True, bigendian=True, inclheader=False)

Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don’t raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument *align* is true, chunks are assumed to be aligned on 2-byte boundaries. If *align* is false, no alignment is assumed. The default value is true. If the optional argument *bigendian* is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument *inclheader* is true, the size given in the chunk header includes the size of the header. The default value is false.

A **Chunk** object supports the following methods:

**getname()**

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

**getsize()**

Returns the size of the chunk.

**close()**

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise **OSError** if called after the `close()` method has been called. Before Python 3.3, they used to raise **IOError**, now an alias of **OSError**.
isatty()

Returns False.

seek(pos, whence=0)

Set the chunk's current position. The whence argument is optional and defaults to 0 (absolute file positioning); other values are 1 (seek relative to the current position) and 2 (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

tell()

Return the current position into the chunk.

read(size=-1)

Read at most size bytes from the chunk (less if the read hits the end of the chunk before obtaining size bytes). If the size argument is negative or omitted, read all data until the end of the chunk. The bytes are returned as a string object. An empty string is returned when the end of the chunk is encountered immediately.

skip()

Skip to the end of the chunk. All further calls to read() for the chunk will return ''. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

Footnotes

22.6. `colorsys` — Conversions between color systems

Source code: Lib/colors.py

The `colors` module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

The `colors` module defines the following functions:

```python
colors.rgb_to_yiq(r, g, b)
    Convert the color from RGB coordinates to YIQ coordinates.

colors.yiq_to_rgb(y, i, q)
    Convert the color from YIQ coordinates to RGB coordinates.

colors.rgb_to_hls(r, g, b)
    Convert the color from RGB coordinates to HLS coordinates.

colors.hls_to_rgb(h, l, s)
```
Convert the color from HLS coordinates to RGB coordinates.

colorsys.rgb_to_hsv(r, g, b)

Convert the color from RGB coordinates to HSV coordinates.

colorsys.hsv_to_rgb(h, s, v)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```python
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```
22.7. `imghdr` — Determine the type of an image

**Source code:** Lib/imghdr.py

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

```
imghdr.what(filename, h=None)
```

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pbm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>'rast'</td>
<td>Sun Raster Files</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
</tbody>
</table>

You can extend the list of file types `imghdr` can recognize by appending to this variable:

`imghdr.tests`

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be None.

The test function should return a string describing the image type if the test succeeded, or None if it failed.

Example:

```
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```
22.8. sndhdr — Determine type of sound file

Source code: Lib/sndhdr.py

The sndhdr provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a tuple (type, sampling_rate, channels, frames, bits_per_sample). The value for type indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The sampling_rate will be either the actual value or 0 if unknown or difficult to decode. Similarly, channels will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for frames will be either the number of frames or -1. The last item in the tuple, bits_per_sample, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

sndhdr . what(filename)

Determines the type of sound data stored in the file filename using whathdr(). If it succeeds, returns a tuple as described above, otherwise None is returned.

sndhdr . whathdr(filename)

Determines the type of sound data stored in a file based on the file header. The name of the file is given by filename. This function returns a tuple as described above on success, or None.
22.9. **ossaudiodev** — Access to OSS-compatible audio devices

*Platforms*: Linux, FreeBSD

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

*Changed in version 3.3*: Operations in this module now raise **OSError** where **IOError** was raised.

**See also:**

**Open Sound System Programmer’s Guide**

the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

ossaudiodev defines the following variables and functions:

**exception** ossaudiodev. **OSSAudioError**

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If `ossaudiodev` receives an error from a system call such as `open()`, `write()`, or `ioctl()`, it raises **OSError**. Errors detected directly by `ossaudiodev` result in **OSSAudioError**.)
ossaudiodev.open\(mode\)
ossaudiodev.open\(device, mode\)

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as \texttt{read()}, \texttt{write()}, and \texttt{fileno()} (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

\textit{device} is the audio device filename to use. If it is not specified, this module first looks in the environment variable \texttt{AUDIODEV} for a device to use. If not found, it falls back to \texttt{/dev/dsp}.

\textit{mode} is one of \texttt{r}' for read-only (record) access, \texttt{w}' for write-only (playback) access and \texttt{rw}' for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the \textit{first} argument is optional, and the second is required. This is a historical artifact for compatibility with the older \texttt{linuxaudiodev} module which \texttt{ossaudiodev} supersedes.

ossaudiodev.openmixer\([device]\)

Open a mixer device and return an OSS mixer device object. \textit{device} is the mixer device filename to use. If it is not specified, this module first looks in the environment variable \texttt{MIXERDEV} for a
device to use. If not found, it falls back to /dev/mixer.
22.9.1. Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

`oss_audio_device.close()`

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`

Return the file descriptor associated with the device.

`oss_audio_device.read(size)`

Read size bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

`oss_audio_device.write(data)`

Write the Python string `data` to the audio device and return the
number of bytes written. If the audio device is in blocking mode (the default), the entire string is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written — see writeall().

oss_audio_device.writeall(data)

Write the entire Python string data to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until data has been completely written. If the device is in blocking mode (the default), this has the same effect as write(); writeall() is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

Changed in version 3.2: Audio device objects also support the context manager protocol, i.e. they can be used in a with statement.

The following methods each map to exactly one ioctl() system call. The correspondence is obvious: for example, setfmt() corresponds to the SNDCTL_DSP_SETFMT ioctl, and sync() to SNDCTL_DSP_SYNC (this can be useful when consulting the OSS documentation). If the underlying ioctl() fails, they all raise OSError.

oss_audio_device.nonblock()

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

oss_audio_device.getfmts()

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:
<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMT_IMA_ADPCM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
<tr>
<td>AFMT_U8</td>
<td>Unsigned, 8-bit audio</td>
</tr>
<tr>
<td>AFMT_S16_LE</td>
<td>Signed, 16-bit audio, little-endian byte order (as used by Intel processors)</td>
</tr>
<tr>
<td>AFMT_S16_BE</td>
<td>Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)</td>
</tr>
<tr>
<td>AFMT_S8</td>
<td>Signed, 8 bit audio</td>
</tr>
<tr>
<td>AFMT_U16_LE</td>
<td>Unsigned, 16-bit little-endian audio</td>
</tr>
<tr>
<td>AFMT_U16_BE</td>
<td>Unsigned, 16-bit big-endian audio</td>
</tr>
</tbody>
</table>

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support AFMT_U8; the most common format used today is AFMT_S16_LE.

oss_audio_device.setfmt(format)

Try to set the current audio format to format—see getfmts() for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of AFMT_QUERY.

oss_audio_device.channels(nchannels)

Set the number of output channels to nchannels. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may
have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

**oss_audio_device.**\texttt{speed}(\texttt{samplerate})

Try to set the audio sampling rate to \texttt{samplerate} samples per second. Returns the rate actually set. Most sound devices don’t support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>default rate for \texttt{/dev/audio}</td>
</tr>
<tr>
<td>11025</td>
<td>speech recording</td>
</tr>
<tr>
<td>22050</td>
<td></td>
</tr>
<tr>
<td>44100</td>
<td>CD quality audio (at 16 bits/sample and 2 channels)</td>
</tr>
<tr>
<td>96000</td>
<td>DVD quality audio (at 24 bits/sample)</td>
</tr>
</tbody>
</table>

**oss_audio_device.**\texttt{sync}()

Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using \texttt{sync}().

**oss_audio_device.**\texttt{reset}()

Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling \texttt{reset}().

**oss_audio_device.**\texttt{post}()

Tell the driver that there is likely to be a pause in the output,
making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctl's, or one ioctl and some simple calculations.

**oss_audio_device.setparameters**(*format, nchannels, samplerate*, *strict=False*)

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. *format*, *nchannels*, and *samplerate* should be as specified in the **setfmt**, **channels()**, and **speed()** methods. If *strict* is true, **setparameters()** checks to see if each parameter was actually set to the requested value, and raises **OSSAudioError** if not. Returns a tuple (*format, nchannels, samplerate*) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of **setfmt()**, **channels()**, and **speed()**)

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, ch
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(rate)
```

**oss_audio_device.bufsize()**

Returns the size of the hardware buffer, in samples.
oss_audio_device.*obufcount()*
Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.*obuffree()*
Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.*closed*
Boolean indicating whether the device has been closed.

oss_audio_device.*name*
String containing the name of the device file.

oss_audio_device.*mode*
The I/O mode for the file, either "r", "rw", or "w".
22.9.2. Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an OSError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

Changed in version 3.2: Mixer objects also support the context manager protocol.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_* constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIX # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that
uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, SOUND_MIXER_VOLUME does not exist.

**oss.mixer_device.stereocontrols()**

Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with controls() to determine which).

See the code example for the `controls()` function for an example of getting data from a bitmask.

**oss.mixer_device.reccontrols()**

Returns a bitmask specifying the mixer controls that may be used to record. See the code example for `controls()` for an example of reading from a bitmask.

**oss.mixer_device.get(control)**

Returns the volume of a given mixer control. The returned volume is a 2-tuple (left_volume, right_volume). Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises **OSSAudioError** if an invalid control was is specified, or **OSError** if an unsupported control is specified.

**oss.mixer_device.set(control, (left, right))**

Sets the volume for a given mixer control to (left, right). left and right must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple.
Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises `OSSAudioError` if an invalid mixer control was specified, or if the specified volumes were out-of-range.

```python
oss.mixer_device.get_recsrc()
```
This method returns a bitmask indicating which control(s) are currently being used as a recording source.

```python
oss.mixer_device.set_recsrc(bitmask)
```
Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises `OSError` if an invalid source was specified. To set the current recording source to the microphone input:

```python
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```
23. Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **23.1. gettext — Multilingual internationalization services**
  - 23.1.1. GNU gettext API
  - 23.1.2. Class-based API
    - 23.1.2.1. The NullTranslations class
    - 23.1.2.2. The GNUTranslations class
    - 23.1.2.3. Solaris message catalog support
    - 23.1.2.4. The Catalog constructor
  - 23.1.3. Internationalizing your programs and modules
    - 23.1.3.1. Localizing your module
    - 23.1.3.2. Localizing your application
    - 23.1.3.3. Changing languages on the fly
    - 23.1.3.4. Deferred translations
  - 23.1.4. Acknowledgements
- **23.2. locale — Internationalization services**
  - 23.2.1. Background, details, hints, tips and caveats
  - 23.2.2. For extension writers and programs that embed Python
  - 23.2.3. Access to message catalogs
23.1. **gettext** — Multilingual internationalization services

**Source code:** Lib/gettext.py

The **gettext** module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU gettext message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
23.1.1. GNU gettext API

The `gettext` module defines the following API, which is very similar to the GNU `gettext` API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

`gettext.bindtextdomain(domain, localedir=None)`

Bind the `domain` to the locale directory `localedir`. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix):

```
localedir/language/LC_MESSAGES/domain.mo,
```

where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or None, then the current binding for `domain` is returned. [1]

`gettext.bind_textdomain_codeset(domain, codeset=None)`

Bind the `domain` to `codeset`, changing the encoding of strings returned by the `gettext()` family of functions. If `codeset` is omitted, then the current binding is returned.

`gettext.textdomain(domain=None)`

Change or query the current global domain. If `domain` is None, then the current global domain is returned, otherwise the global domain is set to `domain`, which is returned.
gettext. **gettext(message)**

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as `_( )` in the local namespace (see examples below).

gettext. **lgettext(message)**

Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

gettext. **dgettext(domain, message)**

Like `gettext()`, but look the message up in the specified *domain*.

gettext. **ldgettext(domain, message)**

Equivalent to `dgettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

gettext. **ngettext(singular, plural, n)**

Like `gettext()`, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in `.po` files and the formulas for a variety of languages.
gettext.\texttt{lngettext}(\textit{singular, plural, n})

Equivalent to \texttt{ngettext()}, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with \texttt{bind_textdomain_codeset()}. 

gettext.\texttt{dngettext}(\textit{domain, singular, plural, n})

Like \texttt{ngettext()}, but look the message up in the specified \textit{domain}. 

gettext.\texttt{ldngettext}(\textit{domain, singular, plural, n})

Equivalent to \texttt{dngettext()}, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with \texttt{bind_textdomain_codeset()}. 

Note that GNU \texttt{gettext} also defines a \texttt{dcgettext()} method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:

```python
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my
gettext.textdomain('myapplication')
_ = gettext.gettext
#
print(_('This is a translatable string.'))
```
23.1.2. Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function _().

gettext.find(domain, localedir=None, languages=None, all=False)

This function implements the standard .mo file search algorithm. It takes a domain, identical to what textdomain() takes. Optional localedir is as in bindtextdomain() Optional languages is a list of strings, where each string is a language code.

If localedir is not given, then the default system locale directory is used. [2] If languages is not given, then the following environment variables are searched: LANGUAGE, LC_ALL, LC_MESSAGES, and LANG. The first one returning a non-empty value is used for the languages variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

localedir/language/LC_MESSAGES/domain.mo
The first such file name that exists is returned by \texttt{find()}. If no such file is found, then \texttt{None} is returned. If \texttt{all} is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

\texttt{gettext.translation(domain, localedir=None, languages=None, class_=None, fallback=False, codeset=None)}

Return a Translations instance based on the \texttt{domain}, \texttt{localedir}, and \texttt{languages}, which are first passed to \texttt{find()} to get a list of the associated .mo file paths. Instances with identical .mo file names are cached. The actual class instantiated is either \texttt{class_} if provided, otherwise GNUTranslations. The class's constructor must take a single \texttt{file object} argument. If provided, \texttt{codeset} will change the charset used to encode translated strings in the \texttt{lgettext()} and \texttt{lngettext()} methods.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, \texttt{copy.copy()} is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no .mo file is found, this function raises \texttt{OSError} if \texttt{fallback} is false (which is the default), and returns a \texttt{NullTranslations} instance if \texttt{fallback} is true.

\textit{Changed in version 3.3}: \texttt{IOError} used to be raised instead of \texttt{OSError}.

\texttt{gettext.install(domain, localedir=None, codeset=None, names=None)}

This installs the function \texttt{()()} in Python's builtins namespace, based on \texttt{domain}, \texttt{localedir}, and \texttt{codeset} which are passed to the
function translation().

For the names parameter, please see the description of the translation object's install() method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the _() function, like this:

```python
print(_('This string will be translated.'))
```

For convenience, you want the _() function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

### 23.1.2.1. The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is NullTranslations; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of NullTranslations:

```python
class gettext.NullTranslations(fp=None)
```

Takes an optional file object fp, which is ignored by the base class. Initializes “protected” instance variables _info and _charset which are set by derived classes, as well as _fallback, which is set through add_fallback(). It then calls self._parse(fp) if fp is not None.

```python
_parse(fp)
```
No-op’d in the base class, this method takes file object \( fp \), and reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add\_fallback**\((fallback)\)

Add \( fallback \) as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext**\((message)\)

If a fallback has been set, forward \( \text{gettext}() \) to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lgettext**\((message)\)

If a fallback has been set, forward \( \text{lgettext}() \) to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**ngettext**\((singular, plural, n)\)

If a fallback has been set, forward \( \text{ngettext}() \) to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lngettext**\((singular, plural, n)\)

If a fallback has been set, forward \( \text{lngettext}() \) to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**info**()

Return the “protected” \_\_info variable.
charset()
Returns the "protected" _charset variable, which is the encoding of the message catalog file.

output_charset()
Returns the "protected" _output_charset variable, which defines the encoding used to return translated messages in lgettext() and lngettext().

set_output_charset(charset)
Change the "protected" _output_charset variable, which defines the encoding used to return translated messages.

install(names=None)
This method installs self.gettext() into the built-in namespace, binding it to _.

If the names parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to _(). Supported names are 'gettext' (bound to self.gettext()), 'ngettext' (bound to self.ngettext()), lgettext and lngettext.

Note that this is only one way, albeit the most convenient way, to make the _() function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install _(). Instead, they should use this code to make _() available to their module:

```python
import gettext
```
\[
t = \text{gettext.translation('mymodule', ...)} \\
_ = t.gettext
\]

This puts \(\_\) only in the module's global namespace and so only affects calls within this module.

### 23.1.2.2. The GNUTranslations class

The `gettext` module provides one additional class derived from `NullTranslations`: `GNUTranslations`. This class overrides `_parse()` to enable reading GNU `gettext` format `.mo` files in both big-endian and little-endian format.

`GNUTranslations` parses optional meta-data out of the translation catalog. It is convention with GNU `gettext` to include meta-data as the translation for the empty string. This meta-data is in `RFC 822`-style key: value pairs, and should contain the `Project-Id-Version` key. If the key `Content-Type` is found, then the `charset` property is used to initialize the “protected” `_charset` instance variable, defaulting to None if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII encoding is assumed.

Since message ids are read as Unicode strings too, all `*gettext()` methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” `_info` instance variable.

If the `.mo` file's magic number is invalid, or if other problems occur while reading the file, instantiating a `GNUTranslations` class can
raise OSError.

The following methods are overridden from the base class implementation:

**GNUTranslations.gettext(message)**

Look up the message id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the message id, and a fallback has been set, the look up is forwarded to the fallback's gettext() method. Otherwise, the message id is returned.

**GNUTranslations.lgettext(message)**

Equivalent to gettext(), but the translation is returned as a bytestring encoded in the selected output charset, or in the preferred system encoding if no encoding was explicitly set with set_output_charset().

**GNUTranslations.ngettext(singular, plural, n)**

Do a plural-forms lookup of a message id. singular is used as the message id for purposes of lookup in the catalog, while n is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's ngettext() method. Otherwise, when n is 1 singular is returned, and plural is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
```
message = cat.ngettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}

GNUTranslations. **lngettext**(singular, plural, n)

Equivalent to **gettext()**, but the translation is returned as a bytestring encoded in the selected output charset, or in the preferred system encoding if no encoding was explicitly set with `set_output_charset()`.

**23.1.2.3. Solaris message catalog support**

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

**23.1.2.4. The Catalog constructor**

GNOME uses a version of the **gettext** module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```python
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print(_('hello world'))
```

For compatibility with this older module, the function `Catalog()` is an alias for the `translation()` function described above.

One difference between this module and Henstridge’s: his catalog
objects supported access through a mapping API, but this appears to be unused and so is not currently supported.
23.1.3. Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the gettext module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_(...)` — that is, a call to the function `_()`. For example:

```python
filename = 'mylog.txt'
message = _( 'writing a log message')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

In this example, the string 'writing a log message' is marked as a candidate for translation, while the strings 'mylog.txt' and 'w' are not.
The Python distribution comes with two tools which help you generate the message catalogs once you’ve prepared your source code. These may or may not be available from a binary distribution, but they can be found in a source distribution, in the Tools/i18n directory.

The `pygettext` [3] program scans all your Python source code looking for the strings you previously marked as translatable. It is similar to the GNU `gettext` program except that it understands all the intricacies of Python source code, but knows nothing about C or C++ source code. You don’t need GNU `gettext` unless you’re also going to be translating C code (such as C extension modules).

`pygettext` generates textual Uniforum-style human readable message catalog `.pot` files, essentially structured human readable files which contain every marked string in the source code, along with a placeholder for the translation strings. `pygettext` is a command line script that supports a similar command line interface as `xgettext`; for details on its use, run:

```
pygettext.py --help
```

Copies of these `.pot` files are then handed over to the individual human translators who write language-specific versions for every supported natural language. They send you back the filled in language-specific versions as a `.po` file. Using the `msgfmt.py` [4] program (in the Tools/i18n directory), you take the `.po` files from your translators and generate the machine-readable `.mo` binary catalog files. The `.mo` files are what the `gettext` module uses for the actual translation processing during run-time.

How you use the `gettext` module in your code depends on whether you are internationalizing a single module or your entire application.
The next two sections will discuss each case.

### 23.1.3.1. Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU gettext API but instead the class-based API.

Let's say your module is called “spam” and the module's various natural language translation .mo files reside in `/usr/share/locale` in GNU gettext format. Here's what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.lgettext
```

### 23.1.3.2. Localizing your application

If you are localizing your application, you can install the `_()` function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use `_('...')` without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
gettext.install('myapplication')
```

If you need to set the locale directory, you can pass these into the `install()` function:
23.1.3.3. Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', '/usr/share/locale'
lang2 = gettext.translation('myapplication', '
lang3 = gettext.translation('myapplication', '

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

23.1.3.4. Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:

```python
animals = ['mollusk',
           'albatross',
```
Here, you want to mark the strings in the `animals` list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

```python
def _(message):  return  message

animals = [_('mollusk'),
            _('albatross'),
            _('rat'),
            _('penguin'),
            _('python'),
            ]

del _

# ...
for a in animals:
    print(_(a))
```

This works because the dummy definition of `_()` simply returns the string unchanged. And this dummy definition will temporarily override any definition of `_()` in the built-in namespace (until the `del` command). Take care, though if you have a previous definition of `_()` in the local namespace.

Note that the second use of `_()` will not identify “a” as being translatable to the `pygettext` program, since it is not a string.
Another way to handle this is with the following example:

```python
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function `N_()`, [5] which won’t conflict with any definition of `_( )`. However, you will need to teach your message extraction program to look for translatable strings marked with `N_()`. `pygettext` and `xpot` both support this through the use of command line switches.
23.1.4. Acknowledgements

The following people contributed code, feedback, design suggestions, previous implementations, and valuable experience to the creation of this module:

- Peter Funk
- James Henstridge
- Juan David Ibáñez Palomar
- Marc-André Lemburg
- Martin von Löwis
- François Pinard
- Barry Warsaw
- Gustavo Niemeyer

Footnotes

The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call bindtextdomain() with an explicit absolute path at the start of your application.

[1] See the footnote for bindtextdomain() above.

François Pinard has written a program called xpot which does a similar job. It is available as part of his po-utils package.

[2] msgfmt.py is binary compatible with GNU msgfmt except that it provides a simpler, all-Python implementation. With this and pygettext.py, you generally won’t need to install the GNU gettext package to internationalize your Python applications.

[3] pygettext.py

[4]
The choice of N() here is totally arbitrary; it could have just as easily been MarkThisStringForTranslation().
23.2. `locale` — Internationalization services

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

**exception `locale.Error`**

Exception raised when the locale passed to `setlocale()` is not recognized.

**`locale.setlocale(category, locale=None)`**

If `locale` is given and not None, `setlocale()` modifies the locale setting for the `category`. The available categories are listed in the data description below. `locale` may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user's default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If `locale` is omitted or None, the current setting for `category` is returned.
setlocale() is not thread-safe on most systems. Applications typically start with a call of

```
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

locale. **localeconv()**

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>'decimal_point'</td>
<td>Decimal point character. Sequence of numbers specifying which relative positions the thousands_sep is expected. If the sequence terminates with a char, further grouping is performed. If the sequence terminates with a char, the last group size is repeatedly used.</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td></td>
</tr>
<tr>
<td></td>
<td>'thousands_sep'</td>
<td></td>
</tr>
<tr>
<td><strong>LC_MONETARY</strong></td>
<td><strong>Columns</strong></td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>'int_curr_symbol'</td>
<td>International currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether the currency symbol precedes the value (for positive resp. negative values).</td>
<td></td>
</tr>
<tr>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether the currency symbol is separated from the value (for positive resp. negative values).</td>
<td></td>
</tr>
<tr>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>'int_frac_digits'</td>
<td>Number of fractional digits used in international formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>'mon_thousands_sep'</td>
<td>Group separator used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'mon_grouping'</td>
<td>Equivalent to 'grouping' for monetary values.</td>
<td></td>
</tr>
</tbody>
</table>
'positive_sign'  Symbol used to annotate a positive monetary value.

'negative_sign'  Symbol used to annotate a negative monetary value.

'p_sign_posn/n_sign_posn'  The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to `CHAR_MAX` to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
<tr>
<td>1</td>
<td>The sign should precede the value and currency symbol.</td>
</tr>
<tr>
<td>2</td>
<td>The sign should follow the value and currency symbol.</td>
</tr>
<tr>
<td>3</td>
<td>The sign should immediately precede the value.</td>
</tr>
<tr>
<td>4</td>
<td>The sign should immediately follow the value.</td>
</tr>
<tr>
<td>CHAR_MAX</td>
<td>Nothing is specified in this locale.</td>
</tr>
</tbody>
</table>

`locale.nl_langinfo(option)`

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are
numbers, for which symbolic constants are available in the locale module.

The `nl_langinfo()` function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

**locale.CODESET**
Get a string with the name of the character encoding used in the selected locale.

**locale.D_T_FMT**
Get a string that can be used as a format string for `time.strftime()` to represent date and time in a locale-specific way.

**locale.D_FMT**
Get a string that can be used as a format string for `time.strftime()` to represent a date in a locale-specific way.

**locale.T_FMT**
Get a string that can be used as a format string for `time.strftime()` to represent a time in a locale-specific way.

**locale.T_FMT_AMPM**
Get a format string for `time.strftime()` to represent time in the am/pm format.

**DAY_1 ... DAY_7**
Get the name of the n-th day of the week.
Note: This follows the US convention of DAY_1 being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

ABDAY_1 . . . ABDAY_7
Get the abbreviated name of the n-th day of the week.

MON_1 . . . MON_12
Get the name of the n-th month.

ABMON_1 . . . ABMON_12
Get the abbreviated name of the n-th month.

locale. RADIIXCHAR
Get the radix character (decimal dot, decimal comma, etc.)

locale. THOUSEP
Get the separator character for thousands (groups of three digits).

locale. YESEXPR
Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

Note: The expression is in the syntax suitable for the regex() function from the C library, which might differ from the syntax used in re.

locale. NOEXPR
Get a regular expression that can be used with the regex(3) function to recognize a negative response to a yes/no question.

locale. CRNCYSTR
Get the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.

locale. **ERA**

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the `E` modifier in their format strings causes the `time.strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

locale. **ERA_D_T_FMT**

Get a format string for `time.strftime()` to represent date and time in a locale-specific era-based way.

locale. **ERA_D_FMT**

Get a format string for `time.strftime()` to represent a date in a locale-specific era-based way.

locale. **ERA_T_FMT**

Get a format string for `time.strftime()` to represent a time in a locale-specific era-based way.

locale. **ALT_DIGITS**

Get a representation of up to 100 values used to represent the values 0 to 99.
**locale.getdefaultlocale([envvars])**

Tries to determine the default locale settings and returns them as a tuple of the form `(language_code, encoding)`.

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'C' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the LANG variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the LANG variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. `envvars` defaults to the search path used in GNU gettext; it must always contain the variable name 'LANG'. The GNU gettext search path contains 'LC_ALL', 'LC_CTYPE', 'LANG' and 'LANGUAGE', in that order.

Except for the code 'C', the language code corresponds to RFC 1766. `language code` and `encoding` may be None if their values cannot be determined.

**locale.getlocale(category=LC_CTYPE)**

Returns the current setting for the given locale category as sequence containing `language code`, `encoding`. `category` may be one of the LC_* values except LC_ALL. It defaults to LC_CTYPE.

Except for the code 'C', the language code corresponds to RFC 1766. `language code` and `encoding` may be None if their values cannot be determined.
locale.getpreferredencoding(do_setlocale=True)

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke setlocale() to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, do_setlocale should be set to False.

locale.normalize(localename)

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with setlocale(). If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like setlocale().

locale.resetlocale(category=LC_ALL)

Sets the locale for category to the default setting.

The default setting is determined by calling getdefaultlocale(). category defaults to LC_ALL.

locale.strcoll(string1, string2)

Compares two strings according to the current LC_COLLATE setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether string1 collates before or after string2 or is equal to it.

locale.strxfrm(string)
Transforms a string to one that can be used in locale-aware comparisons. For example, `strxfrm(s1) < strxfrm(s2)` is equivalent to `strcoll(s1, s2) < 0`. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

locale. **format**(*format*, *val*, **grouping=False**, **monetary=False*)

Formats a number `val` according to the current `LC_NUMERIC` setting. The format follows the conventions of the `%` operator. For floating point values, the decimal point is modified if appropriate. If `grouping` is true, also takes the grouping into account.

If `monetary` is true, the conversion uses monetary thousands separator and grouping strings.

Please note that this function will only work for exactly one `%char` specifier. For whole format strings, use `format_string()`.

locale. **format_string**(*format*, *val*, **grouping=False*)

Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

locale. **currency**(*val*, **symbol=True**, **grouping=False**, **international=False**)

Formats a number `val` according to the current `LC_MONETARY` settings.

The returned string includes the currency symbol if `symbol` is true, which is the default. If `grouping` is true (which is not the default), grouping is done with the value. If `international` is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have
to set a locale via `setlocale()` first.

```python
to set a locale via `setlocale()` first.

locale.\texttt{str}(float)
Formats a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

locale.\texttt{atof}(string)
Converts a string to a floating point number, following the \texttt{LC_NUMERIC} settings.

locale.\texttt{atoi}(string)
Converts a string to an integer, following the \texttt{LC_NUMERIC} conventions.

locale.\texttt{LC_CTYPE}
Locale category for the character type functions. Depending on the settings of this category, the functions of module \texttt{string} dealing with case change their behaviour.

locale.\texttt{LC_COLLATE}
Locale category for sorting strings. The functions `strcoll()` and `strxfrm()` of the \texttt{locale} module are affected.

locale.\texttt{LC_TIME}
Locale category for the formatting of time. The function `time.strftime()` follows these conventions.

locale.\texttt{LC_MONETARY}
Locale category for formatting of monetary values. The available options are available from the `localeconv()` function.

locale.\texttt{LC_MESSAGES}
Locale category for message display. Python currently does not
support application specific locale-aware messages. Messages displayed by the operating system, like those returned by \texttt{os.strerror()} might be affected by this category.

\texttt{locale.LC\_NUMERIC}

Locale category for formatting numbers. The functions \texttt{format()}, \texttt{atoi()}, \texttt{atof()} and \texttt{str()} of the \texttt{locale} module are affected by that category. All other numeric formatting operations are not affected.

\texttt{locale.LC\_ALL}

Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

\texttt{locale.CHAR\_MAX}

This is a symbolic constant used for different values returned by \texttt{localeconv()}.

Example:

```
>>> import locale
>>> loc = locale.getlocale() # get current locale
# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC\_ALL, 'de\_DE')
>>> locale.strcoll('ß', 'foo') # compare a string
>>> locale.setlocale(locale.LC\_ALL, '') # use user's
>>> locale.setlocale(locale.LC\_ALL, 'C') # use default
>>> locale.setlocale(locale.LC\_ALL, loc) # restore settings
```
23.2.1. Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. There is one exception: the LC_CTYPE category is changed at startup to set the current locale encoding to the user’s preferred locale encoding. The program must explicitly say that it wants the user’s preferred locale settings for other categories by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call `setlocale()` in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with `time.strftime()`), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: `atof()`, `atoi()`, `atol()`, and `atoll()`.
There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.
23.2.2. For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
23.2.3. Access to message catalogs

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, `bindtextdomain()`, and `bind_textdomain_codeset()`. These are similar to the same functions in the `gettext` module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use `gettext` instead. A known exception to this rule are applications that link with additional C libraries which internally invoke `gettext()` or `dcgettext()`. For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
24. Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

  - 24.3.2. Parsing Rules
24.1. turtle — Turtle graphics
24.1.1. Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an import turtle, give it the command turtle.forward(15), and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command turtle.right(25), and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The turtle module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the -n switch.

The turtle module provides turtle graphics primitives, in both object-

Turtle star

Turtle can draw intricate shapes using programs that repeat simple moves.

```python
from turtle import *
color('red', 'yellow')
begin_fill()
while True:
```
oriented and procedure-oriented ways. Because it uses `tkinter` for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The `TurtleScreen` class defines graphics windows as a playground for the drawing turtles. Its constructor needs a `tkinter.Canvas` or a `ScrolledCanvas` as argument. It should be used when `turtle` is used as part of some application.

   The function `Screen()` returns a singleton object of a `TurtleScreen` subclass. This function should be used when `turtle` is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

   All methods of `TurtleScreen/Screen` also exist as functions, i.e. as part of the procedure-oriented interface.

2. `RawTurtle` (alias: `RawPen`) defines Turtle objects which draw on a `TurtleScreen`. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

   Derived from RawTurtle is the subclass `Turtle` (alias: `Pen`), which draws on “the” `Screen` instance which is automatically created, if not already present.

   All methods of `RawTurtle/Turtle` also exist as functions, i.e. part of
the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes Screen and Turtle. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

**Note:** In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
24.1.2. Overview of available Turtle and Screen methods

24.1.2.1. Turtle methods

Turtle motion
  Move and draw
  \texttt{\textbf{forward()} | \texttt{fd()} \}
  \texttt{\textbf{backward()} | \texttt{bk()} | \texttt{back()} \}
  \texttt{\textbf{right()} | \texttt{rt()} \}
  \texttt{\textbf{left()} | \texttt{lt()} \}
  \texttt{\textbf{goto()} | \texttt{setpos()} | \texttt{setposition()} \}
  \texttt{\textbf{setx()} \}
  \texttt{\textbf{sety()} \}
  \texttt{\textbf{setheading()} | \texttt{seth()} \}
  \texttt{\textbf{home()} \}
  \texttt{\textbf{circle()} \}
  \texttt{\textbf{dot()} \}
  \texttt{\textbf{stamp()} \}
  \texttt{\textbf{clearstamp()} \}
  \texttt{\textbf{clearstamps()} \}
  \texttt{\textbf{undo()} \}
  \texttt{\textbf{speed()} \}

Tell Turtle's state
  \texttt{\textbf{position()} | \texttt{pos()} \}
  \texttt{\textbf{towards()} \}
  \texttt{\textbf{xcor()} \}
  \texttt{\textbf{ycor()} \}
  \texttt{\textbf{heading()} \}
  \texttt{\textbf{distance()} \}

Setting and measurement
degrees()
radians()

Pen control

Drawing state
pendown() | pd() | down()
penup() | pu() | up()
pensize() | width()
pen() isdown()

Color control
color()
pencolor()
fillcolor()

Filling
filling()
begin_fill()
end_fill()

More drawing control
reset()
clear()
write()

Turtle state

Visibility
showturtle() | st()
hideturtle() | ht()
isvisible()

Appearance
shape()
resizemode()
shapesize() | turtlesize()
shearfactor()
ssettltangle()
tiltangle()
tilt()
shapetransform()
get_shapepoly()

Using events
onclick()
onrelease()
ondrag()

Special Turtle methods
begin_poly()
end_poly()
get_poly()
clone()
getturtle() | getpen()
getscreen()
setundobuffer()
undobufferentries()

24.1.2.2. Methods of TurtleScreen/Screen

Window control
bgcolor()
bgpic()
clear() | clearscren()
reset() | resetscreen()
screensize()
setworldcoordinates()

Animation control
delay()
tracer()
update()

Using screen events
listen()
onkey() | onkeyrelease()
onkeypress()
onclick() | onscreenclick()
onTimer()
mainloop() | done()

Settings and special methods
mode()
colormode()
getcanvas()
getshapes()
register_shape() | addshape()
turtles()
window_height()
window_width()

Input methods
textinput()
numinput()

Methods specific to Screen
bye()
exitonclick()
setup()
title()
24.1.3. Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

24.1.3.1. Turtle motion

turtle.\texttt{forward}(distance)
turtle.\texttt{fd}(distance)

| Parameters: | distance – a number (integer or float) |

Move the turtle forward by the specified distance, in the direction the turtle is headed.

>>> turtle.position()
(0.00, 0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00, 0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00, 0.00)

turtle.\texttt{back}(distance)
turtle.\texttt{bk}(distance)
turtle.\texttt{backward}(distance)

| Parameters: | distance – a number |

Move the turtle backward by distance, opposite to the direction the turtle is headed. Do not change the turtle's heading.
turtle.right(angle)
turtle.rt(angle)

Parameters: angle – a number (integer or float)

Turn turtle right by angle units. (Units are by default degrees, but can be set via the degrees() and radians() functions.) Angle orientation depends on the turtle mode, see mode().

turtle.left(angle)
turtle.lt(angle)

Parameters: angle – a number (integer or float)

Turn turtle left by angle units. (Units are by default degrees, but can be set via the degrees() and radians() functions.) Angle orientation depends on the turtle mode, see mode().
turtle.goto($x$, $y$=None)
turtle.setpos($x$, $y$=None)
turtle.setPosition($x$, $y$=None)

**Parameters:**
- $x$ – a number or a pair/vector of numbers
- $y$ – a number or None

If $y$ is None, $x$ must be a pair of coordinates or a Vec2D (e.g. as returned by `pos()`).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```python
>>> tp = turtle.pos()
>>> tp
(0.00, 0.00)
>>> turtle.setpos(60, 30)
>>> turtle.pos()
(60.00, 30.00)
>>> turtle.setpos((20, 80))
>>> turtle.pos()
(20.00, 80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00, 0.00)
```

turtle.setx($x$)

**Parameters:**
- $x$ – a number (integer or float)

Set the turtle's first coordinate to $x$, leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00, 240.00)
>>> turtle.setx(10)
```
turtle.\texttt{sety}(y)

**Parameters:** \texttt{y} – a number (integer or float)

Set the turtle's second coordinate to \texttt{y}, leave first coordinate unchanged.

```
>>> turtle.position()
(10.00,240.00)
>>> turtle.sety(y)
>>> turtle.position()
(0.00,40.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00,-10.00)
```

turtle.\texttt{setheading}(to_angle)

turtle.\texttt{seth}(to_angle)

**Parameters:** \texttt{to_angle} – a number (integer or float)

Set the orientation of the turtle to \texttt{to_angle}. Here are some common directions in degrees:

<table>
<thead>
<tr>
<th>standard mode</th>
<th>logo mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - east</td>
<td>0 - north</td>
</tr>
<tr>
<td>90 - north</td>
<td>90 - east</td>
</tr>
<tr>
<td>180 - west</td>
<td>180 - south</td>
</tr>
<tr>
<td>270 - south</td>
<td>270 - west</td>
</tr>
</tbody>
</table>

```
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```
turtle.**home**()

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see `mode()`).

```python
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00,-10.00)
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.**circle**(radius, extent=None, steps=None)

**Parameters:**

- `radius` – a number
- `extent` – a number (or None)
- `steps` – an integer (or None)

Draw a circle with given `radius`. The center is `radius` units left of the turtle; `extent` – an angle – determines which part of the circle is drawn. If `extent` is not given, draw the entire circle. If `extent` is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if `radius` is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of `extent`.

As the circle is approximated by an inscribed regular polygon, `steps` determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```python
>>> turtle.home()
>>> turtle.position()
```
>>> turtle.ellipse(50)
>>> turtle.position()
(-0.00,0.00)
>>> turtle.ellipse()
0.0
>>> turtle.circle(120, 180)  # draw a semicircle
>>> turtle.position()
(0.00,240.00)
>>> turtle.ellipse()
180.0

turtle.**dot**(size=None, *color*)

**Parameters:**
- **size** – an integer >= 1 (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize+4 and 2*pensize* is used.

>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle
>>> turtle.position()
(100.00,-0.00)
>>> turtle.ellipse()
0.0

turtle.**stamp**()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling clearstamp(stamp_id).
turtle.color("blue")
turtle.stamp()
11
turtle.fd(50)

turtle.clearstamp(stampid)

Parameters:

stampid – an integer, must be return value of previous stamp() call

Delete stamp with given stampid.

turtle.clearstamps(n=None)

Parameters:

n – an integer (or None)

Delete all or first/last n of turtle’s stamps. If n is None, delete all stamps, if n > 0 delete first n stamps, else if n < 0 delete last n stamps.

>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
13
14
15
16
turtle.undo()

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```python
>>> for i in range(4):
...     turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...     turtle.undo()
```

turtle.speed(speed=None)

Parameters:

| speed – an integer in the range 0..10 or a speedstring (see below) |

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1

Speeds from 1 to 10 enforce increasingly faster animation of line
drawing and turtle turning.

Attention: speed = 0 means that no animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```python
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

24.1.3.2. Tell Turtle's state

```python
turtle.position()
turtle.pos()
```

Return the turtle's current location (x,y) (as a Vec2D vector).

```python
>>> turtle.pos()
(440.00,-0.00)
```

```python
turtle.towards(x, y=None)
```

**Parameters:**
- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if x is a number, else None

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - "standard"/"world" or "logo").
turtle.goto(10, 10)
turtle.towards(0,0)
225.0

turtle.xcor()
Return the turtle's x coordinate.

turtle.home()
turtle.left(50)
turtle.forward(100)
turtle.pos()
(64.28, 76.60)
print(round(turtle.xcor(), 5))
64.27876

turtle.ycor()
Return the turtle's y coordinate.

turtle.home()
turtle.left(60)
turtle.forward(100)
print(turtle.pos())
(50.00, 86.60)
print(round(turtle.ycor(), 5))
86.60254

turtle.heading()
Return the turtle's current heading (value depends on the turtle mode, see mode()).

turtle.home()
turtle.left(67)
turtle.heading()
67.0
turtle.\texttt{distance}(x, y=\texttt{None})

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x – a number or a pair/vector of numbers or a turtle instance</td>
<td></td>
</tr>
<tr>
<td>y – a number if x is a number, else \texttt{None}</td>
<td></td>
</tr>
</tbody>
</table>

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.home()
>>> turtle.distance(30,40)
50.0
>>> turtle.distance((30,40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

24.1.3.3. Settings for measurement

turtle.\texttt{degrees}(\texttt{fullcircle}=360.0)

| Parameters: | \texttt{fullcircle} – a number |

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0

Change angle measurement unit to grad (also known grade, or gradian and equals 1/100-th of the right angle)
```
turtle. `radians()`
Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

turtle. `home()`
turtle. `left(90)`
turtle. `heading()`
90.0

turtle. `radians()`
turtle. `heading()`
1.5707963267948966

24.1.3.4. Pen control

24.1.3.4.1. Drawing state

turtle. `pendown()`
turtle. `pd()`
turtle. `down()`
Pull the pen down – drawing when moving.

turtle. `penup()`
turtle. `pu()`
turtle. `up()`
Pull the pen up – no drawing when moving.

turtle. `pensize(width=None)`
turtle.width(width=None)

**Parameters:**

- **width** – a positive number

Set the line thickness to `width` or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> turtle.pensize(10)  # from here on lines of
```

turtle.pen(pen=None, **pendict)

**Parameters:**

- **pen** – a dictionary with some or all of the below listed keys
- **pendict** – one or more keyword-arguments with the below listed keys as keywords

Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number

This dictionary can be used as argument for a subsequent call to
pen() to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
g>>> turtle.pen(fillcolor="black", pencolor="red",
g>>> sorted(turtle.pen().items())
[['fillcolor', 'black'], ['outline', 1], ['pencol
[pendown', True], ['pensize', 10], ['resizemode
('shearfactor', 0.0), ['shown', True], ['speed',
('stretchfactor', (1.0, 1.0)), ['tilt', 0.0]]
g>>> penstate=turtle.pen()

```

 turtle. isdown()  
 Return True if pen is down, False if it's up.

```python
g>>> turtle.penup()

```

24.1.3.4.2. Color control

 turtle. pencolor(*args)  
 Return or set the pencolor.
Four input formats are allowed:

\texttt{pencolor()}

Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

\texttt{pencolor(colorstring)}

Set pencolor to \textit{colorstring}, which is a Tk color specification string, such as \texttt{"red"}, \texttt{"yellow"}, or \texttt{"#33cc8c"}.

\texttt{pencolor((r, g, b))}

Set pencolor to the RGB color represented by the tuple of \texttt{r}, \texttt{g}, and \texttt{b}. Each of \texttt{r}, \texttt{g}, and \texttt{b} must be in the range 0..colormode, where colormode is either 1.0 or 255 (see \texttt{colormode()}).

\texttt{pencolor(r, g, b)}

Set pencolor to the RGB color represented by \texttt{r}, \texttt{g}, and \texttt{b}. Each of \texttt{r}, \texttt{g}, and \texttt{b} must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

\begin{verbatim}
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
\end{verbatim}
turtle.pencolor('32c18f')
turtle.pencolor()
(50.0, 193.0, 143.0)

turtle.fillcolor(*args)
Return or set the fillcolor.

Four input formats are allowed:

fillcolor()
Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

fillcolor(colorstring)
Set fillcolor to colorstring, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

fillcolor((r, g, b))
Set fillcolor to the RGB color represented by the tuple of r, g, and b. Each of r, g, and b must be in the range 0..colormode, where colormode is either 1.0 or 255 (see colormode()).

fillcolor(r, g, b)
Set fillcolor to the RGB color represented by r, g, and b. Each of r, g, and b must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

turtle.fillcolor("violet")
turtle.fillcolor()
'violet'
col = turtle.pencolor()
col
(50.0, 193.0, 143.0)
turtle.color(*args)

Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()

Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by pencolor() and fillcolor().

color(colorstring), color((r,g,b)), color(r,g,b)

Inputs as in pencolor(), set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))

Equivalent to pencolor(colorstring1) and fillcolor(colorstring2) and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

>>> turtle.fillcolor(col)
>>> turtle.fillcolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor('#ffffff')
>>> turtle.fillcolor()
(255.0, 255.0, 255.0)
See also: Screen method `colormode()`.

24.1.3.4.3. Filling

`turtle.filling()`
Return fillstate (True if filling, False else).

```python
>>> turtle.begin_fill()
>>> if turtle.filling():
...    turtle.pensize(5)
... else:
...    turtle.pensize(3)
```

`turtle.begin_fill()`
To be called just before drawing a shape to be filled.

`turtle.end_fill()`
Fill the shape drawn after the last call to `begin_fill()`.

```python
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

24.1.3.4.4. More drawing control

`turtle.reset()`
Delete the turtle’s drawings from the screen, re-center the turtle and set variables to the default values.
```python
>>> turtle.goto(0,-22)
>>> turtle.left(100)
>>> turtle.position()
(0.00,-22.00)
>>> turtle.heading()
100.0
>>> turtle.reset()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.clear()

Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.write(arg, move=False, align="left", font=('Arial', 8, "normal"))

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• arg – object to be written to the TurtleScreen</td>
</tr>
<tr>
<td>• move – True/False</td>
</tr>
<tr>
<td>• align – one of the strings “left”, “center” or right&quot;</td>
</tr>
<tr>
<td>• font – a triple (fontname, fontsize, fonttype)</td>
</tr>
</tbody>
</table>

Write text - the string representation of arg - at the current turtle position according to align (“left”, “center” or right”) and with the given font. If move is True, the pen is moved to the bottom-right corner of the text. By default, move is False.

```python
>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
```
24.1.3.5. Turtle state

24.1.3.5.1. Visibility

turtle.**hideturtle**()
turtle.**ht**()

    Make the turtle invisible. It's a good idea to do this while you're in
    the middle of doing some complex drawing, because hiding the
turtle speeds up the drawing observably.

    >>> turtle.hideturtle()

turtle.**showturtle**()
turtle.**st**()

    Make the turtle visible.

    >>> turtle.showturtle()

turtle.**isvisible**()

    Return True if the Turtle is shown, False if it's hidden.

    >>> turtle.hideturtle()
    >>> turtle.isvisible()
    False
    >>> turtle.showturtle()
    >>> turtle.isvisible()
    True

24.1.3.5.2. Appearance

turtle.**shape**(name=None)

    Parameters: name – a string which is a valid shapename
Set turtle shape to shape with given name or, if name is not given, return name of current shape. Shape with name must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”, “triangle”, “classic”. To learn about how to deal with shapes see Screen method register_shape().

```python
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.resizemode(rmode=None)

**Parameters:**

- **rmode** – one of the strings “auto”, “user”, “noresize”

Set resizemode to one of the values: “auto”, “user”, “noresize”. If rmode is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by shapesize().
- “noresize”: no adaption of the turtle’s appearance takes place.

resizemode("user") is called by shapesize() when used with arguments.

```python
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
```
turtle.shapesize(stretch_wid=None, stretch_len=None, outline=None)
turtle.turtlesize(stretch_wid=None, stretch_len=None, outline=None)

Parameters:
- stretch_wid – positive number
- stretch_len – positive number
- outline – positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set resizemode to "user". If and only if resizemode is set to "user", the turtle will be displayed stretched according to its stretchfactors: stretch_wid is stretchfactor perpendicular to its orientation, stretch_len is stretchfactor in direction of its orientation, outline determines the width of the shapes's outline.

turtle.shearfactor(shear=None)

Parameters: shear – number (optional)

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of.
the shear angle. Do not change the turtle's heading (direction of movement). If shear is not given: return the current shear factor, i.e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```python
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()
0.5
```

turtle.\texttt{tilt}(\textit{angle})

**Parameters:**  \textit{angle} – a number

Rotate the turtleshape by \textit{angle} from its current tilt-angle, but do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.\texttt{settiltangle}(\textit{angle})

**Parameters:**  \textit{angle} – a number

Rotate the turtleshape to point in the direction specified by \textit{angle}, regardless of its current tilt-angle. Do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
```
turtle.shapesize(5,2)
turtle.settiltangle(45)
turtle.fd(50)
turtle.settiltangle(-45)
turtle.fd(50)

Deprecated since version 3.1.

turtle.tiltangle(angle=None)

**Parameters:**

| angle | a number (optional) |

Set or return the current tilt-angle. If angle is given, rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do *not* change the turtle’s heading (direction of movement). If angle is not given: return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

turtle.reset()
turtle.shape("circle")
turtle.shapesize(5,2)
turtle.tilt(45)
turtle.tiltangle()

45.0

turtle.shapetransform(t11=None, t12=None, t21=None, t22=None)

**Parameters:**

- t11 – a number (optional)
- t12 – a number (optional)
- t21 – a number (optional)
- t22 – a number (optional)

Set or return the current transformation matrix of the turtle shape.
If none of the matrix elements are given, return the transformation matrix as a tuple of 4 elements. Otherwise set the given elements and transform the turtleshape according to the matrix consisting of first row $t_{11}, t_{12}$ and second row $t_{21}, t_{22}$. The determinant $t_{11} * t_{22} - t_{12} * t_{21}$ must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```python
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4, 2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform()
(4.0, -1.0, -0.0, 2.0)
```

turtle.get_shapepoly()

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```python
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

### 24.1.3.6. Using events

turtle.onclick(fun, btn=1, add=None)

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults

**Parameters:**
Bind *fun* to mouse-click events on this turtle. If *fun* is None, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```python
def turn(x, y):
    ...
    left(180)
...
```

```python
onclick(turn)  # Now clicking into the turtle
onclick(None)  # event-binding will be removed
```

```python
turtle.onrelease(fun, btn=1, add=None)
```

**Parameters:**

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is None, existing bindings are removed.

```python
class MyTurtle(Turtle):
    ...
def glow(self, x, y):
        ...
        self.fillcolor("red")
    ...
def unglow(self, x, y):
        ...
        self.fillcolor(""")
    ...
```
turtle.\texttt{onclick}(turtle.glow) \hspace{1em} \texttt{# clicking on turtle}

turtle.\texttt{onrelease}(turtle.unglow) \hspace{1em} \texttt{# releasing turtle}

turtle.\texttt{ondrag}(\texttt{fun}, \texttt{btn}=1, \texttt{add}=\texttt{None})

\begin{itemize}
  \item \texttt{fun} – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
  \item \texttt{num} – number of the mouse-button, defaults to 1 (left mouse button)
  \item \texttt{add} – True or False – if True, a new binding will be added, otherwise it will replace a former binding
\end{itemize}

Bind \texttt{fun} to mouse-move events on this turtle. If \texttt{fun} is None, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

turtle.\texttt{ondrag}(turtle.goto)

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

24.1.3.7. Special Turtle methods

turtle.\texttt{begin\_poly}()

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

turtle.\texttt{end\_poly}()
Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

turtle.get_poly()
Return the last recorded polygon.

```python
generate_polygon = 
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
```   
turtle.clone()
Create and return a clone of the turtle with same position, heading and turtle properties.

```python
generate_triangle = 
>>> mick = Turtle()
>>> joe = mick.clone()
```   
turtle.getturtle()
turtle.getpen()
Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
get_anonymous_turtle = 
>>> pet = getturtle()
>>> pet.fd(50)  # now a turtle.Turtle is associated with this pet
>>> pet
<turtle.Turtle object at 0x...>
turtle.**getscreen()**

Return the **TurtleScreen** object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```python
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

turtle.**setundobuffer(size)**

**Parameters:**

- **size** – an integer or None

Set or disable undobuffer. If `size` is an integer an empty undobuffer of given size is installed. `size` gives the maximum number of turtle actions that can be undone by the **undo()** method/function. If `size` is None, the undobuffer is disabled.

```python
>>> turtle.setundobuffer(42)
```

turtle.**undobufferentries()**

Return number of entries in the undobuffer.

```python
>>> while undobufferentries():
...    undo()
```

### 24.1.3.8. Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class **Shape** explicitly as described below:

1. Create an empty Shape object of type “compound”.
2. Add as many components to this object as desired, using the `addcomponent()` method.

For example:

```python
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
```

3. Now add the Shape to the Screen's `shapelist` and use it:

```python
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note:** The `Shape` class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the `Shape` class *only* when using compound shapes like shown above!
24.1.4. Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

24.1.4.1. Window control

`turtle.bgcolor(*args)`

**Parameters:**
- `args` – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```python
>>> screen.bgcolor("orange")
'orange'
>>> screen.bgcolor()  
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()  
(128.0, 0.0, 128.0)
```

`turtle.bgpic(picname=None)`

**Parameters:**
- `picname` – a string, name of a gif-file or "nopic", or None

Set background image or return name of current background image. If `picname` is a filename, set the corresponding image as background. If `picname` is "nopic", delete background image, if present. If `picname` is None, return the filename of the current background image.
turtle.\texttt{clear()}
turtle.\texttt{clearscreen()}

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

\textbf{Note:} This TurtleScreen method is available as a global function only under the name \texttt{clearscreen}. The global function \texttt{clear} is a different one derived from the Turtle method \texttt{clear}.

turtle.\texttt{reset()}
turtle.\texttt{resetscreen()}

Reset all Turtles on the Screen to their initial state.

\textbf{Note:} This TurtleScreen method is available as a global function only under the name \texttt{resetscreen}. The global function \texttt{reset} is another one derived from the Turtle method \texttt{reset}.

turtle.\texttt{screensize}(canvwidth=\texttt{None}, canvheight=\texttt{None}, bg=\texttt{None})

\begin{itemize}
  \item \texttt{canvwidth} – positive integer, new width of canvas in pixels
  \item \texttt{canvheight} – positive integer, new height of canvas in pixels
  \item \texttt{bg} – colorstring or color-tuple, new
If no arguments are given, return current (canvaswidth, canvasheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```python
globals()['screen'].screensize(400, 300)
globals()['screen'].screensize(2000, 1500)
globals()['screen'].screensize(2000, 1500)
```
e.g. to search for an erroneously escaped turtle ;-)  

**turtle.** `setworldcoordinates(llx, lly, urx, ury)`

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>llx</code> – a number, x-coordinate of lower left corner of canvas</td>
<td></td>
</tr>
<tr>
<td><code>lly</code> – a number, y-coordinate of lower left corner of canvas</td>
<td></td>
</tr>
<tr>
<td><code>urx</code> – a number, x-coordinate of upper right corner of canvas</td>
<td></td>
</tr>
<tr>
<td><code>ury</code> – a number, y-coordinate of upper right corner of canvas</td>
<td></td>
</tr>
</tbody>
</table>

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION:** in user-defined coordinate systems angles may appear distorted.
24.1.4.2. Animation control

turtle.\texttt{delay}(\textit{delay}=\text{None})

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \textit{delay} – positive integer \\
\hline
\end{tabular}

Set or return the drawing \textit{delay} in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

\begin{verbatim}
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
\end{verbatim}

turtle.\texttt{tracer}(\textit{n}=\text{None}, \textit{delay}=\text{None})

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \begin{itemize}
  \item \textit{n} – nonnegative integer
  \item \textit{delay} – nonnegative integer
\end{itemize} \\
\hline
\end{tabular}

Turn turtle animation on/off and set delay for update drawings. If \textit{n} is given, only each \textit{n}-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value.
of n. Second argument sets delay value (see delay()).

```python
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...    fd(dist)
...    rt(90)
...    dist += 2
```

turtle.**update()**

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method **speed()**.

### 24.1.4.3. Using screen events

turtle.**listen**(xdummy=None, ydummy=None)

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass **listen()** to the onclick method.

turtle.**onkey**(fun, key)
turtle.**onkeyrelease**(fun, key)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fun</strong> – a function with no arguments or None</td>
<td></td>
</tr>
<tr>
<td><strong>key</strong> – a string: key (e.g. “a”) or key-symbol (e.g. “space”)</td>
<td></td>
</tr>
</tbody>
</table>

Bind **fun** to key-release event of **key**. If **fun** is None, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method **listen()**.)
turtle.onkeypress(fun, key=None)

Parameters:
- **fun** – a function with no arguments or None
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind *fun* to key-press event of *key* if *key* is given, or to any key-press-event if no *key* is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method *listen()*.)

turtle.onclick(fun, btn=1, add=None)
turtle.onscreenclick(fun, btn=1, add=None)

Parameters:
- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding
Bind \textit{fun} to mouse-click events on this screen. If \textit{fun} is \texttt{None}, existing bindings are removed.

Example for a TurtleScreen instance named \texttt{screen} and a Turtle instance named \texttt{turtle}:

\begin{verbatim}
>>> screen.onclick(turtle.goto)  # Subsequently clicking into the TurtleScreen will make the turtle move to the clicked point.
>>> screen.onclick(None)  # remove event binding again
\end{verbatim}

\textbf{Note}: This TurtleScreen method is available as a global function only under the name \texttt{onscreenclick}. The global function \texttt{onclick} is another one derived from the Turtle method \texttt{onclick}.

\texttt{turtle.ontimer}(\textit{fun}, \textit{t}=0)

\begin{itemize}
  \item \texttt{fun} – a function with no arguments
  \item \texttt{t} – a number $\geq 0$
\end{itemize}

Install a timer that calls \textit{fun} after \textit{t} milliseconds.

\begin{verbatim}
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...     screen.ontimer(f, 250)
>>> f()  ### makes the turtle march around
>>> running = False
\end{verbatim}

turtle.\texttt{mainloop()}
turtle.\texttt{done()}
Starts event loop - calling Tkinter’s mainloop function. Must be the last statement in a turtle graphics program. Must not be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```python
>>> screen.mainloop()
```

### 24.1.4.4. Input methods

#### turtle.`textinput`(title, prompt)

**Parameters:**
- `title` – string
- `prompt` – string

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, propmt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return None.

```python
>>> screen.textinput("NIM", "Name of first player:")
```

#### turtle.`numinput`(title, prompt, default=None, minval=None, maxval=None)

**Parameters:**
- `title` – string
- `prompt` – string
- `default` – number (optional)
- `minval` – number (optional)
- `maxval` – number (optional)

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value
for input, maxval: maximum value for input The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return None.

```python
>>> screen.numinput("Poker", "Your stakes:", 1000

24.1.4.5. Settings and special methods

turtle. mode(mode=None)

Parameters:
mode – one of the strings “standard”, “logo” or “world”

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old turtle. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention:** in this mode angles appear distorted if $x/y$ unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>“standard”</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>“logo”</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```python
>>> mode("logo")  # resets turtle heading to nor
>>> mode()
'logo'

turtle. colormode(cmode=None)
Parameters:  
**cmode** – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently \( r, g, b \) values of color triples have to be in the range \( 0..cmode \).

```
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
TurtleGraphicsError: bad color sequence: (240, 16
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> screen.colormode()
255
>>> turtle.pencolor(240, 160, 80)
```

turtle.**getcanvas()**

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas object at ...>
```

turtle.**getshapes()**

Return a list of names of all currently available turtle shapes.

```
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

turtle.**register_shape**(name, shape=None)  
turtle.**addshape**(name, shape=None)

There are three different ways to call this function:
1. *name* is the name of a gif-file and *shape* is None: Install the corresponding image shape.

```python
>>> screen.register_shape("turtle.gif")
```

**Note:** Image shapes do not rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```python
>>> screen.register_shape("triangle", ((5, -3),
```

3. *name* is an arbitrary string and shape is a (compound) Shape object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen’s shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

```python
turtle.turtles()

Return the list of turtles on the screen.

```python
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

```python
turtle.window_height()

Return the height of the turtle window.

```python
>>> screen.window_height()
480
```

```python
turtle.window_width()
```
Return the width of the turtle window.

```python
>>> screen.window_width()
640
```

24.1.4.6. Methods specific to Screen, not inherited from TurtleScreen

**turtle.** `bye()`

Shut the turtlegraphics window.

**turtle.** `exitonclick()`

Bind `bye()` method to mouse clicks on the Screen.

If the value “using_IDLE” in the configuration dictionary is False (default value), also enter mainloop. Remark: If IDLE with the `-n` switch (no subprocess) is used, this value should be set to True in `turtle.cfg`. In this case IDLE's own mainloop is active also for the client script.

**turtle.** `setup(width=_CFG["width"], height=_CFG["height"], startx=_CFG["leftright"], starty=_CFG["topbottom"])`

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

- **width** – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- **height** – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
Parameters:

- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if None, center window horizontally.
- **startx** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if None, center window vertically.

```python
>>> screen.setup (width=200, height=200, startx=0)
# sets window to 200x200 pixels,
>>> screen.setup(width=0.75, height=0.5, startx=None)
# sets window to 75% of screen b
```

turtle.**title**(*titlestring*)

Parameters:  

- **titlestring** – a string that is shown in the titlebar of the turtle graphics window.

Set title of turtle window to *titlestring*.

```python
>>> screen.title("Welcome to the turtle zoo!"")
```
24.1.5. Public classes

```python
class turtle.RawTurtle(canvas)
class turtle.RawPen(canvas)
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>canvas – a tkinter.Canvas, a ScrolledCanvas or a TurtleScreen</th>
</tr>
</thead>
</table>

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

```python
class turtle.Turtle
```
Subclass of RawTurtle, has the same interface but draws on a default Screen object created automatically when needed for the first time.

```python
class turtle.TurtleScreen(cv)
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>cv – a tkinter(Canvas</th>
</tr>
</thead>
</table>

Provides screen oriented methods like setbg() etc. that are described above.

```python
class turtle.Screen
```
Subclass of TurtleScreen, with four methods added.

```python
class turtle.ScrolledCanvas(master)
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>master – some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added</th>
</tr>
</thead>
</table>

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.
class turtle. **Shape**(type_, data)

**Parameters:**

<table>
<thead>
<tr>
<th>type_</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the <strong>addcomponent</strong>() method)</td>
</tr>
</tbody>
</table>

Data structure modeling shapes. The pair (type_, data) must follow this specification:

addcomponent(poly, fill, outline=None)

**Parameters:**

- **poly** – a polygon, i.e. a tuple of pairs of numbers
- **fill** – a color the poly will be filled with
- **outline** – a color for the poly’s outline (if given)

Example:

```python
>>> poly = ((0, 0), (10, -5), (0, 10), (-10, -5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

See **Compound shapes**.

class turtle. **Vec2D**(x, y)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics
programs too. Derived from tuple, so a vector is a tuple!

Provides (for $a, b$ vectors, $k$ number):

- $a + b$ vector addition
- $a - b$ vector subtraction
- $a \cdot b$ inner product
- $k \cdot a$ and $a \cdot k$ multiplication with scalar
- $\text{abs}(a)$ absolute value of $a$
- $a\cdot\text{rotate}(\text{angle})$ rotation
24.1.6. Help and configuration

24.1.6.1. How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.

- Calling `help()` on methods or functions displays the docstrings:

```python
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
```
The docstrings of the functions which are derived from methods have a modified form:

```python
>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers.

Example::

    >>> bgcolor("orange")
    >>> bgcolor()
    "orange"
    >>> bgcolor(0.5,0,0.5)
    >>> bgcolor()
    "#800080"
```

```python
>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

Aliases: penup | pu | up
```
These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

24.1.6.2. Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```python
turtle.write_docstringdict(filename="turtle_docstringdict"

Parameters:
filename – a string, used as filename
```

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script `filename.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use `turtle` with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.
At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

24.1.6.3. How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following turtle.cfg:

```python
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
```
Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg-file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`).
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- *using_IDLE*: Set this to True if you regularly work with IDLE and its -n switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The Lib/turtledemo directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the
demos (preferably not from within the demo-viewer).
24.1.7. Demo scripts

There is a set of demo scripts in the turtledemo package. These scripts can be run and viewed using the supplied demo viewer as follows:

```python
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```python
python -m turtledemo.bytedesign
```

The turtledemo package directory contains:

- a set of 15 demo scripts demonstrating different features of the new module `turtle`;
- a demo viewer `__main__.py` which can be used to view the sourcecode of the scripts and run them at the same time. 14 of the examples can be accessed via the Examples menu; all of them can also be run standalone.
- The example `turtledemo.two_canvases` demonstrates the simultaneous use of two canvases with the turtle module. Therefore it only can be run standalone.
- There is a `turtle.cfg` file in this directory, which serves as an example for how to write and use such files.

The demo scripts are:

<table>

Have fun!
24.1.8. Changes since Python 2.6

- The methods Turtle.tracer(), Turtle.window_width() and Turtle.window_height() have been eliminated. Methods with these names and functionality are now available only as methods of Screen. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding TurtleScreen/Screen-methods.)

- The method Turtle.fill() has been eliminated. The behaviour of begin_fill() and end_fill() have changed slightly: now every filling-process must be completed with an end_fill() call.

- A method Turtle.filling() has been added. It returns a boolean value: True if a filling process is under way, False otherwise. This behaviour corresponds to a fill() call without arguments in Python 2.6.
24.1.9. Changes since Python 3.0

- The methods Turtle.shearfactor(), Turtle.shapetransform() and Turtle.get_shapepoly() have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes. Turtle.tiltangle() has been enhanced in functionality: it now can be used to get or set the tiltangle. Turtle.settiltangle() has been deprecated.
- The method Screen.onkeypress() has been added as a complement to Screen.onkey() which in fact binds actions to the keyrelease event. Accordingly the latter has got an alias: Screen.onkeyrelease().
- The method Screen.mainloop() has been added. So when working only with Screen and Turtle objects one must not additonaly import mainloop() anymore.
- Two input methods has been added Screen.textinput() and Screen.numinput(). These popup input dialogs and return strings and numbers respectively.
- Two example scripts tdemo_nim.py and tdemo_round_dance.py have been added to the Lib/turtledemo directory.
24.2. **cmd** — Support for line-oriented command interpreters

**Source code:** Lib/cmd.py

The **Cmd** class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

```python
class cmd.Cmd(completekey='tab', stdin=None, stdout=None):
```

A **Cmd** instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate **Cmd** itself; rather, it’s useful as a superclass of an interpreter class you define yourself in order to inherit **Cmd**’s methods and encapsulate action methods.

The optional argument `completekey` is the **readline** name of a completion key; it defaults to **Tab**. If `completekey` is not `None` and **readline** is available, command completion is done automatically.

The optional arguments `stdin` and `stdout` specify the input and output file objects that the **Cmd** instance or subclass instance will use for input and output. If not specified, they will default to `sys.stdin` and `sys.stdout`.

If you want a given `stdin` to be used, make sure to set the instance's `use_rawinput` attribute to `False`, otherwise `stdin` will
be ignored.
24.2.1. Cmd Objects

A Cmd instance has the following methods:

Cmd.cmdloop(intro=None)

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the intro class attribute).

If the readline module is loaded, input will automatically inherit bash-like history-list editing (e.g. Control-P scrolls back to the last command, Control-N forward to the next one, Control-F moves the cursor to the right non-destructively, Control-B moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string 'EOF'.

An interpreter instance will recognize a command name foo if and only if it has a method do_foo(). As a special case, a line beginning with the character '?' is dispatched to the method do_help(). As another special case, a line beginning with the character '!' is dispatched to the method do_shell() (if such a method is defined).

This method will return when the postcmd() method returns a true value. The stop argument to postcmd() is the return value from the command's corresponding do_*() method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling complete_foo() with arguments text, line, begidx, and endidx. text is the string prefix we are attempting to match: all returned matches must begin with it. line is the current input line with leading whitespace removed, begidx and endidx are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of Cmd inherit a predefined do_help(). This method, called with an argument 'bar', invokes the corresponding method help_bar(), and if that is not present, prints the docstring of do_bar(), if available. With no argument, do_help() lists all available help topics (that is, all commands with corresponding help_*() methods or commands that have docstrings), and also lists any undocumented commands.

Cmd.onecmd(str)
Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the precmd() and postcmd() methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a do_*( ) method for the command str, the return value of that method is returned, otherwise the return value from the default() method is returned.

Cmd.emptyline()
Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.
**Cmd. `default`(line)**

Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

**Cmd. `completedefault`(text, line, begidx, endidx)**

Method called to complete an input line when no command-specific `complete_*()` method is available. By default, it returns an empty list.

**Cmd. `precmd`(line)**

Hook method executed just before the command line `line` is interpreted, but after the input prompt is generated and issued. This method is a stub in `Cmd`; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the `onecmd()` method; the `precmd()` implementation may re-write the command or simply return `line` unchanged.

**Cmd. `postcmd`(stop, line)**

Hook method executed just after a command dispatch is finished. This method is a stub in `Cmd`; it exists to be overridden by subclasses. `line` is the command line which was executed, and `stop` is a flag which indicates whether execution will be terminated after the call to `postcmd();` this will be the return value of the `onecmd()` method. The return value of this method will be used as the new value for the internal flag which corresponds to `stop`; returning false will cause interpretation to continue.

**Cmd. `preloop()`**

Hook method executed once when `cmdloop()` is called. This method is a stub in `Cmd`; it exists to be overridden by subclasses.
**Cmd. postloop()**
Hook method executed once when `cmdloop()` is about to return. This method is a stub in `Cmd`; it exists to be overridden by subclasses.

Instances of `Cmd` subclasses have some public instance variables:

**Cmd. prompt**
The prompt issued to solicit input.

**Cmd. identchars**
The string of characters accepted for the command prefix.

**Cmd. lastcmd**
The last nonempty command prefix seen.

**Cmd. intro**
A string to issue as an intro or banner. May be overridden by giving the `cmdloop()` method an argument.

**Cmd. doc_header**
The header to issue if the help output has a section for documented commands.

**Cmd. misc_header**
The header to issue if the help output has a section for miscellaneous help topics (that is, there are `help_*()` methods without corresponding `do_*()` methods).

**Cmd. undoc_header**
The header to issue if the help output has a section for undocumented commands (that is, there are `do_*()` methods
without corresponding help_*( ) methods).

Cmd. **ruler**

The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to `='.

Cmd. **use_rawinput**

A flag, defaulting to true. If true, `cmdloop()` uses `input()` to display a prompt and read the next command; if false, `sys.stdout.write()` and `sys.stdin.readline()` are used. (This means that by importing `readline`, on systems that support it, the interpreter will automatically support **Emacs**-like line editing and command-history keystrokes.)
24.2.2. Cmd Example

The cmd module is mainly useful for building custom shells that let a user work with a program interactively.

This section presents a simple example of how to build a shell around a few of the commands in the turtle module.

Basic turtle commands such as `forward()` are added to a Cmd subclass with method named `do_forward()`. The argument is converted to a number and dispatched to the turtle module. The docstring is used in the help utility provided by the shell.

The example also includes a basic record and playback facility implemented with the `precmd()` method which is responsible for converting the input to lowercase and writing the commands to a file. The `do_playback()` method reads the file and adds the recorded commands to the cmdqueue for immediate playback:

```python
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = 'Welcome to the turtle shell. Type help or ? to list commands.'
    prompt = '(turtle) '
    file = None

    # ---- basic turtle commands ----
    def do_forward(self, arg):
        'Move the turtle forward by the specified distance:
        FORWARD 10'
        forward(*parse(arg))

    def do_right(self, arg):
        'Turn turtle right by given number of degrees:
        RIGHT 20'
```

def do_left(self, arg):
    'Turn turtle left by given number of degrees:
    left(*parse(arg))

def do_goto(self, arg):
    'Move turtle to an absolute position with changing orientation.
    goto(*parse(arg))

def do_home(self, arg):
    'Return turtle to the home position:  HOME'
    home()

def do_circle(self, arg):
    'Draw circle with given radius and options except line
    circle(*parse(arg))

def do_position(self, arg):
    'Print the current turtle position:  POSITION'
    print('Current position is %d %d\n' % position)

def do_heading(self, arg):
    'Print the current turtle heading in degrees:
    print('Current heading is %d\n' % (heading())

def do_color(self, arg):
    'Set the color:  COLOR BLUE'
    color(arg.lower())

def do_undo(self, arg):
    'Undo (repeatedly) the last turtle action(s)

def do_reset(self, arg):
    'Clear the screen and return turtle to center
    reset()

def do_bye(self, arg):
    'Stop recording, close the turtle window,
    and exit:
    print('Thank you for using Turtle')
    self.close()
    bye()
    return True

# ----- record and playback -----  
def do_record(self, arg):
    'Save future commands to filename:  RECORD rose.cmd'
self.file = open(arg, 'w')

def do_playback(self, arg):
    'Playback commands from a file: PLAYBACK record file
self.close()
with open(arg) as f:
    self.cmdqueue.extend(f.read().splitlines)

def precmd(self, line):
    line = line.lower()
    if self.file and 'playback' not in line:
        print(line, file=self.file)
    return line

def close(self):
    if self.file:
        self.file.close()
    self.file = None

def parse(arg):
    'Convert a series of zero or more numbers to an argument tuple'
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()

Here is a sample session with the turtle shell showing the help functions, using blank lines to repeat commands, and the simple record and playback facility:

Welcome to the turtle shell. Type help or ? to list commands.
(turtle) ?

Documented commands (type help <topic>):
========================================
bye  color  goto  home  playback  record  right  circle  forward  heading  left  position  reset  undo
(turtle) help forward
Move the turtle forward by the specified distance:
(turtle) record spiral.cmd
(turtle) position
Current position is 0 0

(turtle) heading
Current heading is 0

(turtle) reset
(turtle) circle 20
(turtle) right 30
(turtle) circle 40
(turtle) right 30
(turtle) circle 60
(turtle) right 30
(turtle) circle 80
(turtle) right 30
(turtle) circle 100
(turtle) right 30
(turtle) circle 120
(turtle) right 30
(turtle) circle 120
(turtle) heading
Current heading is 180

(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 500
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 300
(turtle) playback spiral.cmd
Current position is 0 0

Current heading is 0

Current heading is 180

(turtle) bye
Thank you for using Turtle
The `shlex` class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

The `shlex` module defines the following functions:

```
shlex.split(s, comments=False, posix=True)
```

Split the string `s` using shell-like syntax. If `comments` is `False` (the default), the parsing of comments in the given string will be disabled (setting the `commenters` attribute of the `shlex` instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the `posix` argument is false.

**Note:** Since the `split()` function instantiates a `shlex` instance, passing `None` for `s` will read the string to split from standard input.

```
shlex.quote(s)
```

Return a shell-escaped version of the string `s`. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe:
quote() lets you plug the security hole:

```python
>>> filename = 'somefile; rm -rf ~'
>>> command = 'ls -l {}'.format(filename)
>>> print(command)  # executed by a shell: boom!
ls -l somefile; rm -rf ~
```

```python
>>> command = 'ls -l {}'.format(quote(filename))
>>> print(command)
ls -l 'somefile; rm -rf ~'
```

```python
>>> remote_command = 'ssh home {}'.format(quote(command))
>>> print(remote_command)
ssh home 'ls -l """"somefile; rm -rf ~""""
```

The quoting is compatible with UNIX shells and with `split()`:

```python
>>> remote_command = split(remote_command)
>>> remote_command
['ssh', 'home', 'ls -l "somefile; rm -rf ~"']
>>> command = split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
```

*New in version 3.3.*

The `shlex` module defines the following class:

```python
class shlex, shlex(instream=None, infile=None, posix=False)
```

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string. If no argument is given, input will be taken from `sys.stdin`. The second optional
argument is a filename string, which sets the initial value of the `infilename` attribute. If the `instream` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument defines the operational mode: when `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules.

**See also:**

**Module** [configparser](https://docs.python.org/3/library/configparser.html)

Parser for configuration files similar to the Windows `.ini` files.
24.3.1. shlex Objects

A shlex instance has the following methods:

shlex.get_token()
Return a token. If tokens have been stacked using push_token(), pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, eof is returned (the empty string ('') in non-POSIX mode, and None in POSIX mode).

shlex.push_token(str)
Push the argument onto the token stack.

shlex.read_token()
Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

shlex.sourcehook(filename)
When shlex detects a source request (see source below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as sys.stdin), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles
The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding ‘close’ hook, but a shlex instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

```python
shlex.push_source(newstream, newfile=None)
```

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

```python
shlex.pop_source()
```

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

```python
shlex.error_leader(infile=None, lineno=None)
```

This method generates an error message leader in the format of a Unix C compiler error label; the format is `"%s", line %d: '`, where the `%s` is replaced with the name of the current source file and the `%d` with the current input line number (the optional
arguments can be used to override these).

This convenience is provided to encourage shlex users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of shlex subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

shlex.**commenters**

The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just '#' by default.

shlex.**wordchars**

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore.

shlex.**whitespace**

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

shlex.**escape**

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.

shlex.**quotes**

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.
shlex.**escapedquotes**
Characters in **quotes** that will interpret escape characters defined in **escape**. This is only used in POSIX mode, and includes just `'`` by default.

shlex.**whitespace_split**
If True, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with **shlex**, getting tokens in a similar way to shell arguments.

shlex.**infile**
The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

shlex.**instream**
The input stream from which this **shlex** instance is reading characters.

shlex.**source**
This attribute is None by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion request similar to the **source** keyword in various shells. That is, the immediately following token will opened as a filename and input taken from that stream until EOF, at which point the **close()** method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

shlex.**debug**
If this attribute is numeric and 1 or more, a **shlex** instance will print verbose progress output on its behavior. If you need to use
this, you can read the module source code to learn the details.

\texttt{shlex.linenno}

Source line number (count of newlines seen so far plus one).

\texttt{shlex.token}

The token buffer. It may be useful to examine this when catching exceptions.

\texttt{shlex.eof}

Token used to determine end of file. This will be set to the empty string (""), in non-POSIX mode, and to None in POSIX mode.
24.3.2. Parsing Rules

When operating in non-POSIX mode, `shlex` will try to obey to the following rules.

- Quote characters are not recognized within words (Do"Not"Separate is parsed as the single word Do"Not"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do"Separate is parsed as "Do" and Separate);
- If whitespace_split is False, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is True, `shlex` will only split words in whitespaces;
- EOF is signaled with an empty string ('');
- It's not possible to parse empty strings, even if quoted.

When operating in POSIX mode, `shlex` will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do"Not"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of escapedquotes (e.g. "'"') preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of
escapedquotes (e.g. `'"'`) preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a None value;
- Quoted empty strings ('') are allowed.
25. Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the tkinter package, and its extension, the tkinter.tix and the tkinter.ttk modules.

The tkinter package is a thin object-oriented layer on top of Tcl/Tk. To use tkinter, you don't need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. tkinter is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module _tkinter provides a threadsafe mechanism which allows Python and Tcl to interact.

 tkinter's chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. tkinter is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the Other Graphical User Interface Packages section.

25.1. **tkinter — Python interface to Tcl/Tk**

The **tkinter** package (“Tk interface”) is the standard Python interface to the Tk GUI toolkit. Both Tk and **tkinter** are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.) You can check that **tkinter** is properly installed on your system by running `python -m tkinter` from the command line; this should open a window demonstrating a simple Tk interface.

**Python and Tkinter Programming**
25.1.1. Tkinter Modules

Most of the time, `tkinter` is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, `tkinter` includes a number of Python modules, `tkinter.constants` being one of the most important. Importing `tkinter` will automatically import `tkinter.constants`, so, usually, to use Tkinter all you need is a simple import statement:

```
import tkinter
```

Or, more often:

```
from tkinter import *
```

class `tkinter.Tk`(`screenName=None, baseName=None, className='Tk', useTk=1)

The `Tk` class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

class `tkinter.Tcl`(`screenName=None, baseName=None, className='Tk', useTk=0)

The `Tcl()` function is a factory function which creates an object much like that created by the `Tk` class, except that it does not
initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn’t want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the Tcl() object can have a Toplevel window created (and the Tk subsystem initialized) by calling its loadtk() method.

Other modules that provide Tk support include:

**tkinter.scrolledtext**
Text widget with a vertical scroll bar built in.

**tkinter.colorchooser**
Dialog to let the user choose a color.

**tkinter.commondialog**
Base class for the dialogs defined in the other modules listed here.

**tkinter.filedialog**
Common dialogs to allow the user to specify a file to open or save.

**tkinter.font**
Utilities to help work with fonts.

**tkinter.messagebox**
Access to standard Tk dialog boxes.

**tkinter.simplesdialog**
Basic dialogs and convenience functions.

**tkinter.dnd**
Drag-and-drop support for tkinter. This is experimental and should become deprecated when it is replaced with the Tk DND.

**turtle**
Turtle graphics in a Tk window.
25.1.2. Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tk was written by John Ousterhout while at Berkeley.
- Tkinter was written by Steen Lumholt and Guido van Rossum.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The HTML rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

25.1.2.1. How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do“blah” in straight Tk, and then convert this back into the corresponding tkinter call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists.
Here are some hints:

- The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the `manN` directory are most useful. The `man3` man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
- Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
- `tkinter/__init__.py` is a last resort for most, but can be a good place to go when nothing else makes sense.

25.1.2.2. A Simple Hello World Program

```python
import tkinter as tk

class Application(tk.Frame):
    def __init__(self, master=None):
        tk.Frame.__init__(self, master)
        self.pack()
        self.createWidgets()
```
def createWidgets(self):
    self.hi_there = tk.Button(self)
    self.hi_there["text"] = "Hello World
(click me)"
    self.hi_there["command"] = self.say_hi
    self.hi_there.pack(side="top")

    self.QUIT = tk.Button(self, text="QUIT", fg=
                       command=self.QUIT.pack(side="bottom")

    def say_hi(self):
        print("hi there, everyone!")

root = tk.Tk()
app = Application(master=root)
app.mainloop()
25.1.3. A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren’t meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

```
classCommand newPathname options
```
**classCommand**

denotes which kind of widget to make (a button, a label, a menu...)

**newPathname**

is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with *pathnames*, just like files in a file system. The top level widget, the *root*, is called (period) and children are delimited by more periods. For example, `.myApp.controlPanel.okButton` might be the name of a widget.

**options**

configure the widget's appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

```
button .fred -fg red -text "hi there"
```

Once created, the pathname to the widget becomes a new command. This new *widget command* is the programmer’s handle for getting the new widget to perform some *action*. In C, you’d express this as `someAction(fred, someOptions)`, in C++, you would express this as `fred.someAction(someOptions)`, and in Tk, you say:

```
.fred someAction someOptions
```

Note that the object name, `.fred`, starts with a dot.
As you’d expect, the legal values for \textit{someAction} will depend on the widget’s class: \texttt{.fred disable} works if \texttt{fred} is a button (\texttt{fred} gets greyed out), but does not work if \texttt{fred} is a label (disabling of labels is not supported in Tk).

The legal values of \textit{someOptions} is action dependent. Some actions, like \texttt{disable}, require no arguments, others, like a text-entry box’s \texttt{delete} command, would need arguments to specify what range of text to delete.
25.1.4. Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

\[
\text{button .fred} \quad \Rightarrow \quad \text{fred = Button()}
\]

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

\[
\text{button .panel.fred} \quad \Rightarrow \quad \text{fred = Button(panel)}
\]

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

\[
\text{button .fred -fg red} \quad \Rightarrow \quad \text{fred = Button(panel)}
\]

\[
\text{.fred configure -fg red} \quad \Rightarrow \quad \text{fred["fg"] = red}
\]

OR \[
\Rightarrow \quad \text{fred.config(fg='red')}
\]

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in tkinter/__init__.py.

\[
\text{.fred invoke} \quad \Rightarrow \quad \text{fred.invoke()}
\]

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this
functionality, and the various forms of the pack command are implemented as methods. All widgets in tkinter are subclassed from the Packer, and so inherit all the packing methods. See the tkinter.tix module documentation for additional information on the Form geometry manager.

pack .fred -side left =====> fred.pack(side='
25.1.5. How Tk and Tkinter are Related

From the top down:

Your App Here (Python)
A Python application makes a `tkinter` call.

tkinter (Python Package)
This call (say, for example, creating a button widget), is implemented in the `tkinter` package, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

ltkinter (C)
These commands and their arguments will be passed to a C function in the `_tkinter` - note the underscore - extension module.

Tk Widgets (C and Tcl)
This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python `tkinter` package is imported. (The user never sees this stage).

Tk (C)
The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)
the Xlib library to draw graphics on the screen.
25.1.6. Handy Reference

25.1.6.1. Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg="red", bg="blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the `config()` method to update multiple attrs subsequent to object creation

```python
fred.config(fg="red", bg="blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the `options(3)` man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a `command` option, labels do not.
The options supported by a given widget are listed in that widget's man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `relief`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (bg is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as `('bg', 'background')`).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print(fred.config())
{'relief' : ('relief', 'relief', 'Relief', 'raised',
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

25.1.6.2. The Packer
The packer is one of Tk’s geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual master. In contrast to the more cumbersome placer (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - above, to the left of, filling, etc - and works everything out to determine the exact placement coordinates for you.

The size of any master widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It’s a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s pack() method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
fred.pack()  # defaults to side =
fred.pack(side="left")
fred.pack(expand=1)
```

25.1.6.3. Packer Options
For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

anchor

Anchor type. Denotes where the packer is to place each slave in its parcel.

expand

Boolean, 0 or 1.

fill

Legal values: 'x', 'y', 'both', 'none'.

ipadx and ipady

A distance - designating internal padding on each side of the slave widget.

padx and pady

A distance - designating external padding on each side of the slave widget.

side

Legal values are: 'left', 'right', 'top', 'bottom'.

25.1.6.4. Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are variable, textvariable, onvalue, offvalue, and value. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of tkinter it is not possible to hand over an arbitrary Python variable to a widget through
a variable or textvariable option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in tkinter.

There are many useful subclasses of Variable already defined: StringVar, IntVar, DoubleVar, and BooleanVar. To read the current value of such a variable, call the get() method on it, and to change its value you call the set() method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return
        # we will have the program print out the value of the application variable when the user hits return
        self.entrythingy.bind('<<Key-Return>>',
                               self.print_contents)

    def print_contents(self, event):
        print(self.contents.get())
25.1.6.5. The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In `tkinter`, these commands have been implemented as methods on the `Wm` class. Toplevel widgets are subclassed from the `Wm` class, and so can call the `Wm` methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won't represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
from tkinter import *
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

# create the application
myapp = App()
```

```python
print("hi. contents of entry is now ----->", self.contents.get())
```
```python
# here are method calls to the window manager class
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()
```

25.1.6.6. Tk Option Data Types

anchor

Legal values are points of the compass: "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

bitmap

There are eight built-in, named bitmaps: 'error', 'gray25', 'gray50', 'hourglass', 'info', 'questhead', 'question', 'warning'. To specify an X bitmap filename, give the full path to the file, preceded with an @, as in "@/usr/contrib/bitmap/gumby.bit".

boolean

You can pass integers 0 or 1 or the strings "yes" or "no".

callback

This is any Python function that takes no arguments. For example:

```python
def print_it():
    print("hi there")
fred["command"] = print_it
```

color

Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: "#RGB", 8 bit: "#RRGGBB", 12 bit: "#RRRGGGBBB", or 16 bit

cursor
The standard X cursor names from cursorfont.h can be used, without the XC_ prefix. For example to get a hand cursor (XC_hand2), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

font
Tk uses a list font name format, such as \{courier 10 bold\}. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry
This is a string of the form widthxheight, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: fred["geometry"] = "200x100".

justify
Legal values are the strings: "left", "center", "right", and "fill".

region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.
relief
Determines what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

scrollcommand
This is almost always the set( ) method of some scrollbar widget, but can be any widget method that takes a single argument.

wrap:
Must be one of: "none", "char", or "word".

25.1.6.7. Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:

```python
def bind(self, sequence, func, add=' '):
```

where:

sequence
is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout's book for details).

func
is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as callbacks.)

add
is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.
For example:

```python
def turnRed(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turnRed)
```

Notice how the widget field of the event is being accessed in the `turnRed()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
<td>%A</td>
<td>char</td>
</tr>
<tr>
<td>%h</td>
<td>height</td>
<td>%E</td>
<td>send_event</td>
</tr>
<tr>
<td>%k</td>
<td>keycode</td>
<td>%K</td>
<td>keysym</td>
</tr>
<tr>
<td>%s</td>
<td>state</td>
<td>%N</td>
<td>keysym_num</td>
</tr>
<tr>
<td>%t</td>
<td>time</td>
<td>%T</td>
<td>type</td>
</tr>
<tr>
<td>%w</td>
<td>width</td>
<td>%W</td>
<td>widget</td>
</tr>
<tr>
<td>%x</td>
<td>x</td>
<td>%X</td>
<td>x_root</td>
</tr>
<tr>
<td>%y</td>
<td>y</td>
<td>%Y</td>
<td>y_root</td>
</tr>
</tbody>
</table>

25.1.6.8. The index Parameter

A number of widgets require “index” parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)
Entry widgets have options that refer to character positions in the text being displayed. You can use these `tkinter` functions to access these special points in text widgets:

- `tkinter.AtEnd()` refers to the last position in the text
  
  *Deprecated since version 3.3.*

- `tkinter.AtInsert()` refers to the point where the text cursor is
  
  *Deprecated since version 3.3.*

- `tkinter.AtSelFirst()` indicates the beginning point of the selected text
  
  *Deprecated since version 3.3.*

- `tkinter.AtSelLast()` denotes the last point of the selected text and finally
  
  *Deprecated since version 3.3.*

- `tkinter.At(x[,y])` refers to the character at pixel location *x*, *y* (with *y* not used in the case of a text entry widget, which contains a single line of text).
  
  *Deprecated since version 3.3.*

Text widget indexes
The index notation for Text widgets is very rich and is best described in the Tk man pages.

Menu indexes (menu.invoke(), menu.entryconfig(), etc.)
Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string "active", which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

25.1.6.9. Images

Bitmap/Pixelmap images can be created through the subclasses of tkinter.Image:

- BitmapImage can be used for X11 bitmap data.
- PhotoImage can be used for GIF and PPM/PGM color bitmaps.
Either type of image is created through either the file or the data option (other options are available as well).

The image object can then be used wherever an image option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
25. Graphical User Interfaces with Tk
25.2. **tkinter.ttk** — Tk themed widgets

The **tkinter.ttk** module provides access to the Tk themed widget set, introduced in Tk 8.5. If Python has not been compiled against Tk 8.5, this module can still be accessed if *Tile* has been installed. The former method using Tk 8.5 provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for **tkinter.ttk** is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

**See also:**

**Tk Widget Styling Support**
A document introducing theming support for Tk
25.2.1. Using Ttk

To start using Ttk, import its module:

```python
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```python
from tkinter import *  
from tkinter.ttk import *
```

That code causes several `tkinter.ttk` widgets (Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Instead, use the `ttk.Style` class for improved styling effects.

**See also:**

**Converting existing applications to use Tile widgets**

A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.
25.2.2. Ttk Widgets

Ttk comes with 17 widgets, eleven of which already existed in tkinter: Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar. The other six are new: Combobox, Notebook, Progressbar, Separator, Sizegrip and Treeview. And all them are subclasses of Widget.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```python
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```python
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling, see the Style class documentation.
25.2.3. Widget

`ttk.Widget` defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

25.2.3.1. Standard Options

All the `ttk` Widgets accepts the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This is a read-only which may only be specified when the window is created.</td>
</tr>
<tr>
<td>cursor</td>
<td>Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.</td>
</tr>
<tr>
<td>takefocus</td>
<td>Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.</td>
</tr>
<tr>
<td>style</td>
<td>May be used to specify a custom widget style.</td>
</tr>
</tbody>
</table>

25.2.3.2. Scrollable Widget Options
The following options are supported by widgets that are controlled by a scrollbar.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xscrollcommand</td>
<td>Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method Scrollbar.set() of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.</td>
</tr>
<tr>
<td>yscrollcommand</td>
<td>Used to communicate with vertical scrollbars. For some more information, see above.</td>
</tr>
</tbody>
</table>

25.2.3.3. Label Options

The following options are supported by labels, buttons and other button-like widgets.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Specifies a text string to be displayed inside the widget.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value will be used in place of the text option resource.</td>
</tr>
<tr>
<td>underline</td>
<td>If set, specifies the index (0-based) of a character to underline in the text string. The underline character is used for mnemonic activation.</td>
</tr>
</tbody>
</table>
image

Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list if a sequence of statespec/value pairs as defined by `Style.map()`, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.

compound

Specifies how to display the image relative to the text, in the case both text and images options are present. Valid values are:

- text: display text only
- image: display image only
- top, bottom, left, right: display image above, below, left of, or right of the text, respectively.
- none: the default. display the image if present, otherwise the text.

width

If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.

25.2.3.4. Compatibility Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the <code>Widget.state()</code> method does not affect this option.</td>
</tr>
</tbody>
</table>
25.2.3.5. Widget States

The widget state is a bitmap of independent state flags.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>The mouse cursor is over the widget and pressing a mouse button will cause some action to occur</td>
</tr>
<tr>
<td>disabled</td>
<td>Widget is disabled under program control</td>
</tr>
<tr>
<td>focus</td>
<td>Widget has keyboard focus</td>
</tr>
<tr>
<td>pressed</td>
<td>Widget is being pressed</td>
</tr>
<tr>
<td>selected</td>
<td>“On”, “true”, or “current” for things like Checkbuttons and radiobuttons</td>
</tr>
<tr>
<td>background</td>
<td>Windows and Mac have a notion of an “active” or foreground window. The background state is set for widgets in a background window, and cleared for those in the foreground window</td>
</tr>
<tr>
<td>readonly</td>
<td>Widget should not allow user modification</td>
</tr>
<tr>
<td>alternate</td>
<td>A widget-specific alternate display format</td>
</tr>
<tr>
<td>invalid</td>
<td>The widget's value is invalid</td>
</tr>
</tbody>
</table>

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

25.2.3.6. ttk.Widget

Besides the methods described below, the ttk.Widget supports the methods `tkinter.Widget.cget()` and `tkinter.Widget.configure()`.
class tkinter.ttk.Widget

`identify(x, y)`

Returns the name of the element at position $x$, $y$, or the empty string if the point does not lie within any element.

$x$ and $y$ are pixel coordinates relative to the widget.

`instate(statespec, callback=None, *args, **kw)`

Test the widget's state. If a callback is not specified, returns True if the widget state matches $statespec$ and False otherwise. If callback is specified then it is called with args if widget state matches $statespec$.

`state(statespec=None)`

Modify or inquire widget state. If $statespec$ is specified, sets the widget state according to it and return a new $statespec$ indicating which flags were changed. If $statespec$ is not specified, returns the currently-enabled state flags.

$statespec$ will usually be a list or a tuple.
25.2.4. Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget`: `Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()` and `Widget.state()`, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.inset()`, `Entry.selection()`, `Entry.xview()`, it has some other methods, described at `ttk.Combobox`.

25.2.4.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exportselection</td>
<td>Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).</td>
</tr>
<tr>
<td>justify</td>
<td>Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the height of the pop-down listbox, in rows.</td>
</tr>
<tr>
<td>postcommand</td>
<td>A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.</td>
</tr>
</tbody>
</table>
One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the “normal” state, the text field is directly editable. In the “disabled” state, no interaction is possible.

Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See `tkinter.StringVar`.

Specifies the list of values to display in the drop-down listbox.

Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget’s font.

### 25.2.4.2. Virtual events

The combobox widgets generates a `<<ComboboxSelected>>` virtual event when the user selects an element from the list of values.

### 25.2.4.3. ttk.Combobox

```python
class tkinter.ttk.Combobox
current(newindex=None)

If `newindex` is specified, sets the combobox value to the element position `newindex`. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

get()

Returns the current value of the combobox.
```
**set**(value)

Sets the value of the combobox to *value*.
25.2.5. Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

25.2.5.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.</td>
</tr>
<tr>
<td>width</td>
<td>If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.</td>
</tr>
</tbody>
</table>

25.2.5.2. Tab Options

There are also specific options for tabs:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
...
<table>
<thead>
<tr>
<th>state</th>
<th>Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If “hidden”, then the tab is not shown.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sticky</td>
<td>Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the grid() geometry manager.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.</td>
</tr>
<tr>
<td>text</td>
<td>Specifies a text to be displayed in the tab.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies an image to display in the tab. See the option image described in Widget.</td>
</tr>
<tr>
<td>compound</td>
<td>Specifies how to display the image relative to the text, in the case both options text and image are present. See Label Options for legal values.</td>
</tr>
<tr>
<td>underline</td>
<td>Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if Notebook.enable_traversal() is called.</td>
</tr>
</tbody>
</table>

### 25.2.5.3. Tab Identifiers

The `tab_id` present in several methods of `ttk.Notebook` may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form “@x,y”, which identifies the tab
- The literal string “current”, which identifies the currently-selected tab
- The literal string “end”, which returns the number of tabs (only valid for Notebook.index())

25.2.5.4. Virtual Events

This widget generates a 
<<NotebookTabChanged>> virtual event after a new tab is selected.

25.2.5.5. ttk.Notebook

class tkinter.ttk.Notebook

    add(child, **kw)

    Adds a new tab to the notebook.

    If window is currently managed by the notebook but hidden, it is restored to its previous position.

    See Tab Options for the list of available options.

    forget(tab_id)

    Removes the tab specified by tab_id, unmaps and unmanages the associated window.

    hide(tab_id)

    Hides the tab specified by tab_id.

    The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the add() command.
**identify**(*x*, *y*)

Returns the name of the tab element at position *x*, *y*, or the empty string if none.

**index**(tab_id)

Returns the numeric index of the tab specified by `tab_id`, or the total number of tabs if `tab_id` is the string “end”.

**insert**(pos, child, **kw**)

Inserts a pane at the specified position.

*pos* is either the string “end”, an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

See Tab Options for the list of available options.

**select**(tab_id=None)

Selects the specified *tab_id*.

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If *tab_id* is omitted, returns the widget name of the currently selected pane.

**tab**(tab_id, option=None, **kw**)

Query or modify the options of the specific *tab_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

**tabs**()
Returns a list of windows managed by the notebook.

**enable_traversal()**

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- Control-Tab: selects the tab following the currently selected one.
- Shift-Control-Tab: selects the tab preceding the currently selected one.
- Alt-K: where K is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.
25.2.6. Progressbar

The ttk.Progressbar widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

25.2.6.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).</td>
</tr>
<tr>
<td>mode</td>
<td>One of “determinate” or “indeterminate”.</td>
</tr>
<tr>
<td>maximum</td>
<td>A number specifying the maximum value. Defaults to 100.</td>
</tr>
<tr>
<td>value</td>
<td>The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo maximum; that is, the progress bar completes one “cycle” when its value increases by maximum.</td>
</tr>
<tr>
<td>variable</td>
<td>A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.</td>
</tr>
<tr>
<td></td>
<td>Read-only option. The widget periodically</td>
</tr>
</tbody>
</table>
phase | increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

25.2.6.2. ttk.Progressbar

class tkinter.ttk.Progressbar

   start(interval=None)
   Begin autoincrement mode: schedules a recurring timer event that calls Progressbar.step() every interval milliseconds. If omitted, interval defaults to 50 milliseconds.

   step(amount=None)
   Increments the progress bar’s value by amount.

       amount defaults to 1.0 if omitted.

   stop()
   Stop autoincrement mode: cancels any recurring timer event initiated by Progressbar.start() for this progress bar.
25.2.7. Separator

The ttk.Separator widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from ttk.Widget.

25.2.7.1. Options

This widget accepts the following specific option:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the separator.</td>
</tr>
</tbody>
</table>
25.2.8. Sizegrip

The ttk.Sizegrip widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from ttk.Widget.

25.2.8.1. Platform-specific notes

- On MacOS X, toplevel windows automatically include a built-in size grip by default. Adding a Sizegrip is harmless, since the built-in grip will just mask the widget.

25.2.8.2. Bugs

- If the containing toplevel’s position was specified relative to the right or bottom of the screen (e.g. ...), the Sizegrip widget will not resize the window.
- This widget supports only “southeast” resizing.
25.2.9. Treeview

The `ttk.Treeview` widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by an unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods `Treeview.xview()` and `Treeview.yview()`.

25.2.9.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>A list of column identifiers, specifying the number of columns and their names.</td>
</tr>
<tr>
<td><strong>displaycolumns</strong></td>
<td>A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>height</strong></td>
<td>Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.</td>
</tr>
<tr>
<td><strong>padding</strong></td>
<td>Specifies the internal padding for the widget. The padding is a list of up to four length specifications.</td>
</tr>
<tr>
<td><strong>selectmode</strong></td>
<td>Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.</td>
</tr>
</tbody>
</table>
| **show**          | A list containing zero or more of the following values, specifying which elements of the tree to display.  
  - tree: display tree labels in column #0.  
  - headings: display the heading row.  
  
  The default is “tree headings”, i.e., show all elements.  
  
  **Note:** Column #0 always refers to the tree |
column, even if show=”tree” is not specified.

25.2.9.2. Item Options

The following item options may be specified for items in the insert and item widget commands.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The textual label to display for the item.</td>
</tr>
<tr>
<td>image</td>
<td>A Tk Image, displayed to the left of the label.</td>
</tr>
<tr>
<td>values</td>
<td>The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.</td>
</tr>
<tr>
<td>open</td>
<td>True/False value indicating whether the item’s children should be displayed or hidden.</td>
</tr>
<tr>
<td>tags</td>
<td>A list of tags associated with this item.</td>
</tr>
</tbody>
</table>

25.2.9.3. Tag Options

The following options may be specified on tags:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground</td>
<td>Specifies the text foreground color.</td>
</tr>
<tr>
<td>background</td>
<td>Specifies the cell or item background color.</td>
</tr>
<tr>
<td>font</td>
<td>Specifies the font to use when drawing text.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies the item image, in case the item's image option is empty.</td>
</tr>
</tbody>
</table>

25.2.9.4. Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer \( n \), specifying the \( n \)th data column.
- A string of the form \( \#n \), where \( n \) is an integer, specifying the \( n \)th display column.

Notes:

- Item's option values may be displayed in a different order than the order in which they are stored.
- Column \( \#0 \) always refers to the tree column, even if show="tree" is not specified.

A data column number is an index into an item's option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column \( \#0 \). If option displaycolumns is not set, then data column \( n \) is displayed in column \( \#n+1 \). Again, **column \#0 always refers to the tree column**.

25.2.9.5. Virtual Events

The Treeview widget generates the following virtual events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&lt;TreeviewSelect&gt;&gt;</td>
<td>Generated whenever the selection changes.</td>
</tr>
<tr>
<td>&lt;&lt;TreeviewOpen&gt;&gt;</td>
<td>Generated just before settings the focus</td>
</tr>
<tr>
<td>item to open=True.</td>
<td>Generated just after setting the focus item to open=False.</td>
</tr>
</tbody>
</table>

The `Treeview.focus()` and `Treeview.selection()` methods can be used to determine the affected item or items.

### 25.2.9.6. ttk.Treeview

class `tkinter.ttk.Treeview`

- `bbox(item, column=None)`
  Returns the bounding box (relative to the treeview widget's window) of the specified `item` in the form (x, y, width, height).

  If `column` is specified, returns the bounding box of that cell. If the `item` is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

- `get_children(item=None)`
  Returns the list of children belonging to `item`.

  If `item` is not specified, returns root children.

- `set_children(item, *newchildren)`
  Replaces `item`'s child with `newchildren`.

  Children present in `item` that are not present in `newchildren` are detached from the tree. No items in `newchildren` may be an ancestor of `item`. Note that not specifying `newchildren` results in detaching `item`'s children.

- `column(column, option=None, **kw)`
  Query or modify the options for the specified `column`. 
If `kw` is not given, returns a dict of the column option values. If `option` is specified then the value for that `option` is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **id**
  Returns the column name. This is a read-only option.

- **anchor**: One of the standard Tk anchor values.
  Specifies how the text in this column should be aligned with respect to the cell.

- **minwidth**: width
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- **stretch**: True/False
  Specifies whether the column’s width should be adjusted when the widget is resized.

- **width**: width
  The width of the column in pixels.

To configure the tree column, call this with `column = "#0"

```python
delete(*items)
```
Delete all specified `items` and all their descendants.

The root item may not be deleted.

```python
detach(*items)
```
Unlinks all of the specified *items* from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

**exists**(item)

Returns True if the specified *item* is present in the tree.

**focus**(item=None)

If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or '' if there is none.

**heading**(column, option=None, **kw)

Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **text**: text
  The text to display in the column heading.

- **image**: imageName
  Specifies an image to display to the right of the column heading.

- **anchor**: anchor
  Specifies how the heading text should be aligned. One of the standard Tk anchor values.
command: callback
A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = "#0".

**identify**(component, x, y)
Returns a description of the specified component under the point given by x and y, or the empty string if no such component is present at that position.

**identify_row**(y)
Returns the item ID of the item at position y.

**identify_column**(x)
Returns the data column identifier of the cell at position x.

The tree column has ID #0.

**identify_region**(x, y)
Returns one of:

<table>
<thead>
<tr>
<th>region</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>Tree heading area.</td>
</tr>
<tr>
<td>separator</td>
<td>Space between two columns headings.</td>
</tr>
<tr>
<td>tree</td>
<td>The tree area.</td>
</tr>
<tr>
<td>cell</td>
<td>A data cell.</td>
</tr>
</tbody>
</table>

Availability: Tk 8.6.

**identify_element**(x, y)
Returns the element at position $x, y$.

Availability: Tk 8.6.

**index**(item)

Returns the integer index of item within its parent's list of children.

**insert**(parent, index, iid=None, **kw)

Creates a new item and returns the item identifier of the newly created item.

*parent* is the item ID of the parent item, or the empty string to create a new top-level item. *index* is an integer, or the value "end", specifying where in the list of parent's children to insert the new item. If *index* is less than or equal to zero, the new node is inserted at the beginning; if *index* is greater than or equal to the current number of children, it is inserted at the end. If *iid* is specified, it is used as the item identifier; *iid* must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

**item**(item, option=None, **kw)

Query or modify the options for the specified item.

If no options are given, a dict with options/values for the item is returned. If *option* is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by *kw*.

**move**(item, parent, index)
Moves *item* to position *index* in *parent*'s list of children.

It is illegal to move an item under one of its descendants. If *index* is less than or equal to zero, *item* is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If *item* was detached it is reattached.

**next**(item)

Returns the identifier of *item*'s next sibling, or " if *item* is the last child of its parent.

**parent**(item)

Returns the ID of the parent of *item*, or " if *item* is at the top level of the hierarchy.

**prev**(item)

Returns the identifier of *item*'s previous sibling, or " if *item* is the first child of its parent.

**reattach**(item, parent, index)

An alias for `Treeview.move()`.

**see**(item)

Ensure that *item* is visible.

Sets all of *item*'s ancestors open option to True, and scrolls the widget if necessary so that *item* is within the visible portion of the tree.

**selection**(selop=None, items=None)

If *selop* is not specified, returns selected items. Otherwise, it will act according to the following selection methods.
**selection_set**(items)

*items* becomes the new selection.

**selection_add**(items)

Add *items* to the selection.

**selection_remove**(items)

Remove *items* from the selection.

**selection_toggle**(items)

Toggle the selection state of each item in *items*.

**set**(item, column=None, value=None)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With three arguments, sets the value of given *column* in given *item* to the specified *value*.

**tag_bind**(tagname, sequence=None, callback=None)

Bind a callback for the given event *sequence* to the tag *tagname*. When an event is delivered to an item, the callbacks for each of the item's tags option are called.

**tag_configure**(tagname, option=None, **kw)

Query or modify the options for the specified *tagname*.

If *kw* is not given, returns a dict of the option settings for *tagname*. If *option* is specified, returns the value for that *option* for the specified *tagname*. Otherwise, sets the options to the corresponding values for the given *tagname*.

**tag_has**(tagname, item=None)

If *item* is specified, returns 1 or 0 depending on whether the
specified item has the given tagname. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

**xview(***args**)
Query or modify horizontal position of the treeview.

**yview(***args**)
Query or modify vertical position of the treeview.
25.2.10. Ttk Styling

Each widget in ttk is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class name of a widget, use the method Misc.winfo_class() (somewidget.winfo_class()).

See also:

Tcl'2004 conference presentation
This document explains how the theme engine works

class tkinter.ttk.Style
This class is used to manipulate the style database.

configure(style, query_opt=None, **kw)
Query or set the default value of the specified option(s) in style.

Each key in kw is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color:

code:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
ttk.Style().configure("TButton", padding=6, relief='flat', background="#ccc")

btn = ttk.Button(text="Sample")
btn.pack()

root.mainloop()
```

**map(style, query_opt=None, **kw)**

Query or sets dynamic values of the specified option(s) in style.

Each key in kw is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```python
import tkinter
from tkinter import ttk

root = tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active',
    background=[('pressed', '!disabled', 'black')]

colored_btn = ttk.Button(text="Test", style="C.

root.mainloop()
```

Note that the order of the (states, value) sequences for an
option does matter, if the order is changed to [('active', 'blue'), ('pressed', 'red')] in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

**lookup(style, option, state=None, default=None)**

Returns the value specified for *option* in *style*.

If *state* is specified, it is expected to be a sequence of one or more states. If the *default* argument is set, it is used as a fallback value in case no specification for *option* is found.

To check what font a Button uses by default:

```python
from tkinter import ttk

print(ttk.Style().lookup("TButton", "font"))
```

**layout(style, layoutspec=None)**

Define the widget layout for given *style*. If *layoutspec* is omitted, return the layout specification for given *style*.

*layoutspec*, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
style = ttk.Style()
style.layout("TMenubutton", [
    ("Menubutton.background", None),
    ("Menubutton.button", {"children":
        ["Menubutton.focus", {"children":
            ["Menubutton.padding", {"children":
                ["Menubutton.label", {"side": "
            }]
        }]
    }])
]),
]

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
```

element_create(elementname, etype, *args, **kw)

Create a new element in the current theme, of the given etype which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, args should contain the default image name followed by statespec/value pairs (this is the imagespec), and kw may have the following options:

- border=padding
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- height=height
  Specifies a minimum height for the element. If less than zero, the base image’s height is used as a
default.

- **padding=padding**
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

- **sticky=spec**
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

- **width=width**
  Specifies a minimum width for the element. If less than zero, the base image's width is used as a default.

If “from” is used as the value of etype, `element_create()` will clone an existing element. `args` is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. `kw` is discarded.

**element_names()**
Returns the list of elements defined in the current theme.

**element_options(elementname)**
Returns the list of elementname's options.

**theme_create(themename, parent=None, settings=None)**
Create a new theme.

It is an error if themename already exists. If parent is specified,
the new theme will inherit styles, elements and layouts from the parent theme. If settings are present they are expected to have the same syntax used for theme_settings().

**theme_settings(themename, settings)**
Temporarily sets the current theme to themename, apply specified settings and then restore the previous theme.

Each key in settings is a style and each value may contain the keys ‘configure’, ‘map’, ‘layout’ and ‘element create’ and they are expected to have the same format as specified by the methods ```Style.configure()```, ```Style.map()```, ```Style.layout()``` and ```Style.element_create()``` respectively.

As an example, let's change the Combobox for the default theme a bit:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": ["active", "green2"],
            "!disabled": "green4",
            "fieldbackground": ["!disabled", "green3"],
            "foreground": ["focus", "OliveDrab1"],
            "!disabled": "OliveDrab2"
        }
    }
}
```
combo = ttk.Comboxbox().pack()
root.mainloop()

theme_names()
Returns a list of all known themes.

theme_use(themename=None)
If themename is not given, returns the theme in use. Otherwise, sets the current theme to themename, refreshes all widgets and emits a <<ThemeChanged>> event.

25.2.10.1. Layouts

A layout can be just None, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:

- side: whichside
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- sticky: nswe
  Specifies where the element is placed inside its allocated parcel.

- unit: 0 or 1
  If set to 1, causes the element and all of its descendants
to be treated as a single element for the purposes of `Widget.identify()` et al. It's used for things like scrollbar thumbs with grips.

- children: [sublayout... ]
  Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a `Layout`.
25.3. `tkinter.tix` — Extension widgets for Tk

The `tkinter.tix` (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The `tkinter.tix` library provides most of the commonly needed widgets that are missing from standard Tk: `HList`, `ComboBox`, `Control` (a.k.a. SpinBox) and an assortment of scrollable widgets. `tkinter.tix` also includes many more widgets that are generally useful in a wide range of applications: `NoteBook`, `FileEntry`, `PanedWindow`, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

On-line version of the programmer’s reference material.

**Tix Development Applications**
Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
25.3.1. Using Tix

```
class tkinter.tix.Tk(screenName=None, baseName=None, className='Tix')
```

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the `tkinter.tix` module subclasses the classes in the `tkinter`. The former imports the latter, so to use `tkinter.tix` with Tkinter, all you need to do is to import one module. In general, you can just import `tkinter.tix`, and replace the toplevel call to `tkinter.Tk` with `tix.Tk`:

```python
from tkinter import tix
from tkinter.constants import *
root = tix.Tk()
```

To use `tkinter.tix`, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```python
from tkinter import tix
root = tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (`tix8183.dll` or `libtix8183.so`) in the same directory that contains your Tk dynamic object library (`tk8183.dll` or `libtk8183.so`). The directory with the dynamic
object library should also have a file called `pkgIndex.tcl` (case sensitive), which contains the line:

```tcl
package ifneeded Tix 8.1 [list load "[file join $dir tix8183.dll]"
```
25.3.2. Tix Widgets

Tix introduces over 40 widget classes to the tkinter repertoire.

25.3.2.1. Basic Widgets

class tkinter.tix.Balloon
A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

class tkinter.tix.ButtonBox
The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

class tkinter.tix.ComboBox
The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

class tkinter.tix.Control
The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

class tkinter.tix.LabelEntry
The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used be used to simplify the creation of “entry-form” type of interface.
**class tkinter.tix.LabelFrame**

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

**class tkinter.tix.Meter**

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

**class tkinter.tix.OptionMenu**

The OptionMenu creates a menu button of options.

**class tkinter.tix.PopupMenu**

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

**class tkinter.tix.Select**

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

**class tkinter.tix.StdButtonBox**

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

### 25.3.2.2. File Selectors

**class tkinter.tix.DirList**

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the
directories displayed in the list or change to another directory.

**class tkinter.tix.DirTree**

The DirTree widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class tkinter.tix.DirSelectDialog**

The DirSelectDialog widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

**class tkinter.tix.DirSelectBox**

The DirSelectBox is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class tkinter.tix.ExFileSelectBox**

The ExFileSelectBox widget is usually embedded in a tixExFileSelectDialog widget. It provides an convenient method for the user to select files. The style of the ExFileSelectBox widget is very similar to the standard file dialog on MS Windows 3.1.

**class tkinter.tix.FileSelectBox**

The FileSelectBox is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class tkinter.tix.FileEntry**

The FileEntry widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the
button widget that sits next to the entry, which will bring up a file selection dialog.

25.3.2.3. Hierarchical ListBox

class tkinter.tix.HList

The HList widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

class tkinter.tix.CheckList

The CheckList widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

class tkinter.tix.Tree

The Tree widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

25.3.2.4. Tabular ListBox

class tkinter.tix.TList

The TList widget can be used to display data in a tabular format. The list entries of a TList widget are similar to the entries in the Tk listbox widget. The main differences are (1) the TList widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.
25.3.2.5. Manager Widgets

*class tkinter.tix.PanedWindow*

The `PanedWindow` widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

*class tkinter.tix.ListNoteBook*

The `ListNoteBook` widget is very similar to the `TixNoteBook` widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the `hlist` subwidget.

*class tkinter.tix.NoteBook*

The `NoteBook` widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the `NoteBook` widget.

25.3.2.6. Image Types

The `tkinter.tix` module adds:

- `pixmap` capabilities to all `tkinter.tix` and `tkinter` widgets to create color images from XPM files.
- `Compound` image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from
left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

25.3.2.7. Miscellaneous Widgets

class tkinter.tix.**InputOnly**

The **InputOnly** widgets are to accept inputs from the user, which can be done with the **bind** command (Unix only).

25.3.2.8. Form Geometry Manager

In addition, **tkinter.tix** augments **tkinter** by providing:

**class tkinter.tix.****Form**

The **Form** geometry manager based on attachment rules for all Tk widgets.
25.3.3. Tix Commands

class tkinter.tix.tixCommand

    The tix commands provide access to miscellaneous elements of Tix's internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

    To view the current settings, the common usage is:

        from tkinter import tix
        root = tix.Tk()
        print(root.tix_configure())

    tixCommand.tix_configure(cnf=None, **kw)
        Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

    tixCommand.tix_cget(option)
        Returns the current value of the configuration option given by option. Option may be any of the configuration options.

    tixCommand.tix_getbitmap(name)
        Locates a bitmap file of the name name.xpm or name in one of the
bitmap directories (see the `tix_addbitmapdir()` method). By using `tix_getbitmap()`, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character `@`. The returned value can be used to configure the `bitmap` option of the Tk and Tix widgets.

*tixCommand.**tix_addbitmapdir**(directory)

Tix maintains a list of directories under which the `tix_getimage()` and `tix_getbitmap()` methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The `tix_addbitmapdir()` method adds `directory` into this list. By using this method, the image files of an applications can also be located using the `tix_getimage()` or `tix_getbitmap()` method.

*tixCommand.**tix_filedialog**(dlgclass)

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to `tix_filedialog()`. An optional `dlgclass` parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are `tix`, `FileSelectDialog` or `tixExFileSelectDialog`.

*tixCommand.**tix_getimage**(self, name)

Locates an image file of the name `name.xpm`, `name.xbm` or `name.ppm` in one of the bitmap directories (see the `tix_addbitmapdir()` method above). If more than one file with the same name (but different extensions) exist, then the image type
is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are chosen on color displays. By using \texttt{tix\_getimage()}, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the \texttt{image} option of the Tk and Tix widgets.

\texttt{tixCommand.\texttt{tix\_option\_get}(name)}

Gets the options maintained by the Tix scheme mechanism.

\texttt{tixCommand.\texttt{tix\_resetoptions}(newScheme, newFontSet[, newScmPrio])}

Resets the scheme and fontset of the Tix application to \texttt{newScheme} and \texttt{newFontSet}, respectively. This affects only those widgets created after this call. Therefore, it is best to call the \texttt{resetoptions} method before the creation of any widgets in a Tix application.

The optional parameter \texttt{newScmPrio} can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and inited, it is not possible to reset the color schemes and font sets using the \texttt{tix\_config()} method. Instead, the \texttt{tix\_resetoptions()} method must be used.
25.4. `tkinter.scrolledtext` — Scrolled Text Widget

*Platforms:* Tk

The `tkinter.scrolledtext` module provides a class of the same name which implements a basic text widget which has a vertical scrollbar configured to do the “right thing.” Using the `ScrolledText` class is a lot easier than setting up a text widget and scroll bar directly. The constructor is the same as that of the `tkinter.Text` class.

The text widget and scrollbar are packed together in a Frame, and the methods of the Grid and Pack geometry managers are acquired from the Frame object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

- `ScrolledText.frame`
  - The frame which surrounds the text and scroll bar widgets.

- `ScrolledText.vbar`
  - The scroll bar widget.
25.5. IDLE

IDLE is the Python IDE built with the `tkinter` GUI toolkit.

IDLE has the following features:

- coded in 100% pure Python, using the `tkinter` GUI toolkit
- cross-platform: works on Windows and Unix
- multi-window text editor with multiple undo, Python colorizing and many other features, e.g. smart indent and call tips
- Python shell window (a.k.a. interactive interpreter)
- debugger (not complete, but you can set breakpoints, view and step)
25.5.1. Menus

25.5.1.1. File menu

New file
   create a new file editing window
Open...
   open an existing file
Open module...
   open an existing module (searches sys.path)
Class browser
   show classes and methods in current file
Path browser
   show sys.path directories, modules, classes and methods
Save
   save current window to the associated file (unsaved windows have a * before and after the window title)
Save As...
   save current window to new file, which becomes the associated file
Save Copy As...
   save current window to different file without changing the associated file
Close
   close current window (asks to save if unsaved)
Exit
   close all windows and quit IDLE (asks to save if unsaved)

25.5.1.2. Edit menu
Undo
  Undo last change to current window (max 1000 changes)
Redo
  Redo last undone change to current window
Cut
  Copy selection into system-wide clipboard; then delete selection
Copy
  Copy selection into system-wide clipboard
Paste
  Insert system-wide clipboard into window
Select All
  Select the entire contents of the edit buffer
Find...
  Open a search dialog box with many options
Find again
  Repeat last search
Find selection
  Search for the string in the selection
Find in Files...
  Open a search dialog box for searching files
Replace...
  Open a search-and-replace dialog box
Go to line
  Ask for a line number and show that line
Indent region
  Shift selected lines right 4 spaces
Dedent region
  Shift selected lines left 4 spaces
Comment out region
Insert ## in front of selected lines

Uncomment region

Remove leading # or ## from selected lines

Tabify region

Turns leading stretches of spaces into tabs

Untabify region

Turn all tabs into the right number of spaces

Expand word

Expand the word you have typed to match another word in the same buffer; repeat to get a different expansion

Format Paragraph

Reformat the current blank-line-separated paragraph

Import module

Import or reload the current module

Run script

Execute the current file in the __main__ namespace

25.5.1.3. Windows menu

Zoom Height

toggles the window between normal size (24x80) and maximum height.

The rest of this menu lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

25.5.1.4. Debug menu

- in the Python Shell window only

Go to file/line
Look around the insert point for a filename and line number, open the file, and show the line. Useful to view the source lines referenced in an exception traceback.

Debugger
  Run commands in the shell under the debugger.

Stack viewer
  Show the stack traceback of the last exception.

Auto-open Stack Viewer
  Open stack viewer on traceback.

25.5.1.5. Edit context menu

- Right-click in Edit window (Control-click on OS X)

Cut
  Copy selection into system-wide clipboard; then delete selection

Copy
  Copy selection into system-wide clipboard

Paste
  Insert system-wide clipboard into window

Set Breakpoint
  Sets a breakpoint. Breakpoints are only enabled when the debugger is open.

Clear Breakpoint
  Clears the breakpoint on that line.

25.5.1.6. Shell context menu

- Right-click in Python Shell window (Control-click on OS X)

Cut
Copy selection into system-wide clipboard; then delete selection

Copy
  Copy selection into system-wide clipboard

Paste
  Insert system-wide clipboard into window

Go to file/line
  Same as in Debug menu.
25.5.2. Basic editing and navigation

- Backspace deletes to the left; Del deletes to the right
- Arrow keys and Page Up/Page Down to move around
- Home/End go to begin/end of line
- C-Home/C-End go to begin/end of file
- Some Emacs bindings may also work, including C-B, C-P, C-A, C-E, C-D, C-L

25.5.2.1. Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, Backspace deletes up to 4 spaces if they are there. Tab inserts 1-4 spaces (in the Python Shell window one tab). See also the indent/dedent region commands in the edit menu.

25.5.2.2. Python Shell window

- C-C interrupts executing command
- C-D sends end-of-file; closes window if typed at a >>>> prompt
- Alt-p retrieves previous command matching what you have typed
- Alt-n retrieves next
- Return while on any previous command retrieves that command
- Alt-/ (Expand word) is also useful here
25.5.3. Syntax colors

The coloring is applied in a background “thread,” so you may occasionally see uncolorized text. To change the color scheme, edit the [Colors] section in config.txt.

Python syntax colors:
  Keywords
    orange
  Strings
    green
  Comments
    red
  Definitions
    blue

Shell colors:
  Console output
    brown
  stdout
    blue
  stderr
    dark green
  stdin
    black
25.5.4. Startup

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables IDLESTARTUP or PYTHONSTARTUP. Idle first checks for IDLESTARTUP; if IDLESTARTUP is present the file referenced is run. If IDLESTARTUP is not present, Idle checks for PYTHONSTARTUP. Files referenced by these environment variables are convenient places to store functions that are used frequently from the Idle shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is .Idle.py and is looked for in the user's home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from Idle's Python shell.

25.5.4.1. Command line usage

```
idle.py [-c command] [-d] [-e] [-s] [-t title] [arg]
```

- `-c command` run this command
- `-d` enable debugger
- `-e` edit mode; arguments are files to be edited
- `-s` run `$IDLESTARTUP` or `$PYTHONSTARTUP` first
- `-t title` set title of shell window

If there are arguments:

1. If `-e` is used, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.
2. Otherwise, if `-c` is used, all arguments are placed in `sys.argv[1:...]`, with `sys.argv[0]` set to `-c`.

3. Otherwise, if neither `-e` nor `-c` is used, the first argument is a script which is executed with the remaining arguments in `sys.argv[1:]` and `sys.argv[0]` set to the script name. If the script name is `'-'`, no script is executed but an interactive Python session is started; the arguments are still available in `sys.argv`. 
25.6. Other Graphical User Interface Packages

Major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits are available for Python:

See also:

**PyGObject**
provides introspection bindings for C libraries using `GObject`. One of these libraries is the GTK+ 3 widget set. GTK+ comes with many more widgets than Tkinter provides. An online Python GTK+ 3 Tutorial is available.

**PyGTK** provides bindings for an older version of the library, GTK+ 2. It provides an object oriented interface that is slightly higher level than the C one. There are also bindings to GNOME. An online tutorial is available.

**PyQt**
PyQt is a `sip`-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. `sip` is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python. The `PyQt3` bindings have a book, GUI Programming with Python: QT Edition by Boudewijn Rempt. The `PyQt4` bindings also have a book, Rapid GUI Programming with Python and Qt, by Mark Summerfield.

**PySide**
is a newer binding to the Qt toolkit, provided by Nokia. Compared to PyQt, its licensing scheme is friendlier to non-open source applications.
wxPython

wxPython is a cross-platform GUI toolkit for Python that is built around the popular wxWidgets (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules. wxPython has a book, wxPython in Action, by Noel Rappin and Robin Dunn.

PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the GUI Programming page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
The Python Standard Library
26. Development Tools

The modules described in this chapter help you write software. For example, the `pydoc` module takes a module and generates documentation based on the module’s contents. The `doctest` and `unittest` modules contain frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. `2to3` can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **26.1. pydoc** — Documentation generator and online help system
- **26.2. doctest** — Test interactive Python examples
  - 26.2.1. Simple Usage: Checking Examples in Docstrings
  - 26.2.2. Simple Usage: Checking Examples in a Text File
  - 26.2.3. How It Works
    - 26.2.3.1. Which Docstrings Are Examined?
    - 26.2.3.2. How are Docstring Examples Recognized?
    - 26.2.3.3. What’s the Execution Context?
    - 26.2.3.4. What About Exceptions?
    - 26.2.3.5. Option Flags
    - 26.2.3.6. Directives
    - 26.2.3.7. Warnings
  - 26.2.4. Basic API
  - 26.2.5. Unitest API
  - 26.2.6. Advanced API
    - 26.2.6.1. DocTest Objects
    - 26.2.6.2. Example Objects
    - 26.2.6.3. DocTestFinder objects
    - 26.2.6.4. DocTestParser objects
    - 26.2.6.5. DocTestRunner objects
26.2.6.6. OutputChecker objects

- 26.2.7. Debugging
- 26.2.8. Soapbox

- 26.3. unittest — Unit testing framework
  - 26.3.1. Basic example
  - 26.3.2. Command-Line Interface
    - 26.3.2.1. Command-line options
  - 26.3.3. Test Discovery
  - 26.3.4. Organizing test code
  - 26.3.5. Re-using old test code
  - 26.3.6. Skipping tests and expected failures
  - 26.3.7. Classes and functions
    - 26.3.7.1. Test cases
      - 26.3.7.1.1. Deprecated aliases
    - 26.3.7.2. Grouping tests
    - 26.3.7.3. Loading and running tests
      - 26.3.7.3.1. load_tests Protocol
  - 26.3.8. Class and Module Fixtures
    - 26.3.8.1. setUpClass and tearDownClass
    - 26.3.8.2. setUpModule and tearDownModule
  - 26.3.9. Signal Handling

- 26.4. unittest.mock — mock object library
  - 26.4.1. Quick Guide
  - 26.4.2. The Mock Class
    - 26.4.2.1. Calling
    - 26.4.2.2. Deleting Attributes
    - 26.4.2.3. Mock names and the name attribute
    - 26.4.2.4. Attaching Mocks as Attributes
  - 26.4.3. The patchers
    - 26.4.3.1. patch
    - 26.4.3.2. patch.object
    - 26.4.3.3. patch.dict
    - 26.4.3.4. patch.multiple
    - 26.4.3.5. patch methods: start and stop
- 26.4.3.6. TEST_PREFIX
- 26.4.3.7. Nesting Patch Decorators
- 26.4.3.8. Where to patch
- 26.4.3.9. Patching Descriptors and Proxy Objects
  - 26.4.4. MagicMock and magic method support
    - 26.4.4.1. Mocking Magic Methods
    - 26.4.4.2. Magic Mock
  - 26.4.5. Helpers
    - 26.4.5.1. sentinel
    - 26.4.5.2. DEFAULT
    - 26.4.5.3. call
    - 26.4.5.4. create_autospec
    - 26.4.5.5. ANY
    - 26.4.5.6. FILTER_DIR
    - 26.4.5.7. mock_open
    - 26.4.5.8. Autospecing
- 26.5. unittest.mock — getting started
  - 26.5.1. Using Mock
    - 26.5.1.1. Mock Patching Methods
    - 26.5.1.2. Mock for Method Calls on an Object
    - 26.5.1.3. Mocking Classes

26.1. pydoc — Documentation generator and online help system

Source code: Lib/pydoc.py

The pydoc module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

The built-in function help() invokes the online help system in the interactive interpreter, which uses pydoc to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running pydoc as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the sys module, in a style similar to the manual pages shown by the Unix man command. The argument to pydoc can be the name of a function, module, or package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to pydoc looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

Note: In order to find objects and their documentation, pydoc imports the module(s) to be documented. Therefore, any code on
module level will be executed on that occasion. Use an if __name__ == '__main__': guard to only execute code when a file is invoked as a script and not just imported.

Specifying a -w flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a -k flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix man command. The synopsis line of a module is the first line of its documentation string.

You can also use pydoc to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. pydoc -p 1234 will start a HTTP server on port 1234, allowing you to browse the documentation at http://localhost:1234/ in your preferred Web browser. Specifying 0 as the port number will select an arbitrary unused port.

pydoc -g will start the server and additionally bring up a small tkinter-based graphical interface to help you search for documentation pages. The -g option is deprecated, since the server can now be controlled directly from HTTP clients.

pydoc -b will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can Get help on an individual item, Search all modules with a keyword in their synopsis line, and go to the Module index, Topics and Keywords pages.

When pydoc generates documentation, it uses the current environment and path to locate modules. Thus, invoking pydoc spam
documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `http://docs.python.org/X.Y/library/` where `X` and `Y` are the major and minor version numbers of the Python interpreter. This can be overridden by setting the `PYTHONDOCS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

*Changed in version 3.2:* Added the `-b` option, deprecated the `-g` option.
26.2. **doctest** — Test interactive Python examples

The **doctest** module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
"""
This is the "example" module.

The example module supplies one function, factorial().

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >
    
    >>> [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
```
>>> factorial(30)
2652528598121910586363084800000000
>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must
>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer
>>> factorial(30.0)
2652528598121910586363084800000000

It must also not be ridiculously large:
>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

"""

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result
if __name__ == "__main__":
    import doctest
    doctest.testmod()

If you run `example.py` directly from the command line, `doctest` works its magic:

```
$ python example.py
$ 
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
      ... 
    OverflowError: n too large
ok
```
2 items passed all tests:
  1 tests in __main__
  8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$

That's all you need to know to start making productive use of doctest! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file Lib/test/test_doctest.py.
26.2.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module M with:

```python
if __name__ == '__main__':
    import doctest
doctest.testmod()
```

doctest then examines docstrings in module M.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```bash
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures`, where N is the number of examples that failed.

Run it with the `-v` switch instead:

```bash
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing
-v or not has no effect).

There is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```python
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section `Basic API`. 
26.2.2. Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn’t need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
=================================

Using ``factorial``
------------------

This is an example text file in reStructuredText for ``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the
error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with `testmod()`, `testfile()` won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section `Basic API` for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

There is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section `Basic API`. 
26.2.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

26.2.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if M.__test__ exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from M.__test__ are searched, and strings are treated as if they were docstrings. In output, a key K in M.__test__ appears with name

\[<\text{name of M}>._\text{test}.K\]

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

26.2.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn’t trying to do an exact emulation of any specific Python shell.
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
    ...     print("yes")
    ... else:
    ...     print("no")
    ...     print("NO")
    ...     print("NO!!!")
...
no
NO
NO!!!

Any expected output must immediately follow the final `>>>` or `...` line containing the code, and the expected output (if any) extends to the next `>>>` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output are expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the `NORMALIZE_WHITESPACE` option or `directive` is in effect. Alternatively, the test can be rewritten to capture the output and
compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom `DocTestParser` class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

  ```
  >>> def f(x):
  ...     r'''Backslashes in a raw docstring: m
  >>> print(f.__doc__)
  Backslashes in a raw docstring: m
  ```

  Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

  ```
  >>> def f(x):
  ...     '''Backslashes in a raw docstring: m
  >>> print(f.__doc__)
  Backslashes in a raw docstring: m
  ```

- The starting column doesn’t matter:

  ```
  >>> assert "Easy!"
  >>> import math
  ```
>>> math.floor(1.9)
1

and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

26.2.3.3. What’s the Execution Context?

By default, each time doctest finds a docstring to test, it uses a shallow copy of M's globals, so that running tests doesn't change the module's real globals, and so that one test in M can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing globs=your_dict to testmod() or testfile() instead.

26.2.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:

>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```python
>>> raise ValueError('multi
 line
detail')
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: multi
 line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception’s type and detail, and the rest are ignored.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably
better as:

```python
>>> raise ValueError('multi
   line
   detail')
Traceback (most recent call last):
 ...  
ValueError: multi
   line
   detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's `ELLIPSIS` option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.

- When the `IGNORE_EXCEPTION_DETAIL` doctest option is specified, everything following the leftmost colon and any module
information in the exception name is ignored.

- The interactive shell omits the traceback header line for some `SyntaxError`s. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.

- For some `SyntaxError`s, Python displays the character position of the syntax error, using a `^` marker:

```python
>>> 1 1
   File "<stdin>", line 1
   1 1
   ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```python
>>> 1 1
Traceback (most recent call last):
   File "<stdin>", line 1
   1 1
   ^
SyntaxError: invalid syntax
```

26.2.3.5. Option Flags

A number of option flags control various aspects of doctest’s behavior.
Symbolic names for the flags are supplied as module constants, which can be or'ed together and passed to various functions. The names can also be used in doctest directives.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:

**doctest.**\texttt{DONT\_ACCEPT\_TRUE\_FOR\_1}

By default, if an expected output block contains just 1, an actual output block containing just 1 or just True is considered to be a match, and similarly for 0 versus False. When \texttt{DONT\_ACCEPT\_TRUE\_FOR\_1} is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest.**\texttt{DONT\_ACCEPT\_BLANKLINE}

By default, if an expected output block contains a line containing only the string \texttt{<BLANKLINE>}, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When \texttt{DONT\_ACCEPT\_BLANKLINE} is specified, this substitution is not allowed.

**doctest.**\texttt{NORMALIZE\_WHITESPACE}

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. \texttt{NORMALIZE\_WHITESPACE} is especially useful when a line of
expected output is very long, and you want to wrap it across multiple lines in your source.

doctest. **ELLIPSIS**

When specified, an ellipsis marker (\ldots) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that \.* is prone to in regular expressions.

doctest. **IGNORE_EXCEPTION_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting \*ValueError: 42\* will pass if the actual exception raised is \*ValueError: 3*14\*, but will fail, e.g., if TypeError is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```
>>> raise CustomError('message')
Traceback (most recent call last):
  CustomError: message

>>> raise CustomError('message')
Traceback (most recent call last):
  my_module.CustomError: message
```

Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether
or not the module details are printed as part of the exception name. Using `IGNORE_EXCEPTION_DETAIL` and the details from Python 2.3 is also the only clear way to write a doctest that doesn't care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support doctest directives and ignore them as irrelevant comments). For example:

```python
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say “does not” instead of “doesn't”.

*Changed in version 3.2:* `IGNORE_EXCEPTION_DETAIL` now also ignores any information relating to the module containing the exception under test.

doctest.SKIP

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out” examples.

doctest.COMPARISON_FLAGS

A bitmask or’ing together all the comparison flags above.
The second group of options controls how test failures are reported:

**doctest.REPORT_UDIFF**
When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

**doctest.REPORT_CDIFF**
When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

**doctest.REPORT_NDIFF**
When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

**doctest.REPORT_ONLY_FIRST_FAILURE**
When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When `REPORT_ONLY_FIRST_FAILURE` is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

**doctest.REPORTING_FLAGS**
A bitmask or'ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn’t useful unless you intend to extend `doctest` internals via subclassing:
**doctest**.\texttt{register\_optionflag(name)}

Create a new option flag with a given name, and return the new flag's integer value. \texttt{register\_optionflag()} can be used when subclassing \texttt{OutputChecker} or \texttt{DocTestRunner} to create new options that are supported by your subclasses. \texttt{register\_optionflag()} should always be called using the following idiom:

\begin{verbatim}
MY\_FLAG = register\_optionflag('MY\_FLAG')
\end{verbatim}

### 26.2.3.6. Directives

Doctest directives may be used to modify the \texttt{option flags} for an individual example. Doctest directives are special Python comments following an example's source code:

\begin{verbatim}
directive ::= "#" "doctest:" directive\
directive\_options ::= directive\_option ("," directive\_option)\
directive\_option ::= on\_or\_off directive\_option\_name\
on\_or\_off ::= "+" | "-"
directive\_option\_name ::= "DONT\_ACCEPT\_BLANKLINE"
\end{verbatim}

Whitespace is not allowed between the \texttt{+} or \texttt{-} and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use \texttt{+} to enable the named behavior, or \texttt{-} to disable it.

For example, this test passes:
Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```python
>>> print(list(range(20))) # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
  10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```python
>>> print(list(range(20))) # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

If multiple directive comments are used for a single example, then they are combined:

```python
>>> print(list(range(20))) # doctest: +ELLIPSIS # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```python
>>> print(list(range(5)) + list(range(10, 20)) + list(... # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39]
```
Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

26.2.3.7. Warnings

doctest is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a dict, Python doesn't guarantee that the key-value pairs will be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = sorted(foo().items())
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.
Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0) # certain to fail some of the time
7948648
>>> class C: pass
>>> C() # the default repr() for instances embeds
<__main__.C instance at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:

```python
>>> C() #doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```python
>>> 1./7  # risky
0.14285714285714285
>>> print(1./7) # safer
0.142857142857
>>> print(round(1./7, 6)) # much safer
0.142857
```

Numbers of the form \(I/2.**J\) are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```python
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.
26.2.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections *Simple Usage: Checking Examples in Docstrings* and *Simple Usage: Checking Examples in a Text File*.

```python
doctest.testfile(filename, module_relative=True, name=None, package=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, parser=DocTestParser(), encoding=None)
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.
Optional argument *name* gives the name of the test; by default, or if None, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is False.

Optional argument * globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if None, a new empty dict is used.

Optional argument * extraglobs* gives a dict merged into the globals used to execute examples. This works like `dict.update()` : if `globs` and `extraglobs` have a common key, the associated value in `extraglobs` appears in the combined dict. By default, or if None, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an `extraglobs` dict mapping the generic name to the subclass to be tested.

Optional argument * verbose* prints lots of stuff if true, and prints only failures if false; by default, or if None, it's true if and only if `-v` is in `sys.argv`.

Optional argument * report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).
Optional argument *optionflags* or’s together option flags. See section *Option Flags*.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

```
import doctest

doctest.testmod(m=None, name=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, exclude_empty=False)
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is None), starting with *m.__doc__*.

Also test examples reachable from dict *m.__test__*, if it exists and is not None. *m.__test__* maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (*failure_count*, *test_count*).
Optional argument *name* gives the name of the module; by default, or if None, `m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The *exclude_empty* argument to the newer `DocTestFinder` constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise_on_error*, and *globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

There's also a function to run the doctests associated with a single object. This function is provided for backward compatibility. There are no plans to deprecate it, but it's rarely useful:

```python
doctest.run_docstring_examples(f, globs, verbose=False, name="NoName", compileflags=None, optionflags=0)
```

Test examples associated with object `f`; for example, `f` may be a module, function, or class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of
an example failure.

Optional argument `compileflags` gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in `globs`.

Optional argument `optionflags` works as for function `testfile()` above.
26.2.5. Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

```python
doctest.DocFileSuite(*paths, module_relative=True, package=None, setUp=None, tearDown=None, globs=None, optionflags=0, parser=DocTestParser(), encoding=None)
```

Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.
Options may be provided as keyword arguments:

Optional argument `module_relative` specifies how the filenames in `paths` should be interpreted:

- If `module_relative` is `True` (the default), then each filename in `paths` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then each filename in `paths` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in `paths`. If no package is specified, then the calling module’s directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `setUp` specifies a set-up function for the test suite. This is called before running the tests in each file. The `setUp` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The `tearDown` function can access the test globals as the `globs` attribute of the test passed.
Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `optionflags` specifies the default doctest options for the tests, created by or-ing together individual option flags. See section `Option Flags`. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

```
import doctest

DocTestSuite(module=None, globs=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None)
```

Convert doctest tests for a module to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument `module` provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not
specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above.

This function uses the same search technique as *testmod()*.

**Note:** Unlike *testmod()* and *DocTestFinder*, this function raises a *ValueError* if *module* contains no docstrings. You can prevent this error by passing a *DocTestFinder* instance as the *test_finder* argument with its *exclude_empty* keyword argument set to False:

```python
>>> finder = doctest.DocTestFinder(exclude_empty=False)
>>> suite = doctest.DocTestSuite(test_finder=finder)
```

Under the covers, *DocTestSuite()* creates a unittest.TestSuite out of doctest.DocTestCase instances, and DocTestCase is a subclass of unittest.TestCase. DocTestCase isn't documented here (it's an internal detail), but
studying its code can answer questions about the exact details of unittest integration.

Similarly, DocFileSuite() creates a unittest.TestSuite out of doctest.DocFileCase instances, and DocFileCase is a subclass of DocTestCase.

So both ways of creating a unittest.TestSuite run instances of DocTestCase. This is important for a subtle reason: when you run doctest functions yourself, you can control the doctest options in use directly, by passing option flags to doctest functions. However, if you're writing a unittest framework, unittest ultimately controls when and how tests get run. The framework author typically wants to control doctest reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through unittest to doctest test runners.

For this reason, doctest also supports a notion of doctest reporting flags specific to unittest support, via this function:

doctest.set_unittest_reportflags(flags)

Set the doctest reporting flags to use.

Argument flags or's together option flags. See section Option Flags. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module unittest: the runTest() method of DocTestCase looks at the option flags specified for the test case when the DocTestCase instance was constructed. If no reporting flags were specified (which is the typical and expected case), doctest's unittest reporting flags are or'ed into the option flags, and the
option flags so augmented are passed to the `DocTestRunner` instance created to run the doctest. If any reporting flags were specified when the `DocTestTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the function was called is returned by the function.
26.2.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python *statement*, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a **DocTestParser** to create a **DocTest** from every docstring that contains interactive examples.
- **DocTestParser**: Creates a **DocTest** object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a **DocTest**, and uses an **OutputChecker** to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
26.2.6.1. DocTest Objects

```python
class doctest.DocTest(examples, globs, name, filename, lineno, docstring)
```

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

DocTest defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**examples**
A list of Example objects encoding the individual interactive Python examples that should be run by this test.

**globs**
The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in globs after the test is run.

**name**
A string name identifying the DocTest. Typically, this is the
name of the object or file that the test was extracted from.

**filename**
The name of the file that this `DocTest` was extracted from; or None if the filename is unknown, or if the `DocTest` was not extracted from a file.

**lineno**
The line number within `filename` where this `DocTest` begins, or None if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**
The string that the test was extracted from, or ‘None’ if the string is unavailable, or if the test was not extracted from a string.

### 26.2.6.2. Example Objects

```python
class doctest.Example(source, want, exc_msg=None, lineno=0, indent=0, options=None)
```
A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

**Example** defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**
A string containing the example’s source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.
want
The expected output from running the example's source code (either from stdout, or a traceback in case of exception). `want` ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

exc_msg
The exception message generated by the example, if the example is expected to generate an exception; or None if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. `exc_msg` ends with a newline unless it's None. The constructor adds a newline if needed.

lineno
The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

indent
The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

options
A dictionary mapping from option flags to True or False, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the `DocTestRunner`'s `optionflags`). By default, no options are set.
26.2.6.3. DocTestFinder objects

class doctest.DocTestFinder(verbos

A processing class used to extract the DocTests that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTests can currently be extracted from the following object types: modules, functions, classes, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

DocTestFinder defines the following method:

find(obj[, name][, module][, globs][, extraglobs])

Return a list of the DocTests that are defined by obj’s docstring, or by any of its contained objects’ docstrings.

The optional argument name specifies the object’s name; this
name will be used to construct names for the returned DocTests. If name is not specified, then obj.__name__ is used.

The optional parameter module is the module that contains the given object. If the module is not specified or is None, then the test finder will attempt to automatically determine the correct module. The object's module is used:

- As a default namespace, if globs is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than module are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If module is False, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if module is False, or is None but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each DocTest is formed by combining globs and extraglobs (bindings in extraglobs override bindings in globs). A new shallow copy of the globals dictionary is created for each DocTest. If globs is not specified, then it defaults to the module's __dict__, if specified, or {} otherwise. If extraglobs is not specified, then it defaults to {}.

26.2.6.4. DocTestParser objects
**class doctest.**DocTestParser

A processing class used to extract interactive examples from a string, and use them to create a **DocTest** object.

**DocTestParser** defines the following methods:

**get_doctest**(string, globs, name, filename, lineno)

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

*globs, name, filename, and lineno* are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples**(string, name='<string>')

Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse**(string, name='<string>')

Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**26.2.6.5. DocTestRunner objects**

**class doctest.**DocTestRunner**(checker=None, verbose=None, optionflags=0)**

A processing class used to execute and verify the interactive
examples in a DocTest.

The comparison between expected outputs and actual outputs is done by an OutputChecker. This comparison may be customized with a number of option flags; see section Option Flags for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of OutputChecker to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to TestRunner.run(); this function will be called with strings that should be displayed. It defaults to sys.stdout.write. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods report_start(), report_success(), report_unexpected_exception(), and report_failure().

The optional keyword argument checker specifies the OutputChecker object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument verbose controls the DocTestRunner’s verbosity. If verbose is True, then information is printed about each example, as it is run. If verbose is False, then only failures are printed. If verbose is unspecified, or None, then verbose output is used iff the command-line switch -v is used.

The optional keyword argument optionflags can be used to control
how the test runner compares expected output to actual output, and how it displays failures. For more information, see section *Option Flags*.

**DocTestParser** defines the following methods:

**report_start**(out, test, example)
Report that the test runner is about to process the given example. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test *containing example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_success**(out, test, example, got)
Report that the given example ran successfully. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_failure**(out, test, example, got)
Report that the given example failed. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. 
out is the output function that was passed to DocTestRunner.run().

report_unexpected_exception(out, test, example, exc_info)
Report that the given example raised an unexpected exception. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. exc_info is a tuple containing information about the unexpected exception (as returned by sys.exc_info()). test is the test containing example. out is the output function that was passed to DocTestRunner.run().

run(test, compileflags=None, out=None, clear_globs=True)
Run the examples in test (a DocTest object), and display the results using the writer function out.

The examples are run in the namespace test.globs. If clear_globs is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use clear_globs=False.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to globs.

The output of each example is checked using the DocTestRunner's output checker, and the results are
formatted by the DocTestRunner.report_*() methods.

**summarize**(verbose=None)

Print a summary of all the test cases that have been run by this DocTestRunner, and return a *named tuple* `TestResults(failed, attempted)`.

The optional `verbose` argument controls how detailed the summary is. If the verbosity is not specified, then the `DocTestRunner`'s verbosity is used.

### 26.2.6.6. OutputChecker objects

class doctest.**OutputChecker**

A class used to check the whether the actual output from a doctest example matches the expected output. *OutputChecker* defines two methods: `check_output()`, which compares a given pair of outputs, and returns true if they match; and `output_difference()`, which returns a string describing the differences between two outputs.

*OutputChecker* defines the following methods:

**check_output**(want, got, optionflags)

Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section *Option Flags* for more information about option flags.

**output_difference**(example, got, optionflags)
Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
26.2.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```
'''
>>> def f(x):
...    g(x*2)
>>> def g(x):
...    print(x+3)
...    import pdb; pdb.set_trace()
>>> f(3)
g
'''
```

Then an interactive Python session may look like this:
Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

```
doctest.script_from_examples(s)
```

Convert text with examples to a script.
Argument `s` is a string containing doctest examples. The string is converted to a Python script, where doctest examples in `s` are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```python
import doctest
print(doctest.script_from_examples(r""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
""))
```

displays:

```python
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

`doctest.testsource(module, name)`

Convert the doctest for an object to a script.

Argument `module` is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument
name is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for script_from_examples() above. For example, if module a.py contains a top-level function f(), then

```python
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function f()'s docstring, with doctests converted to code, and the rest placed in comments.

**doctest.debug**(module, name, pm=False)

Debug the doctests for an object.

The module and name arguments are the same as for function testsource() above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, pdb.

A shallow copy of module.__dict__ is used for both local and global execution context.

Optional argument pm controls whether post-mortem debugging is used. If pm has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via pdb.post_mortem(), passing the traceback object from the unhandled exception. If pm is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate exec() call to pdb.run().

**doctest.debug_src**(src, pm=False, globs=None)
Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.

Optional argument `pm` has the same meaning as in function `debug()` above.

Optional argument `globs` gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest.DebugRunner(checker=None, verbose=None, optionflags=0)
```

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section `Advanced API`.

There are two exceptions that may be raised by `DebugRunner`
instances:

*exception doctest.*\[DocTestFailure\](\textit{test, example, got})

An exception raised by \texttt{DocTestRunner} to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

\texttt{DocTestFailure} defines the following attributes:

\texttt{DocTestFailure.test}

The \texttt{DocTest} object that was being run when the example failed.

\texttt{DocTestFailure.example}

The \texttt{Example} that failed.

\texttt{DocTestFailure.got}

The example's actual output.

*exception doctest.*\[UnexpectedException\](\textit{test, example, exc_info})

An exception raised by \texttt{DocTestRunner} to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

\texttt{UnexpectedException} defines the following attributes:

\texttt{UnexpectedException.test}

The \texttt{DocTest} object that was being run when the example failed.

\texttt{UnexpectedException.example}

The \texttt{Example} that failed.
UnexpectedException\.exc_info

A tuple containing information about the unexpected exception, as returned by \texttt{sys.exc_info()}. 
26.2.8. Soapbox

As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper
than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It’s a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

**Footnotes**

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.
26.3. `unittest` — Unit testing framework

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The `unittest` unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, `unittest` supports some important concepts in an object-oriented way:

**test fixture**

A test fixture represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case**

A test case is the individual unit of testing. It checks for a specific response to a particular set of inputs. `unittest` provides a base class, `TestCase`, which may be used to create new test cases.

**test suite**

A test suite is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner**

A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a
graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

Kent Beck's original paper on testing frameworks using the pattern shared by unittest.

**Nose and py.test**

Third-party unittest frameworks with a lighter-weight syntax for writing tests. For example, `assert func(10) == 42`.

**The Python Testing Tools Taxonomy**

An extensive list of Python testing tools including functional testing frameworks and mock object libraries.

**Testing in Python Mailing List**

A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot, Jenkins or Hudson.
26.3.1. Basic example

The unittest module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three functions from the random module:

```python
import random
import unittest

class TestSequenceFunctions(unittest.TestCase):

    def setUp(self):
        self.seq = list(range(10))

    def test_shuffle(self):
        # make sure the shuffled sequence does not lose any elements
        random.shuffle(self.seq)
        self.seq.sort()
        self.assertEqual(self.seq, list(range(10)))

        # should raise an exception for an immutable sequence
        self.assertRaises(TypeError, random.shuffle, self.seq)

    def test_choice(self):
        element = random.choice(self.seq)
        self.assertIn(element, self.seq)

    def test_sample(self):
        with self.assertRaises(ValueError):
            random.sample(self.seq, 20)

        for element in random.sample(self.seq, 5):
            self.assertIn(element, self.seq)
```
A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` to verify a condition; or `assertRaises()` to verify that an expected exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

When a `setUp()` method is defined, the test runner will run that method prior to each test. Likewise, if a `tearDown()` method is defined, the test runner will invoke that method after each test. In the example, `setUp()` was used to create a fresh sequence for each test.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
Ran 3 tests in 0.000s
OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce
the following output:

```python

test_choice (__main__.TestSequenceFunctions) ... ok
test_sample (__main__.TestSequenceFunctions) ... ok
test_shuffle (__main__.TestSequenceFunctions) ... ok

Ran 3 tests in 0.110s

OK
```

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
26.3.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the ‘.py’ and converting path separators into ‘.’. If you want to execute a test file that isn’t importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the -v flag:

```
python -m unittest -v test_module
```

When executed without arguments *Test Discovery* is started:

```
python -m unittest
```
For a list of all the command-line options:

```python
python -m unittest -h
```

*Changed in version 3.2:* In earlier versions it was only possible to run individual test methods and not modules or classes.

### 26.3.2.1. Command-line options

`unittest` supports these command-line options:

**-b, --buffer**

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

**-c, --catch**

Control-C during the test run waits for the current test to end and then reports all the results so far. A second control-C raises the normal `KeyboardInterrupt` exception.

See [Signal Handling](#) for the functions that provide this functionality.

**-f, --failfast**

Stop the test run on the first error or failure.

*New in version 3.2:* The command-line options `-b`, `-c` and `-f` were added.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
26.3.3. Test Discovery

New in version 3.2.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in TestLoader.discover(), but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

**Note:** As a shortcut, python -m unittest is the equivalent of python -m unittest discover. If you want to pass arguments to test discovery the discover sub-command must be used explicitly.

The discover sub-command has the following options:

- **-v, --verbose**
  - Verbose output

- **-s, --start-directory directory**
  - Directory to start discovery (. default)

- **-p, --pattern pattern**
  - Pattern to match test files (test*.py default)
**-t, --top-level-directory** directory

Top level directory of project (defaults to start directory)

The **-s, -p, and -t** options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p
python -m unittest discover project_directory '*_test.py'
```

As well as being a path it is possible to pass a package name, for example **myproject.subpackage.test**, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example **foo/bar/baz.py** will be imported as **foo.bar.baz**.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import could happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the **load_tests protocol**.
26.3.4. Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In unittest, test cases are represented by unittest.TestCase instances. To make your own test cases you must write subclasses of TestCase or use FunctionTestCase.

The testing code of a TestCase instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest TestCase subclass will simply implement a test method (i.e. a method whose name starts with test) in order to perform specific testing code:

```python
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the assert*() methods provided by the TestCase base class. If the test fails, an exception will be raised, and unittest will identify the test case as a failure. Any other exceptions will be treated as errors.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called setUp(), which the testing framework will automatically call for every single test we run:
import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

Note: The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the setUp() method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a tearDown() method that tidies up after the test method has been run:

import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *fixture*.

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the *test suite*, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module's test cases for you, and then execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules
anyway, so why not be consistent?
• If the testing strategy changes, there is no need to change the source code.
26.3.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from `unittest`, without converting every old test function to a `TestCase` subclass.

For this reason, `unittest` provides a `FunctionTestCase` class. This subclass of `TestCase` can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```python
testcase = unittest.FunctionTestCase(testSomething, setUp=makeSomethingDB, tearDown=deleteSomethingDB)
```

**Note:** Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the
**doctest** module. If so, **doctest** provides a DocTestSuite class that can automatically build **unittest.TestSuite** instances from the existing **doctest**-based tests.
26.3.6. Skipping tests and expected failures

New in version 3.1.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as a “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a TestResult.

Skipping a test is simply a matter of using the skip() decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3), "not supported in this library")
    def test_format(self):
        # Tests that work for only a certain version
        pass

    @unittest.skipUnless(sys.platform.startswith("win"),
                         "windows specific testing code")
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:
Classes can be skipped just like methods:

```python
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
```
The following decorators implement test skipping and expected failures:

```python
return unittest.skip("{!r} doesn't have {!r}".format(reason, obj))
```

@unittest.skip(reason)
Unconditionally skip the decorated test. `reason` should describe why the test is being skipped.

@unittest.skipIf(condition, reason)
Skip the decorated test if `condition` is true.

@unittest.skipUnless(condition, reason)
Skip the decorated test unless `condition` is true.

@unittest.expectedFailure
Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

`exception unittest.SkipTest(reason)`
This exception is raised to skip a test.

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run.
26.3.7. Classes and functions

This section describes in depth the API of `unittest`.

26.3.7.1. Test cases

```python
class unittest.TestCase(methodName='runTest')
```

Instances of the `TestCase` class represent the logical test units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single base method: the method named `methodName`. However, the standard implementation of the default `methodName`, `runTest()`, will run every method starting with `test` as an individual test, and count successes and failures accordingly. Therefore, in most uses of `TestCase`, you will neither change the `methodName` nor reimplement the default `runTest()` method.

*Changed in version 3.2:* `TestCase` can be instantiated successfully without providing a `methodName`. This makes it easier to experiment with `TestCase` from the interactive interpreter.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.
Methods in the first group (running the test) are:

**setUp()**
Method called to prepare the test fixture. This is called immediately before calling the test method; any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**
Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception raised by this method will be considered an error rather than a test failure. This method will only be called if the `setUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**
A class method called before tests in an individual class run. `setUpClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def setUpClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

**tearDownClass()**
A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

### `run(result=None)`

Run the test, collecting the result into the `TestResult` object passed as `result`. If `result` is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

*Changed in version 3.3:* Previous versions of `run` did not return the result. Neither did calling an instance.

### `skipTest(reason)`

Calling this during a test method or `setUp()` skips the current test. See [*Skipping tests and expected failures*](#) for more information.

*New in version 3.1.*

### `debug()`
Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The **TestCase** class provides a number of methods to check for and report failures, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual(a, b)</code></td>
<td><code>a == b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotEqual(a, b)</code></td>
<td><code>a != b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertTrue(x)</code></td>
<td><code>bool(x) is True</code></td>
<td></td>
</tr>
<tr>
<td><code>assertFalse(x)</code></td>
<td><code>bool(x) is False</code></td>
<td></td>
</tr>
<tr>
<td><code>assertIs(a, b)</code></td>
<td><code>a is b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNot(a, b)</code></td>
<td><code>a is not b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNone(x)</code></td>
<td><code>x is None</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNotNone(x)</code></td>
<td><code>x is not None</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIn(a, b)</code></td>
<td><code>a in b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertNotIn(a, b)</code></td>
<td><code>a not in b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsInstance(a, b)</code></td>
<td><code>isinstance(a, b)</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertNotIsInstance(a, b)</code></td>
<td><code>not instanceof(a, b)</code></td>
<td>3.2</td>
</tr>
</tbody>
</table>

All the assert methods accept a *msg* argument that, if specified, is used as the error message on failure (see also `longMessage`). Note that the *msg* keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context
manager.

**assertEqual**(first, second, msg=None)
Test that first and second are equal. If the values do not compare equal, the test will fail.

In addition, if first and second are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with *addTypeEqualityFunc()* the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

*Changed in version 3.1:* Added the automatic calling of type-specific equality function.

*Changed in version 3.2:* **assertMultiLineEqual()** added as the default type equality function for comparing strings.

**assertNotEqual**(first, second, msg=None)
Test that first and second are not equal. If the values do compare equal, the test will fail.

**assertTrue**(expr, msg=None)
**assertFalse**(expr, msg=None)
Test that expr is true (or false).

Note that this is equivalent to *bool(expr)* is True and not to expr is True (use **assertIs**(expr, True) for the latter). This method should also be avoided when more specific methods are available (e.g. **assertEqual**(a, b) instead of **assertTrue**(a == b)), because they provide a better error message in case of failure.
assertIs(first, second, msg=None)
assertIsNot(first, second, msg=None)
Test that first and second evaluate (or don’t evaluate) to the same object.

New in version 3.1.

assertIsNone(expr, msg=None)
assertIsNotNone(expr, msg=None)
Test that expr is (or is not) None.

New in version 3.1.

assertIn(first, second, msg=None)
assertNotIn(first, second, msg=None)
Test that first is (or is not) in second.

New in version 3.1.

assertIsInstance(obj, cls, msg=None)
assertNotIsInstance(obj, cls, msg=None)
Test that obj is (or is not) an instance of cls (which can be a class or a tuple of classes, as supported by isinstance()). To check for the exact type, use assertIs(type(obj), cls).

New in version 3.2.

It is also possible to check that exceptions and warnings are raised using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
assertRaises(exc, fun, *args, **kwds)

fun(*args, **kwds) raises exc

assertRaisesRegex(exc, r, fun, *args, **kwds)

fun(*args, **kwds) raises exc and the message matches regex r

assertWarns(warn, fun, *args, **kwds)

fun(*args, **kwds) raises warn

assertWarnsRegex(warn, r, fun, *args, **kwds)

fun(*args, **kwds) raises warn and the message matches regex r

assertRaises

Test that an exception is raised when callable is called with any positional or keyword arguments that are also passed to assertRaises(). The test passes if exception is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as exception.

If only the exception and possibly the msg arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, assertRaises() accepts the additional keyword argument msg.

The context manager will store the caught exception object in
its exception attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 3.1:* Added the ability to use `assertRaises()` as a context manager.

*Changed in version 3.2:* Added the exception attribute.

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

`assertRaisesRegex(exception, regex, callable, *args, **kwds)`

`assertRaisesRegex(exception, regex, msg=None)`

Like `assertRaises()` but also tests that `regex` matches on the string representation of the raised exception. `regex` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```python
self.assertRaisesRegex(ValueError, "invalid literal for.*XYZ'$", int, 'XYZ')
```

or:

```python
with self.assertRaisesRegex(ValueError, "literal", int) as cm:
    cm
```

or:

```python
with self.assertRaisesRegex(ValueError, 'literal', int) as cm:
    cm
```
New in version 3.1: under the name `assertRaisesRegexp`.

Changed in version 3.2: Renamed to `assertRaisesRegex()`.

Changed in version 3.3: Added the `msg` keyword argument when used as a context manager.

```python
assertWarns(warning, callable, *args, **kwds)
```
```python
assertWarns(warning, msg=None)
```

Test that a warning is triggered when `callable` is called with any positional or keyword arguments that are also passed to `assertWarns()`. The test passes if `warning` is triggered and fails if it isn’t. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as `warnings`.

If only the `warning` and possibly the `msg` arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, `assertWarns()` accepts the additional keyword argument `msg`.

The context manager will store the caught warning object in its `warning` attribute, and the source line which triggered the warnings in the `filename` and `lineno` attributes. This can be useful if the intention is to perform additional checks on the warning caught:
```python
with self.assertWarns(SomeWarning) as cm:
    do_something()

self.assertIn('myfile.py', cm.filename)
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

```python
assertWarnsRegex(warning, regex, callable, *args, **kwds)
assertWarnsRegex(warning, regex, msg=None)
```

Like `assertWarns()` but also tests that `regex` matches on the message of the triggered warning. `regex` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Example:

```python
self.assertWarnsRegex(DeprecationWarning,
    r'legacy_function\(\) is legacy_function, 'XYZ')
```

or:

```python
with self.assertWarnsRegex(RuntimeWarning, 'unsafe frobnicate(/etc/passwd')
```

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument
when used as a context manager.

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertLess(a, b)</code></td>
<td><code>a &lt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertLessEqual(a, b)</code></td>
<td><code>a &lt;= b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertRegex(s, r)</code></td>
<td><code>r.search(s)</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertNotRegex(s, r)</code></td>
<td><code>not r.search(s)</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertCountEqual(a, b)</code></td>
<td><code>a and b have the same elements in the same number, regardless of their order</code></td>
<td>3.2</td>
</tr>
</tbody>
</table>

`assertAlmostEqual(first, second, places=7, msg=None, delta=None)`

`assertNotAlmostEqual(first, second, places=7, msg=None, delta=None)`

Test that `first` and `second` are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal `places` (default 7), and comparing to zero. Note that these methods round the values to the given
number of *decimal places* (i.e. like the `round()` function) and not *significant digits*.

If `delta` is supplied instead of `places` then the difference between `first` and `second` must be less or equal to (or greater than) `delta`.

Supplying both `delta` and `places` raises a `TypeError`.

*Changed in version 3.2:* `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the `delta` keyword argument.

```python
assertGreater(first, second, msg=None)
assertGreaterEqual(first, second, msg=None)
assertLess(first, second, msg=None)
assertLessEqual(first, second, msg=None)
```

Test that `first` is respectively >, >=, < or <= than `second` depending on the method name. If not, the test will fail:

```python
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than "4"
```

*New in version 3.1.*

```python
assertRegex(text, regex, msg=None)
assertNotRegex(text, regex, msg=None)
```

Test that a `regex` search matches (or does not match) `text`. In case of failure, the error message will include the pattern and the `text` (or the pattern and the part of `text` that unexpectedly matched). `regex` may be a regular expression object or a string.
containing a regular expression suitable for use by \texttt{re.search()}. 

\textit{New in version 3.1}: under the name \texttt{assertRegexpMatches}.

\textit{Changed in version 3.2}: The method \texttt{assertRegexpMatches()} has been renamed to \texttt{assertRegex()}. 

\textit{New in version 3.2}: \texttt{assertNotRegex()}. 

\textbf{assertCountEqual}(first, second, msg=None) 

Test that sequence \texttt{first} contains the same elements as \texttt{second}, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are \textit{not} ignored when comparing \texttt{first} and \texttt{second}. It verifies whether each element has the same count in both sequences. Equivalent to: \texttt{assertEqual(Counter(list(first)), Counter(list(second))} but works with sequences of unhashable objects as well.

\textit{New in version 3.2}.

The \texttt{assertEqual()} method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using \texttt{addTypeEqualityFunc()}:

\textbf{addTypeEqualityFunc}(typeobj, function)
Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same `typeobj` (not subclasses) compare equal. `function` must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

*New in version 3.1.*

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertMultiLineEqual(a, b)</code></td>
<td>strings</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSequenceEqual(a, b)</code></td>
<td>sequences</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertListEqual(a, b)</code></td>
<td>lists</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertTupleEqual(a, b)</code></td>
<td>tuples</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSetEqual(a, b)</code></td>
<td>sets or frozensets</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertDictEqual(a, b)</code></td>
<td>dicts</td>
<td>3.1</td>
</tr>
</tbody>
</table>

`assertMultiLineEqual(first, second, msg=None)`

Test that the multiline string `first` is equal to the string `second`. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with
assertEqual() 

*New in version 3.1.*

**assertSequenceEqual**(first, second, msg=None, seq_type=None)

Tests that two sequences are equal. If a seq_type is supplied, both first and second must be instances of seq_type or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by assertEqual(), but it’s used to implement assertListEqual() and assertTupleEqual().

*New in version 3.1.*

**assertListEqual**(first, second, msg=None)

**assertTupleEqual**(first, second, msg=None)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with assertEqual().

*New in version 3.1.*

**assertSetEqual**(first, second, msg=None)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with assertEqual().
Fails if either of \textit{first} or \textit{second} does not have a \texttt{set.difference()} method.

\textit{New in version 3.1.}

\textbf{assertDictEqual}(\textit{first, second, msg=None})

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to \texttt{assertEqual()}.  

\textit{New in version 3.1.}

Finally the \texttt{TestCase} provides the following methods and attributes:

\textbf{fail}(\textit{msg=None})

Signals a test failure unconditionally, with \textit{msg} or None for the error message.

\textbf{failureException}

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is \texttt{AssertionError}.

\textbf{longMessage}

If set to True then any explicit failure message you pass in to the \texttt{assert methods} will be appended to the end of the normal failure message. The normal messages contain useful information about the objects involved, for example the
message from assertEquals shows you the repr of the two unequal objects. Setting this attribute to True allows you to have a custom error message in addition to the normal one.

This attribute defaults to True. If set to False then a custom message passed to an assert method will silence the normal message.

The class setting can be overridden in individual tests by assigning an instance attribute to True or False before calling the assert methods.

*New in version 3.1.*

**maxDiff**

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are assertEquals() (including all the sequence comparison methods that delegate to it), assertDictEqual() and assertMultiLineEqual().

Setting maxDiff to None means that there is no maximum length of diffs.

*New in version 3.2.*

Testing frameworks can use the following methods to collect information on the test:

**countTestCases()**

Return the number of tests represented by this test object. For TestCase instances, this will always be 1.
defaultTestResult()
Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the run() method).

For TestCase instances, this will always be an instance of TestResult; subclasses of TestCase should override this as necessary.

id()
Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

shortDescription()
Returns a description of the test, or None if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or None.

Changed in version 3.1: In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the TextTestResult in Python 3.2.

addCleanup(function, *args, **kwargs)
Add a function to be called after tearDown() to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into addCleanup() when they are added.
If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

*New in version 3.1.*

**doCleanups()**

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.1.*

```
class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)
```

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### 26.3.7.1.1. Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:
<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias</th>
<th>Deprecated since version 3.1:</th>
</tr>
</thead>
<tbody>
<tr>
<td>assertEqual()</td>
<td>failUnlessEqual</td>
<td></td>
</tr>
<tr>
<td>assertNotEqual()</td>
<td>failIfEqual</td>
<td></td>
</tr>
<tr>
<td>assertTrue()</td>
<td>failUnless</td>
<td></td>
</tr>
<tr>
<td>assertFalse()</td>
<td>failIf</td>
<td></td>
</tr>
<tr>
<td>assertRaises()</td>
<td>failUnlessRaises</td>
<td></td>
</tr>
<tr>
<td>assertAlmostEqual()</td>
<td>failUnlessAlmostEqual</td>
<td></td>
</tr>
<tr>
<td>assertNotAlmostEqual()</td>
<td>failIfAlmostEqual</td>
<td></td>
</tr>
<tr>
<td>assertRegex()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>assertRaisesRegex()</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Deprecated since version 3.1: the fail* aliases listed in the second column.

*Deprecated since version 3.2: the assert* aliases listed in the third column.

*Deprecated since version 3.2: assertRegexpMatches and assertRaisesRegexp have been renamed to assertRegex() and assertRaisesRegex()*

26.3.7.2. Grouping tests

```python
class unittest.TestSuite(tests=())
```

This class represents an aggregation of individual tests cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite,
If tests is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

TestSuite objects behave much like TestCase objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to TestSuite instances:

**addTest(test)**
Add a TestCase or TestSuite to the suite.

**addTests(tests)**
Add all the tests from an iterable of TestCase and TestSuite instances to this test suite.

This is equivalent to iterating over tests, calling addTest() for each element.

TestSuite shares the following methods with TestCase:

**run(result)**
Run the tests associated with this suite, collecting the result into the test result object passed as result. Note that unlike TestCase.run(), TestSuite.run() requires the result object to be passed in.

**debug()**
Run the tests associated with this suite without collecting the
result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases()**

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**__iter__()**

Tests grouped by a TestSuite are always accessed by iteration. Subclasses can lazily provide tests by overriding __iter__(). Note that this method maybe called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned must be the same for repeated iterations.

*Changed in version 3.2:* In earlier versions the TestSuite accessed tests directly rather than through iteration, so overriding __iter__() wasn’t sufficient for providing tests.

In the typical usage of a TestSuite object, the run() method is invoked by a TestRunner rather than by the end-user test harness.

### 26.3.7.3. Loading and running tests

**class unittest.TestLoader**

The TestLoader class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the unittest module provides an instance that can be shared as unittest.defaultTestLoader. Using a subclass or instance, however, allows customization of some configurable
properties.

**TestLoader** objects have the following methods:

**loadTestsFromTestCase**(``testCaseClass``)

Return a suite of all tests cases contained in the **TestCase**-derived testCaseClass.

**loadTestsFromModule**(``module``)

Return a suite of all tests cases contained in the given module. This method searches **module** for classes derived from **TestCase** and creates an instance of the class for each test method defined for the class.

**Note:** While using a hierarchy of **TestCase**-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a **load_tests** function it will be called to load the tests. This allows modules to customize test loading. This is the **load_tests** protocol.

*Changed in version 3.2:* Support for **load_tests** added.

**loadTestsFromName**(``name, module=None``)

Return a suite of all tests cases given a string specifier.

The specifier *name* is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a **TestSuite** instance, or a callable object which returns
a **TestCase** or **TestSuite** instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module SampleTests containing a **TestCase**-derived class SampleTestCase with three test methods (test_one(), test_two(), and test_three()), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the test_two() test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

**loadTestsFromNames(names, module=None)**

Similar to **loadTestsFromName()**, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames(testCaseClass)**

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of **TestCase**.

**discover(start_dir, pattern='test*.py', top_level_dir=None)**

Find and return all test modules from the specified start directory, recursing into subdirectories to find them. Only test
files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue.

If a test package name (directory with *__init__.py*) matches the pattern then the package will be checked for a *load_tests* function. If this exists then it will be called with *loader, tests, pattern*.

If load_tests exists then discovery does not recurse into the package, *load_tests* is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. *top_level_dir* is stored so *load_tests* does not need to pass this argument in to *loader.discover()*.

*start_dir* can be a dotted module name as well as a directory.

*New in version 3.2.*

The following attributes of a *TestLoader* can be configured either by subclassing or assignment on an instance:

*testMethodPrefix*
String giving the prefix of method names which will be interpreted as test methods. The default value is 'test'.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.

class unittest.TestResult

This class is used to compile information about which tests have succeeded and which have failed.

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of `unittest` may want access to the `TestResult` object generated by running a set of tests for reporting purposes; a `TestResult` instance is returned by the TestRunner.run() method for this purpose.

`TestResult` instances have the following attributes that will be of
interest when inspecting the results of running a set of tests:

**errors**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

**failures**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the `TestCase.assert*()` methods.

**skipped**
A list containing 2-tuples of `TestCase` instances and strings holding the reason for skipping the test.

*New in version 3.1.*

**expectedFailures**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**
A list containing `TestCase` instances that were marked as expected failures, but succeeded.

**shouldStop**
Set to True when the execution of tests should stop by `stop()`.

**testsRun**
The total number of tests run so far.

**buffer**

If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 3.2.*

**failfast**

If set to true `stop()` will be called on the first failure or error, halting the test run.

*New in version 3.2.*

**wasSuccessful()**

Return True if all tests run so far have passed, otherwise returns False.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to True. TestRunner objects should respect this flag and return without running any additional tests.

For example, this feature is used by the `TextTestRunner` class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide TestRunner implementations can use this in a similar manner.

The following methods of the `TestResult` class are used to
maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest**(*test*)

Called when the test case *test* is about to be run.

**stopTest**(*test*)

Called after the test case *test* has been executed, regardless of the outcome.

**startTestRun**(*test*)

Called once before any tests are executed.

*New in version 3.1.*

**stopTestRun**(*test*)

Called once after all tests are executed.

*New in version 3.1.*

**addError**(*test*, *err*)

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by `sys.exc_info()`: `(type, value, traceback)`.

The default implementation appends a tuple `(*test, formatted_err)` to the instance's `errors` attribute, where `formatted_err` is a formatted traceback derived from *err*.

**addFailure**(*test*, *err*)

Called when the test case *test* signals a failure. *err* is a tuple of
the form returned by `sys.exc_info()`: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's `failures` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**addSuccess(test)**
Called when the test case `test` succeeds.

The default implementation does nothing.

**addSkip(test, reason)**
Called when the test case `test` is skipped. `reason` is the reason the test gave for skipping.

The default implementation appends a tuple `(test, reason)` to the instance's `skipped` attribute.

**addExpectedFailure(test, err)**
Called when the test case `test` fails, but was marked with the `expectedFailure()` decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's `expectedFailures` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**addUnexpectedSuccess(test)**
Called when the test case `test` was marked with the `expectedFailure()` decorator, but succeeded.

The default implementation appends the test to the instance's
unexpectedSuccesses attribute.

class unittest.TextTestResult(stream, descriptions, verbosity)

A concrete implementation of TestResult used by the TextTestRunner.

New in version 3.2: This class was previously named _TextTestResult. The old name still exists as an alias but is deprecated.

unittest.defaultTestLoader

Instance of the TestLoader class intended to be shared. If no customization of the TestLoader is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.TextTestRunner(stream=None, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None, warnings=None)

A basic test runner implementation that outputs results to a stream. If stream is None, the default, sys.stderr is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations.

By default this runner shows DeprecationWarning, PendingDeprecationWarning, and ImportWarning even if they are ignored by default. Deprecation warnings caused by deprecated unittest methods are also special-cased and, when the warning filters are 'default' or 'always', they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using the -Wd or -Wa options and
leaving warnings to None.

*Changed in version 3.2:* Added the *warnings* argument.

*Changed in version 3.2:* The default stream is set to *sys.stderr* at instantiation time rather than import time.

**_makeResult()**

This method returns the instance of *TestResult* used by *run()* . It is not intended to be called directly, but can be overridden in subclasses to provide a custom *TestResult*.

**_makeResult()** instantiates the class or callable passed in the *TextTestRunner* constructor as the *resultclass* argument. It defaults to *TextTestResult* if no *resultclass* is provided. The result class is instantiated with the following arguments:

```python
stream, descriptions, verbosity
```

*unittest.main(module='__main__', defaultTest=None, argv=None, testRunner=None, testLoader=unittest.defaultTestLoader, exit=True, verbosity=1, failfast=None, catchbreak=None, buffer=None, warnings=None)*

A command-line program that loads a set of tests from *module* and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```python
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the
verbosity argument:

```python
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The `argv` argument can be a list of options passed to the program, with the first element being the program name. If not specified or None, the values of `sys.argv` are used.

The `testRunner` argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success or failure of the tests run.

The `testLoader` argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```python
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The `failfast`, `catchbreak` and `buffer` parameters have the same effect as the same-name command-line options.

The `warning` argument specifies the warning filter that should be used while running the tests. If it's not specified, it will remain None if a `-W` option is passed to `python`, otherwise it will be set to 'default'.

Calling `main` actually returns an instance of the `TestProgram` class. This stores the result of the tests run as the result
attribute.

*Changed in version 3.1:* The `exit` parameter was added.

*Changed in version 3.2:* The `verbosity`, `failfast`, `catchbreak`, `buffer` and `warnings` parameters were added.

26.3.7.3.1. load_tests Protocol

*New in version 3.2.*

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by `TestLoader.loadTestsFromModule()` with the following arguments:

```python
load_tests(loader, standard_tests, None)
```

It should return a `TestSuite`.

`loader` is the instance of `TestLoader` doing the loading. `standard_tests` are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of `TestCase` classes may look like:

```python
test_cases = (TestCase1, TestCase2, TestCase3)
```
def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite

If discovery is started, either from the command line or by calling TestLoader.discover(), with a pattern that matches a package name then the package __init__.py will be checked for load_tests.

Note: The default pattern is 'test*.py'. This matches all Python files that start with 'test' but won't match any test directories.

A pattern like 'test*' will match test packages as well as modules.

If the package __init__.py defines load_tests then it will be called and discovery not continued into the package. load_tests is called with the following arguments:

load_tests(loader, standard_tests, pattern)

This should return a TestSuite representing all the tests from the package. (standard_tests will only contain tests collected from __init__.py.)

Because the pattern is passed into load_tests the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ load_tests function for a test package would look like:

def load_tests(loader, standard_tests, pattern):

# top level directory cached on loader instance
this_dir = os.path.dirname(__file__)
package_tests = loader.discover(start_dir=this_dir)
standard_tests.addTests(package_tests)

return standard_tests
26.3.8. Class and Module Fixtures

Class and module level fixtures are implemented in `TestSuite`. When the test suite encounters a test from a new class then `tearDownClass()` from the previous class (if there is one) is called, followed by `setUpClass()` from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass` / `setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no
corresponding test instance an ErrorHolder object (that has the same interface as a TestCase) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

26.3.8.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest
class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the setUpClass and tearDownClass on base classes called then you must call up to them yourself. The implementations in TestCase are empty.

If an exception is raised during a setUpClass then the tests in the class are not run and the tearDownClass is not run. Skipped classes will not have setUpClass or tearDownClass run. If the exception is a SkipTest exception then the class will be reported as having been skipped instead of as an error.

26.3.8.2. setUpModule and tearDownModule
These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
26.3.9. Signal Handling

New in version 3.2.

The `-c/--catch` command-line option to unittest, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but isn’t the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need unittest control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`  
Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

`unittest.registerResult(result)`
Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

`unittest.removeResult(result)`
Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

`unittest.removeHandler(function=None)`
When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```python
@unittest.removeHandler
def test_signal_handling(self):
    ...
```
26.4. `unittest.mock` — mock object library

*New in version 3.3.*

`unittest.mock` is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

`unittest.mock` provides a core `Mock` class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a `patch()` decorator that handles patching module and class level attributes within the scope of a test, along with `sentinel` for creating unique objects. See the quick guide for some examples of how to use `Mock`, `MagicMock` and `patch()`.

Mock is very easy to use and is designed for use with `unittest`. Mock is based on the ‘action -> assertion’ pattern instead of ‘record -> replay’ used by many mocking frameworks.

There is a backport of `unittest.mock` for earlier versions of Python, available as `mock` on PyPI.

**Source code:** Lib/unittest/mock.py
26.4.1. Quick Guide

Mock and MagicMock objects create all attributes and methods as you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```python
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

side_effect allows you to perform side effects, including raising an exception when a mock is called:

```python
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
  ...
KeyError: 'foo'
```

```python
>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...    return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```
Mock has many other ways you can configure it and control its behaviour. For example the `spec` argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don’t exist on the spec will fail with an `AttributeError`.

The `patch()` decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```python
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
... >>> test()
```

**Note:** When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal python order that decorators are applied). This means from the bottom up, so in the example above the mock for `module.ClassName1` is passed in first.

With `patch` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read `where to patch`.
As well as a decorator `patch` can be used as a context manager in a `with` statement:

```python
>>> with patch.object(ProductionClass, 'method', return_value=thing):
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=False):
...     assert foo == {'newkey': 'newvalue'}
...     assert foo == original
```

Mock supports the mocking of Python `magic methods`. The easiest way of using magic methods is with the `MagicMock` class. It allows you to do things like:

```python
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobaz'
>>> str(mock)
'foobaz'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The `MagicMock` class is just a Mock variant that has all of the magic methods pre-
created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```python
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='wheeeeee')
>>> str(mock)
'wheeeeee'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use `auto-speccing`. Auto-speccing can be done through the `autospec` argument to patch, or the `create_autospec()` function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```python
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_value='fishy')
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
  ...
TypeError: <lambda>() takes exactly 3 arguments (1 given)
```
create_autospec can also be used on classes, where it copies the signature of the __init__ method, and on callable objects where it copies the signature of the __call__ method.
26.4.2. The Mock Class

*Mock* is a flexible mock object intended to replace the use of stubs and test doubles throughout your code.Mocks are callable and create attributes as new mocks when you access them [1]. Accessing the same attribute will always return the same mock.Mocks record how you use them, allowing you to make assertions about what your code has done to them.

*MagicMock* is a subclass of *Mock* with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren't callable: *NonCallableMock* and *NonCallableMagicMock*.

The *patch*() decorators makes it easy to temporarily replace classes in a particular module with a *Mock* object. By default *patch* will create a *MagicMock* for you. You can specify an alternative class of *Mock* using the *new_callable* argument to *patch*.

```python
class unittest.mock.Mock(spec=None, side_effect=None, return_value=DEFAULT, wraps=None, name=None, spec_set=None, **kwargs)
```

Create a new *Mock* object. *Mock* takes several optional arguments that specify the behaviour of the Mock object:

- *spec*: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling dir on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an *AttributeError*. 
If `spec` is an object (rather than a list of strings) then `__class__` returns the class of the spec object. This allows mocks to pass `isinstance` tests.

- **spec_set**: A stricter variant of `spec`. If used, attempting to set or get an attribute on the mock that isn’t on the object passed as `spec_set` will raise an `AttributeError`.

- **side_effect**: A function to be called whenever the Mock is called. See the `side_effect` attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns `DEFAULT`, the return value of this function is used as the return value.

  Alternatively `side_effect` can be an exception class or instance. In this case the exception will be raised when the mock is called.

  If `side_effect` is an iterable then each call to the mock will return the next value from the iterable.

  A `side_effect` can be cleared by setting it to `None`.

- **return_value**: The value returned when the mock is called. By default this is a new Mock (created on first access). See the `return_value` attribute.

- **wraps**: Item for the mock object to wrap. If `wraps` is not `None` then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute
that doesn't exist will raise an *AttributeError*).

If the mock has an explicit *return_value* set then calls are not passed to the wrapped object and the *return_value* is returned instead.

- *name*: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the *configure_mock()* method for details.

**assert_called_with(*args, **kwargs)**

This method is a convenient way of asserting that calls are made in a particular way:

```python
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_with(1, 2, 3, test='wow')
```

**assert_called_once_with(*args, **kwargs)**

Assert that the mock was called exactly once and with the specified arguments.

```python
>>> mock = Mock(return_value=None)
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
Traceback (most recent call last):
... ```
assert_any_call(*args, **kwargs)

assert the mock has been called with the specified arguments.

The assert passes if the mock has ever been called, unlike
assert_called_with() and
assert_called_once_with() that only pass if the call is
the most recent one.

```python
>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')
```

assert_has_calls(calls, any_order=False)

assert the mock has been called with the specified calls. The
mock_calls list is checked for the calls.

If any_order is False (the default) then the calls must be
sequential. There can be extra calls before or after the specified
calls.

If any_order is True then the calls can be in any order, but they
must all appear in mock_calls.

```python
>>> mock = Mock(return_value=None)
>>> mock(1)
>>> mock(2)
>>> mock(3)
>>> mock(4)
>>> calls = [call(2), call(3)]
>>> mock.assert_has_calls(calls)
>>> calls = [call(4), call(2), call(3)]
```
```python
>>> mock = Mock(return_value=None)
>>> mock('hello')
True
>>> mock.reset_mock()
>>> mock.called
False
```

**reset_mock()**

The reset_mock method resets all the call attributes on a mock object:

```python
>>> mock.assert_has_calls(calls, any_order=True)
```

This can be useful where you want to make a series of assertions that reuse the same object. Note that `reset_mock` doesn't clear the return value, `side_effect` or any child attributes you have set using normal assignment. Child mocks and the return value mock (if any) are reset as well.

**mock_add_spec**(spec, spec_set=False)

Add a spec to a mock. `spec` can either be an object or a list of strings. Only attributes on the `spec` can be fetched as attributes from the mock.

If `spec_set` is `True` then only attributes on the spec can be set.

**attach_mock**(mock, attribute)

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the `method_calls` and `mock_calls` attributes of this one.

**configure_mock**(**kwargs)
Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```python
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.side_effect': []}
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ... KeyError
```

The same thing can be achieved in the constructor call to mocks:

```python
>>> attrs = {'method.return_value': 3, 'other.side_effect': []}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute 'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ... KeyError
```

`configure_mock` exists to make it easier to do configuration after the mock has been created.

```
__dir__()
```
Mock objects limit the results of `dir(some_mock)` to useful results. For mocks with a spec this includes all the permitted attributes for the mock.

See `FILTER_DIR` for what this filtering does, and how to switch it off.

`_get_child_mock(**kw)`
Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of Mock may want to override this to customize the way child mocks are made.

For non-callable mocks the callable variant will be used (rather than any custom subclass).

called
A boolean representing whether or not the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

call_count
An integer telling you how many times the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
```
>>> mock()
>>> mock()
>>> mock.call_count
2

**return_value**
Set this to configure the value returned by calling the mock:

>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'

The default return value is a mock object and you can configure it in the normal way:

>>> mock = Mock()
>>> mock.return_value.attribute = sentinel.Attribute
>>> mock.return_value()
<Mock name='mock()' id='...'>
>>> mock.return_value.assert_called_with()

**return_value** can also be set in the constructor:

>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3

**side_effect**
This can either be a function to be called when the mock is called, or an exception (class or instance) to be raised.
If you pass in a function it will be called with same arguments as the mock and unless the function returns the `DEFAULT` singleton the call to the mock will then return whatever the function returns. If the function returns `DEFAULT` then the mock will return its normal value (from the `return_value`).

An example of a mock that raises an exception (to test exception handling of an API):

```python
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```

Using `side_effect` to return a sequence of values:

```python
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
>>> mock(), mock(), mock()
(3, 2, 1)
```

The `side_effect` function is called with the same arguments as the mock (so it is wise for it to take arbitrary args and keyword arguments) and whatever it returns is used as the return value for the call. The exception is if `side_effect` returns `DEFAULT`, in which case the normal `return_value` is used.

```python
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
... >>> mock.side_effect = side_effect
```
side_effect can be set in the constructor. Here’s an example that adds one to the value the mock is called with and returns it:

```python
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
>>> mock(-8)
-7
```

Setting side_effect to None clears it:

```python
>>> m = Mock(side_effect=KeyError, return_value=None)
>>> m()
Traceback (most recent call last):
 ... KeyError
>>> m.side_effect = None
>>> m()
3
```

**call_args**

This is either None (if the mock hasn’t been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member is any ordered arguments the mock was called with (or an empty tuple) and the second member is any keyword arguments (or an empty dictionary).

```python
>>> mock = Mock(return_value=None)
>>> print mock.call_args
None
```
>>> mock()
>>> mock.call_args
call()
>>> mock.call_args == ()
True
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args
call(3, 4, 5, key='fish', next='w00t!')

call_args, along with members of the lists call_args_list, method_calls and mock_calls are call objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See calls as tuples.

call_args_list
This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The call object can be used for conveniently constructing lists of calls to compare with call_args_list.

>>> mock = Mock(return_value=None)
>>> mock()
>>> mock(3, 4)
>>> mock(key='fish', next='w00t!')
>>> mock.call_args_list
[call(), call(3, 4), call(key='fish', next='w00t!')]
>>> expected = [(), ((3, 4),), ({'key': 'fish',
>>> mock.call_args_list == expected
Members of *call_args_list* are *call* objects. These can be unpacked as tuples to get at the individual arguments. See *calls as tuples*.

**method_calls**

As well as tracking calls to themselves, mocks also track calls to methods and attributes, and *their* methods and attributes:

```python
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.property.method.attribute()
<Mock name='mock.property.method.attribute()' id='...'>
>>> mock.method_calls
[call.method(), call.property.method.attribute()]
```

Members of *method_calls* are *call* objects. These can be unpacked as tuples to get at the individual arguments. See *calls as tuples*.

**mock_calls**

*mock_calls* records *all* calls to the mock object, its methods, magic methods *and* return value mocks.

```python
>>> mock = MagicMock()
>>> result = mock(1, 2, 3)
>>> mock.first(a=3)
<MagicMock name='mock.first()' id='...'>
>>> mock.second()
<MagicMock name='mock.second()' id='...'>
>>> int(mock)
```
Members of mock_calls are call objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

__class__
Normally the __class__ attribute of an object will return its type. For a mock object with a spec __class__ returns the spec class instead. This allows mock objects to pass isinstance tests for the object they are replacing / masquerading as:

```python
>>> mock = Mock(spec=3)
>>> isinstance(mock, int)
True
```

__class__ is assignable to, this allows a mock to pass an isinstance check without forcing you to use a spec:

```python
>>> mock = Mock()
>>> mock.__class__ = dict
>>> isinstance(mock, dict)
True
```

class unittest.mock.NonCallableMock(spec=None, wraps=None, name=None, spec_set=None, **kwargs)

A non-callable version of Mock. The constructor parameters have

the same meaning of *Mock*, with the exception of *return_value* and *side_effect* which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a *spec* or *spec_set* are able to pass *isinstance* tests:

```python
>>> mock = Mock(spec=SomeClass)
>>> isinstance(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
>>> isinstance(mock, SomeClass)
True
```

The *Mock* classes have support for mocking magic methods. See *magic methods* for the full details.

The mock classes and the *patch()* decorators all take arbitrary keyword arguments for configuration. For the *patch* decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```python
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can’t use dotted names directly in a call you have to create a dictionary and unpack it using **:

```python
>>> attrs = {'method.return_value': 3, 'other.side_effect': lambda: 'eggs'}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
```
class unittest.mock.PropertyMock(*args, **kwargs)

A mock intended to be used as a property, or other descriptor, on a class. `PropertyMock` provides `__get__` and `__set__` methods so you can specify a return value when it is fetched.

Fetching a `PropertyMock` instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.

```python
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
...
>>> with patch('__main__.Foo.foo', new_callable=PropertyMock)
...     mock_foo = PropertyMock(return_value='mockity-mock')
...     this_foo = Foo()
...     print(this_foo.foo)
...     this_foo.foo = 6
...
mockity-mock
>>> mock_foo.mock_calls
[call(), call(6)]
```

Because of the way mock attributes are stored you can’t directly attach
a PropertyMock to a mock object. Instead you can attach it to the mock type object:

```python
>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()
```

26.4.2.1. Calling

Mock objects are callable. The call will return the value set as the return_value attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like call_args and call_args_list.

If side_effect is set then it will be called after the call has been recorded, so if side_effect raises an exception the call is still recorded.

The simplest way to make a mock raise an exception when called is to make side_effect an exception class or instance:

```python
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
  ...
IndexError
>>> m.mock_calls
[call(1, 2, 3)]
```
If `side_effect` is a function then whatever that function returns is what calls to the mock return. The `side_effect` function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```python
>>> def side_effect(value):
...   return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]
```

If you want the mock to still return the default return value (a new mock), or any set return value, then there are two ways of doing this. Either return `mock.return_value` from inside `side_effect`, or return `DEFAULT`:

```python
>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...   return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
```
To remove a side_effect, and return to the default behaviour, set the side_effect to None:

```python
>>> m = MagicMock(return_value=6)
>>> def side_effect(*args, **kwargs):
...     return 3
... >>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
6
```

The side_effect can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is exhausted and a StopIteration is raised):

```python
>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
```
If any members of the iterable are exceptions they will be raised instead of returned:

```python
>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
 ... ValueError
>>> m()
66
```

26.4.2.2. Deleting Attributes

Mock objects create attributes on demand. This allows them to pretend to be objects of any type.

You may want a mock object to return `False` to a `hasattr` call, or raise an `AttributeError` when an attribute is fetched. You can do this by providing an object as a `spec` for a mock, but that isn’t always convenient.

You “block” attributes by deleting them. Once deleted, accessing an attribute will raise an `AttributeError`.

```python
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
```
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
...  
AttributeError: f

26.4.2.3. Mock names and the name attribute

Since “name” is an argument to the Mock constructor, if you want your mock object to have a “name” attribute you can’t just pass it in at creation time. There are two alternatives. One option is to use configure_mock():

```python
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```

A simpler option is to simply set the “name” attribute after mock creation:

```python
>>> mock = MagicMock()
>>> mock.name = "foo"
```

26.4.2.4. Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a “child” of that mock. Calls to the child are recorded in the method_calls and mock_calls attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all
calls to the children and allows you to make assertions about the order of calls between mocks:

```python
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the “parenting” if for some reason you don’t want it to happen.

```python
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
>>> mock.mock_calls
[]
```

Mocks created for you by `patch()` are automatically given names. To attach mocks that have names to a parent you use the `attach_mock()` method:

```python
>>> thing1 = object()
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None)
...    with patch('__main__.thing2', return_value=None)
...        parent.attach_mock(child1, 'child1')
...        parent.attach_mock(child2, 'child2')
```
The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead of raises an `AttributeError`. This is because the interpreter will often implicitly request these methods, and gets very confused to get a new Mock object when it expects a magic method. If you need magic method support see `magic methods`. 

```python
...    child1('one')
...    child2('two')
...

>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```
26.4.3. The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

26.4.3.1. patch

Note: patch is straightforward to use. The key is to do the patching in the right namespace. See the section where to patch.

unittest.mock.patch(target, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)

patch acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the target is patched with a new object. When the function/with statement exits the patch is undone.

If new is omitted, then the target is replaced with a MagicMock. If patch is used as a decorator and new is omitted, the created mock is passed in as an extra argument to the decorated function. If patch is used as a context manager the created mock is returned by the context manager.

target should be a string in the form ‘package.module.ClassName’. The target is imported and the specified object replaced with the new object, so the target must be importable from the environment you are calling patch from. The target is imported when the decorated function is executed, not at decoration time.
The `spec` and `spec_set` keyword arguments are passed to the `MagicMock` if patch is creating one for you.

In addition you can pass `spec=True` or `spec_set=True`, which causes patch to pass in the object being mocked as the `spec/spec_set` object.

`new_callable` allows you to specify a different class, or callable object, that will be called to create the new object. By default `MagicMock` is used.

A more powerful form of `spec` is `autospec`. If you set `autospec=True` then the mock will be created with a spec from the object being replaced. All attributes of the mock will also have the spec of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a `TypeError` if they are called with the wrong signature. For mocks replacing a class, their return value (the ‘instance’) will have the same spec as the class. See the `create_autospec()` function and `Autospeccing`.

Instead of `autospec=True` you can pass `autospec=some_object` to use an arbitrary object as the spec instead of the one being replaced.

By default `patch` will fail to replace attributes that don’t exist. If you pass in `create=True`, and the attribute doesn’t exist, patch will create the attribute for you when the patched function is called, and delete it again afterwards. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you can write passing tests against APIs that don’t actually exist!
Patch can be used as a `TestCase` class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. `patch` finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is `test`, which matches the way `unittest` finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the `with` statement. Here the patching applies to the indented block after the `with` statement. If you use “as” then the patched object will be bound to the name after the “as”; very useful if `patch` is creating a mock object for you.

`patch` takes arbitrary keyword arguments. These will be passed to the `Mock` (or `new_callable`) on construction.

`patch.dict(...)`, `patch.multiple(...)` and `patch.object(...)` are available for alternate use-cases.

`patch` as function decorator, creating the mock for you and passing it into the decorated function:

```python
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
...
>>> function(None)
True
```

Patching a class replaces the class with a `MagicMock instance`. If the class is instantiated in the code under test then it will be the `return_value` of the mock that will be used.
If the class is instantiated multiple times you could use `side_effect` to return a new mock each time. Alternatively you can set the `return_value` to be anything you want.

To configure return values on methods of `instances` on the patched class you must do this on the `return_value`. For example:

```python
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
```

If you use `spec` or `spec_set` and `patch` is replacing a `class`, then the return value of the created mock will have the same spec.

```python
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()
```

The `new_callable` argument is useful where you want to use an alternative class to the default `MagicMock` for the created mock. For example, if you wanted a `NonCallableMock` to be used:

```python
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock)
...     assert thing is mock_thing
```
Another use case might be to replace an object with a `io.StringIO` instance:

```python
>>> from io import StringIO
>>> def foo():
...    print 'Something'
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...    foo()
...    assert mock_stdout.getvalue() == 'Something

>>> test()
```

When `patch` is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to `patch`. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:

```python
>>> patcher = patch('__main__.thing', first='one', second='two')
>>> mock_thing = patcher.start()
>>> mock_thing.first
'one'
>>> mock_thing.second
'two'
```

As well as attributes on the created mock attributes, like the
return_value and side_effect, of child mocks can also be configured. These aren’t syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a patch call using **:

```python
>>> config = {'method.return_value': 3, 'other.side_effect': None}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
 ... KeyError
```

26.4.3.2. patch.object

patch.object(target, attribute, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)

patch the named member (attribute) on an object (target) with a mock object.

patch.object can be used as a decorator, class decorator or a context manager. Arguments new, spec, create, spec_set, autospec and new_callable have the same meaning as for patch. Like patch, patch.object takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator patch.object honours patch.TEST_PREFIX for choosing which methods to wrap.

You can either call patch.object with three arguments or two
arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```python
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
... >>> test()
```

`spec`, `create` and the other arguments to `patch.object` have the same meaning as they do for `patch`.

26.4.3.3. `patch.dict`

`patch.dict(in_dict, values=(), clear=False, **kwargs)`

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

`in_dict` can be a dictionary or a mapping like container. If it is a mapping then it must at least support getting, setting and deleting items plus iterating over keys.

`in_dict` can also be a string specifying the name of the dictionary, which will then be fetched by importing it.

`values` can be a dictionary of values to set in the dictionary. `values` can also be an iterable of `(key, value)` pairs.

If `clear` is True then the dictionary will be cleared before the new
values are set.

`patch.dict` can also be called with arbitrary keyword arguments to set values in the dictionary.

`patch.dict` can be used as a context manager, decorator or class decorator. When used as a class decorator `patch.dict` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

`patch.dict` can be used to add members to a dictionary, or simply let a test change a dictionary, and ensure the dictionary is restored when the test ends.

```python
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}):
...    assert foo == {'newkey': 'newvalue'}
...    import mymodule
...    mymodule.function('some', 'args')
```

Keywords can be used in the `patch.dict` call to set values in the dictionary:

```python
>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
...    import mymodule
...    mymodule.function('some', 'args')
```
patch.dict can be used with dictionary like objects that aren’t actually
dictionaries. At the very minimum they must support item getting,
setting, deleting and either iteration or membership test. This
corresponds to the magic methods __getitem__, __setitem__,
__delitem__ and either __iter__ or __contains__.

```python
>>> class Container:
...     def __init__(self):
...         self.values = {}
...     def __getitem__(self, name):
...         return self.values[name]
...     def __setitem__(self, name, value):
...         self.values[name] = value
...     def __delitem__(self, name):
...         del self.values[name]
...     def __iter__(self):
...         return iter(self.values)
...>>> thing = Container()
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...     assert thing['one'] == 1
>>> assert list(thing) == ['one']
```

26.4.3.4. patch.multiple

patch.multiple(target, spec=None, create=False,
spec_set=None, autospec=None, new_callable=None, **kwargs)
Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object by importing) and keyword arguments for the patches:

```python
with patch.multiple(settings, FIRST_PATCH='one', ...
```

Use `DEFAULT` as the value if you want `patch.multiple` to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when `patch.multiple` is used as a context manager.

`patch.multiple` can be used as a decorator, class decorator or a context manager. The arguments `spec`, `spec_set`, `create`, `autospec` and `new_callable` have the same meaning as for `patch`. These arguments will be applied to all patches done by `patch.multiple`.

When used as a class decorator `patch.multiple` honours `patch.TEST_PREFIX` for choosing which methods to wrap.

If you want `patch.multiple` to create mocks for you, then you can use `DEFAULT` as the value. If you use `patch.multiple` as a decorator then the created mocks are passed into the decorated function by keyword.

```python
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other...
... def test_function(thing, other):
...     assert isinstance(thing, MagicMock)
...     assert isinstance(other, MagicMock)
...
>>> test_function()
```
patch.multiple can be nested with other patch decorators, but put arguments passed by keyword after any of the standard arguments created by patch:

```python
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other)
... def test_function(mock_exit, other, thing):
...     assert 'other' in repr(other)
...     assert 'thing' in repr(thing)
...     assert 'exit' in repr(mock_exit)
... >>> test_function()
```

If patch.multiple is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```python
>>> with patch.multiple('__main__', thing=DEFAULT, other)
...     assert 'other' in repr(values['other'])
...     assert 'thing' in repr(values['thing'])
...     assert values['thing'] is thing
...     assert values['other'] is other
```

26.4.3.5. patch methods: start and stop

All the patchers have start and stop methods. These make it simpler to do patching in setUp methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call patch, patch.object or patch.dict as normal and keep a reference to the returned patcher object. You can then call start to
put the patch in place and \textit{stop} to undo it.

If you are using \textit{patch} to create a mock for you then it will be returned by the call to \textit{patcher.start}.

\begin{verbatim}
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName \textbf{is not} original
>>> assert module.ClassName \textbf{is} new_mock
>>> patcher.stop()
>>> assert module.ClassName \textbf{is} original
>>> assert module.ClassName \textbf{is not} new_mock
\end{verbatim}

A typical use case for this might be for doing multiple patches in the \texttt{setUp} method of a \texttt{TestCase}:

\begin{verbatim}
>>> class MyTest(TestCase):
...     def setUp(self):
...         self.patcher1 = patch('package.module.Class1')
...         self.patcher2 = patch('package.module.Class2')
...         self.MockClass1 = self.patcher1.start()
...         self.MockClass2 = self.patcher2.start()
...     
...     def tearDown(self):
...         self.patcher1.stop()
...         self.patcher2.stop()
...     
...     def test_something(self):
...         assert package.module.Class1 \textbf{is} self.MockClass1
...         assert package.module.Class2 \textbf{is} self.MockClass2
...     
... 
>>> MyTest('test_something').run()
\end{verbatim}
Caution: If you use this technique you must ensure that the patching is “undone” by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called. `unittest.TestCase.addCleanup()` makes this easier:

```python
>>> class MyTest(TestCase):
    ...
    def setUp(self):
    ...
        patcher = patch('package.module.Class')
    ...
        self.MockClass = patcher.start()
    ...
        ...
    ...
    def test_something(self):
    ...
        assert package.module.Class is self.MockClass
    ...
```

As an added bonus you no longer need to keep a reference to the `patcher` object.

It is also possible to stop all patches which have been started by using `patch.stopall`.

`patch.stopall()`

Stop all active patches. Only stops patches started with `start`.

26.4.3.6. TEST_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with `test` as being test methods. This is the same way that the `unittest.TestLoader` finds test methods by default.
It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:

```python
>>> patch.TEST_PREFIX = 'foo'
>>> value = 3
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print value
...     def foo_two(self):
...         print value

>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3
```

### 26.4.3.7. Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

```python
>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
```
SomeClass\n\n\n... SomeClass.class_method('bar')
... return mock1, mock2
...

>>> mock1, mock2 = test()
>>> mock1.assert_called_once_with('foo')
>>> mock2.assert_called_once_with('bar')

Note that the decorators are applied from the bottom upwards. This is the standard way that Python applies decorators. The order of the created mocks passed into your test function matches this order.

26.4.3.8. Where to patch

*patch* works by (temporarily) changing the object that a name points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is *looked up*, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```
a.py
   -> Defines SomeClass

b.py
   -> from a import SomeClass
   -> some_function instantiates SomeClass
```

Now we want to test *some_function* but we want to mock out *SomeClass* using *patch*. The problem is that when we import module
b, which we will have to do then it imports SomeClass from module a. If we use patch to mock out a.SomeClass then it will have no effect on our test; module b already has a reference to the real SomeClass and it looks like our patching had no effect.

The key is to patch out SomeClass where it is used (or where it is looked up ). In this case some_function will actually look up SomeClass in module b, where we have imported it. The patching should look like:

```python
@patch('b.SomeClass')
```

However, consider the alternative scenario where instead of from a import SomeClass module b does import a and some_function uses a.SomeClass. Both of these import forms are common. In this case the class we want to patch is being looked up on the a module and so we have to patch a.SomeClass instead:

```python
@patch('a.SomeClass')
```

### 26.4.3.9. Patching Descriptors and Proxy Objects

Both patch and patch.object correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the class rather than an instance. They also work with some objects that proxy attribute access, like the django setttings object.
26.4.4. MagicMock and magic method support

26.4.4.1. Mocking Magic Methods

Mock supports mocking the Python protocol methods, also known as “magic methods”. This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods [2], this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes almost all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it must take self as the first argument [3].

```python
>>> def __str__(self):
...     return 'fooble'
... >>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```python
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'
```
One use case for this is for mocking objects used as context managers in a *with* statement:

```python
>>> mock = Mock()
>>> mock.__iter__ = Mock(return_value=iter([]))
>>> list(mock)
[]
```

Calls to magic methods do not appear in *method_calls*, but they are recorded in *mock_calls*.

**Note:** If you use the *spec* keyword argument to create a mock then attempting to set a magic method that isn't in the spec will raise an *AttributeError*.

The full list of supported magic methods is:

- *__hash__*, *__sizeof__*, *__repr__* and *__str__*
- *__dir__*, *__format__* and *__subclasses__*
- *__floor__*, *__trunc__* and *__ceil__*
- Comparisons: *__cmp__*, *__lt__*, *__gt__*, *__le__*, *__ge__*, *__eq__* and *__ne__*
- Container methods: *__getitem__*, *__setitem__*, *__delitem__*, *__contains__*, *__len__*, *__iter__*,
Context manager: __enter__ and __exit__

Unary numeric methods: __neg__, __pos__ and __invert__

The numeric methods (including right hand and in-place variants): __add__, __sub__, __mul__, __div__, __floordiv__, __mod__, __divmod__, __lshift__, __rshift__, __and__, __xor__, __or__, and __pow__

Numeric conversion methods: __complex__, __int__, __float__, __index__ and __coerce__

Descriptor methods: __get__, __set__ and __delete__

Pickling: __reduce__, __reduce_ex__, __getinitargs__, __getnewargs__, __getstate__ and __setstate__

The following methods exist but are not supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- __getattr__, __setattr__, __init__ and __new__
- __prepare__, __instancecheck__, __subclasscheck__, __del__

26.4.4.2. Magic Mock

There are two MagicMock variants: MagicMock and NonCallableMagicMock.

class unittest.mock.MagicMock(*args, **kw)

MagicMock is a subclass of Mock with default implementations of most of the magic methods. You can use MagicMock without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for Mock.
If you use the `spec` or `spec_set` arguments then only magic methods that exist in the spec will be created.

```python
class unittest.mock.NonCallableMock(*args, **kw)
```

A non-callable version of `MagicMock`.

The constructor parameters have the same meaning as for `MagicMock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

The magic methods are setup with `MagicMock` objects, so you can configure them and use them in the usual way:

```python
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren’t interested in the return value. You can still set the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: NotImplemented
- `__gt__`: NotImplemented
- `__le__`: NotImplemented
- `__ge__`: NotImplemented
- `__int__`: 1
- `__contains__`: False
- __len__: 1
- __iter__: iter([])
- __exit__: False
- __complex__: 1j
- __float__: 1.0
- __bool__: True
- __index__: 1
- __hash__: default hash for the mock
- __str__: default str for the mock
- __sizeof__: default sizeof for the mock

For example:

```python
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

The two equality method, __eq__ and __ne__, are special. They do the default equality comparison on identity, using a side effect, unless you change their return value to return something else:

```python
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
>>> mock.__eq__.return_value = True
>>> mock == 3
True
```
The return value of `MagicMock.__iter__` can be any iterable object and isn't required to be an iterator:

```python
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

If the return value is an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```python
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

`MagicMock` has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in `MagicMock` are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`, `__set__` and `__delete__`
- `__reversed__` and `__missing__`
- `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
• **__getformat__** and **__setformat__**

  Magic methods *should* be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

[2] The function is basically hooked up to the class, but each Mock instance is kept isolated from the others.
26.4.5. Helpers

26.4.5.1. sentinel

unittest.mock.sentinel

The sentinel object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible repr so that test failure messages are readable.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named sentinel objects to test this. sentinel provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch method to return sentinel.some_object:

```python
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> sentinel.some_object
```

26.4.5.2. DEFAULT
unittest.mock.**DEFAULT**

The **DEFAULT** object is a pre-created sentinel (actually **sentinel.DEFAULT**). It can be used by **side_effect** functions to indicate that the normal return value should be used.

### 26.4.5.3. call

**unittest.mock.call**(*args, **kwargs)

*call* is a helper object for making simpler assertions, for comparing with **call_args**, **call_args_list**, **mock_calls** and **method_calls**. *call* can also be used with **assert_has_calls**().

```python
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar')]
True
```

**call.call_list()**

For a call object that represents multiple calls, **call_list** returns a list of all the intermediate calls as well as the final call.

**call_list** is particularly useful for making assertions on “chained calls”. A chained call is multiple calls on a single line of code. This results in multiple entries in **mock_calls** on a mock. Manually constructing the sequence of calls can be tedious.

**call_list()** can construct the sequence of calls from the same chained call:

```python
>>> m = MagicMock()
```
A *call* object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn’t particularly interesting, but the *call* objects that are in the `Mock.call_args`, `Mock.call_args_list` and `Mock.mock_calls` attributes can be introspected to get at the individual arguments they contain.

The *call* objects in `Mock.call_args` and `Mock.call_args_list` are two-tuples of (positional args, keyword args) whereas the *call* objects in `Mock.mock_calls`, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their “tupleness” to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:

```python
>>> m = MagicMock(return_value=None)
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> args, kwargs = kall
>>> args
(1, 2, 3)
```
>>> kwargs
{'arg2': 'two', 'arg': 'one'}
>>> args is kall[0]
True
>>> kwargs is kall[1]
True

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
<MagicMock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg2': 'three', 'arg': 'two'}
>>> name is m.mock_calls[0][0]
True

26.4.5.4. create_autospec

unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the spec object as their spec.

Functions or methods being mocked will have their arguments checked to ensure that they are called with the correct signature.

If spec_set is True then attempting to set attributes that don’t exist on the spec object will raise an AttributeError.
If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing `instance=True`. The returned mock will only be callable if instances of the mock are callable.

`create_autospec` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See *Autospeccing* for examples of how to use auto-speccing with `create_autospec` and the `autospec` argument to `patch()`.

### 26.4.5.5. ANY

unittest.mock.**ANY**

Sometimes you may need to make assertions about some of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of `call_args` and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to *everything*. Calls to `assert_called_with()` and `assert_called_once_with()` will then succeed no matter what was passed in.

```python
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)

**ANY** can also be used in comparisons with call lists like `mock_calls`:

```python
>>> m = MagicMock(return_value=None)
```
26.4.5.6. FILTER_DIR

unittest.mock.FILTER_DIR

FILTER_DIR is a module level variable that controls the way mock objects respond to dir (only for Python 2.6 or more recent). The default is True, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set mock.FILTER_DIR = False.

With filtering on, dir(some_mock) shows only useful attributes and will include any dynamically created attributes that wouldn’t normally be shown. If the mock was created with a spec (or autospec of course) then all the attributes from the original are shown, even if they haven’t been accessed yet:

```python
>>> dir(Mock())
['assert_any_call',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'attach_mock',
 ...]

>>> from urllib import request

>>> dir(Mock(spec=request))
['AbstractBasicAuthHandler',
 'AbstractDigestAuthHandler',
 'AbstractHTTPHandler',
]```
Many of the not-very-useful (private to Mock rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling `dir` on a `Mock`. If you dislike this behaviour you can switch it off by setting the module level switch `FILTER_DIR`:

```python
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['__NonCallableMock__get_return_value',
 '__NonCallableMock__get_side_effect',
 '__NonCallableMock__return_value_doc',
 '__NonCallableMock__set_return_value',
 '__NonCallableMock__set_side_effect',
 '__call__',
 '__class__',
...
```

Alternatively you can just use `vars(my_mock)` (instance members) and `dir(type(my_mock))` (type members) to bypass the filtering irrespective of `mock.FILTER_DIR`.

### 26.4.5.7. mock_open

`unittest.mock.mock_open(mock=None, read_data=None)`

A helper function to create a mock to replace the use of `open`. It works for `open` called directly or used as a context manager.

The `mock` argument is the mock object to configure. If `None` (the default) then a `MagicMock` will be created for you, with the API limited to methods or attributes available on standard file handles.
`read_data` is a string for the `~io.IOBase.read` method of the file handle to return. This is an empty string by default.

Using `open` as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```python
with open('/some/path', 'w') as f:
    f.write('something')
```

The issue is that even if you mock out the call to `open` it is the `returned object` that is used as a context manager (and has `__enter__` and `__exit__` called).

Mocking context managers with a `MagicMock` is common enough and fiddly enough that a helper function is useful.

```python
>>> m = mock_open()
>>> with patch('__main__.open', m, create=True):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
 call().write('some stuff'),
 call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')
```

And for reading files:

```python
>>> with patch('__main__.open', mock_open(read_data='some stuff')) as h:
...     with open('foo') as h:
...         result = h.read()
...```
26.4.5.8. Autospeccing

Autospeccing is based on the existing spec feature of mock. It limits the api of mocks to the api of an original object (the spec), but it is recursive (implemented lazily) so that attributes of mocks only have the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a TypeError if they are called incorrectly.

Before I explain how auto-speccing works, here’s why it is needed.

Mock is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the Mock api and the other is a more general problem with using mock objects.

First the problem specific to Mock. Mock has two assert methods that are extremely handy: assert_called_with() and assert_called_once_with().

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
  ...
AssertionError: Expected 'mock' to be called once. Called twice.
```
Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(4, 5, 6)
```

Your tests can pass silently and incorrectly because of the typo.

The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the old api but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don’t test how your units are “wired together” there is still lots of room for bugs that tests might have caught.

`mock` already provides a feature to help with this, called speccing. If you use a class or instance as the spec for a mock then you can only access attributes on the mock that exist on the real class:

```python
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assert_called_with
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assret
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:
Auto-speccing solves this problem. You can either pass `autospec=True` to `patch` or `patch.object` or use the `create_autospec` function to create a mock with a spec. If you use the `autospec=True` argument to `patch` then the object that is being replaced will be used as the spec object. Because the speccing is done “lazily” (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here’s an example of it in use:

```python
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='...'>
```

You can see that `request.Request` has a spec. `request.Request` takes two arguments in the constructor (one of which is `self`). Here’s what happens if we try to call it incorrectly:

```python
>>> req = request.Request()
Traceback (most recent call last):
...
TypeError: <lambda>() takes at least 2 arguments (1 given)
```
The spec also applies to instantiated classes (i.e. the return value of speced mocks):

```python
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Request' id='...'>
```

Request objects are not callable, so the return value of instantiating our mocked out request.Request is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```python
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='...'>
>>> req.add_header.assert_called_with
Traceback (most recent call last):
  ...
AttributeError: Mock object has no attribute 'assert_called_with'
>>> req.add_header.assert_called_with('spam', 'eggs')
```

In many cases you will just be able to add autospec=True to your existing patch calls and then be protected against bugs due to typos and api changes.

As well as using autospec through patch there is a create_autospec() for creating autospecced mocks directly:

```python
>>> from urllib import request
>>> mock_request = create_autospec(request)
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request' id='...'>
```

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are
available on the spec object, autospec has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use autospec. On the other hand it is much better to design your objects so that introspection is safe [4].

A more serious problem is that it is common for instance attributes to be created in the `__init__` method and not to exist on the class at all. autospec can’t know about any dynamically created attributes and restricts the api to visible attributes.

```python
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a

Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because autospec doesn’t allow you to fetch attributes that don’t exist on the spec it doesn’t prevent you setting them:

```python
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a = 33
```
There is a more aggressive version of both `spec` and `autospec` that does prevent you setting non-existent attributes. This is useful if you want to ensure your code only sets valid attributes too, but obviously it prevents this particular scenario:

```python
>>> with patch('__main__.Something', autospec=True,
...           thing = Something()
...           thing.a = 33
...
Traceback (most recent call last):
  ... AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in `__init__`. Note that if you are only setting default attributes in `__init__` then providing them via class attributes (shared between instances of course) is faster too. e.g.

```python
class Something:
    a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn’t let you access any attributes or methods on it. As `None` is never going to be useful as a spec, and probably indicates a member that will normally of some other type, `autospec` doesn’t use a spec for members that are set to `None`. These will just be ordinary mocks (well - `MagicMocks`):
If modifying your production classes to add defaults isn’t to your liking then there are more options. One of these is simply to use an instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully `patch` supports this - you can simply pass the alternative object as the `autospec` argument:

```
>>> class Something:
    ...    def __init__(self):
    ...        self.a = 33

>>> class SomethingForTest(Something):
    ...

>>> p = patch('__main__.Something', autospec=SomethingForTest)
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int'
```

This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance *does not* create a real instance. It is only attribute lookups - along with calls to `dir` - that are done.

---

[4]
26.5. unittest.mock — getting started

New in version 3.3.
26.5.1. Using Mock

26.5.1.1. Mock Patching Methods

Common uses for Mock objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```python
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (`real.method` in this example) it has methods and attributes that allow you to make assertions about how it has been used.

**Note:** In most of these examples the Mock and MagicMock classes are interchangeable. As the MagicMock is the more capable class it makes a sensible one to use by default.

Once the mock has been called its `called` attribute is set to `True`. More importantly we can use the `assert_called_with()` or `assert_called_once_with()` method to check that it was called with the correct arguments.

This example tests that calling `ProductionClass().method` results in a call to the `something` method:
class ProductionClass:
...
    def method(self):
        self.something(1, 2, 3)
...
    def something(self, a, b, c):
        pass
...
real = ProductionClass()
real.something = MagicMock()  
real.method() 
real.something.assert_called_once_with(1, 2, 3)

26.5.1.2. Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple ProductionClass below has a closer method. If it is called with an object then it calls close on it.

>>> class ProductionClass:
...    def closer(self, something):
...        something.close()
...
So to test it we need to pass in an object with a close method and check that it was called correctly.

>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
We don’t have to do any work to provide the ‘close’ method on our mock. Accessing close creates it. So, if ‘close’ hasn’t already been called then accessing it in the test will create it, but `assert_called_with()` will raise a failure exception.

26.5.1.3. Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by calling the class. This means you access the “mock instance” by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to `patch` replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock `return_value`.

```python
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...
>>> assert result == 'the result'
```

26.5.1.4. Naming your mocks

It can be useful to give your mocks a name. The name is shown in the `repr` of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or
methods of the mock:

```python
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
<MagicMock name='foo.method' id='...'>
```

26.5.1.5. Tracking all Calls

Often you want to track more than a single call to a method. The `mock_calls` attribute records all calls to child attributes of the mock - and also to their children.

```python
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute метод(10, x=53)
<MagicMock name='mock.attribute метод(10, x=53)' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute метод(10, x=53)]
```

If you make an assertion about `mock_calls` and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the `call` object to construct lists for comparing with `mock_calls`:

```python
>>> expected = [call.method(), call.attribute метод(10, x=53)]
>>> mock.mock_calls == expected
True
```
26.5.1.6. Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for example `mock.connection.cursor().execute("SELECT 1")`. If we wanted this call to return a list, then we have to configure the result of the nested call.
We can use `call` to construct the set of calls in a “chained call” like this for easy assertion afterwards:

```python
>>> mock = Mock()
>>> cursor = mock.connection.cursor().return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")['foo']
>>> expected = call.connection.cursor().execute("SELECT 1")
[call.connection.cursor(), call.connection.cursor().execute("SELECT 1")]
>>> mock.mock_calls == expected
True
```

It is the call to `call_list()` that turns our call object into a list of calls representing the chained calls.

26.5.1.7. Raising exceptions with mocks

A useful attribute is `side_effect`. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```python
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```

26.5.1.8. Side effect functions and iterables

`side_effect` can also be set to a function or an iterable. The use case for `side_effect` as an iterable is where your mock is going to be called
several times, and you want each call to return a different value. When you set `side_effect` to an iterable every call to the mock returns the next value from the iterable:

```python
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, `side_effect` can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the call returns:

```python
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...    return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock((1, 2))
1
>>> mock((2, 3))
2
```

26.5.1.9. Creating a Mock from an Existing Object

One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that also provides `some_method`. If later you refactor the first class, so that it no longer
has some_method - then your tests will continue to pass even though your code is now broken!

Mock allows you to provide an object as a specification for the mock, using the spec keyword argument. Accessing methods / attributes on the mock that don’t exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```python
>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
  ...
AttributeError: object has no attribute 'old_method'
```

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use spec_set instead of spec.
26.5.2. Patch Decorators

**Note:** With *patch* it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch*.

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

mock provides three convenient decorators for this: *patch, patch.object* and *patch.dict*. *patch* takes a single string, of the form *package.module.Class.attribute* to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with. *patch.object* takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

*patch.object*:

```python
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
... def test():
...     assert SomeClass.attribute == sentinel.attribute
... test()
>>> assert SomeClass.attribute == original

>>> @patch('package.module.attribute', sentinel.attribute)
```
... def test():
    ... from package.module import attribute
    ... assert attribute is sentinel.attribute
    ...
>>> test()

If you are patching a module (including `builtins`) then use `patch` instead of `patch.object`:

```python
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
... >>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle returned"
```

The module name can be ‘dotted’, in the form `package.module` if needed:

```python
>>> @patch('package.module.ClassName.attribute', sentinel)
... def test():
...     ... from package.module import ClassName
...     ... assert ClassName.attribute == sentinel.attribute
...     ...
>>> test()
```

A nice pattern is to actually decorate test methods themselves:

```python
>>> class MyTest(unittest2.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel)
...     ...
>>> original = SomeClass.attribute
```
If you want to patch with a Mock, you can use `patch` with only one argument (or `patch.object` with two arguments). The mock will be created for you and passed into the test function / method:

```python
>>> class MyTest(unittest2.TestCase):
    ...
    @patch.object(SomeClass, 'static_method')
    ...
    def test_something(self, mock_method):
        ...
        SomeClass.static_method()
        ...
        mock_method.assert_called_with()
        ...
    >>> MyTest('test_something').test_something()
```

You can stack up multiple patch decorators using this pattern:

```python
>>> class MyTest(unittest2.TestCase):
    ...
    @patch('package.module.ClassName1')
    ...
    @patch('package.module.ClassName2')
    ...
    def test_something(self, MockClass2, MockClass1):
        ...
        self.assertEqual(MockClass1.return_value, MockClass2)
        ...
    >>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal Python order that decorators are applied). This means from the bottom up, so in the example above the mock for `test_module.ClassName2` is passed in first.

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when
the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...    assert foo == {'newkey': 'newvalue'}
...    assert foo == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use `patch` to create a mock for you, you can get a reference to the mock using the “as” form of the with statement:

```python
>>> class ProductionClass:
...    def method(self):
...        pass
...
>>> with patch.object(ProductionClass, 'method') as mock_method:
...    mock_method.return_value = None
...    real = ProductionClass()
...    real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

As an alternative `patch`, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with “test”.
26.5.3. Further Examples

Here are some more examples for some slightly more advanced scenarios.

26.5.3.1. Mocking chained calls

Mocking chained calls is actually straightforward with mock once you understand the `return_value` attribute. When a mock is called for the first time, or you fetch its `return_value` before it has been called, a new `Mock` is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the `return_value` mock:

```python
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place...

So, suppose we have some code that looks a little bit like this:

```python
class Something:
    def __init__(self):
        self.backend = BackendProvider()
    def method(self):
        response = self.backend.get_endpoint('foobar')
        # more code
```
Assuming that BackendProvider is already well tested, how do we test method()? Specifically, we want to test that the code section # more code uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the backend attribute on a Something instance. In this particular case we are only interested in the return value from the final call to start_call so we don’t have much configuration to do. Let’s assume the object it returns is ‘file-like’, so we’ll ensure that our response object uses the builtin file as its spec.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final start_call we could do this:

    mock_backend.get_endpoint.return_value.create_call.return_value.start_call.return_value = mock_response.

We can do that in a slightly nicer way using the configure_mock() method to directly set the return value for us:

```python
>>> something = Something()
>>> mock_response = Mock(spec=file)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value.start_call.return_value': mock_response}
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the “mock backend” in place and can make the real call:

```python
>>> something.backend = mock_backend
>>> something.method()
```
Using `mock_calls` we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in `mock_calls`. We can use `call.call_list()` to create this list of calls for us:

```python
>>> chained = call.get_endpoint('foobar').create_call
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

### 26.5.3.2. Partial mocking

In some tests I wanted to mock out a call to `datetime.date.today()` to return a known date, but I didn’t want to prevent the code under test from creating new date objects. Unfortunately `datetime.date` is written in C, and so I couldn’t just monkey-patch out the static `date.today` method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The `patch` decorator is used here to mock out the `date` class in the module under test. The `side_effect` attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by `side_effect`.

```python
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10...
...     mock_date.side_effect = lambda *args, **kw:
...```
Note that we don’t patch `datetime.date` globally, we patch `date` in the module that uses it. See *where to patch*.

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (`call_count` and friends) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other builtin classes, is discussed in this blog entry.

### 26.5.3.3. Mocking a Generator Method

A Python generator is a function or method that uses the `yield statement` to return a series of values when iterated over [1].

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is `__iter__`, so we can mock this using a `MagicMock`.

Here’s an example class with an “iter” method implemented as a generator:

```python
>>> class Foo:
...    def iter(self):
```
How would we mock this class, and in particular its “iter” method?

To configure the values returned from the iteration (implicit in the call to \textit{list}), we need to configure the object returned by the call to \textit{foo.iter()}.

There are also generator expressions and more advanced uses of generators, but we aren’t concerned about them here. A very good introduction to generators and how powerful they are is: \textit{Generator Tricks for Systems Programmers}.

26.5.3.4. Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. For Python 2.6 or more recent you can use \textit{patch} (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test method is identified by methods whose names start with \textit{test}:

```python
>>> @patch('mymodule.SomeClass')
... class MyTest(TestCase):
```
...  def test_one(self, MockSomeClass):
    self.assertIs(mymodule.SomeClass, MockSco
...  def test_two(self, MockSomeClass):
    self.assertIs(mymodule.SomeClass, MockSc
...  def not_a_test(self):
    return 'something'
...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'

An alternative way of managing patches is to use the *patch methods: start and stop*. These allow you to move the patching into your *setUp* and *tearDown* methods.

```python
>>> class MyTest(TestCase):
...  def setUp(self):
...    self.patcher = patch('mymodule.foo')
...    self.mock_foo = self.patcher.start()

...  def test_foo(self):
...    self.assertIs(mymodule.foo, self.mock_foo)

...  def tearDown(self):
...    self.patcher.stop()

>>> MyTest('test_foo').run()
```

If you use this technique you must ensure that the patching is “undone” by calling *stop*. This can be fiddlier than you might think,
because if an exception is raised in the setUp then tearDown is not called. `unittest.TestCase.addCleanup()` makes this easier:

```python
>>> class MyTest(TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...     
...     def test_foo(self):
...         self.assertIn(mymodule.foo, self.mock_foo)
... 
>>> MyTest('test_foo').run()
```

### 26.5.3.5. Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed `self` to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can't patch with a mock for this, because if you replace an unbound method with a mock it doesn't become a bound method when fetched from the instance, and so it doesn't get `self` passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to patch then it does the patching with a *real* function object. This function object has the same signature as the one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it
means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have `self` passed in as the first argument, which is exactly what I wanted:

```python
>>> class Foo:
...    def foo(self):
...        pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...    foo_return_value = 'foo'
...    foo = Foo()
...    foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with(foo)
```

If we don't use `autospec=True` then the unbound method is patched out with a Mock instance instead, and isn't called with `self`.

### 26.5.3.6. Checking multiple calls with mock

mock has a nice API for making assertions about how your mock objects are used.

```python
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

If your mock is only being called once you can use the `assert_called_once_with()` method that also asserts that the `call_count` is one.
Both `assert_called_with` and `assert_called_once_with` make assertions about the *most recent* call. If your mock is going to be called several times, and you want to make assertions about *all* those calls you can use `call_args_list`:

```python
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The `call` helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to `call_args_list`. This looks remarkably similar to the repr of the `call_args_list`:

```python
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

### 26.5.3.7. Coping with mutable arguments

Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store references...
to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here’s some example code that shows the problem. Imagine the following functions defined in ‘mymodule’:

```python
def frob(val):
    pass

def grob(val):
    "First frob and then clear val"
    frob(val)
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```python
>>> with patch('mymodule.frob') as mock_frob:
...     val = set([6])
...     mymodule.grob(val)
...     val.set([])
...     mock_frob.assert_called_with(set([6]))
Traceback (most recent call last):
  ... AssertionError: Expected: ((set([6]),), {}) Called with: ((set([]),), {})
```

One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.

Here’s one solution that uses the side_effect functionality. If you
provide a side_effect function for a mock then side_effect will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I’m using another mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```python
>>> from copy import deepcopy
>>> from unittest.mock import Mock, patch, DEFAULT
>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwars):
...         args = deepcopy(args)
...         kwars = deepcopy(kwars)
...         new_mock(*args, **kwars)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock

>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = set([6])
...     mymodule.grob(val)
...     new_mock.assert_called_with(set([6]))
>>> new_mock.call_args
    call(set([6]))
```

copy_call_args is called with the mock that will be called. It returns a new mock that we do the assertion on. The side_effect function makes a copy of the args and calls our new_mock with the copy.

**Note:** If your mock is only going to be used once there is an easier way of checking arguments at the point they are called. You can simply do the checking inside a side_effect function.
An alternative approach is to create a subclass of `Mock` or `MagicMock` that copies (using `copy.deepcopy()`) the arguments. Here's an example implementation:

```
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...     def __call__(self, *args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         return super(CopyingMock, self).__call__
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
  ...
AssertionError: Expected call: mock(set([1]))
Actual call: mock(set([]))
>>> c.foo
<CopyingMock name='mock.foo' id='...'>
```

When you subclass `Mock` or `MagicMock` all dynamically created
attributes, and the `return_value` will use your subclass automatically. That means all children of a `CopyingMock` will also have the type `CopyingMock`.

26.5.3.8. Nesting Patches

Using `patch` as a context manager is nice, but if you do multiple patches you can end up with nested `with` statements indenting further and further to the right:

```python
>>> class MyTest(TestCase):
...    ...
...    def test_foo(self):
...        with patch('mymodule.Foo') as mock_foo:
...            with patch('mymodule.Bar') as mock_bar:
...                with patch('mymodule.Spam') as mock_spam:
...                    assert mymodule.Foo is mock_foo
...                    assert mymodule.Bar is mock_bar
...                    assert mymodule.Spam is mock_spam
...        original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original
```

With unittest `cleanup` functions and the `patch methods: start and stop` we can achieve the same effect without the nested indentation. A simple helper method, `create_patch`, puts the patch in place and returns the created mock for us:

```python
>>> class MyTest(TestCase):
...    ...
...    def create_patch(self, name):
...        patcher = patch(name)
...        thing = patcher.start()
```
26.5.3.9. Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object, recording all access to it whilst having it still behave like a dictionary.

We can do this with MagicMock, which will behave like a dictionary, and using side_effect to delegate dictionary access to a real underlying dictionary that is under our control.

When the __getitem__ and __setitem__ methods of our MagicMock are called (normal dictionary access) then side_effect is called with the key (and in the case of __setitem__ the value too). We can also control what is returned.

After the MagicMock has been used we can use attributes like call_args_list to assert about how the dictionary was used:

```python
>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
```
```python
def getitem(name):
    ...
    return my_dict[name]
...
def setitem(name, val):
    ...
    my_dict[name] = val
...
mock = MagicMock()
mock.__getitem__.side_effect = getitem
mock.__setitem__.side_effect = setitem
```

**Note:** An alternative to using `MagicMock` is to use `Mock` and only provide the magic methods you specifically want:

```python
mock = Mock()
mock.__setitem__ = Mock(side_effect=getitem)
mock.__getitem__ = Mock(side_effect=setitem)
```

A third option is to use `MagicMock` but passing in `dict` as the `spec` (or `spec_set`) argument so that the `MagicMock` created only has dictionary magic methods available:

```python
mock = MagicMock(spec_set=dict)
mock.__getitem__.side_effect = getitem
mock.__setitem__.side_effect = setitem
```

With these side effect functions in place, the `mock` will behave like a normal dictionary but recording the access. It even raises a `KeyError` if you try to access a key that doesn't exist.

```python
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
```
After it has been used you can make assertions about the access using the normal mock methods and attributes:

```python
>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'c': 3, 'b': 'fish', 'd': 'eggs'}
```

26.5.3.10. Mock subclasses and their attributes

There are various reasons why you might want to subclass `Mock`. One reason might be to add helper methods. Here's a silly example:

```python
>>> class MyMock(MagicMock):
...     def has been called(self):
...         return self.called
...     ...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has been called()
False
```
The standard behaviour for *Mock* instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that *Mock* attributes are *Mocks* and *MagicMock* attributes are *MagicMocks* [2]. So if you’re subclassing to add helper methods then they’ll also be available on the attributes and return value mock of instances of your subclass.

Sometimes this is inconvenient. For example, one user is subclassing mock to created a *Twisted adaptor*. Having this applied to attributes too actually causes errors.

*Mock* (in all its flavours) uses a method called *_get_child_mock* to create these “sub-mocks” for attributes and return values. You can prevent your subclass being used for attributes by overriding this method. The signature is that it takes arbitrary keyword arguments (**kwargs) which are then passed onto the mock constructor:

```python
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, **kwargs):
...         return MagicMock(**kwargs)
...
>>> mymock = Subclass()
```
An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn’t have callable methods.

26.5.3.11. Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren’t using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is usually a much better way to solve the problem (refactor the code) or to prevent “up front costs” by delaying the import. This can also be solved in better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use mock to affect the results of an import. Importing fetches an object from the sys.modules dictionary. Note that it fetches an object, which need not be a module. Importing a module for the first time results in a module object being put in sys.modules, so usually when you import something you get a module back. This need not be the case however.

This means you can use patch.dict() to temporarily put a mock in place in sys.modules. Any imports whilst this patch is active will fetch the mock. When the patch is complete (the decorated function exits,
the with statement body is complete or `patcher.stop()` is called) then whatever was there previously will be restored safely.

Here’s an example that mocks out the ‘fooble’ module.

```python
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock})
...   import fooble
...   fooble.blob()
...
<Mock name='mock.blob()' id='...'>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()
```

As you can see the `import fooble` succeeds, but on exit there is no ‘fooble’ left in `sys.modules`.

This also works for the `from module import name` form:

```python
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock})
...   from fooble import blob
...   blob.blip()
...
<Mock name='mock.blob.blip()' id='...'>
>>> mock.blob.blip.assert_called_once_with()
```

With slightly more work you can also mock package imports:

```python
>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock}
>>> with patch.dict('sys.modules', modules):
...   from package.module import fooble
...   fooble()
```
26.5.3.12. Tracking order of calls and less verbose call assertions

The `Mock` class allows you to track the order of method calls on your mock objects through the `method_calls` attribute. This doesn’t allow you to track the order of calls between separate mock objects, however we can use `mock_calls` to achieve the same effect.

Because mocks track calls to child mocks in `mock_calls`, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the `mock_calls` of the parent:

```python
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='...'>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='...'>

>>> manager.mock_calls
[call.foo.something(), call.bar.other.thing()]
```

We can then assert about the calls, including the order, by comparing with the `mock_calls` attribute on the manager mock:
If *patch* is creating, and putting in place, your mocks then you can attach them to a manager mock using the `attach_mock()` method. After attaching calls will be recorded in `mock_calls` of the manager.

```python
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     manager.attach_mock(MockClass1, 'MockClass1')
...     MockClass1()  # ...foo() ...
... 
>>> manager.mock_calls
[call.MockClass1(),
 call.MockClass1().foo(),
 call.MockClass2(),
 call.MockClass2().bar()]
```

If many calls have been made, but you’re only interested in a particular sequence of them then an alternative is to use the `assert_has_calls()` method. This takes a list of calls (constructed with the `call` object). If that sequence of calls are in `mock_calls` then the assert succeeds.

```python
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='...'>
>>> m.one().two().three()
```
Even though the chained call `m.one().two().three()` aren’t the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about some of those calls. You may not even care about the order. In this case you can pass `any_order=True` to `assert_has_calls`:

```
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)
>>> m.assert_has_calls(calls, any_order=True)
```

26.5.3.13. More complex argument matching

Using the same basic concept as `ANY` we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by default compares equal based on object identity (which is the Python default for user defined classes). To use `assert_called_with()` we would need to pass in the exact same object. If we are only interested in some of the attributes of this object then we can create a matcher that will check these attributes for us.

You can see in this example how a ‘standard’ call to `assert_called_with` isn’t sufficient:
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
...
AssertionError: Expected: call(<__main__.Foo object at 0x...>)
Actual call: call(<__main__.Foo object at 0x...>)

A comparison function for our Foo class might look something like this:

```python
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
...     return True
```

And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```python
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
```
Putting all this together:

```python
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The `Matcher` is instantiated with our compare function and the `Foo` object we want to compare against. In `assert_called_with` the `Matcher` equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don't an `AssertionError` is raised:

```python
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
  ...
AssertionError: Expected: ((Matcher object at 0x...), {})
Called with: ((<Foo object at 0x...>,), {})
```

With a bit of tweaking you could have the comparison function raise the `AssertionError` directly and provide a more useful failure message.

As of version 1.5, the Python testing library `PyHamcrest` provides similar functionality, that may be useful here, in the form of its equality matcher (`hamcrest.library.integration.match_equality`).
26.6. 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library \texttt{lib2to3} is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. \texttt{lib2to3} could also be adapted to custom applications in which Python code needs to be edited automatically.
26.6.1. Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3’s basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```python
def greet(name):
    print "Hello, \{0\}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```bash
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag:

```bash
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```python
def greet(name):
    print("Hello, \{0\}!".format(name))
print("What's your name?")
nname = input()
```
greet(name)

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of *predefined fixers*. The `-l` flag lists all available fixers. An explicit set of fixers to run can be given with `-f`. Likewise the `-x` explicitly disables a fixer. The following example runs only the imports and has_key fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the apply fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are *explicit*, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing `all` enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the `-d` flag. Note that *only* doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.
The `-v` option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the `-p` flag. Use `-p` to run fixers on code that already has had its print statements converted.

The `-o` or `--output-dir` option allows specification of an alternate directory for processed output files to be written to. The `-n` flag is required when using this as backup files do not make sense when not overwriting the input files.

*New in version 3.2.3:* The `-o` option was added.

The `-W` or `--write-unchanged-files` flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with `-o` so that an entire Python source tree is copied with translation from one directory to another. This option implies the `-w` flag as it would not make sense otherwise.

*New in version 3.2.3:* The `-W` flag was added.

The `--add-suffix` option specifies a string to append to all output filenames. The `-n` flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

```
$ 2to3 -n -W --add-suffix=3 example.py
```

Will cause a converted file named `example.py3` to be written.
New in version 3.2.3: The --add-suffix option was added.

To translate an entire project from one directory tree to another use:

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
```
26.6.2. Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

**apply**

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

**basestring**

Converts `basestring` to `str`.

**buffer**

Converts `buffer` to `memoryview`. This fixer is optional because the `memoryview` API is similar but not exactly the same as that of `buffer`.

**callable**

Converts `callable(x)` to `isinstance(x, collections.Callable)`, adding an import to `collections` if needed. Note `callable(x)` has returned in Python 3.2, so if you do not intend to support Python 3.1, you can disable this fixer.

**dict**

Fixes dictionary iteration methods. `dict.iteritems()` is converted to `dict.items()`, `dict.iterkeys()` to `dict.keys()`, and `dict.itervalues()` to `dict.values()`. Similarly, `dict.viewitems()`, `dict.viewkeys()` and `dict.viewvalues()` are converted respectively to
dict.items(), dict.keys() and dict.values(). It also wraps existing usages of dict.items(), dict.keys(), and dict.values() in a call to list.

**except**

Converts except X, T to except X as T.

**exec**

Converts the exec statement to the exec() function.

**execfile**

Removes usage of execfile(). The argument to execfile() is wrapped in calls to open(), compile(), and exec().

**exitfunc**

Changes assignment of sys.exitfunc to use of the atexit module.

**filter**

Wraps filter() usage in a list call.

**funcattrs**

Fixes function attributes that have been renamed. For example, my_function.func_closure is converted to my_function.__closure__.

**future**

Removes from __future__ import new_feature statements.

**getcwd**

Renames os.getcwdu() to os.getcwd().
**has_key**

Changes `dict.has_key(key)` to `key in dict`.

**idioms**

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is SomeClass` and `type(x) == SomeClass` are converted to `isinstance(x, SomeClass)`. `while 1` becomes `while True`. This fixer also tries to make use of `sorted()` in appropriate places. For example, this block

```python
L = list(some_iterable)
L.sort()
```

is changed to

```python
L = sorted(some_iterable)
```

**import**

Detects sibling imports and converts them to relative imports.

**imports**

Handles module renames in the standard library.

**imports2**

Handles other modules renames in the standard library. It is separate from the `imports` fixer only because of technical limitations.

**input**

Converts `input(prompt)` to `eval(input(prompt))`

**intern**
Converts `intern()` to `sys.intern()`.

**isinstance**
Fixes duplicate types in the second argument of `isinstance()`.
For example, `isinstance(x, (int, int))` is converted to `isinstance(x, (int,))`.

**itertools_imports**
Removes imports of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()`.
Imports of `itertools.ifilterfalse()` are also changed to `itertools.filterfalse()`.

**itertools**
Changes usage of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()` to their built-in equivalents.
`itertools.ifilterfalse()` is changed to `itertools.filterfalse()`.

**long**
Renames `long` to `int`.

**map**
Wraps `map()` in a `list` call. It also changes `map(None, x)` to `list(x)`.
Using `from future_builtins import map` disables this fixer.

**metaclass**
Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (class `X(metaclass=Meta)`).

**methodattrs**
Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

**ne**

Converts the old not-equal syntax, `<>`, to `!=`.

**next**

Converts the use of iterator's `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

**nonzero**

Renames `__nonzero__()` to `__bool__()`.

**numliterals**

Converts octal literals into the new syntax.

**operator**

Converts calls to various functions in the `operator` module to other, but equivalent, function calls. When needed, the appropriate import statements are added, e.g. `import collections`. The following mapping are made:

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>operator.isCallable(obj)</code></td>
<td><code>hasattr(obj, '__call__')</code></td>
</tr>
<tr>
<td><code>operator.sequenceIncludes(obj)</code></td>
<td><code>operator.contains</code></td>
</tr>
<tr>
<td><code>operator.isSequenceType(obj)</code></td>
<td><code>isinstance(obj, collections.Sequence)</code></td>
</tr>
<tr>
<td><code>operator.isMappingType(obj)</code></td>
<td><code>isinstance(obj, collections.Mapping)</code></td>
</tr>
<tr>
<td><code>operator.isNumberType(obj)</code></td>
<td><code>isinstance(obj, numbers.Number)</code></td>
</tr>
</tbody>
</table>
Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

Converts the `print` statement to the `print()` function.

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

Converts `raw_input()` to `input()`.

Handles the move of `reduce()` to `functools.reduce()`.

Changes `sys.maxint` to `sys.maxsize`.

Replaces backtick `repr` with the `repr()` function.

Replaces use of the `set` constructor with set literals. This fixer is optional.
standard_error
    Renames StandardError to Exception.

sys_exc
    Changes the deprecated sys.exc_value, sys.exc_type, sys.exc_traceback to use sys.exc_info().

throw
    Fixes the API change in generator's throw() method.

tuple_params
    Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

types
    Fixes code broken from the removal of some members in the types module.

unicode
    Renames unicode to str.

urllib
    Handles the rename of urllib and urllib2 to the urllib package.

ws_comma
    Removes excess whitespace from comma separated items. This fixer is optional.

xrange
    Renames xrange() to range() and wraps existing range() calls with list.
**xreadlines**

Changes for `x in file.xreadlines()` to `for x in file`.

**zip**

Wraps `zip()` usage in a `list` call. This is disabled when `from future_builtins import zip` appears.
26.6.3. **lib2to3** - 2to3's library

**Note:** The **lib2to3** API should be considered unstable and may change drastically in the future.
26.7. **test** — Regression tests package for Python

**Note:** The **test** package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The **test** package contains all regression tests for Python as well as the modules **test.support** and **test.regrtest**. **test.support** is used to enhance your tests while **test.regrtest** drives the testing suite.

Each module in the **test** package whose name starts with **test** is a testing suite for a specific module or feature. All new tests should be written using the **unittest** or **doctest** module. Some older tests are written using a “traditional” testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**See also:**

**Module unittest**

  Writing PyUnit regression tests.

**Module doctest**

  Tests embedded in documentation strings.
26.7.1. Writing Unit Tests for the test package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import support

class MyTestCase1(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

def setUp(self):
    ... code to execute in preparation for tests

def tearDown(self):
    ... code to execute to clean up after tests

def test_feature_one(self):
    # Test feature one.
    ... testing code ...
```
def test_feature_two(self):
    # Test feature two.
    ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...

    ... more test classes ...

if __name__ == '__main__':
    unittest.main()

This code pattern allows the testing suite to be run by test.regrtest, on its own as a script that supports the unittest CLI, or via the python -m unittest CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.

Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.

Make sure to clean up after your tests (such as close and remove all temporary files).

If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequencesMixin:
    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequencesMixin,
    arg = [1, 2, 3]```
When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The `Mixin` class in the example above does not have any data and so can't be run by itself, thus it does not inherit from `unittest.TestCase`.

See also:

**Test Driven Development**
A book by Kent Beck on writing tests before code.
26.7.2. Running tests using the command-line interface

The test package can be run as a script to drive Python’s regression test suite, thanks to the -m option: python -m test. Under the hood, it uses test.regrtest; the call python -m test.regrtest used in previous Python versions still works). Running the script by itself automatically starts running all regression tests in the test package. It does this by finding all modules in the package whose name starts with test_, importing them, and executing the function test_main() if present or loading the tests via unittest.TestLoader.loadTestsFromModule if test_main does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (python -m test test_spam) will minimize output and only print whether the test passed or failed.

Running test directly allows what resources are available for tests to use to be set. You do this by using the -u command-line option. Specifying all as the value for the -u option enables all possible resources: python -m test -uall. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after all. The command python -m test -uall,-audio,-largefile will run test with all resources except the audio and largefile resources. For a list of all resources and more command-line options, run python -m test -h.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run make test at the top-level directory where Python was built. On Windows, executing rt.bat from your PCBuil directory will run all regression
tests.
26.8. **test.support** — Utilities for the Python test suite

The **test.support** module provides support for Python’s regression test suite.

**Note:** **test.support** is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

This module defines the following exceptions:

- **exception** **test.support.TestFailed**
  
  Exception to be raised when a test fails. This is deprecated in favor of **unittest**-based tests and **unittest.TestCase**'s assertion methods.

- **exception** **test.support.ResourceDenied**
  
  Subclass of **unittest.SkipTest**. Raised when a resource (such as a network connection) is not available. Raised by the **requires()** function.

The **test.support** module defines the following constants:

- **test.support.verbose**
  
  True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. verbose is set by **test.regrtest**.
test.support.is_jython

True if the running interpreter is Jython.

test.support.TESTFN

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The test.support module defines the following functions:

test.support.forget(module_name)

Remove the module named module_name from sys.modules and delete any byte-compiled files of the module.

test.support.is_resource_enabled(resource)

Return True if resource is enabled and available. The list of available resources is only set when test.regrtest is executing the tests.

test.support.requires(resource, msg=None)

Raise ResourceDenied if resource is not available. msg is the argument to ResourceDenied if it is raised. Always returns True if called by a function whose __name__ is '__main__'. Used when tests are executed by test.regrtest.

test.support.findfile(filename, subdir=None)

Return the path to the file named filename. If no match is found filename is returned. This does not equal a failure since it could be the path to the file.

Setting subdir indicates a relative path to use to find the file rather than looking directly in the path directories.
test.support.run_unittest(*classes)

Execute unittest.TestCase subclasses passed to the function. The function scans the classes for methods starting with the prefix test_ and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in sys.modules. Each associated module will be scanned by unittest.TestLoader.loadTestsFromModule(). This is usually seen in the following test_main() function:

```python
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.support.run_doctest(module, verbosity=None)

Run doctest.testmod() on the given module. Return (failure_count, test_count).

If verbosity is None, doctest.testmod() is run with verbosity set to verbose. Otherwise, it is run with verbosity set to None.

test.support.check_warnings(*filters, quiet=True)

A convenience wrapper for warnings.catch_warnings() that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling warnings.catch_warnings(record=True) with warnings.simplefilter() set to always and with the option to automatically validate the results that are recorded.

check_warnings accepts 2-tuples of the form ("message regexp", WarningCategory) as positional arguments. If one
or more filters are provided, or if the optional keyword argument quiet is False, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set quiet to True.

If no arguments are specified, it defaults to:

```python
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a WarningRecorder instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return None.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```python
with check_warnings(("assertion is always true", "", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning
was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```python
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*Changed in version 3.2:* New optional arguments `filters` and `quiet`.

test.support.captured_stdin()
test.support.captured_stdout()
test.support.captured_stderr()

A context managers that temporarily replaces the named stream with `io.StringIO` object.

Example use with output streams:

```python
with captured_stdout() as stdout, captured_stderr():
    print("hello")
    print("error", file=sys.stderr)
    assert stdout.getvalue() == "hello\n"
    assert stderr.getvalue() == "error\n"
```
Example use with input stream:

```python
with captured_stdin() as stdin:
    stdin.write('hello
')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
captured = input()
self.assertEqual(captured, "hello")
```

test.support.temp_dir(path=None, quiet=False)
A context manager that creates a temporary directory at `path` and yields the directory.

If `path` is None, the temporary directory is created using tempfile.mkdtemp(). If `quiet` is False, the context manager raises an exception on error. Otherwise, if `path` is specified and cannot be created, only a warning is issued.

test.support.change_cwd(path, quiet=False)
A context manager that temporarily changes the current working directory to `path` and yields the directory.

If `quiet` is False, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

test.support.temp_cwd(name='tempcwd', quiet=False)
A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name `name` before temporarily changing the current working directory. If `name` is None, the temporary directory is
created using `tempfile.mkdtemp()`.

If `quiet` is False and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

test.support.**temp_umask**(umask)

A context manager that temporarily sets the process umask.

test.support.**can_symlink**()

Return True if the OS supports symbolic links, False otherwise.

@test.support.**skip_unless_symlink**

A decorator for running tests that require support for symbolic links.

test.support.**suppress_crash_popup**()

A context manager that disables Windows Error Reporting dialogs using `SetErrorMode`. On other platforms it's a no-op.

@test.support.**anticipate_failure**(condition)

A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

@test.support.**run_with_locale**(catstr, *locales)

A decorator for running a function in a different locale, correctly resetting it after it has finished. `catstr` is the locale category as a string (for example "LC_ALL"). The `locales` passed will be tried sequentially, and the first valid locale will be used.

test.support.**make_bad_fd**()

Create an invalid file descriptor by opening and closing a
temporary file, and returning its descpior.

test.support.import_module(name, deprecated=False)

This function imports and returns the named module. Unlike a normal import, this function raises unittest.SkipTest if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if deprecated is True.

New in version 3.1.

test.support.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)

This function imports and returns a fresh copy of the named Python module by removing the named module from sys.modules before doing the import. Note that unlike reload(), the original module is not affected by this operation.

fresh is an iterable of additional module names that are also removed from the sys.modules cache before doing the import.

blocked is an iterable of module names that are replaced with None in the module cache during the import to ensure that attempts to import them raise ImportError.

The named module and any modules named in the fresh and blocked parameters are saved before starting the import and then reinserted into sys.modules when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if deprecated is True.
This function will raise :class:`ImportError` if the named module cannot be imported.

Example use:

```python
# Get copies of the warnings module for testing without affecting the version being used by the rest of the test suite. One copy uses the C implementation, the other is forced to use the pure Python fallback implementation
py_warnings = import_fresh_module('warnings', block=True)
c_warnings = import_fresh_module('warnings', fresh=True)
```

*New in version 3.1.*

**test.support.bind_port(sock, host=HOST)**

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is :const:`AF_INET` and `sock.type` is :const:`SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

**test.support.find_unused_port(family=socket.AF_INET, socktype=socket.SOCK_STREAM)**

Returns an unused port that should be suitable for binding. This is
achieved by creating a temporary socket with the same family and type as the sock parameter (default is AF_INET, SOCK_STREAM), and binding it to the specified host address (defaults to 0.0.0.0) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or bind_port() should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the -accept argument to openssl's s_server mode). Always prefer bind_port() over find_unused_port() where possible. Using a hard coded port is discouraged since it can makes multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

The test.support module defines the following classes:

class test.support.TransientResource(exc, **kwargs)

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.

class test.support.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying
os.environ. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

*Changed in version 3.1:* Added dictionary interface.

EnvironmentVarGuard.set(envvar, value)

Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)

Temporarily unset the environment variable envvar.

class test.support.WarningsRecorder

Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.
26.9. venv — Creation of virtual environments

New in version 3.3.

Source code: Lib/venv

The venv module provides support for creating lightweight “virtual environments” with their own site directories, optionally isolated from system site directories. Each virtual environment has its own Python binary (allowing creation of environments with various Python versions) and can have its own independent set of installed Python packages in its site directories.

See PEP 405 for more information about Python virtual environments.
26.9.1. Creating virtual environments

Creation of *virtual environments* is done by executing the `pyvenv` script:

```
pyenv /path/to/new/virtual/environment
```

Running this command creates the target directory (creating any parent directories that don’t exist already) and places a `pyvenv.cfg` file in it with a home key pointing to the Python installation the command was run from. It also creates a `bin` (or `Scripts` on Windows) subdirectory containing a copy of the python binary (or binaries, in the case of Windows). It also creates an (initially empty) `lib/pythonX.Y/site-packages` subdirectory (on Windows, this is `Lib\site-packages`).

On Windows, you may have to invoke the `pyvenv` script as follows, if you don’t have the relevant PATH and PATHEXT settings:

```
c:\Temp>c:\Python33\python c:\Python33\Tools\Scripts\pyenv.py myenv
```

or equivalently:

```
c:\Temp>c:\Python33\python -m venv myenv
```

The command, if run with `-h`, will show the available options:

```
```

Creates virtual Python environments in one or more t
positional arguments:
  ENV_DIR A directory to create the environment in.

optional arguments:
  -h, --help show this help message and exit
  --system-site-packages Give access to the global site-packages dir to the virtual environment.
  --symlinks Try to use symlinks rather than copies, when symlinks are not the default for the platform.
  --clear Delete the environment directory if it already exists. If not specified and the directory exists, an error is raised.
  --upgrade Upgrade the environment directory to use this version of Python, assuming Python has been upgraded in-place.

If the target directory already exists an error will be raised, unless the --clear or --upgrade option was provided.

The created pyvenv.cfg file also includes the include-system-site-packages key, set to true if venv is run with the --system-site-packages option, false otherwise.

Multiple paths can be given to pyvenv, in which case an identical virtualenv will be created, according to the given options, at each provided path.

Once a venv has been created, it can be “activated” using a script in the venv’s binary directory. The invocation of the script is platform-specific: on a Posix platform, you would typically do:

```
$ source <venv>/bin/activate
```

whereas on Windows, you might do:
C:\> <venv>/Scripts/activate

if you are using the `cmd.exe` shell, or perhaps:

```
PS C:\> <venv>/Scripts/Activate.ps1
```

if you use PowerShell.

You don’t specifically need to activate an environment; activation just prepends the venv’s binary directory to your path, so that “python” invokes the venv’s Python interpreter and you can run installed scripts without having to use their full path. However, all scripts installed in a venv should be runnable without activating it, and run with the venv’s Python automatically.

You can deactivate a venv by typing “deactivate” in your shell. The exact mechanism is platform-specific: for example, the Bash activation script defines a “deactivate” function, whereas on Windows there are separate scripts called `deactivate.bat` and `Deactivate.ps1` which are installed when the venv is created.

**Note:** A virtual environment (also called a venv) is a Python environment such that the Python interpreter, libraries and scripts installed into it are isolated from those installed in other virtual environments, and (by default) any libraries installed in a “system” Python, i.e. one which is installed as part of your operating system.

A venv is a directory tree which contains Python executable files and other files which indicate that it is a venv.

Common installation tools such as Distribute and pip work as expected with venvs - i.e. when a venv is active, they install Python packages into the venv without needing to be told to do so explicitly.
Of course, you need to install them into the venv first: this could be done by running `distribute_setup.py` with the venv activated, followed by running `easy_install` pip. Alternatively, you could download the source tarballs and run `python setup.py install` after unpacking, with the venv activated.

When a venv is active (i.e. the venv's Python interpreter is running), the attributes `sys.prefix` and `sys.exec_prefix` point to the base directory of the venv, whereas `sys.base_prefix` and `sys.base_exec_prefix` point to the non-venv Python installation which was used to create the venv. If a venv is not active, then `sys.prefix` is the same as `sys.base_prefix` and `sys.exec_prefix` is the same as `sys.base_exec_prefix` (they all point to a non-venv Python installation).

When a venv is active, any options that change the installation path will be ignored from all distutils configuration files to prevent projects being inadvertently installed outside of the virtual environment.

When working in a command shell, users can make a venv active by running an `activate` script in the venv's executables directory (the precise filename is shell-dependent), which prepends the venv's directory for executables to the PATH environment variable for the running shell. There should be no need in other circumstances to activate a venv – scripts installed into venvs have a shebang line which points to the venv’s Python interpreter. This means that the script will run with that interpreter regardless of the value of PATH. On Windows, shebang line processing is supported if you have the Python Launcher for Windows installed (this was added to Python in 3.3 - see PEP 397 for more details). Thus, double-clicking an installed script in a Windows Explorer window should run the script with the correct interpreter without there needing to be any reference
to its venv in PATH.
26.9.2. API

The high-level method described above makes use of a simple API which provides mechanisms for third-party virtual environment creators to customize environment creation according to their needs, the `EnvBuilder` class.

```python
class venv.EnvBuilder(system_site_packages=False, clear=False, symlinks=False, upgrade=False)
```

The `EnvBuilder` class accepts the following keyword arguments on instantiation:

- `system_site_packages` – a Boolean value indicating that the system Python site-packages should be available to the environment (defaults to False).
- `clear` – a Boolean value which, if True, will delete any existing target directory instead of raising an exception (defaults to False).
- `symlinks` – a Boolean value indicating whether to attempt to symlink the Python binary (and any necessary DLLs or other binaries, e.g. `pythonw.exe`), rather than copying. Defaults to True on Linux and Unix systems, but False on Windows.
- `upgrade` – a Boolean value which, if True, will upgrade an existing environment with the running Python - for use when that Python has been upgraded in-place (defaults to False).

Creators of third-party virtual environment tools will be free to use the provided `EnvBuilder` class as a base class.

The returned env-builder is an object which has a method, `create:`
**create**(*env_dir*)

This method takes as required argument the path (absolute or relative to the current directory) of the target directory which is to contain the virtual environment. The `create` method will either create the environment in the specified directory, or raise an appropriate exception.

The `create` method of the `EnvBuilder` class illustrates the hooks available for subclass customization:

```python
def create(self, env_dir):
    """
    Create a virtualized Python environment in
    env_dir is the target directory to create a
    """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
```

Each of the methods `ensure_directories()`, `create_configuration()`, `setup_python()`, `setup_scripts()` and `post_setup()` can be overridden.

**ensure_directories**(*env_dir*)

Creates the environment directory and all necessary directories, and returns a context object. This is just a holder for attributes (such as paths), for use by the other methods. The directories are allowed to exist already, as long as either `clear` or `upgrade` were specified to allow operating on an existing environment directory.
create_configuration(context)
  Creates the pyvenv.cfg configuration file in the environment.

setup_python(context)
  Creates a copy of the Python executable (and, under Windows, DLLs) in the environment. On a POSIX system, if a specific executable python3.x was used, symlinks to python and python3 will be created pointing to that executable, unless files with those names already exist.

setup_scripts(context)
  Installs activation scripts appropriate to the platform into the virtual environment.

post_setup(context)
  A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

In addition, EnvBuilder provides this utility method that can be called from setup_scripts() or post_setup() in subclasses to assist in installing custom scripts into the virtual environment.

install_scripts(context, path)
  path is the path to a directory that should contain subdirectories “common”, “posix”, “nt”, each containing scripts destined for the bin directory in the environment. The contents of “common” and the directory corresponding to os.name are copied after some text replacement of placeholders:

  - __VENV_DIR__ is replaced with the absolute path of the environment directory.
- **__VENV_NAME__** is replaced with the environment name (final path segment of environment directory).
- **__VENV_BIN_NAME__** is replaced with the name of the bin directory (either bin or Scripts).
- **__VENV_PYTHON__** is replaced with the absolute path of the environment's executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

There is also a module-level convenience function:

```python
venv.create(env_dir, system_site_packages=False, clear=False, symlinks=False)
```

Create an `EnvBuilder` with the given keyword arguments, and call its `create()` method with the `env_dir` argument.
26.9.3. An example of extending EnvBuilder

The following script shows how to extend EnvBuilder by implementing a subclass which installs setuptools and pip into a created venv:

```python
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    ""
    This builder installs setuptools and pip so that you can pip or easy_install other packages into the created environment.
    
    :param nodist: If True, setuptools and pip are not installed into the created environment.
    :param nopip: If True, pip is not installed into the created environment.
    :param progress: If setuptools or pip are installed, the progress of the installation can be monitored by passing a progress callable. If specified, it is called with two arguments: a string indicating the progress, and a context indicating where the string is coming from. The context argument can have one of three values: 'main', indicating that it is called from virtualize() itself, and 'stdout' and 'stderr', which are obtained by reading lines from the output streams of a subprocess.
    """
```
which is used to install the app.

If a callable is not specified, information is output to sys.stderr.

```python
def __init__(self, *args, **kwargs):
    self.nodist = kwargs.pop('nodist', False)
    self.nopip = kwargs.pop('nopip', False)
    self.progress = kwargs.pop('progress', None)
    self.verbose = kwargs.pop('verbose', False)
    super().__init__(*args, **kwargs)

def post_setup(self, context):
    """
    Set up any packages which need to be pre-installed into the environment being created.

    :param context: The information for the environment being processed.
    """
    os.environ['VIRTUAL_ENV'] = context.env_dir
    if not self.nodist:
        self.install_setuptools(context)
    # Can't install pip without setuptools
    if not self.nopip and not self.nodist:
        self.install_pip(context)

def reader(self, stream, context):
    """
    Read lines from a subprocess' output stream, either pass to a progress callable (if specified) or write progress information to sys.stderr.
    """
    progress = self.progress
    while True:
        s = stream.readline()
        if not s:
            break
        # Handle progress information
```

break
    if progress is not None:
        progress(s, context)
    else:
        if not self.verbose:
            sys.stderr.write('.
        else:
            sys.stderr.write(s.decode('utf-8'))
        sys.stderr.flush()
    stream.close()

def install_script(self, context, name, url):
    _, _, path, _, _, _ = urlparse(url)
    fn = os.path.split(path)[-1]
    binpath = context.bin_path
    distpath = os.path.join(binpath, fn)
    # Download script into the env's binaries folder
    urlretrieve(url, distpath)
    progress = self.progress
    if self.verbose:
        term = '\n'
    else:
        term = ''
    if progress is not None:
        progress('Installing %s ...%s' % (name, term))
    else:
        sys.stderr.write('Installing %s ...%s' % (name, term))
        sys.stderr.flush()
    # Install in the env
    args = [context.env_exe, fn]
    p = Popen(args, stdout=PIPE, stderr=PIPE, cwd=binpath)
    t1 = Thread(target=self.reader, args=(p.stdout, 'stdout'))
    t1.start()
    t2 = Thread(target=self.reader, args=(p.stderr, 'stderr'))
    t2.start()
    p.wait()
    t1.join()
t2.join()
if progress is not None:
    progress('done.', 'main')
else:
    sys.stderr.write('done.
')
# Clean up - no longer needed
os.unlink(distpath)

def install_setupuptools(self, context):
    """
    Install setuptools in the environment.
    :param context: The information for the environment creation request being processed.
    """
    url = 'https://bitbucket.org/pypa/setuptools/downloads/ez_setup.py'
    self.install_script(context, 'setuptools', url)
    # clear up the setuptools archive which gets downloaded
    pred = lambda o: o.startswith('setuptools-') and o.endswith('.tar.gz')
    files = filter(pred, os.listdir(context.bin_path))
    for f in files:
        f = os.path.join(context.bin_path, f)
        os.unlink(f)

    try:
        main()
        rc = 0
    except Exception as e:
        print('Error: %s' % e, file=sys.stderr)
    sys.exit(rc)
This script is also available for download online.
27. Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

- **27.1. bdb — Debugger framework**
- **27.2. faulthandler — Dump the Python traceback**
  - 27.2.1. Dump the traceback
  - 27.2.2. Fault handler state

27.1. **bdb — Debugger framework**

**Source code:** `Lib/bdb.py`

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```python
exception bdb.BdbQuit
    Exception raised by the Bdb class for quitting the debugger.
```

The `bdb` module also defines two classes:

```python
class bdb.Breakpoint
    (self, file, line, temporary=0, cond=None, funcname=None)
```

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by `(file, line)` pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a `funcname` is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

`Breakpoint` instances have the following methods:
deleteMe()
Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

enable()
Mark the breakpoint as enabled.

disable()
Mark the breakpoint as disabled.

bpformat()
Return a string with all the information about the breakpoint, nicely formatted:

- The breakpoint number.
- If it is temporary or not.
- Its file, line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

New in version 3.2.

bpprint(out=None)
Print the output of bpformat() to the file out, or if it is None, to standard output.

class bdb. Bdb(skip=None)
The Bdb class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (pdb.Pdb) is an example.
The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

*New in version 3.1:* The `skip` argument.

The following methods of `Bdb` normally don't need to be overridden.

**canonic**(filename)

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

**reset()**

Set the `botframe`, `stopframe`, `returnframe` and quitting attributes with values ready to start debugging.

**trace_dispatch**(frame, event, arg)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. `event` can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to
return.

- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The arg parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to *The standard type hierarchy*.

**dispatch_line**(frame)

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the Bdb.quitting flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_call**(frame, arg)

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the Bdb.quitting flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return**(frame, arg)

If the debugger should stop on this function return, invoke the
user_return() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_return()). Return a reference to the trace_dispatch() method for further tracing in that scope.

**dispatch_exception(frame, arg)**

If the debugger should stop at this exception, invokes the user_exception() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_exception()). Return a reference to the trace_dispatch() method for further tracing in that scope.

Normally derived classes don’t override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**stop_here(frame)**

This method checks if the frame is somewhere below botframe in the call stack. botframe is the frame in which debugging started.

**break_here(frame)**

This method checks if there is a breakpoint in the filename and line belonging to frame or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**break_anywhere(frame)**

This method checks if there is a breakpoint in the filename of the current frame.
Derived classes should override these methods to gain control over debugger operation.

**user_call(frame, argument_list)**

This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line(frame)**

This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields True.

**user_return(frame, return_value)**

This method is called from `dispatch_return()` when `stop_here()` yields True.

**user_exception(frame, exc_info)**

This method is called from `dispatch_exception()` when `stop_here()` yields True.

**do_clear(arg)**

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set_step()**

Stop after one line of code.

**set_next(frame)**
Stop on the next line in or below the given frame.

**set_return(frame)**

Stop when returning from the given frame.

**set_until(frame)**

Stop when the line with the line no greater than the current one is reached or when returning from current frame.

**set_trace([frame])**

Start debugging from frame. If frame is not specified, debugging starts from caller’s frame.

**set_continue()**

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

**set_quit()**

Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*( ) methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

**set_break(filename, lineno, temporary=0, cond, funcname)**

Set a new breakpoint. If the lineno line doesn’t exist for the filename passed as argument, return an error message. The filename should be in canonical form, as described in the canonic() method.

**clear_break(filename, lineno)**
Delete the breakpoints in `filename` and `lineno`. If none were set, an error message is returned.

**clear_bpbynumber** *(arg)*
Delete the breakpoint which has the index `arg` in the `Breakpoint.bpbynumber`. If `arg` is not numeric or out of range, return an error message.

**clear_all_file_breaks** *(filename)*
Delete all breakpoints in `filename`. If none were set, an error message is returned.

**clear_all_breaks()**
Delete all existing breakpoints.

**get_bpbynumber** *(arg)*
Return a breakpoint specified by the given number. If `arg` is a string, it will be converted to a number. If `arg` is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

*New in version 3.2.*

**get_break** *(filename, lineno)*
Check if there is a breakpoint for `lineno` of `filename`.

**get_breaks** *(filename, lineno)*
Return all breakpoints for `lineno` in `filename`, or an empty list if none are set.

**get_file_breaks** *(filename)*
Return all breakpoints in `filename`, or an empty list if none are set.
get_all_breaks()

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

get_stack(f, t)

Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

format_stack_entry(frame_lineno, lprefix=':')

Return a string with information about a stack entry, identified by a (frame, lineno) tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a statement, given as a string.

run(cmd, globals=None, locals=None)

Debug a statement executed via the exec() function. globals defaults to __main__.__dict__, locals defaults to globals.

runeval(expr, globals=None, locals=None)

Debug an expression executed via the eval() function. globals and locals have the same meaning as in run().

runcxtx(cmd, globals, locals)
For backwards compatibility. Calls the `run()` method.

**runcall** *(func, *args, **kwds)*

Debug a single function call, and return its result.

Finally, the module defines the following functions:

**bdb. checkfuncname(b, frame)**

Check whether we should break here, depending on the way the breakpoint `b` was set.

If it was set via line number, it checks if `b.line` is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

**bdb. effective(file, line, frame)**

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return `(None, None)` if there is no matching breakpoint.

**bdb. set_trace()**

Start debugging with a `Bdb` instance from caller’s frame.
27.2. **faulthandler** — Dump the Python traceback

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS, and SIGILL signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.

By default, the Python traceback is written to `sys.stderr`. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to `faulthandler.enable()`.
The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

*New in version 3.3.*
27.2.1. Dump the traceback

`faulthandler.dump_traceback(file=sys.stderr, all_threads=True)`

Dump the tracebacks of all threads into file. If `all_threads` is False, dump only the current thread.
27.2.2. Fault handler state

`faulthandler.enable(file=sys.stderr, all_threads=True)`

Enable the fault handler: install handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS and SIGILL signals to dump the Python traceback. If `all_threads` is True, produce tracebacks for every running thread. Otherwise, dump only the current thread.

`faulthandler.disable()`

Disable the fault handler: uninstall the signal handlers installed by `enable()`.

`faulthandler.is_enabled()`

Check if the fault handler is enabled.
27.2.3. Dump the tracebacks after a timeout

```python
faulthandler.dump_traceback_later(timeout, repeat=False, file=sys.stderr, exit=False)
```

Dump the tracebacks of all threads, after a timeout of `timeout` seconds, or every `timeout` seconds if `repeat` is True. If `exit` is True, call `_exit()` with status=1 after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

This function is implemented using a watchdog thread and therefore is not available if Python is compiled with threads disabled.

```python
faulthandler.cancel_dump_traceback_later()
```

Cancel the last call to `dump_traceback_later()`.
27.2.4. Dump the traceback on a user signal

```
faulthandler.register(signum, file=sys.stderr, all_threads=True, chain=False)
```

Register a user signal: install a handler for the `signum` signal to dump the traceback of all threads, or of the current thread if `all_threads` is False, into `file`. Call the previous handler if `chain` is True.

Not available on Windows.

```
faulthandler.unregister(signum)
```

Unregister a user signal: uninstall the handler of the `signum` signal installed by `register()`. Return True if the signal was registered, False otherwise.

Not available on Windows.
27.2.5. File descriptor issue

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their `file` argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.
27.2.6. Example

Example of a segmentation fault on Linux:

```
$ python -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
```

Current thread 0x00007fb899f39700:
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 486 in string_at
  File "<stdin>", line 1 in <module>
Segmentation fault
```
27.3. **pdb — The Python Debugger**

The module **pdb** defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible – it is actually defined as the class **Pdb**. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules **bdb** and **cmd**.

The debugger’s prompt is `(Pdb)`. Typical usage to run a program under control of the debugger is:

```python
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

*Changed in version 3.3:* Tab-completion via the **readline** module is available for commands and command arguments, e.g. the current global and local names are offered as arguments of the **print**
command.

`pdb.py` can also be invoked as a script to debug other scripts. For example:

```
python3 -m pdb myscript.py
```

When invoked as a script, `pdb` will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), `pdb` will restart the program. Automatic restarting preserves `pdb`'s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

*New in version 3.2:* `pdb.py` now accepts a `-c` option that executes commands as if given in a `.pdbrc` file, see *Debugger Commands*.

The typical usage to break into the debugger from a running program is to insert

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the `continue` command.

The typical usage to inspect a crashed program is:

```python
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "./mymodule.py", line 4, in test
```
The module defines the following functions; each enters the debugger in a slightly different way:

**pdb. run**(statement, globals=None, locals=None)

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type *continue*, or you can step through the statement using *step* or *next* (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module *__main__* is used. (See the explanation of the built-in *exec()* or *eval()* functions.)

**pdb. runeval**(expression, globals=None, locals=None)

Evaluate the *expression* (given as a string or a code object) under debugger control. When *runeval()* returns, it returns the value of the expression. Otherwise this function is similar to *run()*.

**pdb. runcall**(function, *args, **kwds)

Call the *function* (a function or method object, not a string) with the given arguments. When *runcall()* returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.
pdb.**set_trace**()

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails).

pdb.**post_mortem**(traceback=None)

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

pdb.**pm**()

Enter post-mortem debugging of the traceback found in *sys.last_traceback*.

The *run* functions and *set_trace()* are aliases for instantiating the *Pdb* class and calling the method of the same name. If you want to access further features, you have to do this yourself:

```python
class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False):
    Pdb is the debugger class.

    The *completekey*, *stdin* and *stdout* arguments are passed to the underlying *cmd.Cmd* class; see the description there.

    The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. [1]

    By default, Pdb sets a handler for the SIGINT signal (which is sent when the user presses Ctrl-C on the console) when you give a
continue command. This allows you to break into the debugger again by pressing Ctrl-C. If you want Pdb not to touch the SIGINT handler, set nosigint tot true.

Example call to enable tracing with skip:

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

New in version 3.1: The skip argument.

New in version 3.2: The nosigint argument. Previously, a SIGINT handler was never set by Pdb.

```
run(statement, globals=None, locals=None)
runeval(expression, globals=None, locals=None)
runcall(function, *args, **kwds)
set_trace()
```

See the documentation for the functions explained above.
27.3.1. Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. h(e1p) means that either h or help can be used to enter the help command (but not he or hel, nor H or Help or HELP). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ]) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a list command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by ;;. (A single ; is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first ;; pair, even if it is in the middle of a quoted string.
If a file `.pdbrc` exists in the user’s home directory or in the current directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

*Changed in version 3.2:* `.pdbrc` can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

**h(elp) [command]**
Without argument, print the list of available commands. With a `command` as argument, print help about that command. `help pdb` displays the full documentation (the docstring of the `pdb` module). Since the `command` argument must be an identifier, `help exec` must be entered to get help on the `!` command.

**w(here)**
Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

**d(own) [count]**
Move the current frame `count` (default one) levels down in the stack trace (to a newer frame).

**u(p) [count]**
Move the current frame `count` (default one) levels up in the stack trace (to an older frame).

**b(reak) [[filename:]lineno | function] [, condition]]**
With a `lineno` argument, set a break there in the current file. With a
function argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn’t been loaded yet). The file is searched on sys.path. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[filename:]lineno | function] [, condition]]
Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for break.

clear [filename:lineno | bpnumber [bpnumber ...]]
With a filename:lineno argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber [bpnumber ...]]
Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber [bpnumber ...]]
Enable the breakpoints specified.

**ignore bpnumber [count]**
Set the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

**condition bpnumber [condition]**
Set a new condition for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

**commands [bpnumber]**
Specify a list of commands for breakpoint number *bpnumber*. The commands themselves appear on the following lines. Type a line containing just `end` to terminate the commands. An example:

```
(Pdb) commands 1
(com) print some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with `end`; that is, give no commands.

With no *bpnumber* argument, commands refers to the last breakpoint set.

You can use breakpoint commands to start your program up again.
Simply use the continue command, or step, or any other command that resumes execution.

Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

**s(tep)**

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

**n(ext)**

Continue execution until the next line in the current function is reached or it returns. (The difference between next and step is that step stops inside a called function, while next executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

**unt(i1) [lineno]**

Without argument, continue execution until the line with a number greater than the current one is reached.
With a line number, continue execution until a line with a number greater or equal to that is reached. In both cases, also stop when the current frame returns.

*Changed in version 3.2:* Allow giving an explicit line number.

**r(eturn)**
Continue execution until the current function returns.

**c(ont(inue))**
Continue execution, only stop when a breakpoint is encountered.

**j(ump) lineno**
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don’t want to run.

It should be noted that not all jumps are allowed – for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

**l(ist) [first[, last]]**
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `[]` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.
New in version 3.2: The >> marker.

ll | longlist
List all source code for the current function or frame. Interesting lines are marked as for list.

New in version 3.2.

a(rgs)
Print the argument list of the current function.

p(print) expression
Evaluate the expression in the current context and print its value.

pp expression
Like the print command, except the value of the expression is pretty-printed using the pprint module.

whatis expression
Print the type of the expression.

source expression
Try to get source code for the given object and display it.

New in version 3.2.

display [expression]
Display the value of the expression if it changed, each time execution stops in the current frame.

Without expression, list all display expressions for the current frame.

New in version 3.2.
**undisplay** [expression]

Do not display the expression any more in the current frame. Without expression, clear all display expressions for the current frame.

*New in version 3.2.*

**interact**

Start an interactive interpreter (using the `code` module) whose global namespace contains all the (global and local) names found in the current scope.

*New in version 3.2.*

**alias** [name [command]]

Create an alias called `name` that executes `command`. The command must not be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%*` is replaced by all the parameters. If no command is given, the current alias for `name` is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the `pdb` prompt. Note that internal `pdb` commands can be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print("%1."
unalias name
Delete the specified alias.

! statement
Execute the (one-line) statement in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a global statement on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

run [args ...]
restart [args ...]
Restart the debugged Python program. If an argument is supplied, it is split with shlex and the result is used as the new sys.argv. History, breakpoints, actions and debugger options are preserved. restart is an alias for run.

q(uit)
Quit from the debugger. The program being executed is aborted.

Footnotes

[1] Whether a frame is considered to originate in a certain module is determined by the __name__ in the frame globals.
27.4. The Python Profilers

Source code: Lib/profile.py and Lib/pstats.py
27.4.1. Introduction to the profilers

cProfile and profile provide deterministic profiling of Python programs. A profile is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the pstats module.

The Python standard library provides two different implementations of the same profiling interface:

1. cProfile is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on lsprof, contributed by Brett Rosen and Ted Czotter.
2. profile, a pure Python module whose interface is imitated by cProfile, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module.

Note: The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is timeit for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.
27.4.2. Instant User’s Manual

This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```python
import cProfile
import re

cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
197 function calls (192 primitive calls) in 0.
Ordered by: standard name
ncalls  tottime  percall  cumtime  percall filename:lineno
    1     0.00    0.000    0.001    0.001 <string>:0
    1     0.00    0.000    0.001    0.001 re.py:212
    1     0.00    0.000    0.001    0.001 re.py:268
    1     0.00    0.000    0.000    0.000 sre_compile
    1     0.00    0.000    0.000    0.000 sre_compile
    4     0.00    0.000    0.000    0.000 sre_compile
   3/1    0.00    0.000    0.000    0.000 sre_compile
```

The first line indicates that 197 calls were monitored. Of those calls, 192 were `primitive`, meaning that the call was not induced via
recursion. The next line: Ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls

for the number of calls,

tottime

for the total time spent in the given function (and excluding time made in calls to sub-functions)

percall

is the quotient of tottime divided by ncall

cumtime

is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.

percall

is the quotient of cumtime divided by primitive calls

filename:lineno(function)

provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the run() function:

```python
import cProfile
import re
```
cProfile.run('re.compile("foo|bar"), 'restats')

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The file `cProfile` can also be invoked as a script to profile another script. For example:

```sh
python -m cProfile [-o output_file] [-s sort_order]
```

- `-o` writes the profile results to a file instead of stdout.
- `-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```py
import pstats
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```py
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls
to experiment with:

```python
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```python
p.sort_stats('time').print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```python
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```python
p.sort_stats('time', 'cum').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: .5) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could
now (p is still sorted according to the last criteria) do:

```python
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you’re going to have to read the manual, or guess what the following functions do:

```python
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.
27.4.3. profile and cProfile Module Reference

Both the profile and cProfile modules provide the following functions:

profile.run(command, filename=None, sort=-1)

This function takes a single argument that can be passed to the exec() function, and an optional file name. In all cases this routine executes:

```python
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a Stats instance and prints a simple profiling report. If the sort value is specified it is passed to this Stats instance to control how the results are sorted.

profile.runctx(command, globals, locals, filename=None)

This function is similar to run(), with added arguments to supply the globals and locals dictionaries for the command string. This routine executes:

```python
exec(command, globals, locals)
```

and gathers profiling statistics as in the run() function above.

class profile.Profile(timer=None, timeunit=0.0, subcalls=True, builtins=True)
This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```python
import cProfile, pstats, io
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = 'cumulative'
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

`enable()`
Start collecting profiling data.

`disable()`
Stop collecting profiling data.

`create_stats()`
Stop collecting profiling data and record the results internally as
the current profile.

**print_stats**(*sort=-1*)
Create a **Stats** object based on the current profile and print the results to stdout.

**dump_stats**(filename)
Write the results of the current profile to *filename*.

**run**(cmd)
Profile the cmd via **exec**().

**runcntx**(cmd, globals, locals)
Profile the cmd via **exec**() with the specified global and local environment.

**runcall**(func, *args, **kwargs)
Profile func(*args, **kwargs)
27.4.4. The Stats Class

Analysis of the profiler data is done using the Stats class.

```python
class pstats.Stats(*filenames or profile, stream=sys.stdout)
```

This class constructor creates an instance of a “statistics object” from a filename (or list of filenames) or from a Profile instance. Output will be printed to the stream specified by `stream`.

The file selected by the above constructor must have been created by the corresponding version of `profile` or `cProfile`. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing Stats object, the `add()` method can be used.

Instead of reading the profile data from a file, a `cProfile.Profile` or `profile.Profile` object can be used as the profile data source.

Stats objects have the following methods:

**strip_dirs()**

This method for the Stats class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its
entries in a “random” order, as it was just after object initialization and loading. If strip_dirs() causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

**add(**filenames**)**
This method of the Stats class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of profile.run() or cProfile.run(). Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

**dump_stats**(filename)
Save the data loaded into the Stats object to a file named filename. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the profile.Profile and cProfile.Profile classes.

**sort_stats(***keys***)
This method modifies the Stats object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example: 'time' or 'name').

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, sort_stats('name', 'file') will sort all the entries according to their function
name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the abbreviation is unambiguous. The following are the keys currently defined:

<table>
<thead>
<tr>
<th>Valid Arg</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'calls'</td>
<td>call count</td>
</tr>
<tr>
<td>'cumulative'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'cumtime'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'file'</td>
<td>file name</td>
</tr>
<tr>
<td>'filename'</td>
<td>file name</td>
</tr>
<tr>
<td>'module'</td>
<td>file name</td>
</tr>
<tr>
<td>'ncalls'</td>
<td>call count</td>
</tr>
<tr>
<td>'pcalls'</td>
<td>primitive call count</td>
</tr>
<tr>
<td>'line'</td>
<td>line number</td>
</tr>
<tr>
<td>'name'</td>
<td>function name</td>
</tr>
<tr>
<td>'nfl'</td>
<td>name/file/line</td>
</tr>
<tr>
<td>'stdname'</td>
<td>standard name</td>
</tr>
<tr>
<td>'time'</td>
<td>internal time</td>
</tr>
<tr>
<td>'totime'</td>
<td>internal time</td>
</tr>
</tbody>
</table>

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means
that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, `sort_stats('nfl')` is the same as `sort_stats('name', 'file', 'line')`.

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

**reverse_order()**

This method for the Stats class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

**print_stats(*restrictions)**

This method for the Stats class prints out a report as described in the profile.run() definition.

The order of the printing is based on the last sort_stats() operation done on the object (subject to caveats in add() and strip_dirs()).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction
between 0.0 and 1.0 inclusive (to select a percentage of lines), or a regular expression (to pattern match the standard name that is printed. If several restrictions are provided, then they are applied sequentially. For example:

```python
print_stats(.1, 'foo:)
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.*foo:`. In contrast, the command:

```python
print_stats('foo:', .1)
```

would limit the list to all functions having file names `.*foo:`, and then proceed to only print the first 10% of them.

**print_callers(*restrictions)**

This method for the Stats class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.
**print_callees**(\textit{\texttt{*restrictions}})

This method for the \texttt{Stats} class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the \texttt{print_callers()} method.
27.4.5. What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
27.4.6. Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it can accumulate and become very significant.

The problem is more important with profile than with the lower-overhead cProfile. For this reason, profile provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do not be alarmed by negative numbers in the profile. They should only appear if you have calibrated your profiler, and the results are actually
better than without calibration.
27.4.7. Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see *Limitations*).

```python
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running Mac OS X, and using Python’s `time.clock()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```python
import profile

# 1. Apply computed bias to all Profile instances created thereafter.
profile.Profile.bias = your_computed_bias
```
# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.
27.4.8. Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the Profile class constructor:

\[
\text{pr} = \text{profile}\cdot\text{Profile}(\text{your\_time\_func})
\]

The resulting profiler will then call \text{your\_time\_func}. Depending on whether you are using \text{profile}\cdot\text{Profile} or cProfile\cdot\text{Profile}, \text{your\_time\_func}'s return value will be interpreted differently:

\text{profile}\cdot\text{Profile}

\text{your\_time\_func} should return a single number, or a list of numbers whose sum is the current time (like what \text{os.times()} returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see \text{Calibration}). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (\text{os.times()} is pretty bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

\text{cProfile}\cdot\text{Profile}

\text{your\_time\_func} should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For
example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```python
pr = cProfile.Profile(your_integer_time_func, 0.0)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.
27.5. **timeit** — Measure execution time of small code snippets

**Source code:** Lib/timeit.py

This module provides a simple way to time small bits of Python code. It has both a *Command-Line Interface* as well as a *callable* one. It avoids a number of common traps for measuring execution times. See also Tim Peters’ introduction to the “Algorithms” chapter in the *Python Cookbook*, published by O’Reilly.
27.5.1. Basic Examples

The following example shows how the *Command-Line Interface* can be used to compare three different expressions:

```python
$ python -m timeit ""-.join(str(n) for n in range(100))"
10000 loops, best of 3: 40.3 usec per loop
$ python -m timeit ""-.join([str(n) for n in range(100)])"
10000 loops, best of 3: 33.4 usec per loop
$ python -m timeit ""-.join(map(str, range(100)))"
10000 loops, best of 3: 25.2 usec per loop
```

This can be achieved from the *Python Interface* with:

```python
>>> import timeit
>>> timeit.timeit(""-.join(str(n) for n in range(100))"", number=1)
0.8187260627746582
>>> timeit.timeit(""-.join([str(n) for n in range(100)])"", number=1)
0.7288308143615723
>>> timeit.timeit(""-.join(map(str, range(100)))"", number=1)
0.5858950614929199
```

Note however that *timeit* will automatically determine the number of repetitions only when the command-line interface is used. In the *Examples* section you can find more advanced examples.
27.5.2. Python Interface

The module defines three convenience functions and a public class:

```python
timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000)
```
Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `timeit()` method with `number` executions.

```python
timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=3, number=1000000)
```
Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `repeat()` method with the given `repeat` count and `number` executions.

```python
timeit.default_timer()
```
The default timer, which is always `time.perf_counter()`.

*Changed in version 3.3:* `time.perf_counter()` is now the default timer.

```python
class timeit.Timer(stmt='pass', setup='pass', timer=<timer function>)
```
Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to `'pass'`; the timer function is platform-dependent (see the module doc string). `stmt` and `setup` may also contain multiple statements separated by `;` or newlines, as long as they don't contain multi-line string literals.
To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` method is a convenience to call `timeit()` multiple times and return a list of results.

The `stmt` and `setup` parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.

**timeit**(number=1000000)

Time `number` executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

**Note:** By default, `timeit()` temporarily turns off *garbage collection* during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the `setup` string. For example:

```python
repeat(repeat=3, number=1000000)
```
Call `timeit()` a few times.

This is a convenience function that calls the `timeit()` repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the `number` argument for `timeit()`.

**Note:** It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python’s speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

`print_exc(file=None)`

Helper to print a traceback from the timed code.

Typical use:

```python
t = Timer(...)  # outside the try/except
try:
    t.timeit(...). # or t.repeat(...)
except:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional `file` argument directs where the traceback is sent; it defaults to `sys.stderr`.
27.5.3. Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-s S] [-t] [-c] [-h]
```

Where the following options are understood:

- `-n N`, `--number=N`  
  how many times to execute 'statement'

- `-r N`, `--repeat=N`  
  how many times to repeat the timer (default 3)

- `-s S`, `--setup=S`  
  statement to be executed once initially (default `pass`)

- `-p`, `--process`  
  measure process time, not wallclock time, using `time.process_time()` instead of `time.perf_counter()`, which is the default

  *New in version 3.3.*

- `-t`, `--time`  
  use `time.time()` (deprecated)

- `-c`, `--clock`  
  use `time.clock()` (deprecated)

- `-v`, `--verbose`
print raw timing results; repeat for more digits precision

-h, --help
print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple -s options are treated similarly.

If -n is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.

default_timer() measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The -r option is good for this; the default of 3 repetitions is probably enough in most cases. You can use time.process_time() to measure CPU time.

**Note:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn’t try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.
27.5.4. Examples

It is possible to provide a setup statement that is executed only once at the beginning:

```
$ python -m timeit -s 'text = "sample string"; char = "g"'
10000000 loops, best of 3: 0.0877 usec per loop
$ python -m timeit -s 'text = "sample string"; char = "g"'
1000000 loops, best of 3: 0.342 usec per loop
```

The same can be done using the `Timer` class and its methods:

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"; char = "g"', number=1000000)
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = "g"', number=1000000)
1.7246671520006203
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes:

```
$ python -m timeit 'try:' 'str.__bool__' 'except AttributeError:
    ...'
1000000 loops, best of 3: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__bool__")': pass
```
To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement:
```python
def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))
```

27.6. `trace` — Trace or track

Python statement execution

**Source code:** Lib/trace.py

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.
27.6.1. Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```python
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

**--help**
Display usage and exit.

**--version**
Display the version of the module and exit.

27.6.1.1. Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--counts` options. When `--listfuncs` is provided, neither `--counts` nor `--trace` are accepted, and vice versa.

**-c, --count**
Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

**-t, --trace**
Display lines as they are executed.
-l, --listfuncs
Display the functions executed by running the program.

-r, --report
Produce an annotated list from an earlier program run that used the --count and --file option. This does not execute any code.

-T, --trackcalls
Display the calling relationships exposed by running the program.

27.6.1.2. Modifiers

-f, --file=<file>
Name of a file to accumulate counts over several tracing runs. Should be used with the --count option.

-C, --coverdir=<dir>
Directory where the report files go. The coverage report for package.module is written to file dir/package/module.cover.

-m, --missing
When generating annotated listings, mark lines which were not executed with >>>>>>>.

-s, --summary
When using --count or --report, write a brief summary to stdout for each file processed.

-R, --no-report
Do not generate annotated listings. This is useful if you intend to make several runs with --count, and then produce a single set of
annotated listings at the end.

-g, --timing
Prefix each line with the time since the program started. Only used while tracing.

27.6.1.3. Filters

These options may be repeated multiple times.

--ignore-module=<mod>
Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

--ignore-dir=<dir>
Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by \texttt{os.pathsep}.
27.6.2. Programmatic Interface

class trace.Trace(count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(), infile=None, outfile=None, timing=False)

Create an object to trace execution of a single statement or expression. All parameters are optional. count enables counting of line numbers. trace enables line execution tracing. countfuncs enables listing of the functions called during the run. countcallers enables call relationship tracking. ignoremods is a list of modules or packages to ignore. ignoredirs is a list of directories whose modules or packages should be ignored. infile is the name of the file from which to read stored count information. outfile is the name of the file in which to write updated count information. timing enables a timestamp relative to when tracing was started to be displayed.

run(cmd)

Execute the command and gather statistics from the execution with the current tracing parameters. cmd must be a string or code object, suitable for passing into exec().

runctx(cmd, globals=None, locals=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, globals and locals default to empty dictionaries.

runfunc(func, *args, **kwds)

Call func with the given arguments under control of the Trace object with the current tracing parameters.
results()

Return a CoverageResults object that contains the cumulative results of all previous calls to run, runctx and runfunc for the given Trace instance. Does not reset the accumulated trace results.

class trace.CoverageResults

A container for coverage results, created by Trace.results(). Should not be created directly by the user.

update(other)

Merge in data from another CoverageResults object.

write_results(show_missing=True, summary=False, coverdir=None)

Write coverage results. Set show_missing to show lines that had no hits. Set summary to include in the output the coverage summary per module. coverdir specifies the directory into which the coverage result files will be output. If None, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```python
import sys
import trace

# create a Trace object, telling it what to ignore, # do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
)```
count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")
28. Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

- 28.1. sys — System-specific parameters and functions
- 28.2. sysconfig — Provide access to Python’s configuration information
  - 28.2.1. Configuration variables
  - 28.2.2. Installation paths
  - 28.2.3. Other functions
  - 28.2.4. Using sysconfig as a script
- 28.3. builtins — Built-in objects
- 28.4. __main__ — Top-level script environment
- 28.5. warnings — Warning control
  - 28.5.1. Warning Categories
  - 28.5.2. The Warnings Filter
    - 28.5.2.1. Default Warning Filters
  - 28.5.3. Temporarily Suppressing Warnings
  - 28.5.4. Testing Warnings
  - 28.5.5. Updating Code For New Versions of Python
  - 28.5.6. Available Functions
  - 28.5.7. Available Context Managers
- 28.6. contextlib — Utilities for with-statement contexts
  - 28.6.1. Utilities
  - 28.6.2. Examples and Recipes
    - 28.6.2.1. Supporting a variable number of context managers
    - 28.6.2.2. Simplifying support for single optional context managers
    - 28.6.2.3. Catching exceptions from __enter__
methods

28.6.2.4. Cleaning up in an __enter__ implementation
28.6.2.5. Replacing any use of try-finally and flag variables
28.6.2.6. Using a context manager as a function decorator

- 28.7. abc — Abstract Base Classes
- 28.8. atexit — Exit handlers
  - 28.8.1. atexit Example
- 28.9. traceback — Print or retrieve a stack traceback
  - 28.9.1. Traceback Examples
- 28.10. __future__ — Future statement definitions
- 28.11. gc — Garbage Collector interface
- 28.12. inspect — Inspect live objects
  - 28.12.1. Types and members
  - 28.12.2. Retrieving source code
  - 28.12.3. Introspecting callables with the Signature object
  - 28.12.4. Classes and functions
  - 28.12.5. The interpreter stack
  - 28.12.6. Fetching attributes statically
- 28.13. site — Site-specific configuration hook
- 28.14. fpectl — Floating point exception control
  - 28.14.2. Limitations and other considerations
- 28.15. distutils — Building and installing Python modules
28.1. sys — System-specific parameters and functions

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

sys.abiflags

On POSIX systems where Python is build with the standard configure script, this contains the ABI flags as specified by PEP 3149.

New in version 3.2.

sys.argv

The list of command line arguments passed to a Python script. argv[0] is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the -c command line option to the interpreter, argv[0] is set to the string '-c'. If no script name was passed to the Python interpreter, argv[0] is the empty string.

To loop over the standard input, or the list of files given on the command line, see the fileinput module.

sys.base_exec_prefix

Set during Python startup, before site.py is run, to the same value as exec_prefix. If not running in a virtual environment, the values will stay the same; if site.py finds that a virtual environment is in use, the values of prefix and exec_prefix
will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

*New in version 3.3.*

**sys.** `base_prefix`

Set during Python startup, before `site.py` is run, to the same value as `prefix`. If not running in a virtual environment, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of `prefix` and `exec_prefix` will be changed to point to the virtual environment, whereas `base_prefix` and `base_exec_prefix` will remain pointing to the base Python installation (the one which the virtual environment was created from).

*New in version 3.3.*

**sys.** `byteorder`

An indicator of the native byte order. This will have the value 'big' on big-endian (most-significant byte first) platforms, and 'little' on little-endian (least-significant byte first) platforms.

**sys.** `builtin_module_names`

A tuple of strings giving the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way — `modules.keys()` only lists the imported modules.)

**sys.** `call_tracing(func, args)`

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from
a debugger from a checkpoint, to recursively debug some other code.

sys.\texttt{copyright}

A string containing the copyright pertaining to the Python interpreter.

sys.\texttt{\_clear\_type\_cache()}

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function \textit{only} to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

sys.\texttt{\_current\_frames()}

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the \texttt{traceback} module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

sys.\texttt{\_debugmallocstats()}

Print low-level information to stderr about the state of CPython's
memory allocator.

If Python is configured –with-pydebug, it also performs some expensive internal consistency checks.

*New in version 3.3.*

**CPython implementation detail:** This function is specific to CPython. The exact output format is not defined here, and may change.

**sys.dllhandle**

Integer specifying the handle of the Python DLL. Availability: Windows.

**sys.displayhook(value)**

If `value` is not None, this function prints `repr(value)` to `sys.stdout`, and saves `value` in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably 'strict'), encode it to `sys.stdout.encoding` with 'backslashreplace' error handler.

`sys.displayhook` is called on the result of evaluating an *expression* entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```python
def displayhook(value):
    if value is None:
        return
```
# Set '_' to None to avoid recursion
builtins._ = None
text = repr(value)

try:
sys.stdout.write(text)
except UnicodeEncodeError:
    bytes = text.encode(sys.stdout.encoding,
    if hasattr(sys.stdout, 'buffer'):
        sys.stdout.buffer.write(bytes)
else:
    text = bytes.decode(sys.stdout.encodi
sys.stdout.write(text)
sys.stdout.write("\n")
builtins._ = value

Changed in version 3.2: Use 'backslashreplace' error handler on UnicodeEncodeError.

sys.dont_write_bytecode
If this is true, Python won’t try to write .pyc or .pyo files on the import of source modules. This value is initially set to True or False depending on the -B command line option and the PYTHONDONTWRITEBYTECODE environment variable, but you can set it yourself to control bytecode file generation.

sys.excepthook(type, value, traceback)
This function prints out a given traceback and exception to sys.stderr.

When an exception is raised and uncaught, the interpreter calls sys.excepthook with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt;
in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

```
sys.__displayhook__
sys.__excepthook__
```

These objects contain the original values of `displayhook` and `excepthook` at the start of the program. They are saved so that `displayhook` and `excepthook` can be restored in case they happen to get replaced with broken objects.

```
sys.exc_info()
```

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, “handling an exception” is defined as “executing an except clause.” For any stack frame, only information about the exception being currently handled is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three `None` values is returned. Otherwise, the values returned are `(type, value, traceback)`. Their meaning is: `type` gets the type of the exception being handled (a subclass of `BaseException`); `value` gets the exception instance (an instance of the exception type); `traceback` gets a traceback object (see the Reference Manual) which encapsulates the call stack at the point where the exception originally occurred.

```
sys.exec_prefix
```
A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also '/usr/local'. This can be set at build time with the --exec-prefix argument to the configure script. Specifically, all configuration files (e.g. the pyconfig.h header file) are installed in the directory exec_prefix/lib/pythonX.Y/config, and shared library modules are installed in exec_prefix/lib/pythonX.Y/lib-dynload, where X.Y is the version number of Python, for example 3.2.

Note: If a virtual environment is in effect, this value will be changed in site.py to point to the virtual environment. The value for the Python installation will still be available, via base_exec_prefix.

**sys.executable**

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, **sys.executable** will be an empty string or None.

**sys.exit([arg])**

Exit from Python. This is implemented by raising the SystemExit exception, so cleanup actions specified by finally clauses of try statements are honored, and it is possible to intercept the exit attempt at an outer level.

The optional argument arg can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and the like. Most
systems require it to be in the range 0-127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, None is equivalent to passing zero, and any other object is printed to stderr and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately “only” raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted.

**sys.** **flags**

The *struct sequence flags* exposes the status of command line flags. The attributes are read only.

<table>

</tbody>
</table>

The attribute `sys.float_info.dig` needs further explanation. If s is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting s to a float and back again will recover a string representing the same
decimal value:

```python
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'  # decimal string with 15 significant digits
>>> format(float(s), '.15g')  # convert to float and back -> same value
'3.14159265358979'
```

But for strings with more than `sys.float_info.dig` significant digits, this isn't always true:

```python
>>> s = '9876543211234567'  # 16 significant digits is too many!
>>> format(float(s), '.16g')  # conversion changes value
'9876543211234568'
```

**sys.float_repr_style**

A string indicating how the `repr()` function behaves for floats. If the string has value 'short' then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value 'legacy' and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

*New in version 3.1.*

**sys.getcheckinterval()**

Return the interpreter's "check interval"; see `setcheckinterval()`.

*Deprecated since version 3.2: Use `getswitchinterval()`*
sys. `getdefaultencoding()`
Return the name of the current default string encoding used by the Unicode implementation.

sys. `getdlopenflags()`
Return the current value of the flags that are used for `dlopen()` calls. The flag constants are defined in the `ctypes` and DLFCN modules. Availability: Unix.

sys. `getfilesystemencoding()`
Return the name of the encoding used to convert Unicode filenames into system file names. The result value depends on the operating system:

- On Mac OS X, the encoding is 'utf-8'.
- On Unix, the encoding is the user's preference according to the result of `nl_langinfo(CODESET)`, or 'utf-8' if `nl_langinfo(CODESET)` failed.
- On Windows NT+, file names are Unicode natively, so no conversion is performed. `getfilesystemencoding()` still returns 'mbcs', as this is the encoding that applications should use when they explicitly want to convert Unicode strings to byte strings that are equivalent when used as file names.
- On Windows 9x, the encoding is 'mbcs'.

*Changed in version 3.2*: On Unix, use 'utf-8' instead of None if `nl_langinfo(CODESET)` failed. `getfilesystemencoding()` result cannot be None.

sys. `getrefcount(object)`
Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to `getrefcount()`.

**sys.getrecursionlimit()**

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by `setrecursionlimit()`.

**sys.getsizeof(object[, default])**

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, `default` will be returned if the object does not provide means to retrieve the size. Otherwise a `TypeError` will be raised.

`getsizeof()` calls the object's `__sizeof__` method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

See recursive `sizeof` recipe for an example of using `getsizeof()` recursively to find the size of containers and all their contents.

**sys.getswitchinterval()**

Return the interpreter’s “thread switch interval”; see `setswitchinterval()`.
New in version 3.2.

**sys.\_getframe([\_\_depth\_])**

Return a frame object from the call stack. If optional integer \_\_depth\_ is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, **ValueError** is raised. The default for \_\_depth\_ is zero, returning the frame at the top of the call stack.

**CPython implementation detail:** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

**sys.getprofile()**

Get the profiler function as set by **setprofile()**.

**sys.gettrace()**

Get the trace function as set by **settrace()**.

**CPython implementation detail:** The gettrace() function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

**sys.getwindowsversion()**

Return a named tuple describing the Windows version currently running. The named elements are major, minor, build, platform, service_pack, service_pack_minor, service_pack_major, suite_mask, and product_type. service_pack contains a string while all other values are integers. The components can also be
accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

`platform` may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (VER_PLATFORM_WIN32s)</td>
<td>Win32s on Windows 3.1</td>
</tr>
<tr>
<td>1 (VER_PLATFORM_WIN32_WINDOWS)</td>
<td>Windows 95/98/ME</td>
</tr>
<tr>
<td>2 (VER_PLATFORM_WIN32_NT)</td>
<td>Windows NT/2000/XP/x64</td>
</tr>
<tr>
<td>3 (VER_PLATFORM_WIN32_CE)</td>
<td>Windows CE</td>
</tr>
</tbody>
</table>

`product_type` may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (VER_NT_WORKSTATION)</td>
<td>The system is a workstation.</td>
</tr>
<tr>
<td>2 (VER_NT_DOMAIN_CONTROLLER)</td>
<td>The system is a domain controller.</td>
</tr>
<tr>
<td>3 (VER_NT_SERVER)</td>
<td>The system is a server, but not a domain controller.</td>
</tr>
</tbody>
</table>

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

Availability: Windows.

*Changed in version 3.2:* Changed to a named tuple and added
service_pack_minor, service_pack_major, suite_mask, and product_type.

sys.hash_info

A struct sequence giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see Hashing of numeric types.

<table>
<thead>
<tr>
<th>attribute</th>
<th>explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>width in bits used for hash values</td>
</tr>
<tr>
<td>modulus</td>
<td>prime modulus P used for numeric hash scheme</td>
</tr>
<tr>
<td>inf</td>
<td>hash value returned for a positive infinity</td>
</tr>
<tr>
<td>nan</td>
<td>hash value returned for a nan</td>
</tr>
<tr>
<td>imag</td>
<td>multiplier used for the imaginary part of a complex number</td>
</tr>
</tbody>
</table>

New in version 3.2.

sys.hexversion

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```python
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...
```
This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The `struct sequence sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at *API and ABI Versioning*

**`sys.implementation`**

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

`name` is the implementation's identifier, e.g. `'cpython'`. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

`version` is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python *implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

`hexversion` is the implementation version in hexadecimal format, like `sys.hexversion`.

`cache_tag` is the tag used by the import machinery in the filenames
of cached modules. By convention, it would be a composite of the implementation's name and version, like `cpython-33'. However, a Python implementation may use some other value if appropriate. If `cache_tag` is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See PEP 421 for more information.

*New in version 3.3.*

**sys.int_info**

A *struct sequence* that holds information about Python’s internal representation of integers. The attributes are read only.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>bits_per_digit</td>
<td>number of bits held in each digit. Python integers are stored internally in base (2^{\text{int_info.bits_per_digit}})</td>
</tr>
<tr>
<td>sizeof_digit</td>
<td>size in bytes of the C type used to represent a digit</td>
</tr>
</tbody>
</table>

*New in version 3.1.*

**sys.intern(string)**

Enter `string` in the table of “interned” strings and return the interned string – which is `string` itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup – if the keys in a
dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not immortal; you must keep a reference to the return value of `intern()` around to benefit from it.

```python
sys.last_type
sys.last_value
sys.last_traceback
```

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see `pdb` module for more information.)

The meaning of the variables is the same as that of the return values from `exc_info()` above.

```python
sys.maxsize
```

An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually $2^{**31} - 1$ on a 32-bit platform and $2^{**63} - 1$ on a 64-bit platform.

```python
sys.maxunicode
```

An integer giving the value of the largest Unicode code point, i.e. `1114111 (0x10FFFF in hexadecimal).`
Changed in version 3.3: Before PEP 393, sys.maxunicode used to be either \texttt{0xFFFF} or \texttt{0x10FFFF}, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

\texttt{sys.meta_path}

A list of \texttt{finder} objects that have their \texttt{find_module()} methods called to see if one of the objects can find the module to be imported. The \texttt{find_module()} method is called at least with the absolute name of the module being imported. If the module to be imported is contained in package then the parent package's \texttt{__path__} attribute is passed in as a second argument. The method returns 	exttt{None} if the module cannot be found, else returns a \texttt{loader}.

\texttt{sys.meta_path} is searched before any implicit default finders or \texttt{sys.path}.

See PEP 302 for the original specification.

\texttt{sys.modules}

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail.

\texttt{sys.path}

A list of strings that specifies the search path for modules. Initialized from the environment variable \texttt{PYTHONPATH}, plus an installation-dependent default.

As initialized upon program startup, the first item of this list,
path[0], is the directory containing the script that was used to invoke the Python interpreter. If the script directory is not available (e.g. if the interpreter is invoked interactively or if the script is read from standard input), path[0] is the empty string, which directs Python to search modules in the current directory first. Notice that the script directory is inserted before the entries inserted as a result of PYTHONPATH.

A program is free to modify this list for its own purposes. Only strings and bytes should be added to sys.path; all other data types are ignored during import.

See also: Module site This describes how to use .pth files to extend sys.path.

sys.path_hooks
A list of callables that take a path argument to try to create a finder for the path. If a finder can be created, it is to be returned by the callable, else raise ImportError.

Originally specified in PEP 302.

sys.path_importer_cache
A dictionary acting as a cache for finder objects. The keys are paths that have been passed to sys.path_hooks and the values are the finders that are found. If a path is a valid file system path but no finder is found on sys.path_hooks then None is stored.

Originally specified in PEP 302.

Changed in version 3.3: None is stored instead of imp.NullImporter when no finder is found.
This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For Unix systems, except on Linux, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5' or 'freebsd8', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```python
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
```

For other systems, the values are:

<table>
<thead>
<tr>
<th>System</th>
<th>platform value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>'linux'</td>
</tr>
<tr>
<td>Windows</td>
<td>'win32'</td>
</tr>
<tr>
<td>Windows/Cygwin</td>
<td>'cygwin'</td>
</tr>
<tr>
<td>Mac OS X</td>
<td>'darwin'</td>
</tr>
<tr>
<td>OS/2</td>
<td>'os2'</td>
</tr>
<tr>
<td>OS/2 EMX</td>
<td>'os2emx'</td>
</tr>
</tbody>
</table>

*Changed in version 3.3:* On Linux, `sys.platform` doesn’t contain the major version anymore. It is always 'linux', instead of 'linux2' or 'linux3'. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.
See also: `os.name` has a coarser granularity. `os.uname()` gives system-dependent version information. The `platform` module provides detailed checks for the system's identity.

**sys.**`prefix`  
A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string `'/usr/local'`. This can be set at build time with the `--prefix` argument to the `configure` script. The main collection of Python library modules is installed in the directory `prefix/lib/pythonX.Y` while the platform independent header files (all except `pyconfig.h`) are stored in `prefix/include/pythonX.Y`, where `X.Y` is the version number of Python, for example `3.2`.

**Note:** If a virtual environment is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_prefix`.

**sys.**`ps1`  
**sys.**`ps2`  
Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>>'` and `'... '`. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.
sys. `setcheckinterval(interval)`
Set the interpreter's “check interval”. This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is 100, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value \( \leq 0 \) checks every virtual instruction, maximizing responsiveness as well as overhead.

*Deprecated since version 3.2:* This function doesn’t have an effect anymore, as the internal logic for thread switching and asynchronous tasks has been rewritten. Use `setswitchinterval()` instead.

sys. `setdlopenflags(n)`
Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag modules can be found in the `os` module (`RTLD_xxx` constants, e.g. `os.RTLD_LAZY`).

Availability: Unix.

sys. `setprofile(profilefunc)`
Set the system’s profile function, which allows you to implement a Python source code profiler in Python. See chapter *The Python Profilers* for more information on the Python profiler. The system’s profile function is called similarly to the system’s trace function (see
settrace()), but it isn’t called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return None.

sys.setrecursionlimit(limit)
Set the maximum depth of the Python interpreter stack to limit. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

sys.setswitchinterval(interval)
Set the interpreter’s thread switch interval (in seconds). This floating-point value determines the ideal duration of the “timeslices” allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system’s decision. The interpreter doesn’t have its own scheduler.

New in version 3.2.

sys.settrace(tracefunc)
Set the system’s trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must be
registered using `settrace()` for each thread being debugged.

Trace functions should have three arguments: `frame`, `event`, and `arg`. `frame` is the current stack frame. `event` is a string: ['call', 'line', 'return', 'exception', 'c_call', 'c_return', or 'c_exception']. `arg` depends on the event type.

The trace function is invoked (with `event` set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used that scope, or None if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or None to turn off tracing in that scope.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The global trace function is called; `arg` is None; the return value specifies the local trace function.

'line'

The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; `arg` is None; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works.

'return'

A function (or other code block) is about to return. The local trace function is called; `arg` is the value that will be returned, or None if the event is caused by an exception being raised. The
trace function's return value is ignored.

'exception'
An exception has occurred. The local trace function is called; arg is a tuple (exception, value, traceback); the return value specifies the new local trace function.

'c_call'
A C function is about to be called. This may be an extension function or a built-in. arg is the C function object.

'c_return'
A C function has returned. arg is the C function object.

'c_exception'
A C function has raised an exception. arg is the C function object.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more information on code and frame objects, refer to The standard type hierarchy.

**CPython implementation detail:** The settrace() function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

sys.settscdump(on_flag)
Activate dumping of VM measurements using the Pentium timestamp counter, if on_flag is true. Deactivate these dumps if on_flag is off. The function is available only if Python was compiled with --with-tsc. To understand the output of this dump, read
Python/ceval.c in the Python sources.

**CPython implementation detail:** This function is intimately bound to CPython implementation details and thus not likely to be implemented elsewhere.

```python
sys.stdin
sys.stdout
sys.stderr
```

*File objects* used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);
- `stdout` is used for the output of `print()` and `expression` statements and for the prompts of `input()`;
- The interpreter's own prompts and its error messages go to `stderr`.

By default, these streams are regular text streams as returned by the `open()` function. Their parameters are chosen as follows:

- The character encoding is platform-dependent. Under Windows, if the stream is interactive (that is, if its `isatty()` method returns `True`), the console codepage is used, otherwise the ANSI code page. Under other platforms, the `locale` encoding is used (see `locale.getpreferredencoding()`).

  Under all platforms though, you can override this value by setting the `PYTHONIOENCODING` environment variable.

- When interactive, standard streams are line-buffered.
Otherwise, they are block-buffered like regular text files. You can override this value with the -u command-line option.

To write or read binary data from/to the standard streams, use the underlying binary `buffer`. For example, to write bytes to `stdout`, use `sys.stdout.buffer.write(b'abc')`. Using `io.TextIOBase.detach()`, streams can be made binary by default. This function sets `stdin` and `stdout` to binary:

```python
def make_streams_binary():
    sys.stdin = sys.stdin.detach()
    sys.stdout = sys.stdout.detach()
```

Note that the streams may be replaced with objects (like `io.StringIO`) that do not support the buffer attribute or the `detach()` method and can raise `AttributeError` or `io.UnsupportedOperation`.

```python
sys.__stdin__
sys.__stdout__
sys.__stderr__
```

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

**Note:** Under some conditions `stdin`, `stdout` and `stderr` as
well as the original values __stdin__, __stdout__ and __stderr__ can be None. It is usually the case for Windows GUI apps that aren’t connected to a console and Python apps started with pythonw.

**sys. thread_info**

A *struct sequence* holding information about the thread implementation.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td>Name of the thread implementation:</td>
</tr>
<tr>
<td></td>
<td>• 'nt': Windows threads</td>
</tr>
<tr>
<td></td>
<td>• 'os2': OS/2 threads</td>
</tr>
<tr>
<td></td>
<td>• 'pthread': POSIX threads</td>
</tr>
<tr>
<td></td>
<td>• 'solaris': Solaris threads</td>
</tr>
<tr>
<td><strong>lock</strong></td>
<td>Name of the lock implementation:</td>
</tr>
<tr>
<td></td>
<td>• 'semaphore': a lock uses a semaphore</td>
</tr>
<tr>
<td></td>
<td>• 'mutex+cond': a lock uses a mutex and a condition variable</td>
</tr>
<tr>
<td></td>
<td>• None if this information is unknown</td>
</tr>
<tr>
<td><strong>version</strong></td>
<td>Name and version of the thread library. It is a string, or None if these informations are unknown.</td>
</tr>
</tbody>
</table>

*New in version 3.3.*

**sys. tracebacklimit**

When this variable is set to an integer value, it determines the
maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

**sys.version**
A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use `version_info` and the functions provided by the `platform` module.

**sys.api_version**
The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

**sys.version_info**
A tuple containing the five components of the version number: `major`, `minor`, `micro`, `releaselevel`, and `serial`. All values except `releaselevel` are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The `version_info` value corresponding to the Python version 2.0 is `(2, 0, 0, 'final', 0)`. The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

*Changed in version 3.1:* Added named component attributes.

**sys.warnoptions**
This is an implementation detail of the warnings framework; do not
modify this value. Refer to the warnings module for more information on the warnings framework.

sys.\texttt{winver}

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of version. It is provided in the sys module for informational purposes; modifying this value has no effect on the registry keys used by Python. Availability: Windows.

sys.\texttt{\_xoptions}

A dictionary of the various implementation-specific flags passed through the -X command-line option. Option names are either mapped to their values, if given explicitly, or to True. Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license"
>>> import sys
>>> sys.\_xoptions
{'a': 'b', 'c': True}
```

\textbf{CPython implementation detail:} This is a CPython-specific way of accessing options passed through -X. Other implementations may export them through other means, or not at all.

\textit{New in version 3.2.}

\textbf{Citations}

28.2. `sysconfig` — Provide access to Python’s configuration information

*New in version 3.2.*

**Source code:** `Lib/sysconfig.py`

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.
28.2.1. Configuration variables

A Python distribution contains a Makefile and a pyconfig.h header file that are necessary to build both the Python binary itself and third-party C extensions compiled using distutils.

sysconfig puts all variables found in these files in a dictionary that can be accessed using get_config_vars() or get_config_var().

Notice that on Windows, it's a much smaller set.

sysconfig.get_config_vars(*args)

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return None.

sysconfig.get_config_var(name)

Return the value of a single variable name. Equivalent to get_config_vars().get(name).

If name is not found, return None.

Example of usage:

```python
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
```
'/usr/local/lib'

```python
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++]
```
28.2.2. Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`.

Every new component that is installed using `distutils` or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports seven schemes:

- **posix_prefix**: scheme for Posix platforms like Linux or Mac OS X. This is the default scheme used when Python or a component is installed.
- **posix_home**: scheme for Posix platforms used when a `home` option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- **posix_user**: scheme for Posix platforms used when a component is installed through Distutils and the `user` option is used. This scheme defines paths located under the user home directory.
- **nt**: scheme for NT platforms like Windows.
- **nt_user**: scheme for NT platforms, when the `user` option is used.
- **os2**: scheme for OS/2 platforms.
- **os2_home**: scheme for OS/2 platforms, when the `user` option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- **stdlib**: directory containing the standard Python library files that
are not platform-specific.

- **plaststdlib**: directory containing the standard Python library files that are platform-specific.
- **platlib**: directory for site-specific, platform-specific files.
- **purelib**: directory for site-specific, non-platform-specific files.
- **include**: directory for non-platform-specific header files.
- **platininclude**: directory for platform-specific header files.
- **scripts**: directory for script files.
- **data**: directory for data files.

**sysconfig** provides some functions to determine these paths.

**sysconfig.**\texttt{get\_scheme\_names()}\texttt{ }\texttt{ }

Return a tuple containing all schemes currently supported in **sysconfig**.

**sysconfig.**\texttt{get\_path\_names()}\texttt{ }\texttt{ }

Return a tuple containing all path names currently supported in **sysconfig**.

**sysconfig.**\texttt{get\_path(name[, scheme[, vars[, expand]]])}\texttt{ }\texttt{ }

Return an installation path corresponding to the path name, from the install scheme named scheme.

name has to be a value from the list returned by **get\_path\_names()**.

**sysconfig** stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the stdlib path for the nt scheme is: \{base\}/Lib.

**get\_path()** will use the variables returned by **get\_config\_vars()** to expand the path. All variables have
default values for each platform so one may call this function and get the default value.

If `scheme` is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary return by `get_config_vars()`.

If `expand` is set to False, the path will not be expanded using the variables.

If `name` is not found, return None.

```python
sysconfig.get_paths([scheme, vars, expand])
```
Return a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If `scheme` is not provided, will use the default scheme for the current platform.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If `expand` is set to False, the paths will not be expanded.

If `scheme` is not an existing scheme, `get_paths()` will raise a `KeyError`. 
28.2.3. Other functions

sysconfig.get_python_version()

Return the MAJOR.MINOR Python version number as a string. Similar to sys.version[:3].

sysconfig.get_platform()

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by os.uname()), although the exact information included depends on the OS; e.g. for IRIX the architecture isn’t particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn’t particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u
- irix-5.3
- irix64-6.2

Windows will return one of:

- win-amd64 (64bit Windows on AMD64 (aka x86_64, Intel64, EM64T, etc)
- win-ia64 (64bit Windows on Itanium)
- win32 (all others - specifically, sys.platform is returned)

Mac OS X can return:
- macosx-10.6-ppc
- macosx-10.4-ppc64
- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`  
Return True if the current Python installation was built from source.

`sysconfig.parse_config_h(fp[, vars])`  
Parse a `config.h`-style file.

`fp` is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`  
Return the path of `pyconfig.h`.

`sysconfig.get_makefile_filename()`  
Return the path of Makefile.
28.2.4. Using `sysconfig` as a script

You can use `sysconfig` as a script with Python’s `-m` option:

```bash
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"

Paths:
  data = "/usr/local"
  include = "/Users/tarek/Dev/svn.python.org/py3k/Include"
  platininclude = "."
  platlib = "/usr/local/lib/python3.2/site-packages"
  platstdlib = "/usr/local/lib/python3.2"
  purelib = "/usr/local/lib/python3.2/site-packages"
  scripts = "/usr/local/bin"
  stdlib = "/usr/local/lib/python3.2"

Variables:
  AC_APPLE_UNIVERSAL_BUILD = "0"
  AIX_GENUINE_CPLUSPLUS = "0"
  AR = "ar"
  ARFLAGS = "rc"
  ASDLGEN = "/Parser/asdl_c.py"
  ...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.
28.3. builtins — Built-in objects

This module provides direct access to all 'built-in' identifiers of Python; for example, `builtins.open` is the full name for the built-in function `open()`. See Built-in Functions and Built-in Constants for documentation.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an `open()` function that wraps the built-in `open()`, this module can be used directly:

```python
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

As an implementation detail, most modules have the name
__builtins__ made available as part of their globals. The value of __builtins__ is normally either this module or the value of this module's __dict__ attribute. Since this is an implementation detail, it may not be used by alternate implementations of Python.
28.4. __main__ — Top-level script environment

This module represents the (otherwise anonymous) scope in which the interpreter’s main program executes — commands read either from standard input, from a script file, or from an interactive prompt. It is this environment in which the idiomatic “conditional script” stanza causes a script to run:

```python
if __name__ == "__main__":
    main()
```
28.5. **warnings** — Warning control

**Source code:** Lib/warnings.py

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn’t warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see *Exception Handling* for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category (see below), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and
actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

**See also:** `logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.
28.5.1. Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings. The following warnings category classes are currently defined:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>This is the base class of all warning category classes. It is a subclass of <code>Exception</code>.</td>
</tr>
<tr>
<td>UserWarning</td>
<td>The default category for <code>warn()</code>.</td>
</tr>
<tr>
<td>DeprecationWarning</td>
<td>Base category for warnings about deprecated features (ignored by default).</td>
</tr>
<tr>
<td>SyntaxWarning</td>
<td>Base category for warnings about dubious syntactic features.</td>
</tr>
<tr>
<td>RuntimeWarning</td>
<td>Base category for warnings about dubious runtime features.</td>
</tr>
<tr>
<td>FutureWarning</td>
<td>Base category for warnings about constructs that will change semantically in the future.</td>
</tr>
<tr>
<td>PendingDeprecationWarning</td>
<td>Base category for warnings about features that will be deprecated in the future (ignored by default).</td>
</tr>
<tr>
<td>ImportWarning</td>
<td>Base category for warnings triggered during the process of importing a module (ignored by</td>
</tr>
</tbody>
</table>
While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.

<table>
<thead>
<tr>
<th>Warning Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UnicodeWarning</td>
<td>Base category for warnings related to Unicode.</td>
</tr>
<tr>
<td>BytesWarning</td>
<td>Base category for warnings related to <code>bytes</code> and <code>bytearray</code>.</td>
</tr>
<tr>
<td>ResourceWarning</td>
<td>Base category for warnings related to resource usage.</td>
</tr>
</tbody>
</table>
28.5.2. The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the match determines the disposition of the match. Each entry is a tuple of the form \((\text{action}, \text{message}, \text{category}, \text{module}, \text{lineno})\), where:

- \textit{action} is one of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Disposition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;error&quot;</td>
<td>turn matching warnings into exceptions</td>
</tr>
<tr>
<td>&quot;ignore&quot;</td>
<td>never print matching warnings</td>
</tr>
<tr>
<td>&quot;always&quot;</td>
<td>always print matching warnings</td>
</tr>
<tr>
<td>&quot;default&quot;</td>
<td>print the first occurrence of matching warnings for each location where the warning is issued</td>
</tr>
<tr>
<td>&quot;module&quot;</td>
<td>print the first occurrence of matching warnings for each module where the warning is issued</td>
</tr>
<tr>
<td>&quot;once&quot;</td>
<td>print only the first occurrence of matching warnings, regardless of location</td>
</tr>
</tbody>
</table>

- \textit{message} is a string containing a regular expression that the warning message must match (the match is compiled to always be case-insensitive).

- \textit{category} is a class (a subclass of \texttt{Warning}) of which the warning
category must be a subclass in order to match.

- **module** is a string containing a regular expression that the module name must match (the match is compiled to be case-sensitive).

- **lineno** is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the `Warning` class is derived from the built-in `Exception` class, to turn a warning into an error we simply raise `category(message)`.

The warnings filter is initialized by `-W` options passed to the Python interpreter command line. The interpreter saves the arguments for all `-W` options without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

### 28.5.2.1. Default Warning Filters

By default, Python installs several warning filters, which can be overridden by the command-line options passed to `-W` and calls to `filterwarnings()`.

- `DeprecationWarning` and `PendingDeprecationWarning`, and `ImportWarning` are ignored.
- `BytesWarning` is ignored unless the `-b` option is given once or twice; in this case this warning is either printed (`-b`) or turned into an exception (`-bb`).
- `ResourceWarning` is ignored unless Python was built in debug mode.

*Changed in version 3.2:* `DeprecationWarning` is now ignored by
default in addition to PendingDeprecationWarning.
28.5.3. Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning, then it is possible to suppress the warning using the `catch_warnings` context manager:

```python
import warnings
def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.
28.5.4. Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```python
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert issubclass(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the
module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).
28.5.5. Updating Code For New Versions of Python

Warnings that are only of interest to the developer are ignored by default. As such you should make sure to test your code with typically ignored warnings made visible. You can do this from the command-line by passing `-Wd` to the interpreter (this is shorthand for `-W default`). This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you simply change what argument is passed to `-W`, e.g. `-W error`. See the `-W` flag for more details on what is possible.

To programmatically do the same as `-Wd`, use:

```python
warnings.simplefilter('default')
```

Make sure to execute this code as soon as possible. This prevents the registering of what warnings have been raised from unexpectedly influencing how future warnings are treated.

Having certain warnings ignored by default is done to prevent a user from seeing warnings that are only of interest to the developer. As you do not necessarily have control over what interpreter a user uses to run their code, it is possible that a new version of Python will be released between your release cycles. The new interpreter release could trigger new warnings in your code that were not there in an older interpreter, e.g. `DeprecationWarning` for a module that you are using. While you as a developer want to be notified that your code is using a deprecated module, to a user this information is essentially noise and provides no benefit to them.
The `unittest` module has been also updated to use the 'default' filter while running tests.
28.5.6. Available Functions

warnings.\texttt{warn}(message, category=None, stacklevel=1)

Issue a warning, or maybe ignore it or raise an exception. The \texttt{category} argument, if given, must be a warning category class (see above); it defaults to \texttt{UserWarning}. Alternatively \texttt{message} can be a \texttt{Warning} instance, in which case \texttt{category} will be ignored and \texttt{message.__class__} will be used. In this case the message text will be \texttt{str(message)}. This function raises an exception if the particular warning issued is changed into an error by the \texttt{warnings} filter see above. The \texttt{stacklevel} argument can be used by wrapper functions written in Python, like this:

\begin{verbatim}
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=1)
\end{verbatim}

This makes the warning refer to \texttt{deprecation()}'s caller, rather than to the source of \texttt{deprecation()} itself (since the latter would defeat the purpose of the warning message).

warnings.\texttt{warn_explicit}(message, category, filename, lineno, module=None, registry=None, module_globals=None)

This is a low-level interface to the functionality of \texttt{warn()}, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the \texttt{__warningregistry__} dictionary of the module). The module name defaults to the filename with \texttt{.py} stripped; if no registry is passed, the warning is never suppressed. \texttt{message} must be a string and \texttt{category} a subclass of \texttt{Warning} or \texttt{message} may be a \texttt{Warning} instance, in which case \texttt{category} will be ignored.
module_globals, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

`warnings.showwarning(message, category, filename, lineno, file=None, line=None)`

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to `file`, which defaults to `sys.stderr`. You may replace this function with any callable by assigning to `warnings.showwarning`. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `showwarning()` will try to read the line specified by `filename` and `lineno`.

`warnings.formatwarning(message, category, filename, lineno, line=None)`

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. `line` is a line of source code to be included in the warning message; if `line` is not supplied, `formatwarning()` will try to read the line specified by `filename` and `lineno`.

`warnings.filterwarnings(action, message='', category=Warning, module='', lineno=0, append=False)`

Insert an entry into the list of `warnings filter specifications`. The entry is inserted at the front by default; if `append` is true, it is inserted at the end. This checks the types of the arguments, compiles the `message` and `module` regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a
particular warning. Omitted arguments default to a value that matches everything.

```
warnings.simplefilter(action, category=Warning, lineno=0, append=False)
```
Insert a simple entry into the list of `warnings filter specifications`. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

```
warnings.resetwarnings()
```
Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.
28.5.7. Available Context Managers

```python
class warnings.catch_warnings(*, record=False, module=None)
```

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the `record` argument is `False` (the default) the context manager returns `None` on entry. If `record` is `True`, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The `module` argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

**Note:** The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.
28.6. `contextlib` — Utilities for `with`-statement contexts

**Source code:** Lib/contextlib.py

This module provides utilities for common tasks involving the `with` statement. For more information see also *Context Manager Types* and *With Statement Context Managers.*
28.6.1. Utilities

Functions and classes provided:

@contextlib.contextmanager

This function is a decorator that can be used to define a factory function for with statement context managers, without needing to create a class or separate __enter__() and __exit__() methods.

A simple example (this is not recommended as a real way of generating HTML!):

```python
from contextlib import contextmanager

@contextmanager
def tag(name):
    print("<%s>" % name)
    yield
    print("</%s>" % name)

>>> with tag("h1"):
...     print("foo")
...<h1>
foo
</h1>
```

The function being decorated must return a generator-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the with statement’s as clause, if any.

At the point where the generator yields, the block nested in the
The `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise “one-shot” context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

*Changed in version 3.2:* Use of `ContextDecorator`.

`contextlib.closing(thing)`

Return a context manager that closes `thing` upon completion of the block. This is basically equivalent to:

```python
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
```

with
```
And lets you write code like this:

```python
from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('http://www.python.org')) as page:
    for line in page:
        print(line)
```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

**class** `contextlib.ContextDecorator`
A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

`ContextDecorator` is used by `contextmanager()`, so you get this functionality automatically.

Example of `ContextDecorator`:

```python
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self
```
```python
def __exit__(self, *exc):
    print('Finishing')
    return False
```

```text
>>> @mycontext()
... def function():
...     print('The bit in the middle')
...
>>> function()
Starting
The bit in the middle
Finishing
```

```text
>>> with mycontext():
...     print('The bit in the middle')
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```python
def f():
    with cm():
        # Do stuff
```

ContextDecorator lets you instead write:

```python
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).
Existing context managers that already have a base class can be extended by using `ContextDecorator` as a mixin class:

```python
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
        return False
```

**Note:** As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple `with` statements. If this is not the case, then the original construct with the explicit `with` statement inside the function should be used.

*New in version 3.2.*

```python
class contextlib.ExitStack
```

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single `with` statement as follows:

```python
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for
    # All opened files will automatically be closed
    # the with statement, even if attempts to open
    # in the list raise an exception
```
Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

*New in version 3.3.*

**enter_context**(*cm*)

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager’s own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.
**push**(exit)

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

**callback**(callback, *args, **kwds)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

**pop_all()**

Transfers the callback stack to a fresh `ExitStack` instance
and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a \texttt{with} statement).

For example, a group of files can be opened as an “all or nothing” operation as follows:

```python
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in fnames]
    close_files = stack.pop_all()
    close_files.close
```

\texttt{close()}

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.
28.6.2. Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by `contextlib`.

28.6.2.1. Supporting a variable number of context managers

The primary use case for `ExitStack` is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single `with` statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```python
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource:
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
```

As shown, `ExitStack` also makes it quite easy to use `with` statements to manage arbitrary resources that don’t natively support the context management protocol.

28.6.2.2. Simplifying support for single optional context managers
In the specific case of a single optional context manager, `ExitStack` instances can be used as a “do nothing” context manager, allowing a context manager to easily be omitted without affecting the overall structure of the source code:

```python
def debug_trace(details):
    if __debug__:
        return TraceContext(details)
    # Don't do anything special with the context in release mode
    return ExitStack()

with debug_trace():
    # Suite is traced in debug mode, but runs normally otherwise
```

28.6.2.3. Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, without inadvertently catching exceptions from the `with` statement body or the context manager’s `__exit__` method. By using `ExitStack` the steps in the context management protocol can be separated slightly in order to allow this:

```python
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API
should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then `ExitStack` can make it easier to handle various situations that can't be handled directly in a `with` statement.

28.6.2.4. Cleaning up in an `__enter__` implementation

As noted in the documentation of `ExitStack.push()`, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```python
from contextlib import contextmanager, ExitStack

class ResourceManager:
    def __init__(self, acquire_resource, release_resource)
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
                self.check_resource_ok = check_resource_ok

@contextmanager
def _cleanup_on_error(self):
```
with ExitStack() as stack:
    stack.push(self)
    yield
    # The validation check passed and didn't raise an exception
    # Accordingly, we want to keep the resource, and pass it back to our caller
    stack.pop_all()

def __enter__(self):
    resource = self.acquire_resource()
    with self._cleanup_on_error():
        if not self.check_resource_ok(resource):
            msg = "Failed validation for {!r}"
            raise RuntimeError(msg.format(resource))
    return resource

def __exit__(self, *exc_details):
    # We don't need to duplicate any of our resource release logic
    self.release_resource()

28.6.2.5. Replacing any use of try-finally and flag variables

A pattern you will sometimes see is a **try-finally** statement with a flag variable to indicate whether or not the body of the **finally** clause should be executed. In its simplest form (that can't already be handled just by using an **except** clause instead), it looks something like this:

cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
```python
finally:
    if cleanup_needed:
        cleanup_resources()
```

As with any `try` statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

**ExitStack** makes it possible to instead register a callback for execution at the end of a `with` statement, and then later decide to skip executing that callback:

```python
from contextlib import ExitStack

with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()
```

This allows the intended cleanup up behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```python
from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, *args, **kwds):
        super(Callback, self).__init__()
        self.callback(callback, *args, **kwds)

    def cancel(self):
        self.pop_all()
```
with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```python
from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
def cleanup_resources():
        ...
        result = perform_operation()
        if result:
            stack.pop_all()
```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables

28.6.2.6. Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context
manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```python
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
        self.name = name

    def __enter__(self):
        logging.info('Entering: {}'.format(self.name))

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: {}'.format(self.name))
```

Instances of this class can be used as both a context manager:

```python
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

And also as a function decorator:

```python
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there’s no way to access the return value of `__enter__()`. If that value is needed, then it is still necessary to use an explicit `with` statement.

**PEP 0343 - The “with” statement**

The specification, background, and examples for the Python `with` statement.
28.7. abc — Abstract Base Classes

Source code: Lib/abc.py

This module provides the infrastructure for defining abstract base classes (ABCs) in Python, as outlined in PEP 3119; see the PEP for why this was added to Python. (See also PEP 3141 and the numbers module regarding a type hierarchy for numbers based on ABCs.)

The collections module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition the collections.abc submodule has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, is it hashable or a mapping.

This module provides the following class:

class abc.ABCMeta

  Metaclass for defining Abstract Base Classes (ABCs).

  Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as “virtual subclasses” – these and their descendants will be considered subclasses of the registering ABC by the built-in issubclass() function, but the registering ABC won’t show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via super()). [1]
Classes created with a metaclass of `ABCMeta` have the following method:

**register**(subclass)

Register `subclass` as a “virtual subclass” of this ABC. For example:

```python
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

*Changed in version 3.3:* Returns the registered subclass, to allow usage as a class decorator.

You can also override this method in an abstract base class:

**__subclasshook__**(subclass)

(Must be defined as a class method.)

Check whether `subclass` is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the **__subclasscheck__()** method of the ABC.)

This method should return True, False or `NotImplemented`. If it returns True, the `subclass` is considered a subclass of this
ABC. If it returns False, the subclass is not considered a subclass of this ABC, even if it would normally be one. If it returns `NotImplemented`, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:

```python
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(metaclass=ABCMeta):
    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
    def __subclasshook__(cls, C):
        if cls is MyIterable:
            if any("__iter__" in B.__dict__ for B
                    return True
        return NotImplemented

MyIterable.register(Foo)
```
The ABC `MyIterable` defines the standard iterable method, `__iter__()`, as an abstract method. The implementation given here can still be called from subclasses. The `get_iterator()` method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an `__iter__()` method (it uses the old-style iterable protocol, defined in terms of `__len__()` and `__getitem__()`). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

The `abc` module also provides the following decorators:

`@abc.abstractmethod`
A decorator indicating abstract methods.

Using this decorator requires that the class’s metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal ‘super’ call mechanisms. `abstractmethod()` may be used to declare abstract methods for properties and descriptors.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is
created, are not supported. The `abstractmethod()` only affects subclasses derived using regular inheritance; “virtual subclasses” registered with the ABC’s `register()` method are not affected.

When `abstractmethod()` is applied in combination with other method descriptors, it should be applied as the innermost decorator, as shown in the following usage examples:

```python
class C(metaclass=ABCMeta):
    @abstractmethod
    def my_abstract_method(self, ...):
        ...
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, ...):
        ...
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(...):
        ...
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
    @my_abstract_property.setter
    @abstractmethod
    def my_abstract_property(self, val):
        ...
    @abstractmethod
    def _get_x(self):
        ...
    @abstractmethod
    def _set_x(self, val):
        ...
```
In order to correctly interoperate with the abstract base class machinery, the descriptor must identify itself as abstract using \_isabstractmethod\_. In general, this attribute should be True if any of the methods used to compose the descriptor are abstract. For example, Python’s built-in property does the equivalent of:

```python
class Descriptor:
    ...
    @property
    def \_isabstractmethod\_(self):
        return any(getattr(f, '\_isabstractmethod\_', f in (self._fget, self._fset,
```

**Note:** Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the `super()` mechanism from the class that overrides it. This could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.

@\texttt{abc.\texttt{abstractclassmethod}}

A subclass of the built-in `\texttt{classmethod()}`, indicating an abstract classmethod. Otherwise it is similar to `\texttt{abstractmethod()}`.

This special case is deprecated, as the `\texttt{classmethod()}` decorator is now correctly identified as abstract when applied to an abstract method:

```python
class C(metaclass=ABCMeta):
    @classmethod
```

```
@abstractmethod
def my_abstract_classmethod(cls, ...):
...

New in version 3.2.

*Deprecated since version 3.3:* It is now possible to use `classmethod` with `abstractmethod()`, making this decorator redundant.

@abc.abstractmethod
A subclass of the built-in `staticmethod()`, indicating an abstract staticmethod. Otherwise it is similar to `abstractmethod()`.

This special case is deprecated, as the `staticmethod()` decorator is now correctly identified as abstract when applied to an abstract method:

class C(metaclass=ABCMeta):
    @staticmethod
    @abstractmethod
def my_abstract_staticmethod(...):
    ...

New in version 3.2.

*Deprecated since version 3.3:* It is now possible to use `staticmethod` with `abstractmethod()`, making this decorator redundant.

@abc.abstractproperty(fget=None, fset=None, fdel=None, doc=None)
A subclass of the built-in `property()`, indicating an abstract
property.

Using this function requires that the class's metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract properties can be called using any of the normal 'super' call mechanisms.

This special case is deprecated, as the `property()` decorator is now correctly identified as abstract when applied to an abstract method:

```python
class C(metaclass=ABCMeta):
    @property
    @abstractmethod
def my_abstract_property(self):
    ...
```

The above example defines a read-only property; you can also define a read-write abstract property by appropriately marking one or more of the underlying methods as abstract:

```python
class C(metaclass=ABCMeta):
    @property
def x(self):
    ...

    @x.setter
    @abstractmethod
def x(self, val):
    ...
```

If only some components are abstract, only those components need to be updated to create a concrete property in a subclass:
class D(C):
    @C.x.setter
    def x(self, val):
        ...

Deprecated since version 3.3: It is now possible to use property, property.getter(), property.setter() and property.deleter() with abstractmethod(), making this decorator redundant.

Footnotes

[1] C++ programmers should note that Python’s virtual base class concept is not the same as C++’s.
28.8. `atexit` — Exit handlers

The `atexit` module defines functions to register and unregister cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the reverse order in which they were registered; if you register A, B, and C, at interpreter termination time they will be run in the order C, B, A.

**Note:** The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

```python
atexit.register(func, *args, **kargs)
```

Register `func` as a function to be executed at termination. Any optional arguments that are to be passed to `func` must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run the last exception to be raised is re-raised.

This function returns `func`, which makes it possible to use it as a
decorator.

**atexit. unregister**(*func*)

Remove *func* from the list of functions to be run at interpreter shutdown. After calling `unregister()`, *func* is guaranteed not to be called when the interpreter shuts down, even if it was registered more than once. `unregister()` silently does nothing if *func* was not previously registered.

**See also:**

**Module readline**

Useful example of `atexit` to read and write `readline` history files.
28.8.1. atexit Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter’s updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```python
try:
    with open("counterfile") as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open("counterfile", "w") as outfile:
        outfile.write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```python
import atexit
atexit.register(goodbye, 'Donny', 'nice')
```
Usage as a *decorator*:

```python
import atexit

@atexit.register
def goodbye():
    print("You are now leaving the Python sector.")
```

This only works with functions that can be called without arguments.
28.9. `traceback` — Print or retrieve a stack traceback

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects — this is the object type that is stored in the `sys.last_traceback` variable and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

```
traceback.print_tb(traceback, limit=None, file=None)
```

Print up to `limit` stack trace entries from `traceback`. If `limit` is omitted or None, all entries are printed. If `file` is omitted or None, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

```
traceback.print_exception(type, value, traceback, limit=None, file=None, chain=True)
```

Print exception information and up to `limit` stack trace entries from `traceback` to `file`. This differs from `print_tb()` in the following ways:

- if `traceback` is not None, it prints a header `Traceback (most recent call last):
- it prints the exception `type` and `value` after the stack trace
• if type is `SyntaxError` and value has the appropriate format,
  it prints the line where the syntax error occurred with a caret
  indicating the approximate position of the error.

If `chain` is true (the default), then chained exceptions (the
`__cause__` or `__context__` attributes of the exception) will be
printed as well, like the interpreter itself does when printing an
unhandled exception.

```python
traceback.print_exc(limit=None, file=None, chain=True)
```
This is a shorthand for `print_exception(*sys.exc_info())`.

```python
traceback.print_last(limit=None, file=None, chain=True)
```
This is a shorthand for `print_exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file)`.
In general it will work only after an exception has reached an
interactive prompt (see `sys.last_type`).

```python
traceback.print_stack(f=None, limit=None, file=None)
```
This function prints a stack trace from its invocation point. The
optional `f` argument can be used to specify an alternate stack frame
to start. The optional `limit` and `file` arguments have the same
meaning as for `print_exception()`.

```python
traceback.extract_tb(traceback, limit=None)
```
Return a list of up to `limit` “pre-processed” stack trace entries
extracted from the traceback object `traceback`. It is useful for
alternate formatting of stack traces. If `limit` is omitted or None, all
entries are extracted. A “pre-processed” stack trace entry is a
quadruple `(filename, line number, function name, text)` representing
the information that is usually printed for a stack trace. The `text` is a
string with leading and trailing whitespace stripped; if the source is
not available it is None.

`traceback.extract_stack(f=None, limit=None)`

Extract the raw traceback from the current stack frame. The return value has the same format as for `extract_tb()`. The optional `f` and `limit` arguments have the same meaning as for `print_stack()`.

`traceback.format_list(list)`

Given a list of tuples as returned by `extract_tb()` or `extract_stack()`, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not None.

`traceback.format_exception_only(type, value)`

Format the exception part of a traceback. The arguments are the exception type and value such as given by `sys.last_type` and `sys.last_value`. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for `SyntaxError` exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

`traceback.format_exception(type, value, tb, limit=None, chain=True)`

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines.
these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.

`traceback.format_exc(limit=None, chain=True)`
This is like `print_exc(limit)` but returns a string instead of printing to a file.

`traceback.format_tb(tb, limit=None)`
A shorthand for `format_list(extract_tb(tb, limit))`.

`traceback.format_stack(f=None, limit=None)`
A shorthand for `format_list(extract_stack(f, limit))`.
28.9.1. Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the code module.

```python
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except:
        print("Exception in user code:")
        print("-"*60)
        traceback.print_exc(file=sys.stdout)
        print("-"*60)

envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```python
import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]
```
try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
print("*** print_tb:")
traceback.print_tb(exc_traceback, limit=1, file=sys.stdout)
print("*** print_exception:")
traceback.print_exception(exc_type, exc_value, exc_traceback, limit=2, file=sys.stdout)
print("*** print_exc:")
traceback.print_exc()
print("*** format_exc, first and last line:")
formatted_lines = traceback.format_exc().splitlines()
print(formatted_lines[0])
print(formatted_lines[-1])
print("*** format_exception:")
print(repr(traceback.format_exception(exc_type, exc_value, exc_traceback)))
print("*** extract_tb:")
print(repr(traceback.extract_tb(exc_traceback)))
print("*** format_tb:")
print(repr(traceback.format_tb(exc_traceback)))
print("*** tb_lineno:", exc_traceback.tb_lineno)

The output for the example would look similar to this:

*** print_tb:
File "<doctest...>", line 10, in <module>
    lumberjack()
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_death()
IndexError: tuple index out of range
The following example shows the different ways to print and format the stack:

```python
>>> import traceback
>>> def another_function():
    ...    lumberstack()
    ...

>>> def lumberstack():
    ...    traceback.print_stack()
    ...
    print(repr(traceback.extract_stack()))
```
...   print(repr(traceback.format_stack()))
...

>>> another_function()
    File "<doctest>", line 10, in <module>
    another_function()
    File "<doctest>", line 3, in another_function
    lumberstack()
    File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('"<doctest>"', 10, '"<module>"', 'another_function()')
 ('"<doctest>"', 3, 'another_function', 'lumberstack()')
 ('"<doctest>"', 7, 'lumberstack', 'print(repr(traceback.extract_stack()))')
    File "<doctest>", line 10, in <module>
    another_function()
    File "<doctest>", line 3, in another_function
    lumberstack()
    File "<doctest>", line 8, in lumberstack
    print(repr(traceback.extract_stack()))

This last example demonstrates the final few formatting functions:

>>> import traceback

>>> traceback.format_list([('spam.py', 3, '"<module>"')
...    ('eggs.py', 42, 'eggs', '')
[ 'File "spam.py", line 3, in <module>
  spam.eggs()
 'File "eggs.py", line 42, in eggs
  return "bacon"

>>> an_error = IndexError('tuple index out of range')

>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range']
28.10. __future__ — Future statement definitions

Source code: Lib/__future__.py

__future__ is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they’re importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of __future__ will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing __future__ and examining its contents.

Each statement in __future__.py is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease, CompilerFlag)
```

where, normally, OptionalRelease is less than MandatoryRelease, and both are 5-tuples of the same form as sys.version_info:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or
 PY_RELEASE_SERIAL # the 3; an int
```
OptionalRelease records the first release in which the feature was accepted.

In the case of a MandatoryRelease that has not yet occurred, MandatoryRelease predicts the release in which the feature will become part of the language.

Else MandatoryRelease records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

MandatoryRelease may also be None, meaning that a planned feature got dropped.

Instances of class _Feature have two corresponding methods, getOptionalRelease() and getMandatoryRelease().

CompilerFlag is the (bitfield) flag that should be passed in the fourth argument to the built-in function compile() to enable the feature in dynamically compiled code. This flag is stored in the compiler_flag attribute on _Feature instances.

No feature description will ever be deleted from __future__. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

<table>
<thead>
<tr>
<th>feature</th>
<th>optional in</th>
<th>mandatory in</th>
<th>effect</th>
</tr>
</thead>
<tbody>

How the compiler treats future imports.
28.11. gc — Garbage Collector interface

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

`gc.enable()`  
Enable automatic garbage collection.

`gc.disable()`  
Disable automatic garbage collection.

`gc.isenabled()`  
Returns true if automatic collection is enabled.

`gc.collect(generations=2)`  
With no arguments, run a full collection. The optional argument `generation` may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is
invalid. The number of unreachable objects found is returned.

The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular float.

gc.set_debug(flags)
Set the garbage collection debugging flags. Debugging information will be written to sys.stderr. See below for a list of debugging flags which can be combined using bit operations to control debugging.

gc.get_debug()
Return the debugging flags currently set.

gc.get_objects()
Returns a list of all objects tracked by the collector, excluding the list returned.

gc.set_threshold(threshold0[, threshold1[, threshold2]]])
Set the garbage collection thresholds (the collection frequency). Setting threshold0 to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of
allocations minus the number of deallocations exceeds \textit{threshold0}, collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than \textit{threshold1} times since generation 1 has been examined, then generation 1 is examined as well. Similarly, \textit{threshold2} controls the number of collections of generation 1 before collecting generation 2.

\texttt{gc.get\_count()}

Return the current collection counts as a tuple of \((\text{count0, count1, count2})\).

\texttt{gc.get\_threshold()}

Return the current collection thresholds as a tuple of \((\text{threshold0, threshold1, threshold2})\).

\texttt{gc.get\_referrers(*objs)}

Return the list of objects that directly refer to any of \texttt{objs}. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call \texttt{collect()} before calling \texttt{get\_referrers()}.

Care must be taken when using objects returned by \texttt{get\_referrers()} because some of them could still be under construction and hence in a temporarily invalid state. Avoid using \texttt{get\_referrers()} for any purpose other than debugging.
**gc.** **get_referents**(*objs*)

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments’ C-level `tp_traverse` methods (if any), and may not be all objects actually directly reachable. `tp_traverse` methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

**gc.** **is_tracked**(obj)

Returns True if the object is currently tracked by the garbage collector, False otherwise. As a general rule, instances of atomic types aren’t tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):

```python
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

*New in version 3.1.*
The following variables are provided for read-only access (you can mutate the values but should not rebind them):

**gc.garbage**

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). By default, this list contains only objects with `__del__()`. Objects that have `__del__()` methods and are part of a reference cycle cause the entire reference cycle to be uncollectable, including objects not necessarily in the cycle but reachable only from it. Python doesn’t collect such cycles automatically because, in general, it isn’t possible for Python to guess a safe order in which to run the `__del__()` methods. If you know a safe order, you can force the issue by examining the `garbage` list, and explicitly breaking cycles due to your objects within the list. Note that these objects are kept alive even so by virtue of being in the `garbage` list, so they should be removed from `garbage` too. For example, after breaking cycles, do `del gc.garbage[:]` to empty the list. It’s generally better to avoid the issue by not creating cycles containing objects with `__del__()` methods, and `garbage` can be examined in that case to verify that no such cycles are being created.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

*Changed in version 3.2:* If this list is non-empty at interpreter shutdown, a `ResourceWarning` is emitted, which is silent by default. If `DEBUG_UNCOLLECTABLE` is set, in addition all uncollectable objects are printed.

**gc.callbacks**

A list of callbacks that will be invoked by the garbage collector
before and after collection. The callbacks will be called with two arguments, *phase* and *info*.

*phase* can be one of two values:

“start”: The garbage collection is about to start.

“stop”: The garbage collection has finished.

*info* is a dict providing more information for the callback. The following keys are currently defined:

“generation”: The oldest generation being collected.

“collected”: When *phase* is “stop”, the number of objects successfully collected.

“uncollectable”: When *phase* is “stop”, the number of objects that could not be collected and were put in *garbage*.

Applications can add their own callbacks to this list. The primary use cases are:

Gathering statistics about garbage collection, such as how often various generations are collected, and how long the collection takes.

Allowing applications to identify and clear their own uncollectable types when they appear in *garbage*.

*New in version 3.3.*

The following constants are provided for use with *set_debug()*:

```
gc.DEBUG_STATS
```
Print statistics during collection. This information can be useful when tuning the collection frequency.

```
gc.DEBUG_COLLECTABLE
```

Print information on collectable objects found.

```
gc.DEBUG_UNCOLLECTABLE
```

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the garbage list.

*Changed in version 3.2:* Also print the contents of the garbage list at interpreter shutdown, if it isn’t empty.

```
gc.DEBUG_SAVEALL
```

When set, all unreachable objects found will be appended to garbage rather than being freed. This can be useful for debugging a leaking program.

```
gc.DEBUG_LEAK
```

The debugging flags necessary for the collector to print information about a leaking program (equal to DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL).
28.12. **inspect** — Inspect live objects

**Source code:** Lib/inspect.py

The `inspect` module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.
28.12.1. Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The sixteen functions whose names begin with “is” are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes:

<table>
<thead>
<tr>
<th>Type</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>file</strong></td>
<td>filename (missing for built-in modules)</td>
</tr>
<tr>
<td>class</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>module</strong></td>
<td>name of module in which this class was defined</td>
</tr>
<tr>
<td>method</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>name</strong></td>
<td>name with which this method was defined</td>
</tr>
<tr>
<td></td>
<td><strong>func</strong></td>
<td>function object containing implementation of method</td>
</tr>
<tr>
<td></td>
<td><strong>self</strong></td>
<td>instance to which this method is bound, or None</td>
</tr>
<tr>
<td>function</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>name</strong></td>
<td>name with which this function was defined</td>
</tr>
<tr>
<td></td>
<td><strong>code</strong></td>
<td>code object containing compiled function bytecode</td>
</tr>
<tr>
<td></td>
<td><strong>defaults</strong></td>
<td>tuple of any default values for arguments</td>
</tr>
<tr>
<td><strong>traceback</strong></td>
<td><strong>tb_frame</strong></td>
<td>frame object at this level</td>

<tr>
<td><strong>doc</strong></td>
<td>documentation string</td>
<td></td>
</tr>
<tr>
<td><strong>name</strong></td>
<td>original name of this function or method</td>
<td></td>
</tr>
<tr>
<td><strong>self</strong></td>
<td>instance to which a method is bound, or None</td>
<td></td>
</tr>
</tbody>
</table>

**inspect.getmembers(object[, predicate])**

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional `predicate` argument is supplied, only members for which the predicate returns a true value are included.
Note: `getmembers()` does not return metaclass attributes when the argument is a class (this behavior is inherited from the `dir()` function).

`inspect.getmoduleinfo(path)`

Returns a `named tuple` `ModuleInfo(name, suffix, mode, module_type)` of values that describe how Python will interpret the file identified by `path` if it is a module, or `None` if it would not be identified as a module. In that tuple, `name` is the name of the module without the name of any enclosing package, `suffix` is the trailing part of the file name (which may not be a dot-delimited extension), `mode` is the `open()` mode that would be used (`'r'` or `'rb'`), and `module_type` is an integer giving the type of the module. `module_type` will have a value which can be compared to the constants defined in the `imp` module; see the documentation for that module for more information on module types.

*Deprecated since version 3.3:* You may check the file path's suffix against the supported suffixes listed in `importlib.machinery` to infer the same information.

`inspect.getmodulename(path)`

Return the name of the module named by the file `path`, without including the names of enclosing packages. The file extension is checked against all of the entries in `importlib.machinery.all_suffixes()`. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function only returns a meaningful name for actual Python modules - paths that potentially refer to Python packages
will still return None.

*Changed in version 3.3:* This function is now based directly on *importlib* rather than the deprecated *getmoduleinfo()*.

`inspect.ismodule(object)`

Return true if the object is a module.

`inspect.isclass(object)`

Return true if the object is a class, whether built-in or created in Python code.

`inspect.ismethod(object)`

Return true if the object is a bound method written in Python.

`inspect.isfunction(object)`

Return true if the object is a Python function, which includes functions created by a *lambda* expression.

`inspect.isgeneratorfunction(object)`

Return true if the object is a Python generator function.

`inspect.isgenerator(object)`

Return true if the object is a generator.

`inspect.istraceback(object)`

Return true if the object is a traceback.

`inspect.isframe(object)`

Return true if the object is a frame.

`inspect.iscode(object)`

Return true if the object is a code.
inspect.isbuiltin(object)
Return true if the object is a built-in function or a bound built-in method.

inspect.isroutine(object)
Return true if the object is a user-defined or built-in function or method.

inspect.isabstract(object)
Return true if the object is an abstract base class.

inspect.ismethoddescriptor(object)
Return true if the object is a method descriptor, but not if ismethod(), isclass(), isfunction() or isbuiltin() are true.

This, for example, is true of int.__add__. An object passing this test has a __get__ attribute but not a __set__ attribute, but beyond that the set of attributes varies. __name__ is usually sensible, and __doc__ often is.

Methods implemented via descriptors that also pass one of the other tests return false from the ismethoddescriptor() test, simply because the other tests promise more – you can, e.g., count on having the __func__ attribute (etc) when an object passes ismethod().

inspect.isdatadescriptor(object)
Return true if the object is a data descriptor.

Data descriptors have both a __get__ and a __set__ attribute. Examples are properties (defined in Python), getsets, and
members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have \_\_name\_ and \_\_doc\_ attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

inspect.isgetsetdescriptor(object)
Return true if the object is a getset descriptor.

CPython implementation detail: getsets are attributes defined in extension modules via PyGetSetDef structures. For Python implementations without such types, this method will always return False.

inspect.ismemberdescriptor(object)
Return true if the object is a member descriptor.

CPython implementation detail: Member descriptors are attributes defined in extension modules via PyMemberDef structures. For Python implementations without such types, this method will always return False.
28.12.2. Retrieving source code

inspect.\texttt{getdoc}(\textit{object})

Get the documentation string for an object, cleaned up with \texttt{cleandoc()}.  

inspect.\texttt{getcomments}(\textit{object})

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module).

inspect.\texttt{getfile}(\textit{object})

Return the name of the (text or binary) file in which an object was defined. This will fail with a \texttt{TypeError} if the object is a built-in module, class, or function.

inspect.\texttt{getmodule}(\textit{object})

Try to guess which module an object was defined in.

inspect.\texttt{getsourcefile}(\textit{object})

Return the name of the Python source file in which an object was defined. This will fail with a \texttt{TypeError} if the object is a built-in module, class, or function.

inspect.\texttt{getsourcelines}(\textit{object})

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was
found. An OSError is raised if the source code cannot be retrieved.

Changed in version 3.3: OSError is raised instead of IOError, now an alias of the former.

inspect.getsource(object)

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An OSError is raised if the source code cannot be retrieved.

Changed in version 3.3: OSError is raised instead of IOError, now an alias of the former.

inspect.cleandoc(doc)

Clean up indentation from docstrings that are indented to line up with blocks of code. Any whitespace that can be uniformly removed from the second line onwards is removed. Also, all tabs are expanded to spaces.
28.12.3. Introspecting callables with the Signature object

*New in version 3.3.*

The Signature object represents the call signature of a callable object and its return annotation. To retrieve a Signature object, use the `signature()` function.

`inspect.signature(callable)`

Return a `Signature` object for the given `callable`:

```python
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...    pass

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b:int, **kwargs)'

>>> str(sig.parameters['b'])
'b:int'

>>> sig.parameters['b'].annotation
<class 'int'>
```

Accepts a wide range of python callables, from plain functions and classes to `functools.partial()` objects.

**Note:** Some callables may not be introspectable in certain implementations of Python. For example, in CPython, built-in functions defined in C provide no metadata about their
class inspect.Signature

A Signature object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a Parameter object in its parameters collection.

Signature objects are immutable. Use Signature.replace() to make a modified copy.

empty

A special class-level marker to specify absence of a return annotation.

parameters

An ordered mapping of parameters' names to the corresponding Parameter objects.

return_annotation

The “return” annotation for the callable. If the callable has no “return” annotation, this attribute is set to Signature.empty.

bind(*args, **kwargs)

Create a mapping from positional and keyword arguments to parameters. Returns BoundArguments if *args and **kwargs match the signature, or raises a TypeError.

bind_partial(*args, **kwargs)

Works the same way as Signature.bind(), but allows the omission of some required arguments (mimics functools.partial() behavior.) Returns BoundArguments, or raises a TypeError if the passed
arguments do not match the signature.

**replace(\*[\, parameters][\, return_annotation])**

Create a new Signature instance based on the instance replace was invoked on. It is possible to pass different parameters and/or return_annotation to override the corresponding properties of the base signature. To remove return_annotation from the copied Signature, pass in Signature.empty.

```python
>>> def test(a, b):
...     pass
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="new return anno")
>>> str(new_sig)
"(a, b) -> 'new return anno'"
```

**class inspect.Parameter**

Parameter objects are immutable. Instead of modifying a Parameter object, you can use Parameter.replace() to create a modified copy.

**empty**

A special class-level marker to specify absence of default values and annotations.

**name**

The name of the parameter as a string. Must be a valid python identifier name (with the exception of POSITIONAL_ONLY parameters, which can have it set to None).

**default**

The default value for the parameter. If the parameter has no
default value, this attribute is set to `Parameter.empty`.

**annotation**
The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

**kind**
Describes how argument values are bound to the parameter. Possible values (accessible via `Parameter`, like `Parameter.KEYWORD_ONLY`):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>POSITIONAL_ONLY</code></td>
<td>Value must be supplied as a positional argument. Python has no explicit syntax for defining positional-only parameters, but many built-in and extension module functions (especially those that accept only one or two parameters) accept them.</td>
</tr>
<tr>
<td><code>POSITIONAL_OR_KEYWORD</code></td>
<td>Value may be supplied as either a keyword or positional argument (this is the standard binding behaviour for functions implemented in Python.)</td>
</tr>
<tr>
<td><code>VAR_POSITIONAL</code></td>
<td>A tuple of positional arguments that aren’t bound to any other parameter. This</td>
</tr>
</tbody>
</table>
corresponds to a "*args" parameter in a Python function definition.

**KEYWORD**

Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a "*" or "*args" entry in a Python function definition.

**VAR**

A dict of keyword arguments that aren't bound to any other parameter. This corresponds to a "**kwargs" parameter in a Python function definition.

Example: print all keyword-only arguments without default values:

```python
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and param.default is param)
...         print('Parameter:', param)
Parameter: c
```

**replace([*, name][, kind][, default][, annotation])**

Create a new Parameter instance based on the instance replaced was invoked on. To override a Parameter attribute, pass the corresponding argument. To remove a default value or/and an annotation from a Parameter, pass
Parameter.empty.

```python
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY)
>>> str(param)
'foo=42'

>>> str(param.replace())  # Will create a shallow copy
'foo=42'

>>> str(param.replace(default=Parameter.empty, 'foo':'spam')
```

```python
class inspect.BoundArguments

Result of a Signature.bind() or Signature.bind_partial() call. Holds the mapping of arguments to the function's parameters.

**arguments**

An ordered, mutable mapping (collections.OrderedDict) of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in arguments will reflect in args and kwargs.

Should be used in conjunction with Signature.parameters for any argument processing purposes.

**Note:** Arguments for which Signature.bind() or Signature.bind_partial() relied on a default value are skipped. However, if needed, it is easy to include them.

```python
>>> def foo(a, b=10):
...     pass
```
>>> sig = signature(foo)
>>> ba = sig.bind(5)

>>> ba.args, ba.kwvars
((5,), {})

>>> for param in sig.parameters.values():
...     if param.name not in ba.arguments:
...         ba.arguments[param.name] = param.default

>>> ba.args, ba.kwvars
((5, 10), {})

**args**

A tuple of positional arguments values. Dynamically computed from the `arguments` attribute.

**kwargs**

A dict of keyword arguments values. Dynamically computed from the `arguments` attribute.

The `args` and `kwargs` properties can be used to invoke functions:

```python
def test(a, *, b):
...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwvars)
```

See also:

**PEP 362 - Function Signature Object.**
The detailed specification, implementation details and examples.
28.12.4. Classes and functions

inspect.getclasstree(classes, unique=False)

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the unique argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

inspect.getargspec(func)

Get the names and default values of a Python function's arguments. A named tuple ArgSpec(args, varargs, keywords, defaults) is returned. args is a list of the argument names. varargs and keywords are the names of the * and ** arguments or None. defaults is a tuple of default argument values or None if there are no default arguments; if this tuple has n elements, they correspond to the last n elements listed in args.

Deprecated since version 3.0: Use getfullargspec() instead, which provides information about keyword-only arguments and annotations.

inspect.getfullargspec(func)

Get the names and default values of a Python function's arguments. A named tuple is returned:

FullArgSpec(args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations)
args is a list of the argument names. varargs and varkw are the names of the * and ** arguments or None. defaults is an n-tuple of the default values of the last n arguments, or None if there are no default arguments. kwonlyargs is a list of keyword-only argument names. kwonlydefaults is a dictionary mapping names from kwonlyargs to defaults. annotations is a dictionary mapping argument names to annotations.

The first four items in the tuple correspond to getargspec().

**Note:** Consider using the new Signature Object interface, which provides a better way of introspecting functions.

inspect.getargvalues(frame)

Get information about arguments passed into a particular frame. A named tuple ArgInfo(args, varargs, keywords, locals) is returned. args is a list of the argument names. varargs and keywords are the names of the * and ** arguments or None. locals is the locals dictionary of the given frame.

inspect.formatargspec(args[, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations[, formatarg, formatvarargs, formatvarkw, formatvalue, formatreturns, formatannotations]])

Format a pretty argument spec from the values returned by getargspec() or getfullargspec().

The first seven arguments are (args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations). The other five arguments are the corresponding optional formatting functions that are called to turn names and values into strings. The last argument is an optional function to format the sequence of
arguments. For example:

```python
>>> from inspect import formatargspec, getfullargspec
>>> def f(a: int, b: float):
...     pass
...     
>>> formatargspec(*getfullargspec(f))
'(a: int, b: float)'
```

`inspect.formatargvalues` takes the four values returned by `getargvalues()` and formats them in a pretty argument spec. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

`inspect.getmro(cls)`

Return a tuple of class `cls`'s base classes, including `cls`, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on `cls`'s type. Unless a very peculiar user-defined metatype is in use, `cls` will be the first element of the tuple.

`inspect.getcallargs(func[, *args][, **kwds])`

Bind the `args` and `kwds` to the argument names of the Python function or method `func`, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the * and ** arguments, if any) to their values from `args` and `kwds`. In case of invoking `func` incorrectly, i.e. whenever `func(*args, **kwds)` would raise an exception because of incompatible signature, an exception of the
same type and the same or similar message is raised. For example:

```python
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...    pass
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': True}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': True}
True
>>> getcallargs(f)
Traceback (most recent call last):
  ...TypeError: f() missing 1 required positional argument
```

New in version 3.2.

**Note:** Consider using the new `Signature.bind()` instead.

`inspect.getclosurevars(func)`

Get the mapping of external name references in a Python function or method `func` to their current values. A named tuple `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. `nonlocals` maps referenced names to lexical closure variables, `globals` to the function’s module globals and `builtins` to the builtins visible from the function body. `unbound` is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

`TypeError` is raised if `func` is not a Python function or method.

New in version 3.3.
28.12.5. The interpreter stack

When the following functions return “frame records,” each record is a tuple of six items: the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

**Note:** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python’s optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```python
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

The optional `context` argument supported by most of these functions specifies the number of lines of context to return, which are centered
around the current line.

inspect.getframeinfo(frame, context=1)

Get information about a frame or traceback object. A named tuple Traceback(filename, lineno, function, code_context, index) is returned.

inspect.getouterframes(frame, context=1)

Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of frame. The first entry in the returned list represents frame; the last entry represents the outermost call on frame's stack.

inspect.getinnerframes(traceback, context=1)

Get a list of frame records for a traceback's frame and all inner frames. These frames represent calls made as a consequence of frame. The first entry in the list represents traceback; the last entry represents where the exception was raised.

inspect.currentframe()

Return the frame object for the caller's stack frame.

**CPython implementation detail:** This function relies on Python stack frame support in the interpreter, which isn’t guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns None.

inspect.stack(context=1)

Return a list of frame records for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.
inspect.trace(context=1)

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.
28.12.6. Fetching attributes statically

Both `getattr()` and `hasattr()` can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and `__getattr__()` and `__getattribute__()` may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. `getattr_static()` has the same signature as `getattr()` but avoids executing code when it fetches attributes.

```python
inspect.getattr_static(obj, attr, default=None)
```

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, `__getattr__()` or `__getattribute__()`. Note: this function may not be able to retrieve all attributes that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can’t (like descriptors that raise AttributeError). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

*New in version 3.2.*

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.
You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```python
# example code for resolving the builtin descriptor
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'][ '__add__' ])
descriptor_types = (slot_descriptor, getset_descriptor)

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

```python
inspect.getgeneratorstate(generator)
```

Get current state of a generator-iterator.

Possible states are:

- **GEN_CREATED**: Waiting to start execution.
- **GEN_RUNNING**: Currently being executed by the interpreter.
- **GEN_SUSPENDED**: Currently suspended at a yield expression.
- **GEN_CLOSED**: Execution has completed.

*New in version 3.2.*

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

```python
inspect.getgeneratorlocals(generator)
```

Get the mapping of live local variables in `generator` to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If `generator` is a `generator` with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if `generator`
is not a Python generator object.

CPython implementation detail: This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

New in version 3.3.
28.13. site — Site-specific configuration hook

Source code: Lib/site.py

This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter’s -S option.

Importing this module will append site-specific paths to the module search path and add a few builtins, unless -S was used. In that case, this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the site.main() function.

Changed in version 3.3: Importing the module used to trigger paths manipulation even when using -S.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses sys.prefix and sys.exec_prefix; empty heads are skipped. For the tail part, it uses the empty string and then lib/site-packages (on Windows) or lib/pythonX.Y/site-packages and then lib/site-python (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to sys.path and also inspects the newly added path for configuration files.

If a file named “pyvenv.cfg” exists one directory above sys.executable, sys.prefix and sys.exec_prefix are set to that directory and it is also checked for site-packages and site-python (sys.base_prefix and
sys.base_exec_prefix will always be the “real” prefixes of the Python installation. If “pyvenv.cfg” (a bootstrap configuration file) contains the key “include-system-site-packages” set to anything other than “false” (case-insensitive), the system-level prefixes will still also be searched for site-packages; otherwise they won’t.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, foo, bar and spam, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration
foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration
```
Then the following version-specific directories are added to sys.path, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that bletch is omitted because it doesn’t exist; the bar directory precedes the foo directory because bar.pth comes alphabetically before foo.pth; and spam is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named sitecustomize, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the site-packages directory. If this import fails with an ImportError exception, it is silently ignored.

After this, an attempt is made to import a module named usercustomize, which can perform arbitrary user-specific customizations, if ENABLE_USER_SITE is true. This file is intended to be created in the user site-packages directory (see below), which is part of sys.path unless disabled by -s. An ImportError will be silently ignored.

Note that for some non-Unix systems, sys.prefix and sys.exec_prefix are empty, and the path manipulations are skipped; however the import of sitecustomize and usercustomize is still attempted.

site.PREFIXES
A list of prefixes for site-packages directories.

site.**ENABLE_USER_SITE**
Flag showing the status of the user site-packages directory. True means that it is enabled and was added to `sys.path`. False means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). None means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

site.**USER_SITE**
Path to the user site-packages for the running Python. Can be None if `getusersitepackages()` hasn't been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework Mac OS X builds, `~/Library/Python/X.Y/lib/python/site-packages` for Mac framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

site.**USER_BASE**
Path to the base directory for the user site-packages. Can be None if `getuserbase()` hasn't been called yet. Default value is `~/.local` for UNIX and Mac OS X non-framework builds, `~/Library/Python/X.Y` for Mac framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils to compute the installation directories for scripts, data files, Python modules, etc. for the *user installation scheme*. See also `PYTHONUSERBASE`.

site.**main**()
Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the `python` interpreter was started with the `-S` flag.

*Changed in version 3.3:* This function used to be called unconditionally.

```
site.addsitedir(sitedir, known_paths=None)
```

Add a directory to `sys.path` and process its `.pth` files. Typically used in `sitecustomize` or `usercustomize` (see above).

```
site.getsitepackages()
```

Return a list containing all global site-packages directories (and possibly site-python).

*New in version 3.2.*

```
site.getuserbase()
```

Return the path of the user base directory, `USER_BASE`. If it is not initialized yet, this function will also set it, respecting `PYTHONUSERBASE`.

*New in version 3.2.*

```
site.getusersitepackages()
```

Return the path of the user-specific site-packages directory, `USER_SITE`. If it is not initialized yet, this function will also set it, respecting `PYTHONNOUSERSITE` and `USER_BASE`.

*New in version 3.2.*

The `site` module also provides a way to get the user directories from
the command line:

```
$ python3 -m site --user-site
/home/user/.local/lib/python3.3/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

**--user-base**

Print the path to the user base directory.

**--user-site**

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

28.14. fpectl — Floating point exception control

Platforms: Unix

Note: The fpectl module is not built by default, and its usage is discouraged and may be dangerous except in the hands of experts. See also the section Limitations and other considerations on limitations for more details.

Most computers carry out floating point operations in conformance with the so-called IEEE-754 standard. On any real computer, some floating point operations produce results that cannot be expressed as a normal floating point value. For example, try

```python
>>> import math
>>> math.exp(1000)
inf
>>> math.exp(1000) / math.exp(1000)
nan
```

(The example above will work on many platforms. DEC Alpha may be one exception.) “Inf” is a special, non-numeric value in IEEE-754 that stands for “infinity”, and “nan” means “not a number.” Note that, other than the non-numeric results, nothing special happened when you asked Python to carry out those calculations. That is in fact the default behaviour prescribed in the IEEE-754 standard, and if it works for you, stop reading now.

In some circumstances, it would be better to raise an exception and stop processing at the point where the faulty operation was attempted.
The `fpectl` module is for use in that situation. It provides control over floating point units from several hardware manufacturers, allowing the user to turn on the generation of SIGFPE whenever any of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid Operation occurs. In tandem with a pair of wrapper macros that are inserted into the C code comprising your python system, SIGFPE is trapped and converted into the Python `FloatingPointError` exception.

The `fpectl` module defines the following functions and may raise the given exception:

```python
fpectl.turnon_sigfpe()
    Turn on the generation of SIGFPE, and set up an appropriate signal handler.

fpectl.turnoff_sigfpe()
    Reset default handling of floating point exceptions.
```

`exception fpectl.FloatingPointError`

After `turnon_sigfpe()` has been executed, a floating point operation that raises one of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid operation will in turn raise this standard Python exception.
28.14.1. Example

The following example demonstrates how to start up and test operation of the `fpectl` module.

```python
>>> import fpectl
>>> import fpetest
>>> fpectl.turnon_sigfpe()
>>> fpetest.test()
overflow     PASS
FloatingPointError: Overflow

div by 0      PASS
FloatingPointError: Division by zero
    [ more output from test elided ]
>>> import math
>>> math.exp(1000)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
FloatingPointError: in math_1
```
28.14.2. Limitations and other considerations

Setting up a given processor to trap IEEE-754 floating point errors currently requires custom code on a per-architecture basis. You may have to modify `fpectl` to control your particular hardware.

Conversion of an IEEE-754 exception to a Python exception requires that the wrapper macros `PyFPE_START_PROTECT` and `PyFPE_END_PROTECT` be inserted into your code in an appropriate fashion. Python itself has been modified to support the `fpectl` module, but many other codes of interest to numerical analysts have not.

The `fpectl` module is not thread-safe.

See also: Some files in the source distribution may be interesting in learning more about how this module operates. The include file `Include/pyfpe.h` discusses the implementation of this module at some length. `Modules/fpetestmodule.c` gives several examples of use. Many additional examples can be found in `Objects/floatobject.c`. 
28.15. **distutils** — Building and installing Python modules

The **distutils** package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

User documentation and API reference are provided in another document:

**See also:**

*Distributing Python Modules*

The manual for developers and packagers of Python modules. This describes how to prepare **distutils**-based packages so that they may be easily installed into an existing Python installation. It also contains instructions for end-users wanting to install a distutils-based package, *Installing Python Modules*. 
29. Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python’s interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the code module. (The codeop module is lower-level, used to support compiling a possibly-incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- 29.1. code — Interpreter base classes
  - 29.1.1. Interactive Interpreter Objects
  - 29.1.2. Interactive Console Objects
- 29.2. codeop — Compile Python code
29.1. code — Interpreter base classes

The code module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

```python
class code.InteractiveInterpreter(locals=None)
```

This class deals with parsing and interpreter state (the user’s namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional locals argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key '__name__' set to '__console__' and key '__doc__' set to None.

```python
class code.InteractiveConsole(locals=None, filename="<console>")
```

Closely emulate the behavior of the interactive Python interpreter. This class builds on InteractiveInterpreter and adds prompting using the familiar sys.ps1 and sys.ps2, and input buffering.

```python
code.interact(banner=None, readfunc=None, local=None)
```

Convenience function to run a read-eval-print loop. This creates a new instance of InteractiveConsole and sets readfunc to be used as the InteractiveConsole.raw_input() method, if provided. If local is provided, it is passed to the
**InteractiveConsole** constructor for use as the default namespace for the interpreter loop. The `interact()` method of the instance is then run with `banner` passed as the banner to use, if provided. The console object is discarded after use.

```python
code.compile_command(source, filename="<input>",
symbol="single")
```

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

- `source` is the source string; `filename` is the optional filename from which source was read, defaulting to `'<input>'`; and `symbol` is the optional grammar start symbol, which should be either `single` (the default) or `eval`.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises `SyntaxError` if the command is complete and contains a syntax error, or raises `OverflowError` or `ValueError` if the command contains an invalid literal.
29.1.1. Interactive Interpreter Objects

`InteractiveInterpreter.runsource(source, filename="<input>", symbol="single")`

Compile and run some source in the interpreter. Arguments are the same as for `compile_command();` the default for `filename` is `'<input>'`, and for `symbol` is `'single'`. One several things can happen:

- The input is incorrect; `compile_command()` raised an exception (SyntaxError or OverflowError). A syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns False.
- The input is incomplete, and more input is required; `compile_command()` returned None. `runsource()` returns True.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for SystemExit). `runsource()` returns False.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

`InteractiveInterpreter.runcode(code)`

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except `SystemExit`, which is allowed to propagate.

A note about `KeyboardInterrupt`: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.
InteractiveInterpreter. **showsyntaxerror** *(filename=None)*
Display the syntax error that just occurred. This does not display a stack trace because there isn’t one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python’s parser, because it always uses `<string>` when reading from a string. The output is written by the `write()` method.

InteractiveInterpreter. **showtraceback**()
Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

InteractiveInterpreter. **write** *(data)*
Write a string to the standard error stream (sys.stderr). Derived classes should override this to provide the appropriate output handling as needed.
29.1.2. Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

**InteractiveConsole.** `interact(banner=None)`

Closely emulate the interactive Python console. The optional `banner` argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it’s so close!).

**InteractiveConsole.** `push(line)`

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter’s `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

**InteractiveConsole.** `resetbuffer()`

Remove any unhandled source text from the input buffer.

**InteractiveConsole.** `raw_input(prompt=``“”``)`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence,
`EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.
29.2. codeop — Compile Python code

The codeop module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the code module. As a result, you probably don’t want to use the module directly; if you want to include such a loop in your program you probably want to use the code module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print ‘>>>’ or ‘...’ next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The codeop module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

codeop.compile_command(source, filename="<input>",
symbol="single")

Tries to compile source, which should be a string of Python code and return a code object if source is valid Python code. In that case, the filename attribute of the code object will be filename, which defaults to '<input>'. Returns None if source is not valid Python code, but is a prefix of valid Python code.

If there is a problem with source, an exception will be raised. SyntaxError is raised if there is invalid Python syntax, and
**OverflowError** or **ValueError** if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement ('single', the default) or as an **expression** ('eval'). Any other value will cause **ValueError** to be raised.

**Note:** It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

**class** codeop. **Compile**

Instances of this class have **__call__()** methods identical in signature to the built-in function **compile()**, but with the difference that if the instance compiles program text containing a **__future__** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

**class** codeop. **CommandCompiler**

Instances of this class have **__call__()** methods identical in signature to **compile_command()**; the difference is that if the instance compiles program text containing a **__future__** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.
30. Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- **30.1. imp — Access the import internals**
  - 30.1.1. Examples
- **30.2. zipimport — Import modules from Zip archives**
  - 30.2.1. zipimporter Objects
  - 30.2.2. Examples
- **30.3. pkgutil — Package extension utility**
- **30.4. modulefinder — Find modules used by a script**
  - 30.4.1. Example usage of ModuleFinder
- **30.5. runpy — Locating and executing Python modules**
- **30.6. importlib – An implementation of import**
  - 30.6.1. Introduction
  - 30.6.2. Functions
  - 30.6.3. importlib.abc – Abstract base classes related to import
  - 30.6.4. importlib.machinery – Importers and path hooks
  - 30.6.5. importlib.util – Utility code for importers
30.1. **imp — Access the *import* internals**

This module provides an interface to the mechanisms used to implement the *import* statement. It defines the following constants and functions:

**Note:** New programs should use *importlib* rather than this module.

**imp.get_magic()**

Return the magic string value used to recognize byte-compiled code files (.pyc files). (This value may be different for each Python version.)

**imp.get_suffixes()**

Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form *(suffix, mode, type)*, where *suffix* is a string to be appended to the module name to form the filename to search for, *mode* is the mode string to pass to the built-in *open()* function to open the file (this can be 'r' for text files or 'rb' for binary files), and *type* is the file type, which has one of the values *PY_SOURCE*, *PY_COMPILED*, or *C_EXTENSION*, described below.

*Deprecated since version 3.3:* Use the constants defined on *importlib.machinery* instead.

**imp.find_module(name[, path])**
Try to find the module *name*. If *path* is omitted or None, the list of directory names given by `sys.path` is searched, but first a few special places are searched: the function tries to find a built-in module with the given name (C_BUILTIN), then a frozen module (PY_FROZEN), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).

Otherwise, *path* must be a list of directory names; each directory is searched for files with any of the suffixes returned by `get_suffixes()` above. Invalid names in the list are silently ignored (but all list items must be strings).

If search is successful, the return value is a 3-element tuple (`file`, `pathname`, `description`):

*file* is an open *file object* positioned at the beginning, *pathname* is the pathname of the file found, and *description* is a 3-element tuple as contained in the list returned by `get_suffixes()` describing the kind of module found.

If the module does not live in a file, the returned *file* is None, *pathname* is the empty string, and the *description* tuple contains empty strings for its suffix and mode; the module type is indicated as given in parentheses above. If the search is unsuccessful, **ImportError** is raised. Other exceptions indicate problems with the arguments or environment.

If the module is a package, *file* is None, *pathname* is the package path and the last item in the *description* tuple is PKG_DIRECTORY.

This function does not handle hierarchical module names (names containing dots). In order to find *P.M*, that is, submodule *M* of
package P, use `find_module()` and `load_module()` to find and load package P, and then use `find_module()` with the `path` argument set to `P.__path__`. When P itself has a dotted name, apply this recipe recursively.

```markdown
**Deprecated since version 3.3:** Use `importlib.find_loader()` instead.
```

```python
imp. `load_module(name, file, pathname, description)`
```
Load a module that was previously found by `find_module()` (or by an otherwise conducted search yielding compatible results). This function does more than importing the module: if the module was already imported, it will reload the module! The `name` argument indicates the full module name (including the package name, if this is a submodule of a package). The `file` argument is an open file, and `pathname` is the corresponding file name; these can be None and '', respectively, when the module is a package or not being loaded from a file. The `description` argument is a tuple, as would be returned by `get_suffixes()`, describing what kind of module must be loaded.

If the load is successful, the return value is the module object; otherwise, an exception (usually `ImportError`) is raised.

**Important:** the caller is responsible for closing the `file` argument, if it was not None, even when an exception is raised. This is best done using a `try ... finally` statement.

```markdown
**Deprecated since version 3.3:** Unneeded as loaders should be used to load modules and `find_module()` is deprecated.
```
imp. `new_module(name)`
Return a new empty module object called `name`. This object is not inserted in `sys.modules`.

imp. `reload(module)`
Reload a previously imported `module`. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (the same as the `module` argument).

When `reload(module)` is executed:

- Python modules' code is recompiled and the module-level code reexecuted, defining a new set of objects which are bound to names in the module's dictionary. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

If a module is syntactically correct but its initialization fails, the first `import` statement for it does not bind its name locally, but does store a (partially initialized) module object in `sys.modules`. To reload the module you must first `import` it again (this will bind the name to the partially initialized module object) before you can
reload() it.

When a module is reloaded, its dictionary (containing the module’s global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module’s advantage if it maintains a global table or cache of objects — with a try statement it can test for the table’s presence and skip its initialization if desired:

```python
try:
    cache
except NameError:
    cache = {}
```

It is legal though generally not very useful to reload built-in or dynamically loaded modules, except for `sys`, `__main__` and `builtins`. In many cases, however, extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using from ... import ..., calling `reload()` for the other module does not redefine the objects imported from it — one way around this is to re-execute the from statement, another is to use `import` and qualified names (`module.*name*`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.
Changed in version 3.3: Relies on both __name__ and __loader__ being defined on the module being reloaded instead of just __name__.

The following functions are conveniences for handling PEP 3147 byte-compiled file paths.

New in version 3.2.

imp.cache_from_source(path, debug_override=None)
Return the PEP 3147 path to the byte-compiled file associated with the source path. For example, if path is /foo/bar/baz.py the return value would be /foo/bar/__pycache__/baz.cpython-32.pyc for Python 3.2. The cpython-32 string comes from the current magic tag (see get_tag(); if sys.implementation.cache_tag is not defined then Not ImplementedError will be raised). The returned path will end in .pyc when __debug__ is True or .pyo for an optimized Python (i.e. __debug__ is False). By passing in True or False for debug_override you can override the system's value for __debug__ for extension selection.

path need not exist.

Changed in version 3.3: If sys.implementation.cache_tag is None, then Not ImplementedError is raised.

imp.source_from_cache(path)
Given the path to a PEP 3147 file name, return the associated source code file path. For example, if path is /foo/bar/__pycache__/baz.cpython-32.pyc the returned path would be /foo/bar/baz.py. path need not exist, however if
it does not conform to PEP 3147 format, a ValueError is raised. If sys.implementation.cache_tag is not defined, NotImplementedError is raised.

*Changed in version 3.3:* Raise NotImplementedError when sys.implementation.cache_tag is not defined.

**imp.get_tag()**

Return the PEP 3147 magic tag string matching this version of Python's magic number, as returned by get_magic().

**Note:** You may use sys.implementation.cache_tag directly starting in Python 3.3.

The following functions help interact with the import system's internal locking mechanism. Locking semantics of imports are an implementation detail which may vary from release to release. However, Python ensures that circular imports work without any deadlocks.

**imp.lock_held()**

Return True if the global import lock is currently held, else False. On platforms without threads, always return False.

On platforms with threads, a thread executing an import first holds a global import lock, then sets up a per-module lock for the rest of the import. This blocks other threads from importing the same module until the original import completes, preventing other threads from seeing incomplete module objects constructed by the original thread. An exception is made for circular imports, which by construction have to expose an incomplete module object at some point.
Changed in version 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

`imp.acquire_lock()`

Acquire the interpreter’s global import lock for the current thread. This lock should be used by import hooks to ensure thread-safety when importing modules.

Once a thread has acquired the import lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

Changed in version 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

`imp.release_lock()`

Release the interpreter’s global import lock. On platforms without threads, this function does nothing.

`imp.PY_SOURCE`

The module was found as a source file.

Deprecated since version 3.3.
imp. **PY\_COMPILED**
The module was found as a compiled code object file.

*Deprecated since version 3.3.*

imp. **C\_EXTENSION**
The module was found as dynamically loadable shared library.

*Deprecated since version 3.3.*

imp. **PKG\_DIRECTORY**
The module was found as a package directory.

*Deprecated since version 3.3.*

imp. **C\_BUILTIN**
The module was found as a built-in module.

*Deprecated since version 3.3.*

imp. **PY\_FROZEN**
The module was found as a frozen module.

*Deprecated since version 3.3.*

class imp. **NullImporter**(path\_string)
The NullImporter type is a PEP 302 import hook that handles non-directory path strings by failing to find any modules. Calling this type with an existing directory or empty string raises ImportError. Otherwise, a NullImporter instance is returned.
Instances have only one method:

```python
find_module(fullname[, path])
```

This method always returns `None`, indicating that the requested module could not be found.

*Changed in version 3.3:* `None` is inserted into `sys.path_importer_cache` instead of an instance of `NullImporter`. 
30.1.1. Examples

The following function emulates what was the standard import statement up to Python 1.4 (no hierarchical module names). (This implementation wouldn’t work in that version, since find_module() has been extended and load_module() has been added in 1.4.)

```python
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist=)
    # Fast path: see if the module has already been
    try:
        return sys.modules[name]
    except KeyError:
        pass

    # If any of the following calls raises an except
    # there's a problem we can't handle -- let the call
    fp, pathname, description = imp.find_module(name)

    try:
        return imp.load_module(name, fp, pathname, description)
    finally:
        # Since we may exit via an exception, close
        if fp:
            fp.close()
```

30.2. zipimport — Import modules from Zip archives

This module adds the ability to import Python modules (*.py, *.py[co]) and packages from ZIP-format archives. It is usually not needed to use the zipimport module explicitly; it is automatically used by the built-in import mechanism for sys.path items that are paths to ZIP archives.

Typically, sys.path is a list of directory names as strings. This module also allows an item of sys.path to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path example.zip/lib/ would only import from the lib/ subdirectory within the archive.

Any files may be present in the ZIP archive, but only files .py and .py[co] are available for import. ZIP import of dynamic modules (.pyd, .so) is disallowed. Note that if an archive only contains .py files, Python will not attempt to modify the archive by adding the corresponding .pyc or .pyo file, meaning that if a ZIP archive doesn’t contain .pyc files, importing may be rather slow.

ZIP archives with an archive comment are currently not supported.

See also:

PKZIP Application Note
Documentation on the ZIP file format by Phil Katz, the creator of
the format and algorithms used.

**PEP 273 - Import Modules from Zip Archives**

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302.

**PEP 302 - New Import Hooks**

The PEP to add the import hooks that help this module work.

This module defines an exception:

```python
exception zipimport.ZipImportError

Exception raised by zipimporter objects. It's a subclass of ImportError, so it can be caught as ImportError, too.
```
30.2.1. zipimporter Objects

`zipimporter` is the class for importing ZIP files.

```python
class zipimport.zipimporter(archivepath)

Create a new zipimporter instance. `archivepath` must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an `archivepath` of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if `archivepath` doesn’t point to a valid ZIP archive.
```

```python
find_module(fullname[, path])

Search for a module specified by `fullname`. `fullname` must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or `None` if it wasn’t. The optional `path` argument is ignored—it’s there for compatibility with the importer protocol.
```

```python
get_code(fullname)

Return the code object for the specified module. Raise `ZipImportError` if the module couldn’t be found.
```

```python
get_data(pathname)

Return the data associated with `pathname`. Raise `OSError` if the file wasn’t found.
```

*Changed in version 3.3:* `IOError` used to be raised instead of `OSError`.
**get_filename**(fullname)

Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn’t be found.

*New in version 3.1.*

**get_source**(fullname)

Return the source code for the specified module. Raise `ZipImportError` if the module couldn’t be found, return `None` if the archive does contain the module, but has no source for it.

**is_package**(fullname)

Return True if the module specified by `fullname` is a package. Raise `ZipImportError` if the module couldn’t be found.

**load_module**(fullname)

Load the module specified by `fullname`. `fullname` must be the fully qualified (dotted) module name. It returns the imported module, or raises `ZipImportError` if it wasn’t found.

**archive**

The file name of the importer’s associated ZIP file, without a possible subpath.

**prefix**

The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

The `archive` and `prefix` attributes, when combined with a
slash, equal the original *archivepath* argument given to the *zipimporter* constructor.
30.2.2. Examples

Here is an example that imports a module from a ZIP archive - note that the zipimport module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
     Length     Date    Time  Name
--------     ----     ----  ----
    8467  11-26-02 22:30  jwzthreading.py
--------     ----
    8467        1 file
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```
30.3. pkgutil — Package extension utility

Source code: Lib/pkgutil.py

This module provides utilities for the import system, in particular package support.

pkgutil.extend_path(path, name)

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's __init__.py:

```python
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's __path__ all subdirectories of directories on sys.path named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for *.pkg files beginning where * matches the name argument. This feature is similar to *.pth files (see the site module for more information), except that it doesn’t special-case lines starting with import. A *.pkg file is trusted at face value: apart from checking for duplicates, all entries found in a *.pkg file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is
returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

```python
class pkgutil.ImpImporter(dirname=None)

PEP 302 Importer that wraps Python’s “classic” import algorithm.

If `dirname` is a string, a PEP 302 importer is created that searches that directory. If `dirname` is None, a PEP 302 importer is created that searches the current `sys.path`, plus any modules that are frozen or built-in.

Note that `ImpImporter` does not currently support being used by placement on `sys.meta_path`.
```

**Deprecated since version 3.3:** This emulation is no longer needed, as the standard import mechanism is now fully PEP 302 compliant and available in `importlib`

```python
class pkgutil.ImpLoader(fullname, file, filename, etc)

PEP 302 Loader that wraps Python’s “classic” import algorithm.

**Deprecated since version 3.3:** This emulation is no longer needed, as the standard import mechanism is now fully PEP 302 compliant and available in `importlib`
```

```python
pkgutil.find_loader(fullname)
```
Retrieve a PEP 302 module loader for the given *fullname*.

This is a convenience wrapper around `importlib.find_loader()` that sets the *path* argument correctly when searching for submodules, and also ensures parent packages (if any) are imported before searching for submodules.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

```
pkgutil.get_importer(path_item)
```

Retrieve a PEP 302 importer for the given *path_item*.

The returned importer is cached in `sys.path_importer_cache` if it was newly created by a path hook.

The cache (or part of it) can be cleared manually if a rescan of `sys.path_hooks` is necessary.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

```
pkgutil.get_loader(module_or_name)
```

Get a PEP 302 “loader” object for *module_or_name*.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns None if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package `__path__`. 
This function uses `iter_importers()`, and is thus subject to the same limitations regarding platform-specific special import locations such as the Windows registry.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

`pkgutil.iter_importers(fullname='')`

Yield **PEP 302** importers for the given module name.

If fullname contains a '.', the importers will be for the package containing fullname, otherwise they will be all registered top level importers (i.e. those on both `sys.meta_path` and `sys.path_hooks`).

If the named module is in a package, that package is imported as a side effect of invoking this function.

If no module name is specified, all top level importers are produced.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

`pkgutil.iter_modules(path=None, prefix='')`

Yields `(module_finder, name, ispkg)` for all submodules on `path`, or, if `path` is None, all top-level modules on `sys.path`.

`path` should be either None or a list of paths to look for modules in.

`prefix` is a string to output on the front of every module name on output.
Note: Only works for a finder which defines an iter_modules() method. This interface is non-standard, so the module also provides implementations for importlib.machinery.FileFinder and zipimport.zipimporter.

Changed in version 3.3: Updated to be based directly on importlib rather than relying on the package internal PEP 302 import emulation.

pkgutil.walk_packages(path=None, prefix='', onerror=None)
Yields (module_finder, name, ispkg) for all modules recursively on path, or, if path is None, all accessible modules.

path should be either None or a list of paths to look for modules in.

prefix is a string to output on the front of every module name on output.

Note that this function must import all packages (not all modules!) on the given path, in order to access the __path__ attribute to find submodules.

onerror is a function which gets called with one argument (the name of the package which was being imported) if any exception occurs while trying to import a package. If no onerror function is supplied, ImportError are caught and ignored, while all other exceptions are propagated, terminating the search.

Examples:

# list all modules python can access
walk_packages()
# list all submodules of ctypes

```python
collections.Counter(collections_abc.Sequence)
```

Note: Only works for a *finder* which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

**pkgutil.get_data**(*package*, *resource*)

Get a resource from a package.

This is a wrapper for the PEP 302 loader `get_data()` API. The *package* argument should be the name of a package, in standard module format (`foo.bar`). The *resource* argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```python
d = os.path.dirname(sys.modules[package].__file__) 
data = open(os.path.join(d, resource), 'rb').read
```
If the package cannot be located or loaded, or it uses a **PEP 302**
loader which does not support `get_data()`, then None is returned.
30.4. `modulefinder` — Find modules used by a script

**Source code:** Lib/modulefinder.py

This module provides a `ModuleFinder` class that can be used to determine the set of modules imported by a script. `modulefinder.py` can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

`modulefinder.AddPackagePath(pkg_name, path)`

Record that the package named `pkg_name` can be found in the specified `path`.

`modulefinder.ReplacePackage(oldname, newname)`

Allows specifying that the module named `oldname` is in fact the package named `newname`.

```python
class modulefinder.ModuleFinder(path=None, debug=0, excludes=[], replace_paths=[])
```

This class provides `run_script()` and `report()` methods to determine the set of modules imported by a script. `path` can be a list of directories to search for modules; if not specified, `sys.path` is used. `debug` sets the debugging level; higher values make the class print debugging messages about what it's doing. `excludes` is a list of module names to exclude from the analysis. `replace_paths` is a list of `(oldpath, newpath)` tuples that will be replaced in module paths.
report()
Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

run_script(pathname)
Analyze the contents of the pathname file, which must contain Python code.

modules
A dictionary mapping module names to modules. See Example usage of ModuleFinder
30.4.1. Example usage of **ModuleFinder**

The script that is going to get analyzed later on (bacon.py):

```python
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```python
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end=''
        print(',').join(list(mod.globalnames.keys()))[3])

print('-'*50)
print('Modules not imported:
print('\n'.join(finder.badmodules.keys()))
```

Sample output (may vary depending on the architecture):
Loaded modules:
_types:
copyreg: _inverted_registry, _slotnames, __all__
sre_compile: isstring, _sre, _optimize_unicode
_sre:
sre_constants: REPEAT_ONE, makedict, AT_END_LINE
sys:
re: __module__, finditer, _expand
itertools:
__main__: re, itertools, baconhameggs
sre_parse: __getslice__, _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types: __module__, IntType, TypeType
---------------------------------------------------
Modules not imported:
guido.python.ham
baconhameggs
30.5. **runpy** — Locating and executing Python modules

Source code: Lib/runpy.py

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

```python
runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)
```

Execute the code of the specified module and return the resulting module globals dictionary. The module’s code is first located using the standard import mechanism (refer to PEP 302 for details) and then executed in a fresh module namespace.

If the supplied module name refers to a package rather than a normal module, then that package is imported and the `__main__`
submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument init_globals may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by run_module().

The special global variables __name__, __file__, __cached__, __loader__ and __package__ are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

__name__ is set to run_name if this optional argument is not None, to mod_name + '.__main__' if the named module is a package and to the mod_name argument otherwise.

__file__ is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to None.

__cached__ will be set to None.

__loader__ is set to the PEP 302 module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism).

__package__ is set to mod_name if the named module is a package and to mod_name.rpartition('.')[0][0] otherwise.

If the argument alter_sys is supplied and evaluates to True, then
sys.argv[0] is updated with the value of __file__ and sys.modules[__name__] is updated with a temporary module object for the module being executed. Both sys.argv[0] and sys.modules[__name__] are restored to their original values before the function returns.

Note that this manipulation of sys is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the sys module be left alone when invoking this function from threaded code.

Changed in version 3.1: Added ability to execute packages by looking for a __main__ submodule.

Changed in version 3.2: Added __cached__ global variable (see PEP 3147).

runpy.run_path(file_path, init_globals=None, run_name=None)

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid sys.path entry containing a __main__ module (e.g. a zipfile containing a top-level __main__.py file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid sys.path entry (typically a zipfile or directory), the entry is first added to the beginning of sys.path. The function then looks for and executes a __main__ module using the updated path. Note that there is no special protection against invoking an existing __main__ entry located elsewhere on sys.path if there is no such module at the specified location.
The optional dictionary argument *initGlobals* may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by *run_path()*.

The special global variables *__name__, *__file__, *__loader__ and *__package__ are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

__name__ is set to *run_name* if this optional argument is not *None* and to '<run_path>' otherwise.

__file__ is set to the name provided by the module loader. If the loader does not make filename information available, this variable is set to *None*. For a simple script, this will be set to *file_path*.

__loader__ is set to the PEP 302 module loader used to retrieve the code for the module (This loader may be a wrapper around the standard import mechanism). For a simple script, this will be set to *None*.

__package__ is set to *__name__.rpartition('./')[0]*.

A number of alterations are also made to the *sys* module. Firstly, *sys.path* may be altered as described above. *sys.argv[0]* is updated with the value of *file_path* and *sys.modules[__name__]* is updated with a temporary module object for the module being executed. All modifications to items in *sys* are reverted before the function returns.
Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

*New in version 3.2.*

The `importlib.import_module()` function
30.6. `importlib` – An implementation of `import`

*New in version 3.1.*
30.6.1. Introduction

The purpose of the `importlib` package is two-fold. One is to provide an implementation of the `import` statement (and thus, by extension, the `__import__()` function) in Python source code. This provides an implementation of `import` which is portable to any Python interpreter. This also provides a reference implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement `import` are exposed in this package, making it easier for users to create their own custom objects (known generically as an `importer`) to participate in the import process. Details on custom importers can be found in PEP 302.

30.6.2. Functions

importlib.__import__(name, globals=None, locals=None, fromlist=(), level=0)

An implementation of the built-in __import__() function.

importlib.import_module(name, package=None)

Import a module. The name argument specifies what module to import in absolute or relative terms (e.g. either pkg.mod or ..mod). If the name is specified in relative terms, then the package argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. import_module('..mod', 'pkg.subpkg') will import pkg.mod).

The import_module() function acts as a simplifying wrapper around importlib.__import__(). This means all semantics of the function are derived from importlib.__import__(), including requiring the package from which an import is occurring to have been previously imported (i.e., package must already be imported). The most important difference is that import_module() returns the most nested package or module that was imported (e.g. pkg.mod), while __import__() returns the top-level package or module (e.g. pkg).

importlib.find_loader(name, path=None)

Find the loader for a module, optionally within the specified path. If the module is in sys.modules, then sys.modules[name].__loader__ is returned (unless the loader would be None, in which case ValueError is raised).
Otherwise a search using `sys.meta_path` is done. None is returned if no loader is found.

A dotted name does not have its parent's implicitly imported as that requires loading them and that may not be desired. To properly import a submodule you will need to import all parent packages of the submodule and use the correct argument to `path`.

**importlib.**`**invalidate_caches()**`

Invalidate the internal caches of finders stored at `sys.meta_path`. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

*New in version 3.3.*
30.6.3. **importlib.abc** – Abstract base classes related to import

The **importlib.abc** module contains all of the core abstract base classes used by **import**. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
  +-- Finder (deprecated)
  |    +-- MetaPathFinder
  |    +-- PathEntryFinder
  +-- Loader
      +-- ResourceLoader --------+
      +-- InspectLoader        |
          +-- ExecutionLoader   +-- FileLoader
          +-- SourceLoader      +-- PyLoader
              +-- PyPycLoader
```

**class importlib.abc.Finder**

An abstract base class representing a *finder*.

*Deprecation warning:* `Finder` is deprecated since version 3.3. Use `MetaPathFinder` or `PathEntryFinder` instead.

**find_module**(*fullname, path=None*)

An abstract method for finding a *loader* for the specified module. Originally specified in PEP 302, this method was meant for use
in `sys.meta_path` and in the path-based import subsystem.

```python
class importlib.abc.MetaPathFinder
An abstract base class representing a meta path finder. For compatibility, this is a subclass of Finder.

New in version 3.3.
```

```python
find_module(fullname, path)
An abstract method for finding a loader for the specified module. If this is a top-level import, path will be None. Otherwise, this is a search for a subpackage or module and path will be the value of __path__ from the parent package. If a loader cannot be found, None is returned.
```

```python
invalidate_caches()
An optional method which, when called, should invalidate any internal cache used by the finder. Used by importlib.invalidate_caches() when invalidating the caches of all finders on sys.meta_path.
```

```python
class importlib.abc.PathEntryFinder
An abstract base class representing a path entry finder. Though it bears some similarities to MetaPathFinder, PathEntryFinder is meant for use only within the path-based import subsystem provided by PathFinder. This ABC is a subclass of Finder for compatibility.

New in version 3.3.
```

```python
find_loader(fullname)
An abstract method for finding a loader for the specified
module. Returns a 2-tuple of (loader, portion) where portion is a sequence of file system locations contributing to part of a namespace package. The loader may be None while specifying portion to signify the contribution of the file system locations to a namespace package. An empty list can be used for portion to signify the loader is not part of a package. If loader is None and portion is the empty list then no loader or location for a namespace package were found (i.e. failure to find anything for the module).

**find_module(fullname)**
A concrete implementation of Finder.find_module() which is equivalent to self.find_loader(fullname)[0].

**invalidate_caches()**
An optional method which, when called, should invalidate any internal cache used by the finder. Used by PathFinder.invalidate_caches() when invalidating the caches of all cached finders.

**class importlib.abc.Loader**
An abstract base class for a loader. See PEP 302 for the exact definition for a loader.

**load_module(fullname)**
An abstract method for loading a module. If the module cannot be loaded, ImportError is raised, otherwise the loaded module is returned.

If the requested module already exists in sys.modules, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into sys.modules
before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from \texttt{sys.modules}; modules already in \texttt{sys.modules} before the loader began execution should be left alone. The \texttt{importlib.util.module_for_loader()} decorator handles all of these details.

The loader should set several attributes on the module. (Note that some of these attributes can change when a module is reloaded.)

- \texttt{__name__}
  
  The name of the module.
- \texttt{__file__}
  
  The path to where the module data is stored (not set for built-in modules).
- \texttt{__cached__}
  
  The path to where a compiled version of the module is/should be stored (not set when the attribute would be inappropriate).
- \texttt{__path__}
  
  A list of strings specifying the search path within a package. This attribute is not set on modules.
- \texttt{__package__}
  
  The parent package for the module/package. If the module is top-level then it has a value of the empty string. The \texttt{importlib.util.set_package()} decorator can handle the details for \texttt{__package__}.
• `__loader__`
  The loader used to load the module. (This is not set by the built-in import machinery, but it should be set whenever a `loader` is used.)

`module_repr(module)`
An abstract method which when implemented calculates and returns the given module's repr, as a string.

class `importlib.abc.ResourceLoader`
An abstract base class for a `loader` which implements the optional [PEP 302](https://www.python.org/dev/peps/pep-0302/) protocol for loading arbitrary resources from the storage back-end.

`get_data(path)`
An abstract method to return the bytes for the data located at `path`. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. `IOError` is to be raised if the `path` cannot be found. The `path` is expected to be constructed using a module's `__file__` attribute or an item from a package's `__path__`.

class `importlib.abc.InspectLoader`
An abstract base class for a `loader` which implements the optional [PEP 302](https://www.python.org/dev/peps/pep-0302/) protocol for loaders that inspect modules.

`get_code(fullname)`
An abstract method to return the `code` object for a module. None is returned if the module does not have a code object (e.g. built-in module). `ImportError` is raised if loader cannot find the requested module.
get_source(fullname)
An abstract method to return the source of a module. It is returned as a text string using universal newlines, translating all recognized line separators into ' \n ' characters. Returns None if no source is available (e.g. a built-in module). Raises ImportError if the loader cannot find the module specified.

is_package(fullname)
An abstract method to return a true value if the module is a package, a false value otherwise. ImportError is raised if the loader cannot find the module.

class importlib.abc.ExecutionLoader
An abstract base class which inherits from InspectLoader that, when implemented, helps a module to be executed as a script. The ABC represents an optional PEP 302 protocol.

get_filename(fullname)
An abstract method that is to return the value of __file__ for the specified module. If no path is available, ImportError is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

class importlib.abc.FileLoader(fullname, path)
An abstract base class which inherits from ResourceLoader and ExecutionLoader, providing concrete implementations of ResourceLoader.get_data() and ExecutionLoader.get_filename().
The `fullname` argument is a fully resolved name of the module the loader is to handle. The `path` argument is the path to the file for the module.

New in version 3.3.

**name**

The name of the module the loader can handle.

**path**

Path to the file of the module.

`load_module(fullname)`

Calls super’s `load_module()`.

`get_filename(fullname)`

Returns `path`.

`get_data(path)`

Returns the open, binary file for `path`.

```python
class importlib.abc.SourceLoader
```

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both `ResourceLoader` and `ExecutionLoader`, requiring the implementation of:

- `ResourceLoader.get_data()`
- `ExecutionLoader.get_filename()`

  Should only return the path to the source file; sourceless loading is not supported.
The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods causes the loader to only work with source code. Implementing the methods allows the loader to work with source and bytecode files; it does not allow for sourceless loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python’s compiler, and so no bytecode-specific API is exposed.

**path_stats(path)**

Optional abstract method which returns a **dict** containing metadata about the specified path. Supported dictionary keys are:

- `mtime` (mandatory): an integer or floating-point number representing the modification time of the source code;
- `size` (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions.

*New in version 3.3.*

**path_mtime(path)**

Optional abstract method which returns the modification time for the specified path.

*Deprecated since version 3.3: This method is deprecated in favour of `path_stats()`. You don’t have to implement it, but it is still available for compatibility purposes.*

**set_data(path, data)**

Optional abstract method which writes the specified bytes to a
file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (errno.EACCES/PermissionError), do not propagate the exception.

**get_code(fullname)**
Concrete implementation of InspectLoader.get_code().

**load_module(fullname)**
Concrete implementation of Loader.load_module().

**get_source(fullname)**
Concrete implementation of InspectLoader.get_source().

**is_package(fullname)**
Concrete implementation of InspectLoader.is_package(). A module is determined to be a package if its file path (as provided by ExecutionLoader.get_filename()) is a file named __init__ when the file extension is removed and the module name itself does not end in __init__.

**class importlib.abc.PyLoader**
An abstract base class inheriting from ExecutionLoader and ResourceLoader designed to ease the loading of Python source modules (bytecode is not handled; see SourceLoader for a source/bytecode ABC). A subclass implementing this ABC will only need to worry about exposing how the source code is stored; all other details for loading Python source code will be handled by the
concrete implementations of key methods.

**Deprecated since version 3.2:** This class has been deprecated in favor of `SourceLoader` and is slated for removal in Python 3.4. See below for how to create a subclass that is compatible with Python 3.1 onwards.

If compatibility with Python 3.1 is required, then use the following idiom to implement a subclass that will work with Python 3.1 onwards (make sure to implement `ExecutionLoader.get_filename()`):

```python
try:
    from importlib.abc import SourceLoader
except ImportError:
    from importlib.abc import PyLoader as SourceLoader

class CustomLoader(SourceLoader):
    def get_filename(self, fullname):
        """Return the path to the source file."""
        # Implement ...

    def source_path(self, fullname):
        """Implement source_path in terms of get_filename."
        try:
            return self.get_filename(fullname)
        except ImportError:
            return None

    def is_package(self, fullname):
        """Implement is_package by looking for an __init__ name as returned by get_filename."""
        filename = os.path.basename(self.get_file)
        return os.path.splitext(filename)[0] == '
source_path(fullname)
An abstract method that returns the path to the source code for a module. Should return None if there is no source code. Raises ImportError if the loader knows it cannot handle the module.

get_filename(fullname)
A concrete implementation of importlib.abc.ExecutionLoader.get_filename() that relies on source_path(). If source_path() returns None, then ImportError is raised.

load_module(fullname)
A concrete implementation of importlib.abc.Loader.load_module() that loads Python source code. All needed information comes from the abstract methods required by this ABC. The only pertinent assumption made by this method is that when loading a package __path__ is set to [os.path.dirname(__file__)].

get_code(fullname)
A concrete implementation of importlib.abc.InspectLoader.get_code() that creates code objects from Python source code, by requesting the source code (using source_path() and get_data()) and compiling it with the built-in compile() function.

get_source(fullname)
A concrete implementation of
importlib.abc.InspectLoader.get_source(). Uses
importlib.abc.ResourceLoader.get_data() and
source_path() to get the source code. It tries to guess the
source encoding using tokenize.detect_encoding().

class importlib.abc.PyPycLoader
An abstract base class inheriting from PyLoader. This ABC is
meant to help in creating loaders that support both Python source
and bytecode.

Deprecated since version 3.2: This class has been deprecated in
favor of SourceLoader and to properly support PEP 3147. If
compatibility is required with Python 3.1, implement both
SourceLoader and PyLoader; instructions on how to do so
are included in the documentation for PyLoader. Do note that
this solution will not support sourceless/bytecode-only loading;
only source and bytecode loading.

Changed in version 3.3: Updated to parse (but not use) the new
source size field in bytecode files when reading and to write out the
field properly when writing.

**source_mtime(fullname)**
An abstract method which returns the modification time for the
source code of the specified module. The modification time
should be an integer. If there is no source code, return None. If
the module cannot be found then ImportError is raised.

**bytecode_path(fullname)**
An abstract method which returns the path to the bytecode for
the specified module, if it exists. It returns None if no bytecode
exists (yet). Raises `ImportError` if the loader knows it cannot handle the module.

**get_filename**(fullname)

A concrete implementation of `ExecutionLoader.get_filename()` that relies on `PyLoader.source_path()` and `bytecode_path()`. If `source_path()` returns a path, then that value is returned. Else if `bytecode_path()` returns a path, that path will be returned. If a path is not available from both methods, `ImportError` is raised.

**write_bytecode**(fullname, bytecode)

An abstract method which has the loader write `bytecode` for future use. If the bytecode is written, return `True`. Return `False` if the bytecode could not be written. This method should not be called if `sys.dont_write_bytecode` is true. The `bytecode` argument should be a bytes string or bytes array.
30.6.4. `importlib.machinery` – Importers and path hooks

This module contains the various objects that help `import` find and load modules.

`importlib.machinery.SOURCE_SUFFIXES`
A list of strings representing the recognized file suffixes for source modules.

*New in version 3.3.*

`importlib.machinery.DEBUG_BYTECODE_SUFFIXES`
A list of strings representing the file suffixes for non-optimized bytecode modules.

*New in version 3.3.*

`importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES`
A list of strings representing the file suffixes for optimized bytecode modules.

*New in version 3.3.*

`importlib.machinery.BYTECODE_SUFFIXES`
A list of strings representing the recognized file suffixes for bytecode modules. Set to either `DEBUG_BYTECODE_SUFFIXES` or `OPTIMIZED_BYTECODE_SUFFIXES` based on whether `__debug__` is true.

*New in version 3.3.*
importlib.machinery.EXTENSION_SUFFIXES
A list of strings representing the recognized file suffixes for extension modules.

New in version 3.3.

importlib.machinery.all_suffixes()
Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, inspect.getmodulename())

New in version 3.3.

class importlib.machinery.BuiltinImporter
An importer for built-in modules. All known built-in modules are listed in sys.builtin_module_names. This class implements the importlib.abc.MetaPathFinder and importlib.abc.InspectLoader ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

class importlib.machinery.FrozenImporter
An importer for frozen modules. This class implements the importlib.abc.MetaPathFinder and importlib.abc.InspectLoader ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

class importlib.machinery.WindowsRegistryFinder
**Finder** for modules declared in the Windows registry. This class implements the `importlib.abc.Finder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

*New in version 3.3.*

class importlib.machinery.PathFinder

A **Finder** for `sys.path` and package `__path__` attributes. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

classmethod **find_module**(fullname, path=None)

Class method that attempts to find a **loader** for the module specified by `fullname` on `sys.path` or, if defined, on `path`. For each path entry that is searched, `sys.path_importer_cache` is checked. If a non-false object is found then it is used as the **path entry finder** to look for the module being searched for. If no entry is found in `sys.path_importer_cache`, then `sys.path_hooks` is searched for a finder for the path entry and, if found, is stored in `sys.path_importer_cache` along with being queried about the module. If no finder is ever found then None is both stored in the cache and returned.

classmethod **invalidate_caches**()

Calls

`importlib.abc.PathEntryFinder.invalidate_caches()`
on all finders stored in `sys.path_importer_cache`. 
class importlib.machinery.FileFinder(path, *loader_details)

A concrete implementation of importlib.abc.PathEntryFinder which caches results from the file system.

The path argument is the directory for which the finder is in charge of searching.

The loader_details argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call importlib.invalidate_caches().

New in version 3.3.

path

The path the finder will search in.

find_loader(fullname)

Attempt to find the loader to handle fullname within path.
invalidate_caches()
Clear out the internal cache.

classmethod path_hook(*loader_details)
A class method which returns a closure for use on sys.path_hooks. An instance of FileFinder is returned by the closure using the path argument given to the closure directly and loader_details indirectly.

If the argument to the closure is not an existing directory, ImportError is raised.

class importlib.machinery.SourceFileLoader(fullname, path)
A concrete implementation of importlib.abc.SourceLoader by subclassing importlib.abc.FileLoader and providing some concrete implementations of other methods.

New in version 3.3.

name
The name of the module that this loader will handle.

path
The path to the source file.

is_package(fullname)
Return true if path appears to be for a package.

path_stats(path)
Concrete implementation of importlib.abc.SourceLoader.path_stats().
**set_data**(path, data)
Concrete implementation of :meth:`importlib.abc.SourceLoader.set_data()`.

```python
class importlib.machinery.SourcelessFileLoader(fullname, path)
```
A concrete implementation of :class:`importlib.abc.FileLoader` which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

*New in version 3.3.*

- **name**
  The name of the module the loader will handle.

- **path**
  The path to the bytecode file.

- **is_package**(fullname)
  Determines if the module is a package based on path.

- **get_code**(fullname)
  Returns the code object for name created from path.

- **get_source**(fullname)
  Returns None as bytecode files have no source when this loader is used.
class
importlib.machinery.**ExtensionFileLoader**(fullname, path)

A concrete implementation of `importlib.abc.InspectLoader` for extension modules.

The `fullname` argument specifies the name of the module the loader is to support. The `path` argument is the path to the extension module's file.

*New in version 3.3.*

**name**

Name of the module the loader supports.

**path**

Path to the extension module.

**load_module**(fullname)

Loads the extension module if and only if `fullname` is the same as `name` or is None.

**is_package**(fullname)

Returns True if the file path points to a package's `__init__` module based on `EXTENSION_SUFFIXES`.

**get_code**(fullname)

Returns None as extension modules lack a code object.

**get_source**(fullname)

Returns None as extension modules do not have source code.
30.6.5. `importlib.util` – Utility code for importers

This module contains the various objects that help in the construction of an `importer`.

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.

If `name` has no leading dots, then `name` is simply returned. This allows for usage such as

```python
importlib.util.resolve_name('sys', __package__)
```

without doing a check to see if the `package` argument is needed.

`ValueError` is raised if `name` is a relative module name but `package` is a false value (e.g. None or the empty string). `ValueError` is also raised if a relative name would escape its containing package (e.g. requesting `.bacon` from within the `spam` package).

`New in version 3.3.`

`@importlib.util.module_for_loader`

A `decorator` for a `loader` method, to handle selecting the proper module object to load with. The decorated method is expected to have a call signature taking two positional arguments (e.g. `load_module(self, module)`) for which the second argument will be the module `object` to be used by the loader. Note that the decorator will not work on static methods because of the assumption of two arguments.
The decorated method will take in the name of the module to be loaded as expected for a loader. If the module is not found in sys.modules then a new one is constructed with its __name__ attribute set to name, __loader__ set to self, and __package__ set if importlib.abc.InspectLoader.is_package() is defined for self and does not raise ImportError for name. If a new module is not needed then the module found in sys.modules will be passed into the method.

If an exception is raised by the decorated method and a module was added to sys.modules it will be removed to prevent a partially initialized module from being in left in sys.modules. If the module was already in sys.modules then it is left alone.

Use of this decorator handles all the details of which module object a loader should initialize as specified by PEP 302 as best as possible.

Changed in version 3.3: __loader__ and __package__ are automatically set (when possible).

@importlib.util.set_loader

A decorator for a loader method, to set the __loader__ attribute on loaded modules. If the attribute is already set the decorator does nothing. It is assumed that the first positional argument to the wrapped method (i.e. self) is what __loader__ should be set to.

Note: It is recommended that module_for_loader() be used over this decorator as it subsumes this functionality.

@importlib.util.set_package
A **decorator** for a **loader** to set the **__package__** attribute on the module returned by the loader. If **__package__** is set and has a value other than None it will not be changed. Note that the module returned by the loader is what has the attribute set on and not the module found in **sys.modules**.

Reliance on this decorator is discouraged when it is possible to set **__package__** before importing. By setting it beforehand the code for the module is executed with the attribute set and thus can be used by global level code during initialization.

**Note:** It is recommended that **module_for_loader()** be used over this decorator as it subsumes this functionality.
31. Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **31.1. parser — Access Python parse trees**
  - 31.1.1. Creating ST Objects
  - 31.1.2. Converting ST Objects
  - 31.1.3. Queries on ST Objects
  - 31.1.4. Exceptions and Error Handling
  - 31.1.5. ST Objects
  - 31.1.6. Example: Emulation of compile()

- **31.2. ast — Abstract Syntax Trees**
  - 31.2.1. Node classes
  - 31.2.2. Abstract Grammar
  - 31.2.3. ast Helpers

- **31.3. symtable — Access to the compiler's symbol tables**
  - 31.3.1. Generating Symbol Tables
  - 31.3.2. Examining Symbol Tables

- **31.4. symbol — Constants used with Python parse trees**

- **31.5. token — Constants used with Python parse trees**

- **31.6. keyword — Testing for Python keywords**

- **31.7. tokenize — Tokenizer for Python source**
  - 31.7.1. Tokenizing Input
  - 31.7.2. Command-Line Usage
  - 31.7.3. Examples

- **31.8. tabnanny — Detection of ambiguous indentation**

- **31.9. pyc1br — Python class browser support**
  - 31.9.1. Class Objects
31.9.2. Function Objects

31.10. `py_compile` — Compile Python source files

31.11. `compileall` — Byte-compile Python libraries
   - 31.11.1. Command-line use
   - 31.11.2. Public functions

31.12. `dis` — Disassembler for Python bytecode
   - 31.12.1. Python Bytecode Instructions

31.13. `pickletools` — Tools for pickle developers
   - 31.13.1. Command line usage
     - 31.13.1.1. Command line options
   - 31.13.2. Programmatic Interface
31.1. parser — Access Python parse trees

The parser module provides an interface to Python's internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

**Note:** From Python 2.5 onward, it's much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the ast module.

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the parser module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to *The Python Language Reference*. The parser itself is created from a grammar specification defined in the file Grammar/Grammar in the standard Python distribution. The parse trees stored in the ST objects created by this module are the actual output from the internal parser when created by the expr() or suite() functions, described below. The ST objects created by sequence2st() faithfully simulate those structures. Be aware that
the values of the sequences which are considered “correct” will vary from one version of Python to another as the formal grammar for the language is revised. However, transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, whereas source code has always been forward-compatible.

Each element of the sequences returned by st2list() or st2tuple() has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file Include/graminit.h and the Python module symbol. Each additional element of the sequence represents a component of the production as recognized in the input string: these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword if in an if_stmt, are included in the node tree without any special treatment. For example, the if keyword is represented by the tuple (1, 'if'), where 1 is the numeric value associated with all NAME tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as (1, 'if', 12), where the 12 represents the line number at which the terminal symbol was found.

Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which was identified. The example of the if keyword above is representative.
The various types of terminal symbols are defined in the C header file `Include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes: to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple “wrapper” class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

**See also:**

**Module symbol**

Useful constants representing internal nodes of the parse tree.

**Module token**

Useful constants representing leaf nodes of the parse tree and functions for testing node values.
31.1.1. Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the 'eval' and 'exec' forms.

`parser.expr(source)`

The `expr()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'eval')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.suite(source)`

The `suite()` function parses the parameter `source` as if it were an input to `compile(source, 'file.py', 'exec')`. If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

`parser.sequence2st(sequence)`

This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the called. If there is a problem creating the internal representation, or if the tree cannot be validated, a `ParserError` exception is raised. An ST object created this way should not be assumed to compile correctly; normal exceptions raised by compilation may still be initiated when the ST object is passed to `compilest()`. This may indicate problems not related to syntax (such as a `MemoryError` exception), but may also be due to constructs such as the result of
parsing `del f(0)`, which escapes the Python parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form `(1, 'name')` or as three-element lists of the form `(1, 'name', 56)`. If the third element is present, it is assumed to be a valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

`parser.tuple2st(sequence)`

This is the same function as `sequence2st()`. This entry point is maintained for backward compatibility.
31.1.2. Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple- trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

```
parser.st2list(st, line_info=False, col_info=False)
```

This function accepts an ST object from the caller in `st` and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, `st2tuple()` should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If `line_info` is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token ends. This information is omitted if the flag is false or omitted.

```
parser.st2tuple(st, line_info=False, col_info=False)
```

This function accepts an ST object from the caller in `st` and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to `st2list()`.

If `line_info` is true, line number information will be included for all
terminal tokens as a third element of the list representing the token. This information is omitted if the flag is false or omitted.

```python
compiler.compile_tree(st, filename='<syntax-tree>')
```

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of a call to the built-in `exec()` or `eval()` functions. This function provides the interface to the compiler, passing the internal parse tree from `st` to the parser, using the source file name specified by the `filename` parameter. The default value supplied for `filename` indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a `SyntaxError` caused by the parse tree for `del f(0)`: this statement is considered legal within the formal grammar for Python but is not a legal language construct. The `SyntaxError` raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the `parser` module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.
31.1.3. Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via `expr()` or `suite()` or from a parse tree via `sequence2st()`.

**parser.isexpr(st)**

When `st` represents an `eval` form, this function returns true, otherwise it returns false. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

**parser.issuite(st)**

This function mirrors `isexpr()` in that it reports whether an ST object represents an `exec` form, commonly known as a “suite.” It is not safe to assume that this function is equivalent to `not isexpr(st)`, as additional syntactic fragments may be supported in the future.
31.1.4. Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

exception parser. **ParserError**

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built-in **SyntaxError** raised during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to **sequence2st()** and an explanatory string. Calls to **sequence2st()** need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions **compilest()**, **expr()**, and **suite()** may raise exceptions which are normally raised by the parsing and compilation process. These include the built-in exceptions **MemoryError**, **OverflowError**, **SyntaxError**, and **SystemError**. In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.
31.1.5. ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the pickle module) is also supported.

**parser.**\texttt{STType}

The type of the objects returned by \texttt{expr()}, \texttt{suite()} and \texttt{sequence2st()}.

ST objects have the following methods:

**ST.**\texttt{compile}(filename='\texttt{<syntax-tree>}'

Same as \texttt{compilest(st, filename)}.

**ST.**\texttt{isexpr()}

Same as \texttt{isexpr(st)}.

**ST.**\texttt{issuite()}

Same as \texttt{issuite(st)}.

**ST.**\texttt{tolist}(line_info=False, col_info=False)

Same as \texttt{st2list(st, line_info, col_info)}.

**ST.**\texttt{totuple}(line_info=False, col_info=False)

Same as \texttt{st2tuple(st, line_info, col_info)}.
31.1.6. Example: Emulation of `compile()`

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the `parser` module to produce an intermediate data structure is equivalent to the code

```python
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the `parser` module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object:

```python
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions:

```python
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()
```
def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()
31.2. `ast` — Abstract Syntax Trees

**Source code:** Lib/ast.py

The `ast` module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programmatically what the current grammar looks like.

An abstract syntax tree can be generated by passing `ast.PyCF_ONLY_AST` as a flag to the `compile()` built-in function, or using the `parse()` helper provided in this module. The result will be a tree of objects whose classes all inherit from `ast.AST`. An abstract syntax tree can be compiled into a Python code object using the built-in `compile()` function.
31.2.1. Node classes

class ast.AST

This is the base of all AST node classes. The actual node classes are derived from the Parser/Python.asdl file, which is reproduced below. They are defined in the _ast C module and re-exported in ast.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, ast.stmt or ast.expr). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, ast.BinOp inherits from ast.expr. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

_fields

Each concrete class has an attribute _fields which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, ast.BinOp instances have an attribute left of type ast.expr.

If these attributes are marked as optional in the grammar (using a question mark), the value might be None. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with
compile().

lineno, col_offset

Instances of ast.expr and ast.stmt subclasses have \texttt{lineno} and \texttt{col\_offset} attributes. The \texttt{lineno} is the line number of source text (1-indexed so the first line is line 1) and the \texttt{col\_offset} is the UTF-8 byte offset of the first token that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

The constructor of a class \texttt{ast.T} parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in \texttt{T._fields}; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an \texttt{ast.UnaryOp} node, you could use

```python
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Num()
node.operand.n = 5
node.operand.lineno = 0
node.operand.col\_offset = 0
node.lineno = 0
node.col\_offset = 0
```

or the more compact

```python
node = ast.UnaryOp(ast.USub(), ast.Num(5, lineno=0, col\_offset=0))
```
31.2.2. Abstract Grammar

The abstract grammar is currently defined as follows:

```plaintext
-- ASDL's five builtin types are identifier, int, string, bytes, object

module Python {
    mod = Module(stmt* body)
    | Interactive(stmt* body)
    | Expression(expr body)

    -- not really an actual node but useful in Jython's typesystem.
    | Suite(stmt* body)

    stmt = FunctionDef(identifier name, arguments and
    stmt* body, expr* decorator_list)
    | ClassDef(identifier name, expr* bases,
    keyword* keywords, expr? starargs,
    expr? kwargs, stmt* body, expr* decorator_list)
    | Return(expr? value)

    | Delete(expr* targets)
    | Assign(expr* targets, expr value)
    | AugAssign(expr target, operator op, expr value)

    -- use 'orelse' because else is a keyword
    | For(expr target, expr iter, stmt* body, stmt* orelse)
    | While(expr test, stmt* body, stmt* orelse)
    | If(expr test, stmt* body, stmt* orelse)
    | With(withitem* items, stmt* body)
```
| Raise(expr? exc, expr? cause) |
| Try(stmt* body, excepthandler* handlers, expr? msg) |
| Assert(expr test, expr? msg) |
| Import(alias* names) |
| ImportFrom(identifier? module, alias* names) |
| Global(identifier* names) |
| Nonlocal(identifier* names) |
| Expr(expr value) |
| Pass | Break | Continue |

-- XXX Jython will be different
-- col_offset is the byte offset in the utf8 string the parser uses attributes (int lineno, int col_offset)

-- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
| BinOp(expr left, operator op, expr right) |
| UnaryOp(unaryop op, expr operand) |
| Lambda(arguments args, expr body) |
| IfExp(expr test, expr body, expr orelse) |
| Dict(expr* keys, expr* values) |
| Set(expr* elts) |
| ListComp(expr elt, comprehension* generators) |
| SetComp(expr elt, comprehension* generators) |
| DictComp(expr key, expr value, comprehension* generators) |
| GeneratorExp(expr elt, comprehension* generators) |

-- the grammar constrains where yield expressions can occur
| Yield(expr? value) |
| YieldFrom(expr value) |

-- need sequences for compare to distinguish
-- x < 4 < 3 and (x < 4) < 3
| Compare(expr left, cmpop* ops, expr* comparators) |
| Call(expr func, expr* args, keyword* kwargs, expr? starargs, expr? kwargs) |
| Num(object n) -- a number as a PyObject. |
| Str(string s) -- need to specify raw, unicode, etc? |
| Bytes(bytes s) |
| Ellipsis |
|-- other literals? bools? |

-- the following expression can appear in an assignment context |
| Attribute(expr value, identifier attr, expr_context ctx) |
| Subscript(expr value, slice slice, expr_context ctx) |
| Starred(expr value, expr_context ctx) |
| Name(identifier id, expr_context ctx) |
| List(expr* elts, expr_context ctx) |
| Tuple(expr* elts, expr_context ctx) |

-- col_offset is the byte offset in the utf-8 string the parser uses |

expr_context = Load | Store | Del | AugLoad | AugStore |

slice = Slice(expr? lower, expr? upper, expr? step) |
| ExtSlice(slice* dims) |
| Index(expr value) |

boolop = And | Or |

operator = Add | Sub | Mult | Div | Mod | Pow | |
| RShift | BitOr | BitXor | BitAnd |

unaryop = Invert | Not | UAdd | USub |

cmpop = Eq | NotEq | Lt | LtE | Gt | GtE | Is |

comprehension = (expr target, expr iter, expr* ifs) |

excepthandler = ExceptHandler(expr? type, identifier? name, stmt* body) |

attributes (int lineno, int col_offset)
arguments = (arg* args, identifier? vararg, expr?
    arg* kwoonlyargs, identifier? kw
    expr? kwargannotation, expr* def
    expr* kw_defaults)
arg = (identifier arg, expr? annotation)

-- keyword arguments supplied to call
keyword = (identifier arg, expr value)

-- import name with optional 'as' alias.
alias = (identifier name, identifier? asname)

withitem = (expr context_expr, expr? optional_vars)
31.2.3. **ast** Helpers

Apart from the node classes, **ast** module defines these utility functions and classes for traversing abstract syntax trees:

```python
ast.parse(source, filename='<unknown>', mode='exec')
```

Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

```python
ast.literal_eval(node_or_string)
```

Safely evaluate an expression node or a string containing a Python expression. The string or node provided may only consist of the following Python literal structures: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, and None.

This can be used for safely evaluating strings containing Python expressions from untrusted sources without the need to parse the values oneself.

*Changed in version 3.2:* Now allows bytes and set literals.

```python
ast.get_docstring(node, clean=True)
```

Return the docstring of the given `node` (which must be a `FunctionDef`, `ClassDef` or `Module` node), or None if it has no docstring. If `clean` is true, clean up the docstring’s indentation with `inspect.cleandoc()`.

```python
ast.fix_missing_locations(node)
```

When you compile a node tree with `compile()`, the compiler expects `lineno` and `col_offset` attributes for every node that
supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at node.

ast.increment_lineno(node, n=1)
    Increment the line number of each node in the tree starting at node by n. This is useful to “move code” to a different location in a file.

ast.copy_location(new_node, old_node)
    Copy source location (lineno and col_offset) from old_node to new_node if possible, and return new_node.

ast.iter_fields(node)
    Yield a tuple of (fieldname, value) for each field in node._fields that is present on node.

ast.iter_child_nodes(node)
    Yield all direct child nodes of node, that is, all fields that are nodes and all items of fields that are lists of nodes.

ast.walk(node)
    Recursively yield all descendant nodes in the tree starting at node (including node itself), in no specified order. This is useful if you only want to modify nodes in place and don’t care about the context.

class ast.NodeVisitor
    A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the visit() method.

    This class is meant to be subclassed, with the subclass adding
visitor methods.

**visit(node)**
Visit a node. The default implementation calls the method called `self.visit_classname` where `classname` is the name of the node class, or `generic_visit()` if that method doesn't exist.

**generic_visit(node)**
This visitor calls `visit()` on all children of the node.

Note that child nodes of nodes that have a custom visitor method won’t be visited unless the visitor calls `generic_visit()` or visits them itself.

Don’t use the `NodeVisitor` if you want to apply changes to nodes during traversal. For this a special visitor exists (`NodeTransformer`) that allows modifications.

```python
class ast.NodeTransformer
A NodeVisitor subclass that walks the abstract syntax tree and allows modification of nodes.

The NodeTransformer will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is None, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (foo) to `data['foo']`:
```python
class RewriteName(NodeTransformer):
    
def visit_Name(self, node):
        return copy_location(Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Index(value=Str(s=node.id)),
            ctx=node.ctx
        ), node)
```

Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the `generic_visit()` method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

Usually you use the transformer like this:

```python
node = YourTransformer().visit(node)
```

```python
ast.dump(node, annotate_fields=True, include_attributes=False)
```

Return a formatted dump of the tree in `node`. This is mainly useful for debugging purposes. The returned string will show the names and the values for fields. This makes the code impossible to evaluate, so if evaluation is wanted `annotate_fields` must be set to False. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, `include_attributes` can be set to True.
31.3. **symtable** — Access to the compiler’s symbol tables

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. **symtable** provides an interface to examine these tables.
31.3.1. Generating Symbol Tables

```
symtable.symtable(code, filename, compile_type)
```

Return the toplevel `SymbolTable` for the Python source `code`. `filename` is the name of the file containing the code. `compile_type` is like the `mode` argument to `compile()`.
31.3.2. Examining Symbol Tables

class symtable.SymbolTable
   A namespace table for a block. The constructor is not public.

   get_type()
      Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

   get_id()
      Return the table's identifier.

   get_name()
      Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (get_type() returns 'module').

   get_lineno()
      Return the number of the first line in the block this table represents.

   is_optimized()
      Return True if the locals in this table can be optimized.

   is_nested()
      Return True if the block is a nested class or function.

   has_children()
      Return True if the block has nested namespaces within it. These can be obtained with get_children().
has_exec()
    Return True if the block uses exec.

has_import_star()
    Return True if the block uses a starred from-import.

get_identifiers()
    Return a list of names of symbols in this table.

lookup(name)
    Lookup name in the table and return a Symbol instance.

get_symbols()
    Return a list of Symbol instances for names in the table.

get_children()
    Return a list of the nested symbol tables.

class symtable.Function
    A namespace for a function or method. This class inherits SymbolTable.

get_parameters()
    Return a tuple containing names of parameters to this function.

get_locals()
    Return a tuple containing names of locals in this function.

get_globals()
    Return a tuple containing names of globals in this function.

get_frees()
    Return a tuple containing names of free variables in this
function.

class symtable.**Class**
A namespace of a class. This class inherits **SymbolTable**.

**get_methods()**
Return a tuple containing the names of methods declared in the class.

class symtable.**Symbol**
An entry in a **SymbolTable** corresponding to an identifier in the source. The constructor is not public.

**get_name()**
Return the symbol's name.

**is_referenced()**
Return True if the symbol is used in its block.

**is_imported()**
Return True if the symbol is created from an import statement.

**is_parameter()**
Return True if the symbol is a parameter.

**is_global()**
Return True if the symbol is global.

**is_declared_global()**
Return True if the symbol is declared global with a global statement.

**is_local()**
Return True if the symbol is local to its block.

**is_free()**
Return True if the symbol is referenced in its block, but not assigned to.

**is_assigned()**
Return True if the symbol is assigned to in its block.

**is_namespace()**
Return True if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

For example:

```python
>>> table = symtable.symtable("def some_func():
>>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is True, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

**get_namespaces()**
Return a list of namespaces bound to this name.

**get_namespace()**
Return the namespace bound to this name. If more than one namespace is bound, a `ValueError` is raised.
31.4. `symbol` — Constants used with Python parse trees

**Source code:** Lib/symbol.py

This module provides constants which represent the numeric values of internal nodes of the parse tree. Unlike most Python constants, these use lower-case names. Refer to the file `Grammar/Grammar` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one additional data object:

```python
symbol.sym_name
```

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.
31.5. `token` — Constants used with Python parse trees

**Source code:** Lib/token.py

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file `Grammar/Grammar` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

**token.** `tok_name`  
Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

**token.** `ISTERMINAL(x)`  
Return true for terminal token values.

**token.** `ISNONTERMINAL(x)`  
Return true for non-terminal token values.

**token.** `ISEOF(x)`  
Return true if x is the marker indicating the end of input.
The token constants are:

token. ENDMARKER
token. NAME
token. NUMBER
token. STRING
token. NEWLINE
token. INDENT
token. DEDENT
token. LPAR
token. RPAR
token. LSQB
token. RSQB
token. COLON
token. COMMA
token. SEMI
token. PLUS
token. MINUS
token. STAR
token. SLASH
token. VBAR
token. AMPER
token. LESS
token. GREATER
token. EQUAL
token. DOT
token. PERCENT
token. LBRACE
token. RBRACE
token. EQEQUAL
token. NOTEQUAL
token. LESSEQUAL
token. GREATEREQUAL
See also:

Module parser

The second example for the parser module shows how to use the symbol module.
31.6. **keyword** — Testing for Python keywords

**Source code:** Lib/keyword.py

This module allows a Python program to determine if a string is a keyword.

**keyword**. `iskeyword(s)`

Return true if `s` is a Python keyword.

**keyword**. `kwlist`

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.
31.7. `tokenizer` — Tokenizer for Python source

**Source code:** `Lib/tokenize.py`

The `tokenizer` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers,” including colorizers for on-screen displays.

To simplify token stream handling, all `Operators` and `Delimiters` tokens are returned using the generic `token.OP` token type. The exact type can be determined by checking the `exact_type` property on the `named tuple` returned from `tokenizer.tokenize()`.
31.7.1. Tokenizing Input

The primary entry point is a generator:

tokenize(). **tokenize**(readline)

The **tokenize()** generator requires one argument, *readline*, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple `(srow, scol)` of ints specifying the row and column where the token begins in the source; a 2-tuple `(erow, ecol)` of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *logical* line; continuation lines are included. The 5 tuple is returned as a *named tuple* with the field names: `type` `string` `start` `end` `line`.

The returned *named tuple* has an additional property named `exact_type` that contains the exact operator type for `token.OP` tokens. For all other token types `exact_type` equals the named tuple `type` field.

*Changed in version 3.1:* Added support for named tuples.

*Changed in version 3.3:* Added support for `exact_type`.

**tokenize()** determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to [PEP 263](https://www.python.org/dev/peps/pep-0263/).

All constants from the *token* module are also exported from
`tokenize`, as are three additional token type values:

- `tokenize.COMMENT`
  Token value used to indicate a comment.

- `tokenize.NL`
  Token value used to indicate a non-terminating newline. The NEWLINE token indicates the end of a logical line of Python code; NL tokens are generated when a logical line of code is continued over multiple physical lines.

- `tokenize.ENCODING`
  Token value that indicates the encoding used to decode the source bytes into text. The first token returned by `tokenize()` will always be an ENCODING token.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

- `tokenize.un_tokenize(iterable)`
  Converts tokens back into Python source code. The `iterable` must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

  The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

  It returns bytes, encoded using the ENCODING token, which is the first token sequence output by `tokenize()`.
**tokenize()** needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

**tokenize.detect_encoding(readline)**

The **detect_encoding()** function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, readline, in the same way as the **tokenize()** generator.

It will call readline a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in **PEP 263**. If both a BOM and a cookie are present, but disagree, a SyntaxError will be raised. Note that if the BOM is found, 'utf-8-sig' will be returned as an encoding.

If no encoding is specified, then the default of 'utf-8' will be returned.

Use **open()** to open Python source files: it uses **detect_encoding()** to detect the file encoding.

**tokenize.open(filename)**

Open a file in read only mode using the encoding detected by **detect_encoding()**.

*New in version 3.2.*
31.7.2. Command-Line Usage

New in version 3.3.

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

- `-h`, `--help`
  - show this help message and exit

- `-e`, `--exact`
  - display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.
31.7.3. Examples

Example of a script rewriter that transforms float literals into Decimal objects:

```python
from tokenize import tokenize, untokenize, NUMBER, STRING
from io import BytesIO

def decistmt(s):
    """Substitute Decimals for floats in a string of statements."

    >>> from decimal import Decimal
    >>> s = 'print(+21.3e-5*-1.234/81.7)'
    >>> decistmt(s)
    "print (+Decimal ('21.3e-5')*-Decimal ('1.234')/Decimal ('81.7'))"

    The format of the exponent is inherited from the platform C library. Known cases are "e-007" (Windows) and "e-07" (not Windows). Since we're only showing 12 digits, and the 13th isn't close to 5, the rest of the output should be platform-independent.

    >>> exec(s) #doctest: +ELLIPSIS
    -3.21716034272e-0...7

    Output from calculations with Decimal should be platform-independent.

    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7

    """

    result = []
    g = tokenize(BytesIO(s.encode('utf-8')).readline)
    for toknum, tokval, _, _, _ in g:
        if toknum == NUMBER and '.' in tokval:  # replace NUMBER tokens
            result.extend([...]
```

"""
Example of tokenizing from the command line. The script:

```python
def say_hello():
    print("Hello, World!")
```
say_hello() will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```
$ python -m tokenize hello.py
0,0-0,0: ENCODING 'utf-8'
1,0-1,3: NAME 'def'
1,4-1,13: NAME 'say_hello'
1,13-1,14: OP '('
1,14-1,15: OP ')'
1,15-1,16: OP ':'
1,16-1,17: NEWLINE '\n'
2,0-2,4: INDENT '    '
2,4-2,9: NAME 'print'
2,9-2,10: OP '('
2,10-2,25: STRING '"Hello, World!"'
2,25-2,26: OP ')'
2,26-2,27: NEWLINE '\n'
```
The exact token type names can be displayed using the `-e` option:

```
$ python -m tokenize -e hello.py
0,0-0,0: ENCODING 'utf-8'
1,0-1,3: NAME 'def'
1,4-1,13: NAME 'say_hello'
1,13-1,14: LPAR '
1,14-1,15: RPAR '
2,0-2,4: INDENT '
2,4-2,9: NAME 'print'
2,9-2,10: LPAR '
2,10-2,25: STRING "Hello, World!"
2,25-2,26: RPAR '
2,26-2,27: NEWLINE '
3,0-3,1: NL '
4,0-4,0: DEDENT '
4,0-4,9: NAME 'say_hello'
4,9-4,10: LPAR '
4,10-4,11: RPAR '
4,11-4,12: NEWLINE '
5,0-5,0: ENDMARKER '
```
31.8. **tabnanny** — Detection of ambiguous indentation

**Source code:** Lib/tabnanny.py

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

**Note:** The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

```python
tabnanny.check(file_or_dir)
```

If `file_or_dir` is a directory and not a symbolic link, then recursively descend the directory tree named by `file_or_dir`, checking all `.py` files along the way. If `file_or_dir` is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the `print()` function.

```python
tabnanny.verbose
```

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

```python
tabnanny.filename_only
```

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.
exception tabnanny. **NannyNag**

Raised by `tokeneater()` if detecting an ambiguous indent. Captured and handled in `check()`.

tabnanny. **tokeneater**(type, token, start, end, line)

This function is used by `check()` as a callback parameter to the function `tokenize.tokenize()`.

**See also:**

**Module** `tokenize`

Lexical scanner for Python source code.
31.9. `pyclbr` — Python class browser support

Source code: `Lib/pyclbr.py`

The `pyclbr` module can be used to determine some limited information about the classes, methods and top-level functions defined in a module. The information provided is sufficient to implement a traditional three-pane class browser. The information is extracted from the source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyclbr.readmodule(module, path=None)`

Read a module and return a dictionary mapping class names to class descriptor objects. The parameter `module` should be the name of a module as a string; it may be the name of a module within a package. The `path` parameter should be a sequence, and is used to augment the value of `sys.path`, which is used to locate module source code.

`pyclbr.readmodule_ex(module, path=None)`

Like `readmodule()`, but the returned dictionary, in addition to mapping class names to class descriptor objects, also maps top-level function names to function descriptor objects. Moreover, if the module being read is a package, the key `__path__` in the returned dictionary has as its value a list which contains the package search path.
31.9.1. Class Objects

The Class objects used as values in the dictionary returned by `readmodule()` and `readmodule_ex()` provide the following data attributes:

**Class. module**

The name of the module defining the class described by the class descriptor.

**Class. name**

The name of the class.

**Class. super**

A list of Class objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule()` are listed as a string with the class name instead of as Class objects.

**Class. methods**

A dictionary mapping method names to line numbers.

**Class. file**

Name of the file containing the `class` statement defining the class.

**Class. lineno**

The line number of the `class` statement within the file named by `file`. 
31.9.2. Function Objects

The Function objects used as values in the dictionary returned by `readmodule_ex()` provide the following attributes:

**Function. module**

The name of the module defining the function described by the function descriptor.

**Function. name**

The name of the function.

**Function. file**

Name of the file containing the `def` statement defining the function.

**Function. lineno**

The line number of the `def` statement within the file named by `file`.
31.10. *py_compile* — Compile Python source files

**Source code:** Lib/py_compile.py

The *py_compile* module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

*exception* *py_compile*. *PyCompileError*

Exception raised when an error occurs while attempting to compile the file.

*py_compile*. *compile*(file, cfile=None, dfile=None, dorfaise=False, optimize=-1)

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file name *file*. The byte-code is written to *cfile*, which defaults to the PEP 3147 path, ending in *`.pyc`* (*`.pyo`* if optimization is enabled in the current interpreter). For example, if *file* is `/foo/bar/baz.py` *cfile* will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If *dfile* is specified, it is used as the name of the source file in error messages when instead of *file*. If *dorraise* is true, a *PyCompileError* is raised when an error is encountered while
compiling *file*. If *doraise* is false (the default), an error string is written to `sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever *cfile* value was used.

*optimize* controls the optimization level and is passed to the built-in `compile()` function. The default of `-1` selects the optimization level of the current interpreter.

*Changed in version 3.2:* Changed default value of *cfile* to be PEP 3147-compliant. Previous default was *file* + `'c'` ('o' if optimization was enabled). Also added the *optimize* parameter.

**py_compile.main** *(args=None)*

Compile several source files. The files named in *args* (or on the command line, if *args* is None) are compiled and the resulting bytecode is cached in the normal manner. This function does not search a directory structure to locate source files; it only compiles files named explicitly. If `'-'` is the only parameter in *args*, the list of files is taken from standard input.

*Changed in version 3.2:* Added support for `'-'`.

When this module is run as a script, the `main()` is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

**See also:**

**Module compileall**

Utilities to compile all Python source files in a directory tree.
31.11. compileall — Byte-compile Python libraries

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.
31.11.1. Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

```
[directory|file]...
```

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

- `-l`
  Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

- `-f`
  Force rebuild even if timestamps are up-to-date.

- `-q`
  Do not print the list of files compiled, print only error messages.

- `-d destdir`
  Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

- `-x regex`
  regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.
-i list
Read the file list and add each line that it contains to the list of files and directories to compile. If list is -, read lines from stdin.

-b
Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their PEP 3147 locations and names, which allows byte-code files from multiple versions of Python to coexist.

Changed in version 3.2: Added the -i, -b and -h options.

There is no command-line option to control the optimization level used by the compile() function, because the Python interpreter itself already provides the option: python -O -m compileall.
31.11.2. Public functions

```
compileall.compile_dir(dir, maxlevels=10, ddir=None, force=False, rx=None, quiet=False, legacy=False, optimize=-1)
```

Recursively descend the directory tree named by `dir`, compiling all `.py` files along the way.

The `maxlevels` parameter is used to limit the depth of the recursion; it defaults to 10.

If `ddir` is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `force` is true, modules are re-compiled even if the timestamps are up to date.

If `rx` is given, its search method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped.

If `quiet` is true, nothing is printed to the standard output unless errors occur.

If `legacy` is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their PEP 3147 locations and names, which allows byte-code files from multiple versions of Python to coexist.

`optimize` specifies the optimization level for the compiler. It is
passed to the built-in `compile()` function.

*Changed in version 3.2:* Added the `legacy` and `optimize` parameter.

```
compileall.compile_file(fullname, ddir=None, force=False, rx=None, quiet=False, legacy=False, optimize=-1)
```

Compile the file with path `fullname`.

If `ddir` is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `rx` is given, its search method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned.

If `quiet` is true, nothing is printed to the standard output unless errors occur.

If `legacy` is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their PEP 3147 locations and names, which allows byte-code files from multiple versions of Python to coexist.

`optimize` specifies the optimization level for the compiler. It is passed to the built-in `compile()` function.

*New in version 3.2.*

```
compileall.compile_path(skip_curdir=True, maxlevels=0, force=False, legacy=False, optimize=-1)
```
Byte-compile all the .py files found along sys.path. If skip_curdir is true (the default), the current directory is not included in the search. All other parameters are passed to the compile_dir() function. Note that unlike the other compile functions, maxlevels defaults to 0.

*Changed in version 3.2:* Added the legacy and optimize parameter.

To force a recompile of all the .py files in the Lib/ subdirectory and all its subdirectories:

```python
import compileall
compileall.compile_dir('Lib/', force=True)
#
```

Perform same compilation, excluding files in .svn

```python
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\]])
```

See also:

**Module py_compile**

Byte-compile a single source file.
31.12. **dis** — Disassembler for Python bytecode

**Source code:** Lib/dis.py

The *dis* module supports the analysis of CPython *bytecode* by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

**CPython implementation detail:** Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Example: Given the function `myfunc()`:

```python
def myfunc(alist):
    return len(alist)
```

the following command can be used to get the disassembly of `myfunc()`:

```python
>>> dis.dis(myfunc)
2          0 LOAD_GLOBAL             0 (len)
3          0 LOAD_FAST              0 (alist)
6          1 CALL_FUNCTION          1
9          0 RETURN_VALUE
```
The "2" is a line number.

The `dis` module defines the following functions and constants:

**dis.code_info(x)**

Return a formatted multi-line string with detailed code object information for the supplied function, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

*New in version 3.2.*

**dis.show_code(x)**

Print detailed code object information for the supplied function, method, source code string or code object to stdout.

This is a convenient shorthand for `print(code_info(x))`, intended for interactive exploration at the interpreter prompt.

*New in version 3.2.*

**dis.dis(x=None)**

Disassemble the `x` object. `x` can denote either a module, a class, a method, a function, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods. For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. Strings are first compiled to code objects with the `compile()` built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.
Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

```python
def disassemble(code, lasti=-1)
def disco(code, lasti=-1)
```

Disassemble a code object, indicating the last instruction if `lasti` was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->
3. a labelled instruction, indicated with `>>`
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

```python
def findlinestarts(code)
```

This generator function uses the `co_firstlineno` and `co_lnotab` attributes of the code object `code` to find the offsets which are starts of lines in the source code. They are generated as `(offset, lineno)` pairs.

```python
def findlabels(code)
```

Detect all offsets in the code object `code` which are jump targets, and return a list of these offsets.

```python
def opname
```

Sequence of operation names, indexable using the bytecode.
dis. **opmap**
  Dictionary mapping operation names to bytecodes.

dis. **cmp_op**
  Sequence of all compare operation names.

dis. **hasconst**
  Sequence of bytecodes that have a constant parameter.

dis. **hasfree**
  Sequence of bytecodes that access a free variable.

dis. **hasname**
  Sequence of bytecodes that access an attribute by name.

dis. **hasjrel**
  Sequence of bytecodes that have a relative jump target.

dis. **hasjabs**
  Sequence of bytecodes that have an absolute jump target.

dis. **haslocal**
  Sequence of bytecodes that access a local variable.

dis. **hascompare**
  Sequence of bytecodes of Boolean operations.
31.12.1. Python Bytecode Instructions

The Python compiler currently generates the following bytecode instructions.

General instructions

**NOP**
Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP_TOP**
Removes the top-of-stack (TOS) item.

**ROT_TWO**
Swaps the two top-most stack items.

**ROT_THREE**
Lifts second and third stack item one position up, moves top down to position three.

**DUP_TOP**
Duplicates the reference on top of the stack.

**DUP_TOP_TWO**
Duplicates the two references on top of the stack, leaving them in the same order.

Unary operations

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY_POSITIVE**
Implements $\text{TOS} = \text{+TOS}$.

**UNARY_NEGATIVE**

Implements $\text{TOS} = \text{-TOS}$.

**UNARY_NOT**

Implements $\text{TOS} = \text{not } \text{TOS}$.

**UNARY_INVERT**

Implements $\text{TOS} = \text{~TOS}$.

**GET_ITER**

Implements $\text{TOS} = \text{iter(TOS)}$.

**Binary operations**

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

**BINARY_POWER**

Implements $\text{TOS} = \text{TOS1} \text{ ** TOS}$.

**BINARY_MULTIPLY**

Implements $\text{TOS} = \text{TOS1} \text{ * TOS}$.

**BINARY_FLOOR_DIVIDE**

Implements $\text{TOS} = \text{TOS1} \text{ // TOS}$.

**BINARY_TRUE_DIVIDE**

Implements $\text{TOS} = \text{TOS1} \text{ / TOS}$.

**BINARY_MODULO**
Implements $\text{TOS} = \text{TOS1} \% \text{TOS}$.

**BINARY_ADD**

Implements $\text{TOS} = \text{TOS1} + \text{TOS}$.

**BINARY_SUBTRACT**

Implements $\text{TOS} = \text{TOS1} - \text{TOS}$.

**BINARY_SUBSCR**

Implements $\text{TOS} = \text{TOS1}[^{\text{TOS}}]$. 

**BINARY_LSHIFT**

Implements $\text{TOS} = \text{TOS1} \ll \text{TOS}$. 

**BINARY_RSHIFT**

Implements $\text{TOS} = \text{TOS1} \gg \text{TOS}$. 

**BINARY_AND**

Implements $\text{TOS} = \text{TOS1} \& \text{TOS}$. 

**BINARY_XOR**

Implements $\text{TOS} = \text{TOS1} \wedge \text{TOS}$. 

**BINARY_OR**

Implements $\text{TOS} = \text{TOS1} \mid \text{TOS}$. 

*In-place operations*

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

**INPLACE_POWER**
Implements in-place $\text{TOS} = \text{TOS1} \ ** \ \text{TOS}$. 

**INPLACE_MULTIPLY**
Implements in-place $\text{TOS} = \text{TOS1} \ * \ \text{TOS}$. 

**INPLACE_FLOOR_DIVIDE**
Implements in-place $\text{TOS} = \text{TOS1} \ // \ \text{TOS}$. 

**INPLACE_TRUE_DIVIDE**
Implements in-place $\text{TOS} = \text{TOS1} \ / \ \text{TOS}$. 

**INPLACE_MODULO**
Implements in-place $\text{TOS} = \text{TOS1} \ % \ \text{TOS}$. 

**INPLACE_ADD**
Implements in-place $\text{TOS} = \text{TOS1} \ + \ \text{TOS}$. 

**INPLACE_SUBTRACT**
Implements in-place $\text{TOS} = \text{TOS1} \ - \ \text{TOS}$. 

**INPLACE_LSHIFT**
Implements in-place $\text{TOS} = \text{TOS1} \ << \ \text{TOS}$. 

**INPLACE_RSHIFT**
Implements in-place $\text{TOS} = \text{TOS1} \ >> \ \text{TOS}$. 

**INPLACE_AND**
Implements in-place $\text{TOS} = \text{TOS1} \ & \ \text{TOS}$. 

**INPLACE_XOR**
Implements in-place $\text{TOS} = \text{TOS1} \ ^\ ^\ \text{TOS}$. 

**INPLACE_OR**
Implements in-place \( \text{TOS} = \text{TOS1} \mid \text{TOS} \).

**STORE_SUBSCR**
Implements \( \text{TOS1}[\text{TOS}] = \text{TOS2} \).

**DELETE_SUBSCR**
Implements \( \text{del} \ \text{TOS1}[\text{TOS}] \).

**Miscellaneous opcodes**

**PRINT_EXPR**
Implements the expression statement for the interactive mode. TOS is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with \( \text{POP}\_\text{STACK} \).

**BREAK_LOOP**
Terminates a loop due to a \texttt{break} statement.

**CONTINUE_LOOP(\texttt{target})**
Continues a loop due to a \texttt{continue} statement. \( \texttt{target} \) is the address to jump to (which should be a \texttt{FOR}\_\texttt{ITER} instruction).

**SET_ADD(\texttt{i})**
Calls \( \texttt{set.add(TOS1[-i], TOS)} \). Used to implement set comprehensions.

**LIST_APPEND(\texttt{i})**
Calls \( \texttt{list.append(TOS[-i], TOS)} \). Used to implement list comprehensions.

**MAP_ADD(\texttt{i})**
Calls \( \texttt{dict.setitem(TOS1[-i], TOS, TOS1)} \). Used to implement dict comprehensions.
For all of the SET_ADD, LIST_APPEND and MAP_ADD instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

**RETURN_VALUE**

Returns with TOS to the caller of the function.

**YIELD_VALUE**

Pops TOS and yields it from a *generator*.

**YIELD_FROM**

Pops TOS and delegates to it as a subiterator from a *generator*.

*New in version 3.3.*

**IMPORT_STAR**

Loads all symbols not starting with `_` directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

**POP_BLOCK**

Removes one block from the block stack. Per frame, there is a stack of blocks, denoting nested loops, try statements, and such.

**POP_EXCEPT**

Removes one block from the block stack. The popped block must be an exception handler block, as implicitly created when entering an except handler. In addition to popping extraneous values from the frame stack, the last three popped values are used to restore the exception state.

**END_FINALLY**
Terminates a **finally** clause. The interpreter recalls whether the exception has to be re-raised, or whether the function returns, and continues with the outer-next block.

**LOAD_BUILD_CLASS**

Pushes `builtins.__build_class__()` onto the stack. It is later called by `CALL_FUNCTION` to construct a class.

**SETUP_WITH**(delta)

This opcode performs several operations before a with block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_CLEANUP`. Then, `__enter__()` is called, and a finally block pointing to `delta` is pushed. Finally, the result of calling the enter method is pushed onto the stack. The next opcode will either ignore it (`POP_TOP`), or store it in (a) variable(s) (`STORE_FAST`, `STORE_NAME`, or `UNPACK_SEQUENCE`).

**WITH_CLEANUP**

Cleans up the stack when a **with** statement block exits. TOS is the context manager's `__exit__()` bound method. Below TOS are 1–3 values indicating how/why the finally clause was entered:

- SECOND = None
- (SECOND, THIRD) = (WHY_{RETURN, CONTINUE}), retval
- SECOND = WHY_*; no retval below it
- (SECOND, THIRD, FOURTH) = exc_info()

In the last case, TOS(SECOND, THIRD, FOURTH) is called, otherwise TOS(None, None, None). In addition, TOS is removed from the stack.

If the stack represents an exception, *and* the function call returns a
'true' value, this information is “zapped” and replaced with a single **WHY_SILENCED** to prevent **END_FINALLY** from re-raising the exception. (But non-local gotos will still be resumed.)

**STORE_LOCALS**

Pops TOS from the stack and stores it as the current frame's f_locals. This is used in class construction.

All of the following opcodes expect arguments. An argument is two bytes, with the more significant byte last.

**STORE_NAME**(namei)

Implements name = TOS. namei is the index of name in the attribute co_names of the code object. The compiler tries to use **STORE_FAST** or **STORE_GLOBAL** if possible.

**DELETE_NAME**(namei)

Implements del name, where namei is the index into co_names attribute of the code object.

**UNPACK_SEQUENCE**(count)

Unpacks TOS into count individual values, which are put onto the stack right-to-left.

**UNPACK_EX**(counts)

Implements assignment with a starred target: Unpacks an iterable in TOS into individual values, where the total number of values can be smaller than the number of items in the iterable: one the new values will be a list of all leftover items.

The low byte of counts is the number of values before the list value, the high byte of counts the number of values after it. The resulting values are put onto the stack right-to-left.
**STORE_ATTR**(namei)
Implements `TOS.name = TOS1`, where namei is the index of name in co_names.

**DELETE_ATTR**(namei)
Implements `del TOS.name`, using namei as index into co_names.

**STORE_GLOBAL**(namei)
Works as **STORE_NAME**, but stores the name as a global.

**DELETE_GLOBAL**(namei)
Works as **DELETE_NAME**, but deletes a global name.

**LOAD_CONST**(consti)
Pushes `co_consts[consti]` onto the stack.

**LOAD_NAME**(namei)
Pushes the value associated with `co_names[namei]` onto the stack.

**BUILD_TUPLE**(count)
Creates a tuple consuming count items from the stack, and pushes the resulting tuple onto the stack.

**BUILD_LIST**(count)
Works as **BUILD_TUPLE**, but creates a list.

**BUILD_SET**(count)
Works as **BUILD_TUPLE**, but creates a set.

**BUILD_MAP**(count)
Pushes a new dictionary object onto the stack. The dictionary is pre-sized to hold `count` entries.

**LOAD_ATTR**(namei)
Replaces TOS with `getattr(TOS, co_names[namei])`.

**COMPARE_OP**(opname)
Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

**IMPORT_NAME**(namei)
Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the `fromlist` and `level` arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent `STORE_FAST` instruction modifies the namespace.

**IMPORT_FROM**(namei)
Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a `STORE_FAST` instruction.

**JUMP_FORWARD**(delta)
Increments bytecode counter by `delta`.

**POP_JUMP_IF_TRUE**(target)
If TOS is true, sets the bytecode counter to `target`. TOS is popped.

**POP_JUMP_IF_FALSE**(target)
If TOS is false, sets the bytecode counter to `target`. TOS is popped.

**JUMP_IF_TRUE_OR_POP**(target)
If TOS is true, sets the bytecode counter to target and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

**JUMP_IF_FALSE_OR_POP**(target)
If TOS is false, sets the bytecode counter to target and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

**JUMP_ABSOLUTE**(target)
Set bytecode counter to target.

**FOR_ITER**(delta)
TOS is an *iterator*. Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the byte code counter is incremented by `delta`.

**LOAD_GLOBAL**(namei)
Loads the global named `co_names[namei]` onto the stack.

**SETUP_LOOP**(delta)
Pushes a block for a loop onto the block stack. The block spans from the current instruction with a size of delta bytes.

**SETUP_EXCEPT**(delta)
Pushes a try block from a try-except clause onto the block stack. `delta` points to the first except block.

**SETUP_FINALLY**(delta)
Pushes a try block from a try-except clause onto the block stack. `delta` points to the finally block.

**STORE_MAP**
Store a key and value pair in a dictionary. Pops the key and value
while leaving the dictionary on the stack.

**LOAD_FAST**(var\_num)

Pushes a reference to the local co\_varnames[var\_num] onto the stack.

**STORE_FAST**(var\_num)

Stores TOS into the local co\_varnames[var\_num].

**DELETE_FAST**(var\_num)

Deletes local co\_varnames[var\_num].

**LOAD\_CLOSURE**(i)

Pushes a reference to the cell contained in slot i of the cell and free variable storage. The name of the variable is co\_cellvars[i] if i is less than the length of co\_cellvars. Otherwise it is co\_freevars[i - len(co\_cellvars)].

**LOAD\_DEREF**(i)

Loads the cell contained in slot i of the cell and free variable storage. Pushes a reference to the object the cell contains on the stack.

**STORE\_DEREF**(i)

Stores TOS into the cell contained in slot i of the cell and free variable storage.

**DELETE\_DEREF**(i)

Empties the cell contained in slot i of the cell and free variable storage. Used by the del statement.

**RAISE\_VARARGS**(argc)
Raises an exception. \texttt{argc} indicates the number of parameters to the raise statement, ranging from 0 to 3. The handler will find the traceback as TOS2, the parameter as TOS1, and the exception as TOS.

\textbf{CALL\_FUNCTION}(\texttt{argc})

Calls a function. The low byte of \texttt{argc} indicates the number of positional parameters, the high byte the number of keyword parameters. On the stack, the opcode finds the keyword parameters first. For each keyword argument, the value is on top of the key. Below the keyword parameters, the positional parameters are on the stack, with the right-most parameter on top. Below the parameters, the function object to call is on the stack. Pops all function arguments, and the function itself off the stack, and pushes the return value.

\textbf{MAKE\_FUNCTION}(\texttt{argc})

Pushes a new function object on the stack. From bottom to top, the consumed stack must consist of

- \texttt{argc \& 0xFF} default argument objects in positional order
- \texttt{(argc >> 8) \& 0xFF} pairs of name and default argument, with the name just below the object on the stack, for keyword-only parameters
- \texttt{(argc >> 16) \& 0x7FFF} parameter annotation objects
- a tuple listing the parameter names for the annotations (only if there are any annotation objects)
- the code associated with the function (at TOS1)
- the \textit{qualified name} of the function (at TOS)

\textbf{MAKE\_CLOSURE}(\texttt{argc})

Creates a new function object, sets its \texttt{__closure__} slot, and pushes it on the stack. TOS is the \textit{qualified name} of the function,
TOS1 is the code associated with the function, and TOS2 is the tuple containing cells for the closure’s free variables. The function also has argc default parameters, which are found below the cells.

**BUILD_SLICE(argc)**

Pushes a slice object on the stack. argc must be 2 or 3. If it is 2, slice(TOS1, TOS) is pushed; if it is 3, slice(TOS2, TOS1, TOS) is pushed. See the slice() built-in function for more information.

**EXTENDED_ARG(ext)**

Prefixes any opcode which has an argument too big to fit into the default two bytes. ext holds two additional bytes which, taken together with the subsequent opcode’s argument, comprise a four-byte argument, ext being the two most-significant bytes.

**CALL_FUNCTION_VAR(argc)**

Calls a function. argc is interpreted as in CALL_FUNCTION. The top element on the stack contains the variable argument list, followed by keyword and positional arguments.

**CALL_FUNCTION_KW(argc)**

Calls a function. argc is interpreted as in CALL_FUNCTION. The top element on the stack contains the keyword arguments dictionary, followed by explicit keyword and positional arguments.

**CALL_FUNCTION_VAR_KW(argc)**

Calls a function. argc is interpreted as in CALL_FUNCTION. The top element on the stack contains the keyword arguments dictionary, followed by the variable-arguments tuple, followed by explicit keyword and positional arguments.
HAVE_ARGUMENT

This is not really an opcode. It identifies the dividing line between opcodes which don’t take arguments \(< \text{HAVE\_ARGUMENT}\) and those which do \(\geq \text{HAVE\_ARGUMENT}\).
31.13. pickletools — Tools for pickle developers

Source code: Lib/pickletools.py

This module contains various constants relating to the intimate details of the pickle module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the pickle; ordinary users of the pickle module probably won't find the pickletools module relevant.
31.13.1. Command line usage

*New in version 3.2.*

When invoked from the command line, `python -m pickletools` will disassemble the contents of one or more pickle files. Note that if you want to see the Python object stored in the pickle rather than the details of pickle format, you may want to use `-m pickle` instead. However, when the pickle file that you want to examine comes from an untrusted source, `-m pickletools` is a safer option because it does not execute pickle bytecode.

For example, with a tuple `(1, 2)` pickled in file `x.pickle`:

```bash
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
    0: \x80 PROTO 3
    2: K BININT1 1
    4: K BININT1 2
    6: \x86 TUPLE2
    7: q BININPUT 0
    9: . STOP
highest protocol among opcodes = 2
```

31.13.1.1. Command line options

- `-a`, `--annotate`
  Annotate each line with a short opcode description.

- `-o`, `--output=<file>`
Name of a file where the output should be written.

-1, --indentlevel=<num>
The number of blanks by which to indent a new MARK level.

-m, --memo
When multiple objects are disassembled, preserve memo between disassemblies.

-p, --preamble=<preamble>
When more than one pickle file are specified, print given preamble before each disassembly.
31.13.2. Programmatic Interface

pickletools.dis(pickle, out=None, memo=None, indentlevel=4, annotate=0)

Outputs a symbolic disassembly of the pickle to the file-like object out, defaulting to sys.stdout. pickle can be a string or a file-like object. memo can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by MARK opcodes in the stream, are indented by indentlevel spaces. If a nonzero value is given to annotate, each opcode in the output is annotated with a short description. The value of annotate is used as a hint for the column where annotation should start.

New in version 3.2: The annotate argument.

pickletools.genops(pickle)

Provides an iterator over all of the opcodes in a pickle, returning a sequence of (opcode, arg, pos) triples. opcode is an instance of an OpcodeInfo class; arg is the decoded value, as a Python object, of the opcode's argument; pos is the position at which this opcode is located. pickle can be a string or a file-like object.

pickletools.optimize(picklestring)

Returns a new equivalent pickle string after eliminating unused PUT opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.
32. Miscellaneous Services

The modules described in this chapter provide miscellaneous services that are available in all Python versions. Here's an overview:

- **32.1. formatter — Generic output formatting**
  - 32.1.1. The Formatter Interface
  - 32.1.2. Formatter Implementations
  - 32.1.3. The Writer Interface
  - 32.1.4. Writer Implementations
32.1. **formatter** — Generic output formatting

This module supports two interface definitions, each with multiple implementations: The *formatter* interface, and the *writer* interface which is required by the formatter interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored; writers need not be able to handle relative changes nor any sort of “change back” operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.
32.1.1. The Formatter Interface

Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level:

`formatter.AS_IS`

Value which can be used in the font specification passed to the `push_font()` method described below, or as the new value to any other `push_property()` method. Pushing the `AS_IS` value allows the corresponding `pop_property()` method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects:

`formatter.writer`

The writer instance with which the formatter interacts.

`formatter.end_paragraph(blanklines)`

Close any open paragraphs and insert at least `blanklines` before the next paragraph.

`formatter.add_line_break()`

Add a hard line break if one does not already exist. This does not break the logical paragraph.

`formatter.add_hor_rule(*args, **kw)`

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the
writer's send_line_break() method.

formatter.**add_flowing_data**(data)
Provide data which should be formatted with collapsed whitespace. whitespace from preceding and successive calls to **add_flowing_data()** is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

formatter.**addliteral_data**(data)
Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of data.

formatter.**addlabel_data**(format, counter)
Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the format value is a string, it is interpreted as a format specification for counter, which should be an integer. The result of this formatting becomes the value of the label; if format is not a string it is used as the label value directly. The label value is passed as the only argument to the writer's send_label_data() method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character \'1\' represents the counter value.
formatter as an Arabic number, the characters 'A' and 'a' represent alphabetic representations of the counter value in upper and lower case, respectively, and 'I' and 'i' represent the counter value in Roman numerals, in upper and lower case. Note that the alphabetic and roman transforms require that the counter value be greater than zero.

formatter.flushソフトスペース()
Send any pending whitespace buffered from a previous call to add_flow_data() to the associated writer object. This should be called before any direct manipulation of the writer object.

formatter.push_alignment(align)
Push a new alignment setting onto the alignment stack. This may be AS_IS if no change is desired. If the alignment value is changed from the previous setting, the writer's new_alignment() method is called with the align value.

formatter.pop_alignment()
Restore the previous alignment.

formatter.push_font(size, italic, bold, teletype))
Change some or all font properties of the writer object. Properties which are not set to AS_IS are set to the values passed in while others are maintained at their current settings. The writer's new_font() method is called with the fully resolved font specification.

formatter.pop_font()
Restore the previous font.

formatter.push_margin(margin)
Increase the number of left margin indentations by one, associating the logical tag *margin* with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than *AS_IS* are not sufficient to change the margin.

`formatter.pop_margin()`

Restore the previous margin.

`formatter.push_style(*styles)`

Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including *AS_IS* values, is passed to the writer's `new_styles()` method.

`formatter.pop_style(n=1)`

Pop the last *n* style specifications passed to `push_style()`. A tuple representing the revised stack, including *AS_IS* values, is passed to the writer's `new_styles()` method.

`formatter.set_spacing(spacing)`

Set the spacing style for the writer.

`formatter.assert_line_data(flag=1)`

Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional *flag* argument can be set to false if the writer manipulations produced a hard line break at the end of the output.
32.1.2. Formatter Implementations

Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

```python
class formatter.NullFormatter(writer=None)
    A formatter which does nothing. If writer is omitted, a NullWriter instance is created. No methods of the writer are called by NullFormatter instances. Implementations should inherit from this class if implementing a writer interface but don’t need to inherit any implementation.

class formatter.AbstractFormatter(writer)
    The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.
```
32.1.3. The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the `AbstractFormatter` class as a formatter, the writer must typically be provided by the application.

```python
writer.flush()
```
Flush any buffered output or device control events.

```python
writer.new_alignment(align)
```
Set the alignment style. The `align` value can be any object, but by convention is a string or None, where None indicates that the writer’s “preferred” alignment should be used. Conventional `align` values are 'left', 'center', 'right', and 'justify'.

```python
writer.new_font(font)
```
Set the font style. The value of `font` will be None, indicating that the device’s default font should be used, or a tuple of the form `(size, italic, bold, teletype)`. Size will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The `italic`, `bold`, and `teletype` values are Boolean values specifying which of those font attributes should be used.

```python
writer.new_margin(margin, level)
```
Set the margin level to the integer `level` and the logical tag to `margin`. Interpretation of the logical tag is at the writer’s discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of `level`. 
writer.\texttt{new\_spacing}(\textit{spacing})

Set the spacing style to \textit{spacing}.

writer.\texttt{new\_styles}(\textit{styles})

Set additional styles. The \textit{styles} value is a tuple of arbitrary values; the value \texttt{AS\_IS} should be ignored. The \textit{styles} tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

writer.\texttt{send\_line\_break}()

Break the current line.

writer.\texttt{send\_paragraph}(\textit{blankline})

Produce a paragraph separation of at least \textit{blankline} blank lines, or the equivalent. The \textit{blankline} value will be an integer. Note that the implementation will receive a call to \texttt{send\_line\_break()} before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

writer.\texttt{send\_hor\_rule}(\texttt{*args}, \texttt{**kw})

Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via \texttt{send\_line\_break()}.

writer.\texttt{send\_flowing\_data}(\textit{data})

Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.
**writer.send_literal_data(data)**

Output character data which has already been formatted for display. Generally, this should be interpreted to mean that line breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the send_formatted_data() interface.

**writer.send_label_data(data)**

Set data to the left of the current left margin, if possible. The value of data is not restricted; treatment of non-string values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.
32.1.4. Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the `NullWriter` class.

```python
class formatter.NullWriter:
    A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.
```

```python
class formatter(AbstractWriter):
    A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.
```

```python
class formatter.DumbWriter(file=None, maxcol=72):
    Simple writer class which writes output on the `file object` passed in as `file` or, if `file` is omitted, on standard output. The output is simply word-wrapped to the number of columns specified by `maxcol`. This class is suitable for reflowing a sequence of paragraphs.
```
33. MS Windows Specific Services

This chapter describes modules that are only available on MS Windows platforms.

- **33.1. msilib** — Read and write Microsoft Installer files
  - 33.1.1. Database Objects
  - 33.1.2. View Objects
  - 33.1.3. Summary Information Objects
  - 33.1.4. Record Objects
  - 33.1.5. Errors
  - 33.1.6. CAB Objects
  - 33.1.7. Directory Objects
  - 33.1.8. Features
  - 33.1.9. GUI classes
  - 33.1.10. Precomputed tables

- **33.2. msvcrt** – Useful routines from the MS VC++ runtime
  - 33.2.1. File Operations
  - 33.2.2. Console I/O
  - 33.2.3. Other Functions

- **33.3. winreg** – Windows registry access
  - 33.3.1. Functions
  - 33.3.2. Constants
    - 33.3.2.1. HKEY_* Constants
    - 33.3.2.2. Access Rights
      - 33.3.2.2.1. 64-bit Specific
    - 33.3.2.3. Value Types
  - 33.3.3. Registry Handle Objects

- **33.4. winsound** — Sound-playing interface for Windows
33.1. msilib — Read and write Microsoft Installer files

*Platforms:* Windows

The msilib supports the creation of Microsoft Installer (.msi) files. Because these files often contain an embedded “cabinet” file (.cab), it also exposes an API to create CAB files. Support for reading .cab files is currently not implemented; read support for the .msi database is possible.

This package aims to provide complete access to all tables in an .msi file, therefore, it is a fairly low-level API. Two primary applications of this package are the distutils command bdist_msi, and the creation of Python installer package itself (although that currently uses a different version of msilib).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

msilib.FCICreate(*cabname*, *files*)

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are
currently not exposed.

**msilib.**`UuidCreate()`

Return the string representation of a new unique identifier. This wraps the Windows API functions `UuidCreate()` and `UuidToString()`.

**msilib.**`OpenDatabase(path, persist)`

Return a new database object by calling `MsiOpenDatabase`. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

**msilib.**`CreateRecord(count)`

Return a new record object by calling `MSICreateRecord()`. *count* is the number of fields of the record.

**msilib.**`init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)`

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

`schema` must be a module object containing `tables` and `_Validation_records` attributes; typically, `msilib.schema` should be used.

The database will contain just the schema and the validation
records when this function returns.

msilib.add_data(database, table, records)
Add all records to the table named table in database.

The table argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

records should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, None can be passed.

Field values can be ints, strings, or instances of the Binary class.

class msilib.Binary(filename)
Represents entries in the Binary table; inserting such an object using add_data() reads the file named filename into the table.

msilib.add_tables(database, module)
Add all table content from module to database. module must contain an attribute tables listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

msilib.add_stream(database, name, path)
Add the file path into the _Stream table of database, with the stream name name.

msilib.gen_uuid()
Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).
See also: FCICreateFile UuidCreate UuidToString
33.1.1. Database Objects

Database. **OpenView**(sql)

Return a view object, by calling MSIDatabaseOpenView(). *sql* is the SQL statement to execute.

Database. **Commit**()

Commit the changes pending in the current transaction, by calling MSIDatabaseCommit().

Database. **GetSummaryInformation**(count)

Return a new summary information object, by calling MsiGetSummaryInformation(). *count* is the maximum number of updated values.

**See also:** MSIDatabaseOpenView MSIDatabaseCommit MsiGetSummaryInformation
33.1.2. View Objects

View. **Execute**(params)
Execute the SQL query of the view, through MSIViewExecute(). If *params* is not None, it is a record describing actual values of the parameter tokens in the query.

View. **GetColumnInfo**(kind)
Return a record describing the columns of the view, through calling MsiViewGetColumnInfo(). *kind* can be either MSICOLINFO_NAMES or MSICOLINFO_TYPES.

View. **Fetch**( )
Return a result record of the query, through calling MsiViewFetch().

View. **Modify**(kind, data)
Modify the view, by calling MsiViewModify(). *kind* can be one of MSIMODIFY_SEEK, MSIMODIFY_REFRESH, MSIMODIFY_INSERT, MSIMODIFY_UPDATE, MSIMODIFY_ASSIGN, MSIMODIFY_REPLACE, MSIMODIFY_MERGE, MSIMODIFY_DELETE, MSIMODIFY_INSERT_TEMPORARY, MSIMODIFY_VALIDATE, MSIMODIFY_VALIDATE_NEW, MSIMODIFY_VALIDATE_FIELD, or MSIMODIFY_VALIDATE_DELETE.

*data* must be a record describing the new data.

View. **Close**( )
Close the view, through MsiViewClose().
See also: MsiViewExecute MSIViewGetColumnInfo MsiViewFetch MsiViewModify MsiViewClose
33.1.3. Summary Information Objects

SummaryInformation. **GetProperty**(field)
Return a property of the summary, through MsiSummaryInfoGetProperty(). *field* is the name of the property, and can be one of the constants PID_CODEPAGE, PID_TITLE, PID_SUBJECT, PID_AUTHOR, PID_KEYWORDS, PID_COMMENTS, PID_TEMPLATE, PID_LASTAUTHOR, PID_REVNUMBER, PID_LASTPRINTED, PID_CREATE_DTM, PID_LASTSAVE_DTM, PID_PAGECOUNT, PID_WORDCOUNT, PID_CHARCOUNT, PID_APPNAME, or PID_SECURITY.

SummaryInformation. **GetPropertyCount**()
Return the number of summary properties, through MsiSummaryInfoGetPropertyCount().

SummaryInformation. **SetProperty**(field, value)
Set a property through MsiSummaryInfoSetProperty(). *field* can have the same values as in **GetProperty**(), *value* is the new value of the property. Possible value types are integer and string.

SummaryInformation. **Persist**()
Write the modified properties to the summary information stream, using MsiSummaryInfoPersist().

**See also:** MsiSummaryInfoGetProperty  
MsiSummaryInfoGetPropertyCount  MsiSummaryInfoSetProperty  
MsiSummaryInfoPersist
33.1.4. Record Objects

Record. **GetFieldCount**

Return the number of fields of the record, through MsiRecordGetFieldCount().

Record. **GetInteger**(field)

Return the value of *field* as an integer where possible. *field* must be an integer.

Record. **GetString**(field)

Return the value of *field* as a string where possible. *field* must be an integer.

Record. **SetString**(field, value)

Set *field* to *value* through MsiRecordSetString(). *field* must be an integer; *value* a string.

Record. **SetStream**(field, value)

Set *field* to the contents of the file named *value*, through MsiRecordSetStream(). *field* must be an integer; *value* a string.

Record. **SetInteger**(field, value)

Set *field* to *value* through MsiRecordSetInteger(). Both *field* and *value* must be an integer.

Record. **ClearData**

Set all fields of the record to 0, through MsiRecordClearData().
See also:  MsiRecordGetFieldCount MsiRecordSetString
MsiRecordSetStream MsiRecordSetInteger MsiRecordClear
33.1.5. Errors

All wrappers around MSI functions raise `MsiError`; the string inside the exception will contain more detail.
33.1.6. CAB Objects

class msilib.CAB(name)

The class CAB represents a CAB file. During MSI construction, files will be added simultaneously to the Files table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

name is the name of the CAB file in the MSI file.

append(full, file, logical)

Add the file with the pathname full to the CAB file, under the name logical. If there is already a file named logical, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

commit(database)

Generate a CAB file, add it as a stream to the MSI file, put it into the Media table, and remove the generated file from the disk.
33.1.7. Directory Objects

class msilib.Directory(database, cab, basedir, physical, logical, default[, componentflags])

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through start_component(), or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be None), the path to the physical directory, and a logical directory name. default specifies the DefaultDir slot in the directory table. componentflags specifies the default flags that new components get.

start_component(component=None, feature=None, flags=None, keyfile=None, uuid=None)

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no feature is given, the current feature is used. If no flags are given, the directory’s default flags are used. If no keyfile is given, the KeyPath is left null in the Component table.

add_file(file, src=None, version=None, language=None)

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the src file is specified, it is interpreted relative to the current directory. Optionally, a version and a language can be specified for the entry in the File table.
**glob**(pattern, exclude=None)

Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the `exclude` list.

**remove_pyc()**

Remove `.pyc/.pyo` files on uninstall.

**See also:** Directory Table File Table Component Table FeatureComponents Table
33.1.8. Features

class msilib.Feature(db, id, title, desc, display, level=1, parent=None, directory=None, attributes=0)

Add a new record to the Feature table, using the values id, parent.id, title, desc, display, level, directory, and attributes. The resulting feature object can be passed to the start_component() method of Directory.

set_current()

Make this feature the current feature of msilib. New components are automatically added to the default feature, unless a feature is explicitly specified.

See also: Feature Table
33.1.9. GUI classes

`msilib` provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use `bdist_msi` to create MSI files with a user-interface for installing Python packages.

```python
class msilib.Control(dlg, name)
    Base class of the dialog controls. `dlg` is the dialog object the control belongs to, and `name` is the control's name.

event(event, argument, condition=1, ordering=None)
    Make an entry into the ControlEvent table for this control.

mapping(event, attribute)
    Make an entry into the EventMapping table for this control.

condition(action, condition)
    Make an entry into the ControlCondition table for this control.

class msilib.RadioButtonGroup(dlg, name, property)
    Create a radio button control named `name`. `property` is the installer property that gets set when a radio button is selected.

    add(name, x, y, width, height, text, value=None)
        Add a radio button named `name` to the group, at the coordinates `x, y, width, height`, and with the label `text`. If `value` is None, it defaults to `name`.

class msilib.Dialog(db, name, x, y, w, h, attr, title, first, default, cancel)
```
Return a new **Dialog** object. An entry in the **Dialog** table is made, with the specified coordinates, dialog attributes, title, name of the first, default, and cancel controls.

**control**(name, type, x, y, width, height, attributes, property, text, control_next, help)

Return a new **Control** object. An entry in the **Control** table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

**text**(name, x, y, width, height, attributes, text)

Add and return a **Text** control.

**bitmap**(name, x, y, width, height, text)

Add and return a **Bitmap** control.

**line**(name, x, y, width, height)

Add and return a **Line** control.

**pushbutton**(name, x, y, width, height, attributes, text, next_control)

Add and return a **PushButton** control.

**radiogroup**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a **RadioButtonGroup** control.

**checkbox**(name, x, y, width, height, attributes, property, text, next_control)

Add and return a **CheckBox** control.
See also: Dialog Table Control Table Control Types
ControlCondition Table ControlEvent Table EventMapping Table
RadioButton Table
33.1.10. Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

`msilib.schema`  
This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `_Validation_records` providing the data for MSI validation.

`msilib.sequence`  
This module contains table contents for the standard sequence tables: `AdminExecuteSequence`, `AdminUISequence`, `AdvtExecuteSequence`, `InstallExecuteSequence`, and `InstallUISequence`.

`msilib.text`  
This module contains definitions for the `UIText` and `ActionText` tables, for the standard installer actions.
33.2. msvcr1 – Useful routines from the MS VC++ runtime

*Platforms*: Windows

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible

*Changed in version 3.3*: Operations in this module now raise `OSError` where `IOError` was raised.
33.2.1. File Operations

**msvcrt.locking(fd, mode, nbytes)**

Lock part of a file based on file descriptor `fd` from the C runtime. Raises `OSError` on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the LK_* constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

**msvcrt.LK_LOCK**
**msvcrt.LK_RLCK**

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `OSError` is raised.

**msvcrt.LK_NBLCK**
**msvcrt.LK_NBRLCK**

Locks the specified bytes. If the bytes cannot be locked, `OSError` is raised.

**msvcrt.LK_UNLCK**

Unlocks the specified bytes, which must have been previously locked.

**msvcrt.setmode(fd, flags)**

Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`. 
msvcrt.open_osfhandle(handle, flags)
Create a C runtime file descriptor from the file handle handle. The flags parameter should be a bitwise OR of os.O_APPEND, os.O_RDONLY, and os.O_TEXT. The returned file descriptor may be used as a parameter to os.fdopen() to create a file object.

msvcrt.get_osfhandle(fd)
Return the file handle for the file descriptor fd. Raises OSError if fd is not recognized.
33.2.2. Console I/O

`msvcrts.kbhit()`
Return true if a keypress is waiting to be read.

`msvcrts.getch()`
Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for Enter to be pressed. If the pressed key was a special function key, this will return '\000' or '\xe0'; the next call will return the keycode. The Control-C keypress cannot be read with this function.

`msvcrts.getwch()`
Wide char variant of `getch()`, returning a Unicode value.

`msvcrts.getche()`
Similar to `getch()`, but the keypress will be echoed if it represents a printable character.

`msvcrts.getwche()`
Wide char variant of `getche()`, returning a Unicode value.

`msvcrts.putch(char)`
Print the byte string `char` to the console without buffering.

`msvcrts.putwch(unicode_char)`
Wide char variant of `putch()`, accepting a Unicode value.

`msvcrts.ungetch(char)`
Cause the byte string `char` to be “pushed back” into the console
buffer; it will be the next character read by `getch()` or `getche()`.

**msvcrt.** **ungetwch**(unicode_char)

Wide char variant of `ungetch()`, accepting a Unicode value.
33.2.3. Other Functions

**msvcrthl**\texttt{heapmin()}\par
Force the malloc() heap to clean itself up and return unused blocks to the operating system. On failure, this raises \texttt{OSError}.
33.3. **winreg** – Windows registry access

*Platforms: Windows*

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a *handle object* is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

*Changed in version 3.3:* Several functions in this module used to raise a `WindowsError`, which is now an alias of `OSError`.
33.3.1. Functions

This module offers the following functions:

**`winreg.CloseKey(hkey)`**

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

**Note:** If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

**`winreg.ConnectRegistry(computer_name, key)`**

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

*computer_name* is the name of the remote computer, of the form \r"\computername". If None, the local computer is used.

*key* is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

*Changed in version 3.3:* See above.

**`winreg.CreateKey(key, sub_key)`**

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY_* constants.
sub_key is a string that names the key this method opens or creates.

If key is one of the predefined keys, sub_key may be None. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an OSError exception is raised.

Changed in version 3.3: See above.

winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)

Creates or opens the specified key, returning a handle object.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the key this method opens or creates.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is KEY_WRITE. See Access Rights for other allowed values.

If key is one of the predefined keys, sub_key may be None. In that case, the handle returned is the same key handle passed in to the function.
If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an `OSError` exception is raised.

*New in version 3.2.*

*Changed in version 3.3:* See *above*.

`winreg.DeleteKey(key, sub_key)`

Deletes the specified key.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

`sub_key` is a string that must be a subkey of the key identified by the `key` parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

*Changed in version 3.3:* See *above*.

`winreg.DeleteKeyEx(key, sub_key, access=KEY_WOW64_64KEY, reserved=0)`

Deletes the specified key.

**Note:** The `DeleteKeyEx()` function is implemented with the RegDeleteKeyEx Windows API function, which is specific to 64-bit versions of Windows. See the RegDeleteKeyEx documentation.
key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that must be a subkey of the key identified by the key parameter. This value must not be None, and the key may not have subkeys.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is KEY_ALL_ACCESS. See Access Rights for other allowed values.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an OSError exception is raised.

On unsupported Windows versions, NotImplementederror is raised.

New in version 3.2.

Changed in version 3.3: See above.

winreg.**DeleteValue**(key, value)

Removes a named value from a registry key.

key is an already open key, or one of the predefined HKEY_* constants.

value is a string that identifies the value to remove.

winreg.**EnumKey**(key, index)
Enumerates subkeys of an open registry key, returning a string.

$key$ is an already open key, or one of the predefined $HKEY_*$ constants.

$index$ is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an OSError exception is raised, indicating, no more values are available.

*Changed in version 3.3:* See above.

```
winreg.EnumValue(key, index)
```

Enumerates values of an open registry key, returning a tuple.

$key$ is an already open key, or one of the predefined $HKEY_*$ constants.

$index$ is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an OSError exception is raised, indicating no more values.

The result is a tuple of 3 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A string that identifies the value name</td>
</tr>
<tr>
<td>1</td>
<td>An object that holds the value data, and whose type depends on the underlying registry type</td>
</tr>
<tr>
<td>2</td>
<td>An integer that identifies the type of the value data (see table in docs for <code>SetValueEx()</code>)</td>
</tr>
</tbody>
</table>
Changed in version 3.3: See above.

**winreg.**_ExpandEnvironmentStrings_(str)

Expands environment variable placeholders `%NAME%` in strings like `REG_EXPAND_SZ`:

```python
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

**winreg.**_FlushKey_(key)

Writes all the attributes of a key to the registry.

`key` is an already open key, or one of the predefined `HKEY_*` constants.

It is not necessary to call `FlushKey()` to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike `CloseKey()`, the `FlushKey()` method returns only when all the data has been written to the registry. An application should only call `FlushKey()` if it requires absolute certainty that registry changes are on disk.

**Note:** If you don’t know whether a `FlushKey()` call is required, it probably isn’t.

**winreg.**_LoadKey_(key, sub_key, file_name)

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

`key` is a handle returned by `ConnectRegistry()` or one of the constants `HKEY_USERS` or `HKEY_LOCAL_MACHINE`. 

`sub_key` is a string that identifies the subkey to load.

`file_name` is the name of the file to load registry data from. This file must have been created with the `SaveKey()` function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to `LoadKey()` fails if the calling process does not have the SE_RESTORE_PRIVILEGE privilege. Note that privileges are different from permissions – see the `RegLoadKey` documentation for more details.

If `key` is a handle returned by `ConnectRegistry()`, then the path specified in `file_name` is relative to the remote computer.

```plaintext
winreg. OpenKey(key, sub_key, reserved=0, access=KEY_READ)
winreg. OpenKeyEx(key, sub_key, reserved=0, access=KEY_READ)
```

Opens the specified key, returning a handle object.

`key` is an already open key, or one of the predefined `HKEY_*` constants.

`sub_key` is a string that identifies the sub_key to open.

`reserved` is a reserved integer, and must be zero. The default is zero.

`access` is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_READ`. See `Access Rights` for other allowed values.

The result is a new handle to the specified key.
If the function fails, `OSError` is raised.

*Changed in version 3.2:* Allow the use of named arguments.

*Changed in version 3.3:* See above.

**`winreg.QueryInfoKey(key)`**

Returns information about a key, as a tuple.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

The result is a tuple of 3 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>An integer giving the number of sub keys this key has.</td>
</tr>
<tr>
<td>1</td>
<td>An integer giving the number of values this key has.</td>
</tr>
<tr>
<td>2</td>
<td>An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1600.</td>
</tr>
</tbody>
</table>

**`winreg.QueryValue(key, sub_key)`**

Retrieves the unnamed value for a key, as a string.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

`sub_key` is a string that holds the name of the subkey with which the value is associated. If this parameter is None or empty, the function retrieves the value set by the `SetValue()` method for the key identified by `key`.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a NULL
name. But the underlying API call doesn’t return the type, so always use \texttt{QueryValueEx()} if possible.

\begin{verbatim}
winreg. \texttt{QueryValueEx(key, value\_name)}
Retrieves the type and data for a specified value name associated with an open registry key.

\textit{key} is an already open key, or one of the predefined \texttt{HKEY\_* constants}.

\textit{value\_name} is a string indicating the value to query.

The result is a tuple of 2 items:

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The value of the registry item.</td>
</tr>
<tr>
<td>1</td>
<td>An integer giving the registry type for this value (see table in docs for \texttt{SetValueEx()})</td>
</tr>
</tbody>
</table>
\end{verbatim}

\begin{verbatim}
winreg. \texttt{SaveKey(key, file\_name)}
Saves the specified key, and all its subkeys to the specified file.

\textit{key} is an already open key, or one of the predefined \texttt{HKEY\_* constants}.

\textit{file\_name} is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the \texttt{LoadKey()} method.

If \textit{key} represents a key on a remote computer, the path described by \textit{file\_name} is relative to the remote computer. The caller of this method must possess the \texttt{SeBackupPrivilege} security
privilege. Note that privileges are different than permissions – see the Conflicts Between User Rights and Permissions documentation for more details.

This function passes NULL for `security_attributes` to the API.

```c
winreg.SetValue(key, sub_key, type, value)
```
Associates a value with a specified key.

- `key` is an already open key, or one of the predefined `HKEY_`*constants*.
- `sub_key` is a string that names the subkey with which the value is associated.
- `type` is an integer that specifies the type of the data. Currently this must be `REG_SZ`, meaning only strings are supported. Use the `SetValueEx()` function for support for other data types.
- `value` is a string that specifies the new value.

If the key specified by the `sub_key` parameter does not exist, the `SetValue` function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the `key` parameter must have been opened with `KEY_SET_VALUE` access.

```c
winreg.SetValueEx(key, value_name, reserved, type, value)
```
Stores data in the value field of an open registry key.
key is an already open key, or one of the predefined HKEY_* constants.

value_name is a string that names the subkey with which the value is associated.

reserved can be anything – zero is always passed to the API.

type is an integer that specifies the type of the data. See Value Types for the available types.

value is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with KEY_SET_VALUE access.

To open the key, use the CreateKey() or OpenKey() methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

winreg.DisableReflectionKey(key)

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

key is an already open key, or one of the predefined HKEY_* constants.

Will generally raise NotImplemented if executed on a 32-bit operating system.
If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

winreg. `EnableReflectionKey(key)`
Restores registry reflection for the specified disabled key.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

Will generally raise `NotImplemented` if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

winreg. `QueryReflectionKey(key)`
Determines the reflection state for the specified key.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

Returns True if reflection is disabled.

Will generally raise `NotImplemented` if executed on a 32-bit operating system.
33.3.2. Constants

The following constants are defined for use in many `winreg` functions.

33.3.2.1. HKEY_* Constants

`winreg.HKEY_CLASSES_ROOT`
Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

`winreg.HKEY_CURRENT_USER`
Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

`winreg.HKEY_LOCAL_MACHINE`
Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

`winreg.HKEY_USERS`
Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

`winreg.HKEY_PERFORMANCE_DATA`
Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry;
the registry functions cause the system to collect the data from its source.

`winreg. HKEY_CURRENT_CONFIG`
Contains information about the current hardware profile of the local computer system.

`winreg. HKEY_DYN_DATA`
This key is not used in versions of Windows after 98.

### 33.3.2.2. Access Rights

For more information, see Registry Key Security and Access.

`winreg. KEY_ALL_ACCESS`
Combines the `STANDARD_RIGHTS_REQUIRED`, `KEY_QUERY_VALUE`, `KEY_SET_VALUE`, `KEY_CREATE_SUB_KEY`, `KEY_ENUMERATE_SUB_KEYS`, `KEY_NOTIFY`, and `KEY_CREATE_LINK` access rights.

`winreg. KEY_WRITE`
Combines the `STANDARD_RIGHTS_WRITE`, `KEY_SET_VALUE`, and `KEY_CREATE_SUB_KEY` access rights.

`winreg. KEY_READ`
Combines the `STANDARD_RIGHTS_READ`, `KEY_QUERY_VALUE`, `KEY_ENUMERATE_SUB_KEYS`, and `KEY_NOTIFY` values.

`winreg. KEY_EXECUTE`
Equivalent to `KEY_READ`.

`winreg. KEY_QUERY_VALUE`
Required to query the values of a registry key.

\texttt{winreg.KEY\_SET\_VALUE}

Required to create, delete, or set a registry value.

\texttt{winreg.KEY\_CREATE\_SUB\_KEY}

Required to create a subkey of a registry key.

\texttt{winreg.KEY\_ENUMERATE\_SUB\_KEYS}

Required to enumerate the subkeys of a registry key.

\texttt{winreg.KEY\_NOTIFY}

Required to request change notifications for a registry key or for subkeys of a registry key.

\texttt{winreg.KEY\_CREATE\_LINK}

Reserved for system use.

33.3.2.2.1. 64-bit Specific

For more information, see Accessing an Alternate Registry View.

\texttt{winreg.KEY\_WOW64\_64KEY}

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view.

\texttt{winreg.KEY\_WOW64\_32KEY}

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view.

33.3.2.3. Value Types

For more information, see Registry Value Types.
winreg. **REG_BINARY**
   Binary data in any form.

winreg. **REG_DWORD**
   32-bit number.

winreg. **REG_DWORD_LITTLE_ENDIAN**
   A 32-bit number in little-endian format.

winreg. **REG_DWORD_BIG_ENDIAN**
   A 32-bit number in big-endian format.

winreg. **REG_EXPAND_SZ**
   Null-terminated string containing references to environment variables (%PATH%).

winreg. **REG_LINK**
   A Unicode symbolic link.

winreg. **REG_MULTI_SZ**
   A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

winreg. **REG_NONE**
   No defined value type.

winreg. **REG_RESOURCE_LIST**
   A device-driver resource list.

winreg. **REG_FULL_RESOURCE_DESCRIPTOR**
   A hardware setting.

winreg. **REG_RESOURCE_REQUIREMENTS_LIST**
   A hardware resource list.
winreg. **REG_SZ**

A null-terminated string.
33.3.3. Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__bool__()` – thus

```python
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

`PyHKEY.close()`

Closes the underlying Windows handle.
If the handle is already closed, no error is raised.

**PyHKEY.** `Detach()`

Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

**PyHKEY.** `__enter__()`

**PyHKEY.** `__exit__(*exc_info)`

The HKEY object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement:

```python
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ...
    # work with key
```

will automatically close `key` when control leaves the `with` block.
33.4. `winsound` — Sound-playing interface for Windows

*Platforms*: Windows

The `winsound` module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

`winsound. Beep(frequency, duration)`
Beep the PC's speaker. The `frequency` parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The `duration` parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

`winsound. PlaySound(sound, flags)`
Call the underlying PlaySound() function from the Platform API. The `sound` parameter may be a filename, audio data as a string, or None. Its interpretation depends on the value of `flags`, which can be a bitwise ORed combination of the constants described below. If the `sound` parameter is None, any currently playing waveform sound is stopped. If the system indicates an error, `RuntimeError` is raised.

`winsound. MessageBeep(type=MB_OK)`
Call the underlying MessageBeep() function from the Platform API. This plays a sound as specified in the registry. The `type` argument specifies which sound to play; possible values are `-1, MB_ICONASTERISK, MB_ICONEXCLAMATION, MB_ICONHAND,`
MB_ICONQUESTION, and MB_OK, all described below. The value -1 produces a “simple beep”; this is the final fallback if a sound cannot be played otherwise.

**winsound. SND_FILENAME**

The sound parameter is the name of a WAV file. Do not use with SND_ALIAS.

**winsound. SND_ALIAS**

The sound parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless SND_NODEFAULT is also specified. If no default sound is registered, raise RuntimeError. Do not use with SND_FILENAME.

All Win32 systems support at least the following; most systems support many more:

<table>
<thead>
<tr>
<th>PlaySound() name</th>
<th>Corresponding Control Panel Sound name</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SystemAsterisk'</td>
<td>Asterisk</td>
</tr>
<tr>
<td>'SystemExclamation'</td>
<td>Exclamation</td>
</tr>
<tr>
<td>'SystemExit'</td>
<td>Exit Windows</td>
</tr>
<tr>
<td>'SystemHand'</td>
<td>Critical Stop</td>
</tr>
<tr>
<td>'SystemQuestion'</td>
<td>Question</td>
</tr>
</tbody>
</table>

For example:

```python
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)
```
Probably play Windows default sound, if any is registered (because "*" probably isn't the registered name of any sound).

winsound. **SND_LOOP**

Play the sound repeatedly. The **SND_ASYNC** flag must also be used to avoid blocking. Cannot be used with **SND_MEMORY**.

winsound. **SND_MEMORY**

The sound parameter to **PlaySound()** is a memory image of a WAV file, as a string.

**Note:** This module does not support playing from a memory image asynchronously, so a combination of this flag and **SND_ASYNC** will raise **RuntimeError**.

winsound. **SND_PURGE**

Stop playing all instances of the specified sound.

**Note:** This flag is not supported on modern Windows platforms.

winsound. **SND_ASYNC**

Return immediately, allowing sounds to play asynchronously.

winsound. **SND_NODEFAULT**

If the specified sound cannot be found, do not play the system default sound.

winsound. **SND_NOSTOP**

Do not interrupt sounds currently playing.

winsound. **SND_NOWAIT**
Return immediately if the sound driver is busy.

**Note:** This flag is not supported on modern Windows platforms.

winsound.**MB_ICONASTERISK**
Play the **SystemDefault** sound.

winsound.**MB_ICONEXCLAMATION**
Play the **SystemExclamation** sound.

winsound.**MB_ICONHAND**
Play the **SystemHand** sound.

winsound.**MB_ICONQUESTION**
Play the **SystemQuestion** sound.

winsound.**MB_OK**
Play the **SystemDefault** sound.
34. Unix Specific Services

The modules described in this chapter provide interfaces to features that are unique to the Unix operating system, or in some cases to some or many variants of it. Here's an overview:

- **34.1. posix** — The most common POSIX system calls
  - 34.1.1. Large File Support
  - 34.1.2. Notable Module Contents
- **34.2. pwd** — The password database
- **34.3. spwd** — The shadow password database
- **34.4. grp** — The group database
- **34.5. crypt** — Function to check Unix passwords
  - 34.5.1. Hashing Methods
  - 34.5.2. Module Attributes
  - 34.5.3. Module Functions
  - 34.5.4. Examples
- **34.6. termios** — POSIX style tty control
  - 34.6.1. Example
- **34.7. tty** — Terminal control functions
- **34.8. pty** — Pseudo-terminal utilities
  - 34.8.1. Example
- **34.9. fcntl** — The fcntl and ioctl system calls
- **34.10. pipes** — Interface to shell pipelines
  - 34.10.1. Template Objects
- **34.11. resource** — Resource usage information
  - 34.11.1. Resource Limits
  - 34.11.2. Resource Usage
- **34.12. nis** — Interface to Sun’s NIS (Yellow Pages)
- **34.13. syslog** — Unix syslog library routines
  - 34.13.1. Examples
    - 34.13.1.1. Simple example
34.1. **posix** — The most common POSIX system calls

*Platforms*: Unix

This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

**Do not import this module directly.** Instead, import the module `os`, which provides a *portable* version of this interface. On Unix, the `os` module provides a superset of the `posix` interface. On non-Unix operating systems the `posix` module is not available, but a subset is always available through the `os` interface. Once `os` is imported, there is no performance penalty in using it instead of `posix`. In addition, `os` provides some additional functionality, such as automatically calling `putenv()` when an entry in `os.environ` is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise `OSError`. 
34.1.1. Large File Support

Several operating systems (including AIX, HP-UX, Irix and Solaris) provide support for files that are larger than 2 GiB from a C programming model where int and long are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as large files.

Large file support is enabled in Python when the size of an off_t is larger than a long and the long long type is available and is at least as large as an off_t. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, it is enabled by default with recent versions of Irix, but with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS"
./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='`-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64
./configure
```
34.1.2. Notable Module Contents

In addition to many functions described in the os module documentation, posix defines the following data item:

posix.environ

A dictionary representing the string environment at the time the interpreter was started. Keys and values are bytes on Unix and str on Windows. For example, environ[b'HOME'] (environ['HOME'] on Windows) is the pathname of your home directory, equivalent to getenv("HOME") in C.

Modifying this dictionary does not affect the string environment passed on by execv(), popen() or system(); if you need to change the environment, pass environ to execve() or add variable assignments and export statements to the command string for system() or popen().

Changed in version 3.2: On Unix, keys and values are bytes.

Note: The os module provides an alternate implementation of environ which updates the environment on modification. Note also that updating os.environ will render this dictionary obsolete. Use of the os module version of this is recommended over direct access to the posix module.
34.2. **pwd** — The password database

*Platforms: Unix*

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>pw_name</code></td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td><code>pw_passwd</code></td>
<td>Optional encrypted password</td>
</tr>
<tr>
<td>2</td>
<td><code>pw_uid</code></td>
<td>Numerical user ID</td>
</tr>
<tr>
<td>3</td>
<td><code>pw_gid</code></td>
<td>Numerical group ID</td>
</tr>
<tr>
<td>4</td>
<td><code>pw_gecos</code></td>
<td>User name or comment field</td>
</tr>
<tr>
<td>5</td>
<td><code>pw_dir</code></td>
<td>User home directory</td>
</tr>
<tr>
<td>6</td>
<td><code>pw_shell</code></td>
<td>User command interpreter</td>
</tr>
</tbody>
</table>

The uid and gid items are integers, all others are strings. *KeyError* is raised if the entry asked for cannot be found.

**Note:** In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module `crypt`). However most modern unices use a so-called *shadow password* system. On those unices the `pw_passwd` field only...
contains an asterisk ('*') or the letter 'x' where the encrypted password is stored in a file /etc/shadow which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent. If available, the `spwd` module should be used where access to the encrypted password is required.

It defines the following items:

```
pwd. getpwuid(uid)

    Return the password database entry for the given numeric user ID.
```

```
pwd. getpwnam(name)

    Return the password database entry for the given user name.
```

```
pwd. getpwall()

    Return a list of all available password database entries, in arbitrary order.
```

See also:

**Module grp**

An interface to the group database, similar to this.

**Module spwd**

An interface to the shadow password database, similar to this.
34.3. spwd — The shadow password database

*Platforms:* Unix

This module provides access to the Unix shadow password database. It is available on various Unix versions.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>sp_nam</td>
<td>Login name</td>
</tr>
<tr>
<td>1</td>
<td>sp_pwd</td>
<td>Encrypted password</td>
</tr>
<tr>
<td>2</td>
<td>sp_1stchg</td>
<td>Date of last change</td>
</tr>
<tr>
<td>3</td>
<td>sp_min</td>
<td>Minimal number of days between changes</td>
</tr>
<tr>
<td>4</td>
<td>sp_max</td>
<td>Maximum number of days between changes</td>
</tr>
<tr>
<td>5</td>
<td>sp_warn</td>
<td>Number of days before password expires to warn user about it</td>
</tr>
<tr>
<td>6</td>
<td>sp_inact</td>
<td>Number of days after password expires until account is blocked</td>
</tr>
<tr>
<td>7</td>
<td>sp_expire</td>
<td>Number of days since 1970-01-01 until account is disabled</td>
</tr>
</tbody>
</table>
The `sp_nam` and `sp_pwd` items are strings, all others are integers. `KeyError` is raised if the entry asked for cannot be found.

The following functions are defined:

```python
spwd.getspnam(name)

    Return the shadow password database entry for the given user name.
```

```python
spwd.getspall()

    Return a list of all available shadow password database entries, in arbitrary order.
```

**See also:**

- **Module** `grp`
  
  An interface to the group database, similar to this.

- **Module** `pwd`
  
  An interface to the normal password database, similar to this.
34.4. **grp** — The group database

*Platforms:* Unix

This module provides access to the Unix group database. It is available on all Unix versions.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<pwd.h>`):

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>gr_name</td>
<td>the name of the group</td>
</tr>
<tr>
<td>1</td>
<td>gr_passwd</td>
<td>the (encrypted) group password; often empty</td>
</tr>
<tr>
<td>2</td>
<td>gr_gid</td>
<td>the numerical group ID</td>
</tr>
<tr>
<td>3</td>
<td>gr_mem</td>
<td>all the group member’s user names</td>
</tr>
</tbody>
</table>

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a `+` or `-` is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid()`.)

It defines the following items:

**grp. getgrgid**(gid)

Return the group database entry for the given numeric group ID.
**KeyError** is raised if the entry asked for cannot be found.

**grp.** getting(name)

Return the group database entry for the given group name. **KeyError** is raised if the entry asked for cannot be found.

**grp. getgrall()**

Return a list of all available group entries, in arbitrary order.

---

**See also:**

**Module** pwd

An interface to the user database, similar to this.

**Module** spwd

An interface to the shadow password database, similar to this.
34.5. `crypt` — Function to check Unix passwords

*Platforms:* Unix

This module implements an interface to the `crypt(3)` routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include storing hashed passwords so you can check passwords without storing the actual password, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the `crypt(3)` routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.
34.5.1. Hashing Methods

*New in version 3.3.*

The `crypt` module defines the list of hashing methods (not all methods are available on all platforms):

`crypt.METHOD_SHA512`

A Modular Crypt Format method with 16 character salt and 86 character hash. This is the strongest method.

`crypt.METHOD_SHA256`

Another Modular Crypt Format method with 16 character salt and 43 character hash.

`crypt.METHOD_MD5`

Another Modular Crypt Format method with 8 character salt and 22 character hash.

`crypt.METHOD_CRYPT`

The traditional method with a 2 character salt and 13 characters of hash. This is the weakest method.
34.5.2. Module Attributes

New in version 3.3.

crypt.\texttt{methods}

A list of available password hashing algorithms, as \texttt{crypt.METHOD_*} objects. This list is sorted from strongest to weakest, and is guaranteed to have at least \texttt{crypt.METHOD_CRYPT}.
34.5.3. Module Functions

The crypt module defines the following functions:

**crypt.**crypt(word, salt=None)**

- **word** will usually be a user’s password as typed at a prompt or in a graphical interface. The optional **salt** is either a string as returned from **mksalt()**, one of the **crypt.METHOD_*** values (though not all may be available on all platforms), or a full encrypted password including salt, as returned by this function. If **salt** is not provided, the strongest method will be used (as returned by **methods()**).

Checking a password is usually done by passing the plain-text password as **word** and the full results of a previous **crypt()** call, which should be the same as the results of this call.

- **salt** (either a random 2 or 16 character string, possibly prefixed with **$digit$** to indicate the method) which will be used to perturb the encryption algorithm. The characters in **salt** must be in the set `[./a-zA-Z0-9]`, with the exception of Modular Crypt Format which prefixes a **$digit$**.

Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt.

Since a few crypt(3) extensions allow different values, with different sizes in the **salt**, it is recommended to use the full crypted password as salt when checking for a password.

*Changed in version 3.3: Accept crypt.METHOD_* values in addition to strings for salt.*
crypt.mksalt(method=None)

Return a randomly generated salt of the specified method. If no method is given, the strongest method available as returned by methods() is used.

The return value is a string either of 2 characters in length for crypt.METHOD_CRYPT, or 19 characters starting with $digit$ and 16 random characters from the set [./a-zA-Z0-9], suitable for passing as the salt argument to crypt().

New in version 3.3.
34.5.4. Examples

A simple example illustrating typical use (a constant-time comparison operation is needed to limit exposure to timing attacks. `hmac.compare_digest()` is suitable for this purpose):

```python
import pwd
import crypt
import getpass
from hmac import compare_digest as compare_hash

def login():
    username = input('Python login: ')
    cryptedpasswd = pwd.getpwnam(username)[1]
    if cryptedpasswd:
        if cryptedpasswd == 'x' or cryptedpasswd == 'y':
            raise ValueError('no support for shadow passwords')
        cleartext = getpass.getpass()
        return compare_hash(crypt.crypt(cleartext, cryptedpasswd))
    else:
        return True
```

To generate a hash of a password using the strongest available method and check it against the original:

```python
import crypt
from hmac import compare_digest as compare_hash

hashed = crypt.crypt(plaintext)
if not compare_hash(hashed, crypt.crypt(plaintext, hash):
    raise ValueError("hashed version doesn't validate")
```
34.6. `termios` — POSIX style tty control

*Platforms*: Unix

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see the POSIX or Unix manual pages. It is only available for those Unix versions that support POSIX `termios` style tty I/O control (and then only if configured at installation time).

All functions in this module take a file descriptor `fd` as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a *file object*, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

`termios.tcgetattr(fd)`

Return a list containing the tty attributes for file descriptor `fd`, as follows: `[iflag, oflag, cflag, lflag, ispeed, ospeed, cc]` where `cc` is a list of the tty special characters (each a string of length 1, except the items with indices VMIN and VTIME, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the `cc` array must be done using the symbolic constants defined in
the termios module.

**termios.tcsetattr(fd, when, attributes)**

Set the tty attributes for file descriptor `fd` from the `attributes`, which is a list like the one returned by `tcgetattr()`. The `when` argument determines when the attributes are changed: TCSANOW to change immediately, TCSADRAIN to change after transmitting all queued output, or TCSAFLUSH to change after transmitting all queued output and discarding all queued input.

**termios.tcsendbreak(fd, duration)**

Send a break on file descriptor `fd`. A zero `duration` sends a break for 0.25 –0.5 seconds; a nonzero `duration` has a system dependent meaning.

**termios.tcdrain(fd)**

Wait until all output written to file descriptor `fd` has been transmitted.

**termios.tcflush(fd, queue)**

Discard queued data on file descriptor `fd`. The `queue` selector specifies which queue: TCIFLUSH for the input queue, TCOFLUSH for the output queue, or TCIOFLUSH for both queues.

**termios.tcflow(fd, action)**

Suspend or resume input or output on file descriptor `fd`. The `action` argument can be TCOOFF to suspend output, TCOON to restart output, TCOOFF to suspend input, or TCION to restart input.

**See also:**

Module tty
Convenience functions for common terminal control operations.
34.6.1. Example

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try` ... `finally` statement to ensure that the old tty attributes are restored exactly no matter what happens:

```python
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)

    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)

    return passwd
```

Created using Sphinx 1.0.7.
34.7. `tty` — Terminal control functions

*Platforms:* Unix

The `tty` module defines functions for putting the tty into cbreak and raw modes.

Because it requires the `termios` module, it will work only on Unix.

The `tty` module defines the following functions:

**`tty.setraw(fd, when=termios.TCSAFLUSH)`**

Change the mode of the file descriptor `fd` to raw. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

**`tty.setcbreak(fd, when=termios.TCSAFLUSH)`**

Change the mode of file descriptor `fd` to cbreak. If `when` is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

### See also:

**Module `termios`**

Low-level terminal control interface.
34.8. pty — Pseudo-terminal utilities

Platforms: Linux

The pty module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

Because pseudo-terminal handling is highly platform dependent, there is code to do it only for Linux. (The Linux code is supposed to work on other platforms, but hasn’t been tested yet.)

The pty module defines the following functions:

pty.fork()

Fork. Connect the child’s controlling terminal to a pseudo-terminal. Return value is (pid, fd). Note that the child gets pid 0, and the fd is invalid. The parent’s return value is the pid of the child, and fd is a file descriptor connected to the child’s controlling terminal (and also to the child’s standard input and output).

pty.openpty()

Open a new pseudo-terminal pair, using os.openpty() if possible, or emulation code for generic Unix systems. Return a pair of file descriptors (master, slave), for the master and the slave end, respectively.

pty.spawn(argv[, master_read[, stdin_read]])

Spawn a process, and connect its controlling terminal with the
current process’s standard io. This is often used to baffle programs which insist on reading from the controlling terminal.

The functions `master_read` and `stdin_read` should be functions which read from a file descriptor. The defaults try to read 1024 bytes each time they are called.
34.8.1. Example

The following program acts like the Unix command `script(1)`, using a pseudo-terminal to record all input and output of a terminal session in a “typescript”.

```python
import sys, os, time, getopt
import pty

mode = 'wb'
shell = 'sh'
filename = 'typescript'
if 'SHELL' in os.environ:
    shell = os.environ['SHELL']

try:
    opts, args = getopt.getopt(sys.argv[1:], 'ap')
except getopt.error as msg:
    print('%s: %s' % (sys.argv[0], msg))
sys.exit(2)

for opt, arg in opts:
    # option -a: append to typescript file
    if opt == '-a':
        mode = 'ab'
    # option -p: use a Python shell as the terminal
    elif opt == '-p':
        shell = sys.executable

if args:
    filename = args[0]

script = open(filename, mode)

def read(fd):
    data = os.read(fd, 1024)
```
```
script.write(data)
return data

sys.stdout.write('Script started, file is %s
' % filename)
script.write(('Script started on %s
' % time.asctime())
pty.spawn(shell, read)
script.write(('Script done on %s
' % time.asctime())
sys.stdout.write('Script done, file is %s
' % filename)
```

34.9. **fcntl** — The `fcntl` and `ioctl` system calls

*Platforms*: Unix

This module performs file control and I/O control on file descriptors. It is an interface to the `fcntl()` and `ioctl()` Unix routines.

All functions in this module take a file descriptor `fd` as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a `io.IOBase` object, such as `sys.stdin` itself, which provides a `fileno()` that returns a genuine file descriptor.

*Changed in version 3.3*: Operations in this module used to raise a `IOError` where they now raise a `OSError`.

The module defines the following functions:

**fcntl**

```python
fcntl(fd, op[, arg])
```

Perform the requested operation on file descriptor `fd` (file objects providing a `fileno()` method are accepted as well). The operation is defined by `op` and is operating system dependent. These codes are also found in the `fcntl` module. The argument `arg` is optional, and defaults to the integer value 0. When present, it can either be an integer value, or a string. With the argument missing or an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is a string it represents a binary structure, e.g. created by `struct.pack()`. The binary data is copied to a buffer whose
address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a string object. The length of the returned string will be the same as the length of the `arg` argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` fails, an `OSError` is raised.

```python
fcntl.iocctl(fd, op[, arg[, mutate_flag]])
```

This function is identical to the `fcntl()` function, except that the argument handling is even more complicated.

The `op` parameter is limited to values that can fit in 32-bits.

The parameter `arg` can be one of an integer, absent (treated identically to the integer 0), an object supporting the read-only buffer interface (most likely a plain Python string) or an object supporting the read-write buffer interface.

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the `mutate_flag` parameter.

If it is false, the buffer’s mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is as least as long as what the operating system wants to put there, things should work.

If `mutate_flag` is true (the default), then the buffer is (in effect) passed to the underlying `iocctl()` system call, the latter’s return
code is passed back to the calling Python, and the buffer’s new contents reflect the action of the ioctl(). This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to ioctl() and copied back into the supplied buffer.

An example:

```python
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPGRP, buf))
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
0
>>> buf
array('h', [13341])
```

**fcntl.flock(fd, op)**

Perform the lock operation op on file descriptor fd (file objects providing a fileno() method are accepted as well). See the Unix manual flock(2) for details. (On some systems, this function is emulated using fcntl().)

**fcntl.lockf(fd, operation[, length[, start[, whence]]])**

This is essentially a wrapper around the fcntl() locking calls. fd is the file descriptor of the file to lock or unlock, and operation is one of the following values:

- LOCK_UN – unlock
- LOCK_SH – acquire a shared lock
- LOCK_EX – acquire an exclusive lock
When operation is LOCK_SH or LOCK_EX, it can also be bitwise ORed with LOCK_NB to avoid blocking on lock acquisition. If LOCK_NB is used and the lock cannot be acquired, an OSError will be raised and the exception will have an errno attribute set to EACCES or EAGAIN (depending on the operating system; for portability, check for both values). On at least some systems, LOCK_EX can only be used if the file descriptor refers to a file opened for writing.

length is the number of bytes to lock, start is the byte offset at which the lock starts, relative to whence, and whence is as with io.IOBase.seek(), specifically:

- 0 – relative to the start of the file (os.SEEK_SET)
- 1 – relative to the current buffer position (os.SEEK_CUR)
- 2 – relative to the end of the file (os.SEEK_END)

The default for start is 0, which means to start at the beginning of the file. The default for length is 0 which means to lock to the end of the file. The default for whence is also 0.

Examples (all on a SVR4 compliant system):

```python
import struct, fcntl, os
f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)
lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable rv will hold an integer value; in the second example it will hold a string value. The
structure lay-out for the `lockdata` variable is system dependent — therefore using the `flock()` call may be better.

**See also:**

**Module os**

If the locking flags `O_SHLOCK` and `O_EXLOCK` are present in the `os` module (on BSD only), the `os.open()` function provides an alternative to the `lockf()` and `flock()` functions.
34. Unix Specific Services
34.10. pipes — Interface to shell pipelines

Platforms: Unix

Source code: Lib/pipes.py

The pipes module defines a class to abstract the concept of a pipeline — a sequence of converters from one file to another.

Because the module uses /bin/sh command lines, a POSIX or compatible shell for os.system() and os.popen() is required.

The pipes module defines the following class:

class pipes.Template
   An abstraction of a pipeline.

Example:

```python
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```
34.10.1. Template Objects

Template objects following methods:

Template. **reset()**

   Restore a pipeline template to its initial state.

Template. **clone()**

   Return a new, equivalent, pipeline template.

Template. **debug(flag)**

   If flag is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given set -x command to be more verbose.

Template. **append(cmd, kind)**

   Append a new action at the end. The cmd variable must be a valid bourne shell command. The kind variable consists of two letters.

   The first letter can be either of ' - ' (which means the command reads its standard input), ' f ' (which means the commands reads a given file on the command line) or ' . ' (which means the commands reads no input, and hence must be first.)

   Similarly, the second letter can be either of ' - ' (which means the command writes to standard output), ' f ' (which means the command writes a file on the command line) or ' . ' (which means the command does not write anything, and hence must be last.)

Template. **prepend(cmd, kind)**

   Add a new action at the beginning. See **append()** for explanations of the arguments.
Template. `open(file, mode)`
Return a file-like object, open to `file`, but read from or written to by the pipeline. Note that only one of `'r'`, `'w'` may be given.

Template. `copy(infile, outfile)`
Copy `infile` to `outfile` through the pipe.
34.11. `resource` — Resource usage information

*Platforms:* Unix

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An `OSError` is raised on syscall failure.

*exception `resource.error`*

A deprecated alias of `OSError`.

*Changed in version 3.3:* Following [PEP 3151](https://www.python.org/dev/peps/pep-03151/), this class was made an alias of `OSError`. 
34.11.1. Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the `getrlimit(2)` man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

**resource.** `RLIM_INFINITY`

Constant used to represent the the limit for an unlimited resource.

**resource.** `getrlimit(resource)`

Returns a tuple `(soft, hard)` with the current soft and hard limits of `resource`. Raises `ValueError` if an invalid resource is specified, or `error` if the underlying system call fails unexpectedly.

**resource.** `setrlimit(resource, limits)`

Sets new limits of consumption of `resource`. The `limits` argument must be a tuple `(soft, hard)` of two integers describing the new limits. A value of `RLIM_INFINITY` can be used to request a limit that is unlimited.

Raises `ValueError` if an invalid resource is specified, if the new
soft limit exceeds the hard limit, or if a process tries to raise its hard
limit. Specifying a limit of RLIM_INFINITY when the hard or
system limit for that resource is not unlimited will result in a
ValueError. A process with the effective UID of super-user can
request any valid limit value, including unlimited, but ValueError
will still be raised if the requested limit exceeds the system
imposed limit.

setrlimit may also raise error if the underlying system call
fails.

These symbols define resources whose consumption can be
controlled using the setrlimit() and getrlimit() functions
described below. The values of these symbols are exactly the
constants used by C programs.

The Unix man page for getrlimit(2) lists the available resources. Note
that not all systems use the same symbol or same value to denote the
same resource. This module does not attempt to mask platform
differences — symbols not defined for a platform will not be available
from this module on that platform.

resource. RLIMIT_CORE

The maximum size (in bytes) of a core file that the current process
can create. This may result in the creation of a partial core file if a
larger core would be required to contain the entire process image.

resource. RLIMIT_CPU

The maximum amount of processor time (in seconds) that a
process can use. If this limit is exceeded, a SIGXCPU signal is sent
to the process. (See the signal module documentation for
information about how to catch this signal and do something useful,
e.g. flush open files to disk.)

resource. **RLIMIT_FSIZE**
The maximum size of a file which the process may create. This only affects the stack of the main thread in a multi-threaded process.

resource. **RLIMIT_DATA**
The maximum size (in bytes) of the process's heap.

resource. **RLIMIT_STACK**
The maximum size (in bytes) of the call stack for the current process.

resource. **RLIMIT_RSS**
The maximum resident set size that should be made available to the process.

resource. **RLIMIT_NPROC**
The maximum number of processes the current process may create.

resource. **RLIMIT_NOFILE**
The maximum number of open file descriptors for the current process.

resource. **RLIMIT_OFILE**
The BSD name for **RLIMIT_NOFILE**.

resource. **RLIMIT_MEMLOCK**
The maximum address space which may be locked in memory.

resource. **RLIMIT_VMEM**
The largest area of mapped memory which the process may
occupy.

resource. **RLIMIT_AS**

The maximum area (in bytes) of address space which may be taken by the process.
34.11.2. Resource Usage

These functions are used to retrieve resource usage information:

resource. `getrusage(who)`

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the `who` parameter. The `who` parameter should be specified using one of the RUSAGE_* constants described below.

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running is user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick internal, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the `getrusage(2)` man page for detailed information about these values. A brief summary is presented here:

<table>
<thead>
<tr>
<th>Index</th>
<th>Field</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>ru_utime</code></td>
<td>time in user mode (float)</td>
</tr>
<tr>
<td>1</td>
<td><code>ru_stime</code></td>
<td>time in system mode (float)</td>
</tr>
<tr>
<td>2</td>
<td><code>ru_maxrss</code></td>
<td>maximum resident set size</td>
</tr>
<tr>
<td>3</td>
<td><code>ru_ixrss</code></td>
<td>shared memory size</td>
</tr>
<tr>
<td></td>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---</td>
<td>-------------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>4</td>
<td>ru_idrss</td>
<td>unshared memory size</td>
</tr>
<tr>
<td>5</td>
<td>ru_isrss</td>
<td>unshared stack size</td>
</tr>
<tr>
<td>6</td>
<td>ru_minflt</td>
<td>page faults not requiring I/O</td>
</tr>
<tr>
<td>7</td>
<td>ru_majflt</td>
<td>page faults requiring I/O</td>
</tr>
<tr>
<td>8</td>
<td>ru_nswap</td>
<td>number of swap outs</td>
</tr>
<tr>
<td>9</td>
<td>ru_inblock</td>
<td>block input operations</td>
</tr>
<tr>
<td>10</td>
<td>ru_oublock</td>
<td>block output operations</td>
</tr>
<tr>
<td>11</td>
<td>ru_msgsnd</td>
<td>messages sent</td>
</tr>
<tr>
<td>12</td>
<td>ru_msgrcv</td>
<td>messages received</td>
</tr>
<tr>
<td>13</td>
<td>ru_nsignals</td>
<td>signals received</td>
</tr>
<tr>
<td>14</td>
<td>ru_nvcsw</td>
<td>voluntary context switches</td>
</tr>
<tr>
<td>15</td>
<td>ru_nivcsw</td>
<td>involuntary context switches</td>
</tr>
</tbody>
</table>

This function will raise a `ValueError` if an invalid `who` parameter is specified. It may also raise `error` exception in unusual circumstances.

**resource. `getpagesize()`**

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.) This function is useful for determining the number of bytes of memory a process is using. The third element of the tuple returned by `getrusage()` describes memory usage in pages; multiplying by page size produces number of bytes.

The following RUSAGE_* symbols are passed to the `getrusage()` function to specify which processes information should be provided for.

**resource. RUSAGE_SELF**
Pass to `getrusage()` to request resources consumed by the calling process, which is the sum of resources used by all threads in the process.

**resource. RUSAGE_CHILDREN**

Pass to `getrusage()` to request resources consumed by child processes of the calling process which have been terminated and waited for.

**resource. RUSAGE_BOTH**

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.

**resource. RUSAGE_THREAD**

Pass to `getrusage()` to request resources consumed by the current thread. May not be available on all systems.

*New in version 3.2.*
34.12. nis — Interface to Sun’s NIS (Yellow Pages)

*Platforms:* Unix

The nis module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

The nis module defines the following functions:

nis.match(*key, mapname, domain=default_domain*)

Return the match for *key* in map *mapname*, or raise an error (*nis.error*) if there is none. Both should be strings, *key* is 8-bit clean. Return value is an arbitrary array of bytes (may contain NULL and other joys).

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

nis.cat(*mapname, domain=default_domain*)

Return a dictionary mapping *key* to *value* such that match(*key, mapname*)==*value*. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that *mapname* is first checked if it is an alias to another name.
The domain argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

```
nis.maps(domain=default_domain)
```

Return a list of all valid maps.

The domain argument allows to override the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

```
nis.get_default_domain()
```

Return the system default NIS domain.

The nis module defines the following exception:

```
exception nis.error
```

An error raised when a NIS function returns an error code.
34.13. **syslog** — Unix syslog library routines

*Platforms:* Unix

This module provides an interface to the Unix `syslog` library routines. Refer to the Unix manual pages for a detailed description of the `syslog` facility.

This module wraps the system `syslog` family of routines. A pure Python library that can speak to a syslog server is available in the `logging.handlers` module as `SysLogHandler`.

The module defines the following functions:

```python
syslog.syslog(message)
syslog.syslog(priority, message)
```

Send the string `message` to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a `facility` and a `level`. The optional `priority` argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in `priority` using logical-or (`LOG_INFO` | `LOG_USER`), the value given in the `openlog()` call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

```python
syslog.openlog([ident[, logoption[, facility]]])
```

Logging options of subsequent `syslog()` calls can be set by calling `openlog()`. `syslog()` will call `openlog()` with no
arguments if the log is not currently open.

The optional `ident` keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional `logoption` keyword argument (default is 0) is a bit field – see below for possible values to combine. The optional `facility` keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

*Changed in version 3.2:* In previous versions, keyword arguments were not allowed, and `ident` was required. The default for `ident` was dependent on the system libraries, and often was `python` instead of the name of the python program file.

**syslog.** **`closelog()`**  
Reset the syslog module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, `openlog()` will be called on the first `syslog()` call (if `openlog()` hasn’t already been called), and `ident` and other `openlog()` parameters are reset to defaults.

**syslog.** **`setlogmask(maskpri)`**  
Set the priority mask to `maskpri` and return the previous mask value. Calls to `syslog()` with a priority level not set in `maskpri` are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority `pri`. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including `pri`. 
The module defines the following constants:

Priority levels (high to low):
  LOG_EMERG, LOG_ALERT, LOG_CRIT, LOG_ERR, LOG_WARNING,
  LOG_NOTICE, LOG_INFO, LOG_DEBUG.

Facilities:
  LOG_KERN, LOG_USER, LOG_MAIL, LOG_DAEMON, LOG_AUTH,
  LOG_LPR, LOG_NEWS, LOG_UUCP, LOG_CRON, LOG_SYSLOG,
  LOG_LOCAL0 to LOG_LOCAL7, and, if defined in <syslog.h>,
  LOG_AUTHPRIV.

Log options:
  LOG_PID, LOG_CONS, LOG_NDELAY, and, if defined in
  <syslog.h>, LOG_ODELAY, LOG_NOWAIT, and LOG_PERROR.
34.13.1. Examples

34.13.1.1. Simple example

A simple set of examples:

```python
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```python
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LLOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```
35. Undocumented Modules

Here’s a quick listing of modules that are currently undocumented, but that should be documented. Feel free to contribute documentation for them! (Send via email to docs@python.org.)

The idea and original contents for this chapter were taken from a posting by Fredrik Lundh; the specific contents of this chapter have been substantially revised.
35.1. Platform specific modules

These modules are used to implement the `os.path` module, and are not documented beyond this mention. There's little need to document these.

`ntpath`
— Implementation of `os.path` on Win32, Win64, WinCE, and OS/2 platforms.

`posixpath`
— Implementation of `os.path` on POSIX.
Extending and Embedding the Python Interpreter »
1. Extending Python with C or C++

It is quite easy to add new built-in modules to Python, if you know how to program in C. Such extension modules can do two things that can’t be done directly in Python: they can implement new built-in object types, and they can call C library functions and system calls.

To support extensions, the Python API (Application Programmers Interface) defines a set of functions, macros and variables that provide access to most aspects of the Python run-time system. The Python API is incorporated in a C source file by including the header "Python.h".

The compilation of an extension module depends on its intended use as well as on your system setup; details are given in later chapters.

Do note that if your use case is calling C library functions or system calls, you should consider using the ctypes module rather than writing custom C code. Not only does ctypes let you write Python code to interface with C code, but it is more portable between implementations of Python than writing and compiling an extension module which typically ties you to CPython.
1.1. A Simple Example

Let's create an extension module called spam (the favorite food of Monty Python fans...) and let's say we want to create a Python interface to the C library function `system()`. [1] This function takes a null-terminated character string as argument and returns an integer. We want this function to be callable from Python as follows:

```python
>>> import spam
>>> status = spam.system("ls -l")
```

Begin by creating a file `spammodule.c`. (Historically, if a module is called `spam`, the C file containing its implementation is called `spammodule.c`; if the module name is very long, like `spammify`, the module name can be just `spammify.c`.)

The first line of our file can be:

```c
#include <Python.h>
```

which pulls in the Python API (you can add a comment describing the purpose of the module and a copyright notice if you like).

**Note:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you must include `Python.h` before any standard headers are included.

All user-visible symbols defined by `Python.h` have a prefix of `Py` or `PY`, except those defined in standard header files. For convenience, and since they are used extensively by the Python interpreter, "Python.h" includes a few standard header files: `<stdio.h>`,
<string.h>, <errno.h>, and <stdlib.h>. If the latter header file does not exist on your system, it declares the functions malloc(), free() and realloc() directly.

The next thing we add to our module file is the C function that will be called when the Python expression `spam.system(string)` is evaluated (we'll see shortly how it ends up being called):

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    return PyLong_FromLong(sts);
}
```

There is a straightforward translation from the argument list in Python (for example, the single expression "ls -l") to the arguments passed to the C function. The C function always has two arguments, conventionally named `self` and `args`.

The `self` argument points to the module object for module-level functions; for a method it would point to the object instance.

The `args` argument will be a pointer to a Python tuple object containing the arguments. Each item of the tuple corresponds to an argument in the call's argument list. The arguments are Python objects — in order to do anything with them in our C function we have to convert them to C values. The function `PyArg_ParseTuple()` in the Python API checks the argument types and converts them to C values. It uses a
template string to determine the required types of the arguments as well as the types of the C variables into which to store the converted values. More about this later.

PyArg_ParseTuple() returns true (nonzero) if all arguments have the right type and its components have been stored in the variables whose addresses are passed. It returns false (zero) if an invalid argument list was passed. In the latter case it also raises an appropriate exception so the calling function can return **NULL** immediately (as we saw in the example).
1.2. Intermezzo: Errors and Exceptions

An important convention throughout the Python interpreter is the following: when a function fails, it should set an exception condition and return an error value (usually a *NULL* pointer). Exceptions are stored in a static global variable inside the interpreter; if this variable is *NULL* no exception has occurred. A second global variable stores the “associated value” of the exception (the second argument to *raise*). A third variable contains the stack traceback in case the error originated in Python code. These three variables are the C equivalents of the result in Python of *sys.exc_info()* (see the section on module *sys* in the Python Library Reference). It is important to know about them to understand how errors are passed around.

The Python API defines a number of functions to set various types of exceptions.

The most common one is *PyErr_SetString()* . Its arguments are an exception object and a C string. The exception object is usually a predefined object like *PyExc_ZeroDivisionError*. The C string indicates the cause of the error and is converted to a Python string object and stored as the “associated value” of the exception.

Another useful function is *PyErr_SetFromErrno()*, which only takes an exception argument and constructs the associated value by inspection of the global variable *errno*. The most general function is *PyErr_SetObject()*, which takes two object arguments, the exception and its associated value. You don’t need to *Py_INCREF()* the objects passed to any of these functions.

You can test non-destructively whether an exception has been set with
PyErr_Occurred(). This returns the current exception object, or NULL if no exception has occurred. You normally don't need to call PyErr_Occurred() to see whether an error occurred in a function call, since you should be able to tell from the return value.

When a function f that calls another function g detects that the latter fails, f should itself return an error value (usually NULL or -1). It should not call one of the PyErr_*() functions — one has already been called by g. f's caller is then supposed to also return an error indication to its caller, again without calling PyErr_*(), and so on — the most detailed cause of the error was already reported by the function that first detected it. Once the error reaches the Python interpreter's main loop, this aborts the currently executing Python code and tries to find an exception handler specified by the Python programmer.

(There are situations where a module can actually give a more detailed error message by calling another PyErr_*() function, and in such cases it is fine to do so. As a general rule, however, this is not necessary, and can cause information about the cause of the error to be lost: most operations can fail for a variety of reasons.)

To ignore an exception set by a function call that failed, the exception condition must be cleared explicitly by calling PyErr_Clear(). The only time C code should call PyErr_Clear() is if it doesn't want to pass the error on to the interpreter but wants to handle it completely by itself (possibly by trying something else, or pretending nothing went wrong).

Every failing malloc() call must be turned into an exception — the direct caller of malloc() (or realloc()) must call PyErr_NoMemory() and return a failure indicator itself. All the
object-creating functions (for example, `PyLong_FromLong()`) already do this, so this note is only relevant to those who call `malloc()` directly.

Also note that, with the important exception of `PyArg_ParseTuple()` and friends, functions that return an integer status usually return a positive value or zero for success and `-1` for failure, like Unix system calls.

Finally, be careful to clean up garbage (by making `Py_XDECREF()` or `Py_DECREF()` calls for objects you have already created) when you return an error indicator!

The choice of which exception to raise is entirely yours. There are predeclared C objects corresponding to all built-in Python exceptions, such as `PyExc_ZeroDivisionError`, which you can use directly. Of course, you should choose exceptions wisely — don’t use `PyExc_TypeError` to mean that a file couldn’t be opened (that should probably be `PyExc_IOError`). If something’s wrong with the argument list, the `PyArg_ParseTuple()` function usually raises `PyExc_TypeError`. If you have an argument whose value must be in a particular range or must satisfy other conditions, `PyExc_ValueError` is appropriate.

You can also define a new exception that is unique to your module. For this, you usually declare a static object variable at the beginning of your file:

```c
static PyObject *SpamError;
```

and initialize it in your module’s initialization function (`PyInit_spam()`) with an exception object (leaving out the error
checking for now):

```python
PyMODINIT_FUNC
PyInit_spam(void)
{
    PyObject *m;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;

    SpamError = PyErr_NewException("spam.error", NULL);
    Py_INCREF(SpamError);
    PyModule_AddObject(m, "error", SpamError);
    return m;
}
```

Note that the Python name for the exception object is spam.error. The `PyErr_NewException()` function may create a class with the base class being `Exception` (unless another class is passed in instead of `NULL`), described in *Built-in Exceptions*.

Note also that the SpamError variable retains a reference to the newly created exception class; this is intentional! Since the exception could be removed from the module by external code, an owned reference to the class is needed to ensure that it will not be discarded, causing SpamError to become a dangling pointer. Should it become a dangling pointer, C code which raises the exception could cause a core dump or other unintended side effects.

We discuss the use of `PyMODINIT_FUNC` as a function return type later in this sample.

The spam.error exception can be raised in your extension module
using a call to `PyErr_SetString()` as shown below:

```c
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    if (sts < 0) {
        PyErr_SetString(SpamError, "System command failed");
        return NULL;
    }
    return PyLong_FromLong(sts);
}
```
1.3. Back to the Example

Going back to our example function, you should now be able to understand this statement:

```c
if (!PyArg_ParseTuple(args, "s", &command))
    return NULL;
```

It returns `NULL` (the error indicator for functions returning object pointers) if an error is detected in the argument list, relying on the exception set by `PyArg_ParseTuple()`. Otherwise the string value of the argument has been copied to the local variable `command`. This is a pointer assignment and you are not supposed to modify the string to which it points (so in Standard C, the variable `command` should properly be declared as `const char *command`).

The next statement is a call to the Unix function `system()`, passing it the string we just got from `PyArg_ParseTuple()`:

```c
sts = system(command);
```

Our `spam.system()` function must return the value of `sts` as a Python object. This is done using the function `PyLong_FromLong()`.  

```c
return PyLong_FromLong(sts);
```

In this case, it will return an integer object. (Yes, even integers are objects on the heap in Python!)

If you have a C function that returns no useful argument (a function returning `void`), the corresponding Python function must return `None`. You need this idiom to do so (which is implemented by the
Py_RETURN_NONE macro):

```c
Py_INCREF(Py_None);
return Py_None;
```

`Py_None` is the C name for the special Python object `None`. It is a genuine Python object rather than a `NULL` pointer, which means “error” in most contexts, as we have seen.
1.4. The Module’s Method Table and Initialization Function

I promised to show how spam_system() is called from Python programs. First, we need to list its name and address in a “method table”:

```c
static PyMethodDef SpamMethods[] = {
    ...,
    {"system", spam_system, METH_VARARGS, "Execute a shell command."},
    ...,
    {NULL, NULL, 0, NULL}      /* Sentinel */
};
```

Note the third entry (METH_VARARGS). This is a flag telling the interpreter the calling convention to be used for the C function. It should normally always be METH_VARARGS or METH_VARARGS | METH_KEYWORDS; a value of 0 means that an obsolete variant of PyArg_ParseTuple() is used.

When using only METH_VARARGS, the function should expect the Python-level parameters to be passed in as a tuple acceptable for parsing via PyArg_ParseTuple(); more information on this function is provided below.

The METH_KEYWORDS bit may be set in the third field if keyword arguments should be passed to the function. In this case, the C function should accept a third PyObject * parameter which will be a dictionary of keywords. Use PyArg_ParseTupleAndKeywords() to parse the arguments to such a function.
The method table must be referenced in the module definition structure:

```c
static struct PyModuleDef spammodule = {
    PyModuleDef_HEAD_INIT,
    "spam", /* name of module */
    spam_doc, /* module documentation, may be NULL */
    -1,      /* size of per-interpreter state of the module, or -1 if the module keeps state in global variables */
    SpamMethods
};
```

This structure, in turn, must be passed to the interpreter in the module’s initialization function. The initialization function must be named `PyInit_name()`, where `name` is the name of the module, and should be the only non-static item defined in the module file:

```c
PyMODINIT_FUNC
PyInit_spam(void)
{
    return PyModule_Create(&spammodule);
}
```

Note that `PyMODINIT_FUNC` declares the function as `PyObject *` return type, declares any special linkage declarations required by the platform, and for C++ declares the function as `extern "C"`.

When the Python program imports module spam for the first time, `PyInit_spam()` is called. (See below for comments about embedding Python.) It calls `PyModule_Create()`, which returns a module object, and inserts built-in function objects into the newly created module based upon the table (an array of `PyMethodDef` structures) found in the module definition. `PyModule_Create()`
returns a pointer to the module object that it creates. It may abort with a fatal error for certain errors, or return NULL if the module could not be initialized satisfactorily. The init function must return the module object to its caller, so that it then gets inserted into sys.modules.

When embedding Python, the PyInit_spam() function is not called automatically unless there's an entry in the PyImport_InitTab table. To add the module to the initialization table, use PyImport_AppendInitTab(), optionally followed by an import of the module:

```c
int main(int argc, char *argv[]) {
    /* Add a built-in module, before Py_Initialize */
    PyImport_AppendInitTab("spam", PyInit_spam);

    /* Pass argv[0] to the Python interpreter */
    Py_SetProgramName(argv[0]);

    /* Initialize the Python interpreter. Required. */
    Py_Initialize();

    /* Optionally import the module; alternatively, import can be deferred until the embedded script imports it. */
    PyImport_ImportModule("spam");
    ...
```

**Note:** Removing entries from sys.modules or importing compiled modules into multiple interpreters within a process (or following a fork() without an intervening exec()) can create problems for
some extension modules. Extension module authors should exercise caution when initializing internal data structures.

A more substantial example module is included in the Python source distribution as Modules/xxmodule.c. This file may be used as a template or simply read as an example.
1.5. Compilation and Linkage

There are two more things to do before you can use your new extension: compiling and linking it with the Python system. If you use dynamic loading, the details may depend on the style of dynamic loading your system uses; see the chapters about building extension modules (chapter *Building C and C++ Extensions with distutils*) and additional information that pertains only to building on Windows (chapter *Building C and C++ Extensions on Windows*) for more information about this.

If you can’t use dynamic loading, or if you want to make your module a permanent part of the Python interpreter, you will have to change the configuration setup and rebuild the interpreter. Luckily, this is very simple on Unix: just place your file (spammodule.c for example) in the Modules/ directory of an unpacked source distribution, add a line to the file Modules/Setup.local describing your file:

```
spam spammodule.o
```

and rebuild the interpreter by running `make` in the toplevel directory. You can also run `make` in the Modules/ subdirectory, but then you must first rebuild Makefile there by running `make Makefile`. (This is necessary each time you change the Setup file.)

If your module requires additional libraries to link with, these can be listed on the line in the configuration file as well, for instance:

```
spam spammodule.o -lX11
```
1.6. Calling Python Functions from C

So far we have concentrated on making C functions callable from Python. The reverse is also useful: calling Python functions from C. This is especially the case for libraries that support so-called “callback” functions. If a C interface makes use of callbacks, the equivalent Python often needs to provide a callback mechanism to the Python programmer; the implementation will require calling the Python callback functions from a C callback. Other uses are also imaginable.

Fortunately, the Python interpreter is easily called recursively, and there is a standard interface to call a Python function. (I won’t dwell on how to call the Python parser with a particular string as input — if you’re interested, have a look at the implementation of the -c command line option in Modules/main.c from the Python source code.)

Calling a Python function is easy. First, the Python program must somehow pass you the Python function object. You should provide a function (or some other interface) to do this. When this function is called, save a pointer to the Python function object (be careful to Py_INCREF() it!) in a global variable — or wherever you see fit. For example, the following function might be part of a module definition:

```c
static PyObject *my_callback = NULL;

static PyObject *
my_set_callback(PyObject *dummy, PyObject *args)
{
    PyObject *result = NULL;
    PyObject *temp;

    if (PyArg_ParseTuple(args, "O:set_callback", &temp)
```
if (!PyCallable_Check(temp)) {
    PyErr_SetString(PyExc_TypeError, "parameter must be callable");
    return NULL;
}
Py_XINCREF(temp);  /* Add a reference */
Py_XDECREF(my_callback);  /* Dispose of prev */
my_callback = temp;  /* Remember new cal */
/* Boilerplate to return "None" */
Py_INCREF(Py_None);
result = Py_None;
}
return result;
}

This function must be registered with the interpreter using the METH_VARARGS flag; this is described in section The Module’s Method Table and Initialization Function. The PyArg_ParseTuple() function and its arguments are documented in section Extracting Parameters in Extension Functions.

The macros Py_XINCREF() and Py_XDECREF() increment/decrement the reference count of an object and are safe in the presence of NULL pointers (but note that temp will not be NULL in this context). More info on them in section Reference Counts.

Later, when it is time to call the function, you call the C function PyObject_CallObject(). This function has two arguments, both pointers to arbitrary Python objects: the Python function, and the argument list. The argument list must always be a tuple object, whose length is the number of arguments. To call the Python function with no arguments, pass in NULL, or an empty tuple; to call it with one argument, pass a singleton tuple. Py_BuildValue() returns a tuple when its format string consists of zero or more format codes between
parenttheses. For example:

```c
int arg;
PyObject *arglist;
PyObject *result;
...
arg = 123;
...
/* Time to call the callback */
arglist = Py_BuildValue("(i)", arg);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
```

`PyObject_CallObject()` returns a Python object pointer: this is the return value of the Python function. `PyObject_CallObject()` is “reference-count-neutral” with respect to its arguments. In the example a new tuple was created to serve as the argument list, which is `Py_DECREF()`-ed immediately after the `PyObject_CallObject()` call.

The return value of `PyObject_CallObject()` is “new”: either it is a brand new object, or it is an existing object whose reference count has been incremented. So, unless you want to save it in a global variable, you should somehow `Py_DECREF()` the result, even (especially!) if you are not interested in its value.

Before you do this, however, it is important to check that the return value isn’t `NULL`. If it is, the Python function terminated by raising an exception. If the C code that called `PyObject_CallObject()` is called from Python, it should now return an error indication to its Python caller, so the interpreter can print a stack trace, or the calling Python code can handle the exception. If this is not possible or desirable, the exception should be cleared by calling
PyErr_Clear(). For example:

```c
if (result == NULL)
    return NULL; /* Pass error back */
...use result...
Py_DECREF(result);
```

Depending on the desired interface to the Python callback function, you may also have to provide an argument list to `PyObject_CallObject()`. In some cases the argument list is also provided by the Python program, through the same interface that specified the callback function. It can then be saved and used in the same manner as the function object. In other cases, you may have to construct a new tuple to pass as the argument list. The simplest way to do this is to call `Py_BuildValue()`. For example, if you want to pass an integral event code, you might use the following code:

```c
PyObject *arglist;
...
arglist = Py_BuildValue("(l)", eventcode);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

Note the placement of `Py_DECREF(arglist)` immediately after the call, before the error check! Also note that strictly speaking this code is not complete: `Py_BuildValue()` may run out of memory, and this should be checked.

You may also call a function with keyword arguments by using `PyObject_Call()`, which supports arguments and keyword
arguments. As in the above example, we use `Py_BuildValue()` to construct the dictionary.

```c
PyObject *dict;
...
dict = Py_BuildValue("{s:i}" , "name", val);
result = PyObject_Call(my_callback, NULL, dict);
Py_DECREF(dict);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```
1.7. Extracting Parameters in Extension Functions

The `PyArg_ParseTuple()` function is declared as follows:

```c
int PyArg_ParseTuple(PyObject *arg, char *format, ...);
```

The `arg` argument must be a tuple object containing an argument list passed from Python to a C function. The `format` argument must be a format string, whose syntax is explained in Parsing arguments and building values in the Python/C API Reference Manual. The remaining arguments must be addresses of variables whose type is determined by the format string.

Note that while `PyArg_ParseTuple()` checks that the Python arguments have the required types, it cannot check the validity of the addresses of C variables passed to the call: if you make mistakes there, your code will probably crash or at least overwrite random bits in memory. So be careful!

Note that any Python object references which are provided to the caller are borrowed references; do not decrement their reference count!

Some example calls:

```c
#define PY_SSIZE_T_CLEAN /* Make "s#" use Py_ssize_ 
#include <Python.h>

int ok;
int i, j;
```
long k, l;
const char *s;
Py_ssize_t size;

ok = PyArg_ParseTuple(args, ""); /* No arguments */
     /* Python call: f() */

ok = PyArg_ParseTuple(args, "s", &s); /* A string */
     /* Possible Python call: f('whoops!') */

ok = PyArg_ParseTuple(args, "lls", &k, &l, &s); /* Two longs and a string */
     /* Possible Python call: f(1, 2, 'three') */

ok = PyArg_ParseTuple(args, "(ii)s#", &i, &j, &s, &size);
     /* A pair of ints and a string, whose size is also returned */
     /* Possible Python call: f((1, 2), 'three') */

{
    const char *file;
    const char *mode = "r";
    int bufsize = 0;
    ok = PyArg_ParseTuple(args, "s|si", &file, &mode);
    /* A string, and optionally another string and an integer */
    /* Possible Python calls: */
    f('spam')
    f('spam', 'w')
    f('spam', 'wb', 100000) */
}

{
    int left, top, right, bottom, h, v;
    ok = PyArg_ParseTuple(args, "(((ii)(ii))(ii))", &left, &top, &right, &bottom, &h, &v);
}
/* A rectangle and a point */
/* Possible Python call:
   f(((0, 0), (400, 300)), (10, 10)) */

{ }
Py_complex c;
ok = PyArg_ParseTuple(args, "D:myfunction", &c);
/* a complex, also providing a function name for */
/* Possible Python call: myfunction(1+2j) */
1.8. Keyword Parameters for Extension Functions

The `PyArg_ParseTupleAndKeywords()` function is declared as follows:

```c
int PyArg_ParseTupleAndKeywords(PyObject *arg, PyObject *format, char *format, char *format
```

The `arg` and `format` parameters are identical to those of the `PyArg_ParseTuple()` function. The `kwdict` parameter is the dictionary of keywords received as the third parameter from the Python runtime. The `kwlist` parameter is a `NULL`-terminated list of strings which identify the parameters; the names are matched with the type information from `format` from left to right. On success, `PyArg_ParseTupleAndKeywords()` returns true, otherwise it returns false and raises an appropriate exception.

**Note:** Nested tuples cannot be parsed when using keyword arguments! Keyword parameters passed in which are not present in the `kwlist` will cause `TypeError` to be raised.

Here is an example module which uses keywords, based on an example by Geoff Philbrick (philbrick@hks.com):

```c
#include "Python.h"

static PyObject *
keywdarg_parrot(PyObject *self, PyObject *args, PyObject *"voltage";
```
char *state = "a stiff";
char *action = "voom";
char *type = "Norwegian Blue";

static char *kwlist[] = {"voltage", "state", "action"};

if (!PyArg_ParseTupleAndKeywords(args, keywds, "i|sss", &voltage, &state, &action))
    return NULL;

printf("-- This parrot wouldn't %s if you put %i Volts through it.\n", action, voltage);
printf("-- Lovely plumage, the %s -- It's %s!\n", state, type);

Py_RETURN_NONE;

static PyMethodDef keywdarg_methods[] = {
    /* The cast of the function is necessary since PyObject* only take two PyObject* parameters, and keywdarg_parrot() takes three. */
    {"parrot", (PyCFunction)keywdarg_parrot, METH_VARARGS,
        "Print a lovely skit to standard output."},
    {NULL, NULL, 0, NULL} /* sentinel */
};

static struct PyModuleDef keywdargmodule = {
    PyModuleDef_HEAD_INIT,
    "keywdarg",
    NULL,
    -1,
    keywdarg_methods
};

PyMODINIT_FUNC
PyInit_keywdarg(void)
{ return PyModule_Create(&keywdargmodule); }
1.9. Building Arbitrary Values

This function is the counterpart to `PyArg_ParseTuple()`. It is declared as follows:

```c
PyObject *Py_BuildValue(char *format, ...);
```

It recognizes a set of format units similar to the ones recognized by `PyArg_ParseTuple()`, but the arguments (which are input to the function, not output) must not be pointers, just values. It returns a new Python object, suitable for returning from a C function called from Python.

One difference with `PyArg_ParseTuple()`: while the latter requires its first argument to be a tuple (since Python argument lists are always represented as tuples internally), `Py_BuildValue()` does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

Examples (to the left the call, to the right the resulting Python value):

```
Py_BuildValue(""")                     None
Py_BuildValue("i", 123)                123
Py_BuildValue("iii", 123, 456, 789)    (123, 456, 789)
Py_BuildValue("s", "hello")           'hello'
Py_BuildValue("y", "hello")           b'hello'
Py_BuildValue("ss", "hello", "world") ('hello', 'world')
Py_BuildValue("s#", "hello", 4)       'hell'
Py_BuildValue("y#", "hello", 4)       b'hell'
Py_BuildValue("()")                   ()
```
Py_BuildValue("(i)", 123) (123,)
Py_BuildValue("(ii)", 123, 456) (123, 456)
Py_BuildValue("(i,i)", 123, 456) (123, 456)
Py_BuildValue("[i,i]", 123, 456) [123, 456]
Py_BuildValue("{s:i,s:i}",
    "abc", 123, "def", 456) {'abc': 123
Py_BuildValue("((ii)(ii)) (ii)",
        1, 2, 3, 4, 5, 6) (((1, 2), (3, 4)), (5, 6))
1.10. Reference Counts

In languages like C or C++, the programmer is responsible for dynamic allocation and deallocation of memory on the heap. In C, this is done using the functions malloc() and free(). In C++, the operators new and delete are used with essentially the same meaning and we'll restrict the following discussion to the C case.

Every block of memory allocated with malloc() should eventually be returned to the pool of available memory by exactly one call to free(). It is important to call free() at the right time. If a block's address is forgotten but free() is not called for it, the memory it occupies cannot be reused until the program terminates. This is called a memory leak. On the other hand, if a program calls free() for a block and then continues to use the block, it creates a conflict with re-use of the block through another malloc() call. This is called using freed memory. It has the same bad consequences as referencing uninitialized data — core dumps, wrong results, mysterious crashes.

Common causes of memory leaks are unusual paths through the code. For instance, a function may allocate a block of memory, do some calculation, and then free the block again. Now a change in the requirements for the function may add a test to the calculation that detects an error condition and can return prematurely from the function. It's easy to forget to free the allocated memory block when taking this premature exit, especially when it is added later to the code. Such leaks, once introduced, often go undetected for a long time: the error exit is taken only in a small fraction of all calls, and most modern machines have plenty of virtual memory, so the leak only becomes apparent in a long-running process that uses the leaking function frequently. Therefore, it's important to prevent leaks from
happening by having a coding convention or strategy that minimizes this kind of errors.

Since Python makes heavy use of malloc() and free(), it needs a strategy to avoid memory leaks as well as the use of freed memory. The chosen method is called reference counting. The principle is simple: every object contains a counter, which is incremented when a reference to the object is stored somewhere, and which is decremented when a reference to it is deleted. When the counter reaches zero, the last reference to the object has been deleted and the object is freed.

An alternative strategy is called automatic garbage collection. (Sometimes, reference counting is also referred to as a garbage collection strategy, hence my use of “automatic” to distinguish the two.) The big advantage of automatic garbage collection is that the user doesn’t need to call free() explicitly. (Another claimed advantage is an improvement in speed or memory usage — this is no hard fact however.) The disadvantage is that for C, there is no truly portable automatic garbage collector, while reference counting can be implemented portably (as long as the functions malloc() and free() are available — which the C Standard guarantees). Maybe some day a sufficiently portable automatic garbage collector will be available for C. Until then, we’ll have to live with reference counts.

While Python uses the traditional reference counting implementation, it also offers a cycle detector that works to detect reference cycles. This allows applications to not worry about creating direct or indirect circular references; these are the weakness of garbage collection implemented using only reference counting. Reference cycles consist of objects which contain (possibly indirect) references to themselves, so that each object in the cycle has a reference count which is non-
zero. Typical reference counting implementations are not able to reclaim the memory belonging to any objects in a reference cycle, or referenced from the objects in the cycle, even though there are no further references to the cycle itself.

The cycle detector is able to detect garbage cycles and can reclaim them so long as there are no finalizers implemented in Python (__del__() methods). When there are such finalizers, the detector exposes the cycles through the gc module (specifically, the garbage variable in that module). The gc module also exposes a way to run the detector (the collect() function), as well as configuration interfaces and the ability to disable the detector at runtime. The cycle detector is considered an optional component; though it is included by default, it can be disabled at build time using the --without-cycle-gc option to the configure script on Unix platforms (including Mac OS X). If the cycle detector is disabled in this way, the gc module will not be available.

1.10.1. Reference Counting in Python

There are two macros, Py_INCREF(x) and Py_DECREF(x), which handle the incrementing and decrementing of the reference count. Py_DECREF() also frees the object when the count reaches zero. For flexibility, it doesn’t call free() directly — rather, it makes a call through a function pointer in the object’s type object. For this purpose (and others), every object also contains a pointer to its type object.

The big question now remains: when to use Py_INCREF(x) and Py_DECREF(x)? Let’s first introduce some terms. Nobody “owns” an object; however, you can own a reference to an object. An object’s reference count is now defined as the number of owned references to it. The owner of a reference is responsible for calling Py_DECREF()
when the reference is no longer needed. Ownership of a reference can be transferred. There are three ways to dispose of an owned reference: pass it on, store it, or call `Py_DECREF()`. Forgetting to dispose of an owned reference creates a memory leak.

It is also possible to borrow [2] a reference to an object. The borrower of a reference should not call `Py_DECREF()`. The borrower must not hold on to the object longer than the owner from which it was borrowed. Using a borrowed reference after the owner has disposed of it risks using freed memory and should be avoided completely. [3]

The advantage of borrowing over owning a reference is that you don’t need to take care of disposing of the reference on all possible paths through the code — in other words, with a borrowed reference you don’t run the risk of leaking when a premature exit is taken. The disadvantage of borrowing over owning is that there are some subtle situations where in seemingly correct code a borrowed reference can be used after the owner from which it was borrowed has in fact disposed of it.

A borrowed reference can be changed into an owned reference by calling `Py_INCREF()`. This does not affect the status of the owner from which the reference was borrowed — it creates a new owned reference, and gives full owner responsibilities (the new owner must dispose of the reference properly, as well as the previous owner).

### 1.10.2. Ownership Rules

Whenever an object reference is passed into or out of a function, it is part of the function’s interface specification whether ownership is transferred with the reference or not.
Most functions that return a reference to an object pass on ownership with the reference. In particular, all functions whose function it is to create a new object, such as `PyLong_FromLong()` and `Py_BuildValue()`, pass ownership to the receiver. Even if the object is not actually new, you still receive ownership of a new reference to that object. For instance, `PyLong_FromLong()` maintains a cache of popular values and can return a reference to a cached item.

Many functions that extract objects from other objects also transfer ownership with the reference, for instance `PyObject_GetAttrString()`. The picture is less clear, here, however, since a few common routines are exceptions: `PyTuple_GetItem()`, `PyList_GetItem()`, `PyDict_GetItem()`, and `PyDict_GetItemString()` all return references that you borrow from the tuple, list or dictionary.

The function `PyImport_AddModule()` also returns a borrowed reference, even though it may actually create the object it returns: this is possible because an owned reference to the object is stored in `sys.modules`.

When you pass an object reference into another function, in general, the function borrows the reference from you — if it needs to store it, it will use `Py_INCREF()` to become an independent owner. There are exactly two important exceptions to this rule: `PyTuple_SetItem()` and `PyList_SetItem()`. These functions take over ownership of the item passed to them — even if they fail! (Note that `PyDict_SetItem()` and friends don’t take over ownership — they are “normal.”)

When a C function is called from Python, it borrows references to its
arguments from the caller. The caller owns a reference to the object, so the borrowed reference's lifetime is guaranteed until the function returns. Only when such a borrowed reference must be stored or passed on, it must be turned into an owned reference by calling `Py_INCREF()`.

The object reference returned from a C function that is called from Python must be an owned reference — ownership is transferred from the function to its caller.

1.10.3. Thin Ice

There are a few situations where seemingly harmless use of a borrowed reference can lead to problems. These all have to do with implicit invocations of the interpreter, which can cause the owner of a reference to dispose of it.

The first and most important case to know about is using `Py_DECREF()` on an unrelated object while borrowing a reference to a list item. For instance:

```c
void bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);

    PyList_SetItem(list, 1, PyLong_FromLong(0L));
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

This function first borrows a reference to `list[0]`, then replaces `list[1]` with the value 0, and finally prints the borrowed reference. Looks harmless, right? But it's not!
Let's follow the control flow into `PyList_SetItem()`. The list owns references to all its items, so when item 1 is replaced, it has to dispose of the original item 1. Now let's suppose the original item 1 was an instance of a user-defined class, and let's further suppose that the class defined a `__del__()` method. If this class instance has a reference count of 1, disposing of it will call its `__del__()` method.

Since it is written in Python, the `__del__()` method can execute arbitrary Python code. Could it perhaps do something to invalidate the reference to `item` in `bug()`? You bet! Assuming that the list passed into `bug()` is accessible to the `__del__()` method, it could execute a statement to the effect of `del list[0]`, and assuming this was the last reference to that object, it would free the memory associated with it, thereby invalidating `item`.

The solution, once you know the source of the problem, is easy: temporarily increment the reference count. The correct version of the function reads:

```c
void no_bug(PyObject *list) {
    PyObject *item = PyList_GetItem(list, 0);

    Py_INCRREF(item);
    PyList_SetItem(list, 1, PyLong_FromLong(0L));
    PyObject_Print(item, stdout, 0);
    PyDECREF(item);
}
```

This is a true story. An older version of Python contained variants of this bug and someone spent a considerable amount of time in a C debugger to figure out why his `__del__()` methods would fail...
The second case of problems with a borrowed reference is a variant involving threads. Normally, multiple threads in the Python interpreter can't get in each other's way, because there is a global lock protecting Python's entire object space. However, it is possible to temporarily release this lock using the macro `Py_BEGIN_ALLOW_THREADS`, and to re-acquire it using `Py_END_ALLOW_THREADS`. This is common around blocking I/O calls, to let other threads use the processor while waiting for the I/O to complete. Obviously, the following function has the same problem as the previous one:

```c
void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_BEGIN_ALLOW_THREADS
    ...some blocking I/O call...
    Py_END_ALLOW_THREADS
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

1.10.4. NULL Pointers

In general, functions that take object references as arguments do not expect you to pass them `NULL` pointers, and will dump core (or cause later core dumps) if you do so. Functions that return object references generally return `NULL` only to indicate that an exception occurred. The reason for not testing for `NULL` arguments is that functions often pass the objects they receive on to other function — if each function were to test for `NULL`, there would be a lot of redundant tests and the code would run more slowly.

It is better to test for `NULL` only at the “source:” when a pointer that may be `NULL` is received, for example, from `malloc()` or from a
function that may raise an exception.

The macros `Py_INCREF()` and `Py_DECREF()` do not check for `NULL` pointers — however, their variants `Py_XINCREF()` and `Py_XDECREF()` do.

The macros for checking for a particular object type (`PyType_Check()`) don’t check for `NULL` pointers — again, there is much code that calls several of these in a row to test an object against various different expected types, and this would generate redundant tests. There are no variants with `NULL` checking.

The C function calling mechanism guarantees that the argument list passed to C functions (`args` in the examples) is never `NULL` — in fact it guarantees that it is always a tuple. [4]

It is a severe error to ever let a `NULL` pointer “escape” to the Python user.
1.11. Writing Extensions in C++

It is possible to write extension modules in C++. Some restrictions apply. If the main program (the Python interpreter) is compiled and linked by the C compiler, global or static objects with constructors cannot be used. This is not a problem if the main program is linked by the C++ compiler. Functions that will be called by the Python interpreter (in particular, module initialization functions) have to be declared using `extern "C"`. It is unnecessary to enclose the Python header files in `extern "C" {...}` — they use this form already if the symbol `__cplusplus` is defined (all recent C++ compilers define this symbol).
1.12. Providing a C API for an Extension Module

Many extension modules just provide new functions and types to be used from Python, but sometimes the code in an extension module can be useful for other extension modules. For example, an extension module could implement a type “collection” which works like lists without order. Just like the standard Python list type has a C API which permits extension modules to create and manipulate lists, this new collection type should have a set of C functions for direct manipulation from other extension modules.

At first sight this seems easy: just write the functions (without declaring them \texttt{static}, of course), provide an appropriate header file, and document the C API. And in fact this would work if all extension modules were always linked statically with the Python interpreter. When modules are used as shared libraries, however, the symbols defined in one module may not be visible to another module. The details of visibility depend on the operating system; some systems use one global namespace for the Python interpreter and all extension modules (Windows, for example), whereas others require an explicit list of imported symbols at module link time (AIX is one example), or offer a choice of different strategies (most Unices). And even if symbols are globally visible, the module whose functions one wishes to call might not have been loaded yet!

Portability therefore requires not to make any assumptions about symbol visibility. This means that all symbols in extension modules should be declared \texttt{static}, except for the module’s initialization function, in order to avoid name clashes with other extension modules (as discussed in section \textit{The Module’s Method Table and Initialization}).
Function). And it means that symbols that should be accessible from other extension modules must be exported in a different way.

Python provides a special mechanism to pass C-level information (pointers) from one extension module to another one: Capsules. A Capsule is a Python data type which stores a pointer (void *). Capsules can only be created and accessed via their C API, but they can be passed around like any other Python object. In particular, they can be assigned to a name in an extension module’s namespace. Other extension modules can then import this module, retrieve the value of this name, and then retrieve the pointer from the Capsule.

There are many ways in which Capsules can be used to export the C API of an extension module. Each function could get its own Capsule, or all C API pointers could be stored in an array whose address is published in a Capsule. And the various tasks of storing and retrieving the pointers can be distributed in different ways between the module providing the code and the client modules.

Whichever method you choose, it's important to name your Capsules properly. The function `PyCapsule_New()` takes a name parameter (const char *); you’re permitted to pass in a NULL name, but we strongly encourage you to specify a name. Properly named Capsules provide a degree of runtime type-safety; there is no feasible way to tell one unnamed Capsule from another.

In particular, Capsules used to expose C APIs should be given a name following this convention:

```
modulename.attributename
```

The convenience function `PyCapsule_Import()` makes it easy to load a C API provided via a Capsule, but only if the Capsule’s name
matches this convention. This behavior gives C API users a high degree of certainty that the Capsule they load contains the correct C API.

The following example demonstrates an approach that puts most of the burden on the writer of the exporting module, which is appropriate for commonly used library modules. It stores all C API pointers (just one in the example!) in an array of void pointers which becomes the value of a Capsule. The header file corresponding to the module provides a macro that takes care of importing the module and retrieving its C API pointers; client modules only have to call this macro before accessing the C API.

The exporting module is a modification of the spam module from section A Simple Example. The function spam.system() does not call the C library function system() directly, but a function PySpam_System(), which would of course do something more complicated in reality (such as adding “spam” to every command). This function PySpam_System() is also exported to other extension modules.

The function PySpam_System() is a plain C function, declared static like everything else:

```c
static int
PySpam_System(const char *command)
{
    return system(command);
}
```

The function spam_system() is modified in a trivial way:

```c
static PyObject *
```
spam_system(PyObject *self, PyObject *args) {
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = PySpam_System(command);
    return PyLong_FromLong(sts);
}

In the beginning of the module, right after the line

#include "Python.h"

two more lines must be added:

#define SPAM_MODULE
#include "spammodule.h"

The #define is used to tell the header file that it is being included in
the exporting module, not a client module. Finally, the module's
initialization function must take care of initializing the C API pointer
array:

PyMODINIT_FUNC
PyInit_spam(void) {
    PyObject *m;
    static void *PySpam_API[PySpam_API_pointers];
    PyObject *c_api_object;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;
/* Initialize the C API pointer array */
PySpam_API[PySpam_System_NUM] = (void *)PySpam_System;

/* Create a Capsule containing the API pointer array */
c_api_object = PyCapsule_New((void *)PySpam_API, NULL);
if (c_api_object != NULL)
    PyModule_AddObject(m, "_C_API", c_api_object);
return m;

Note that PySpam_API is declared static; otherwise the pointer array would disappear when PyInit_spam() terminates!

The bulk of the work is in the header file spammodule.h, which looks like this:

```c
#ifndef Py_SPAMMODULE_H
#define Py_SPAMMODULE_H
#ifndef __cplusplus
extern "C" {
#endif

/* Header file for spammodule */

/* C API functions */
#define PySpam_System_NUM 0
#define PySpam_System_RETURN int
#define PySpam_System_PROTO (const char *command)

/* Total number of C API pointers */
#define PySpam_API_pointers 1
```

```c
}#endif /* #ifndef */
```
All that a client module must do in order to have access to the function \texttt{PySpam\_System()} is to call the function (or rather macro) \texttt{import\_spam()} in its initialization function:
The main disadvantage of this approach is that the file spammodule.h is rather complicated. However, the basic structure is the same for each function that is exported, so it has to be learned only once.

Finally it should be mentioned that Capsules offer additional functionality, which is especially useful for memory allocation and deallocation of the pointer stored in a Capsule. The details are described in the Python/C API Reference Manual in the section `Capsules` and in the implementation of Capsules (files Include/pycapsule.h and Objects/pycapsule.c in the Python source code distribution).

Footnotes

[1] An interface for this function already exists in the standard module os — it was chosen as a simple and straightforward example.

[2] The metaphor of “borrowing” a reference is not completely correct: the owner still has a copy of the reference.
Checking that the reference count is at least 1 **does not work** — the reference count itself could be in freed memory and may thus be reused for another object!

These guarantees don’t hold when you use the “old” style calling convention — this is still found in much existing code.
Extending and Embedding the Python Interpreter »
2. Defining New Types

As mentioned in the last chapter, Python allows the writer of an extension module to define new types that can be manipulated from Python code, much like strings and lists in core Python.

This is not hard; the code for all extension types follows a pattern, but there are some details that you need to understand before you can get started.
2.1. The Basics

The Python runtime sees all Python objects as variables of type `PyObject*`, which serves as a “base type” for all Python objects. `PyObject` itself only contains the refcount and a pointer to the object’s “type object”. This is where the action is; the type object determines which (C) functions get called when, for instance, an attribute gets looked up on an object or it is multiplied by another object. These C functions are called “type methods”.

So, if you want to define a new object type, you need to create a new type object.

This sort of thing can only be explained by example, so here's a minimal, but complete, module that defines a new type:

```c
#include <Python.h>

typedef struct {
    PyObject_HEAD
    /* Type-specific fields go here. */
} noddy_NoddyObject;

static PyTypeObject noddy_NoddyType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    "noddy.Noddy",   /* tp_name */
    sizeof(noddy_NoddyObject), /* tp_basicsize */
    0,              /* tp_itemsize */
    0,              /* tp_dealloc */
    0,              /* tp_print */
    0,              /* tp_getattr */
    0,              /* tp_setattr */
    0,              /* tp_reserved */
    0,              /* tp_repr */
};
```
static PyModuleDef noddymodule = {
    PyModuleDef_HEAD_INIT,
    "noddy",
    "Example module that creates an extension type."
    -1,
    NULL, NULL, NULL, NULL, NULL
};

PyMODINIT_FUNC
PyInit_noddy(void)
{
    PyObject* m;

    noddy_NoddyType.tp_new = PyType_GenericNew;
    if (PyType_Ready(&noddy_NoddyType) < 0)
        return NULL;

    m = PyModule_Create(&noddymodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&noddy_NoddyType);
    PyModule_AddObject(m, "Noddy", (PyObject *)&noddy_NoddyType);
    return m;
Now that's quite a bit to take in at once, but hopefully bits will seem familiar from the last chapter.

The first bit that will be new is:

```c
typedef struct {
    PyObject_HEAD
} noddy_NoddyObject;
```

This is what a Noddy object will contain—in this case, nothing more than what every Python object contains—a refcount and a pointer to a type object. These are the fields the `PyObject_HEAD` macro brings in. The reason for the macro is to standardize the layout and to enable special debugging fields in debug builds. Note that there is no semicolon after the `PyObject_HEAD` macro; one is included in the macro definition. Be wary of adding one by accident; it's easy to do from habit, and your compiler might not complain, but someone else's probably will! (On Windows, MSVC is known to call this an error and refuse to compile the code.)

For contrast, let's take a look at the corresponding definition for standard Python floats:

```c
typedef struct {
    PyObject_HEAD
    double ob_fval;
} PyFloatObject;
```

Moving on, we come to the crunch — the type object.

```c
static PyTypeObject noddy_NoddyType = {
```
Now if you go and look up the definition of PyTypeObject in object.h you'll see that it has many more fields that the definition above. The remaining fields will be filled with zeros by the C compiler, and it's common practice to not specify them explicitly unless you need them.

This is so important that we're going to pick the top of it apart still further:

PyVarObject_HEAD_INIT(NULL, 0)
"noddy.Noddy",
sizeof(noddy_NoddyObject),
0,
0,
0,
0,
0,
0,
0,
0,

Py_TPFLAGS_DEFAULT, "Noddy objects",

};

This line is a bit of a wart; what we'd like to write is:
as the type of a type object is “type”, but this isn’t strictly conforming C
and some compilers complain. Fortunately, this member will be filled in
for us by PyType_Ready().

The name of our type. This will appear in the default textual
representation of our objects and in some error messages, for
example:

```
>>> "" + noddy.new_noddy()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: cannot add type "noddy.Noddy" to string
```

Note that the name is a dotted name that includes both the module
name and the name of the type within the module. The module in this
case is noddy and the type is Noddy, so we set the type name to
noddy.Noddy.

This is so that Python knows how much memory to allocate when you
call PyObject_New().

**Note:** If you want your type to be subclassable from Python, and
your type has the same tp_basicsize as its base type, you may
have problems with multiple inheritance. A Python subclass of your
type will have to list your type first in its __bases__, or else it will
not be able to call your type’s __new__() method without getting an
error. You can avoid this problem by ensuring that your type has a
larger value for `tp_basicsize` than its base type does. Most of the time, this will be true anyway, because either your base type will be `object`, or else you will be adding data members to your base type, and therefore increasing its size.

This has to do with variable length objects like lists and strings. Ignore this for now.

Skipping a number of type methods that we don’t provide, we set the class flags to `Py_TPFLAGS_DEFAULT`.

All types should include this constant in their flags. It enables all of the members defined by the current version of Python.

We provide a doc string for the type in `tp_doc`.

Now we get into the type methods, the things that make your objects different from the others. We aren’t going to implement any of these in this version of the module. We’ll expand this example later to have more interesting behavior.

For now, all we want to be able to do is to create new Noddy objects. To enable object creation, we have to provide a `tp_new` implementation. In this case, we can just use the default implementation provided by the API function `PyType_GenericNew()`. We’d like to just assign this to the `tp_new` slot, but we can’t, for portability sake, On some platforms or compilers,
we can’t statically initialize a structure member with a function defined in another C module, so, instead, we’ll assign the `tp_new` slot in the module initialization function just before calling `PyType_Ready()`:

```c
noddy_NoddyType.tp_new = PyType_GenericNew;
if (PyType_Ready(&noddy_NoddyType) < 0)
return;
```

All the other type methods are `NULL`, so we’ll go over them later — that’s for a later section!

Everything else in the file should be familiar, except for some code in `PyInit_noddy()`:

```c
if (PyType_Ready(&noddy_NoddyType) < 0)
return;
```

This initializes the Noddy type, filing in a number of members, including `ob_type` that we initially set to `NULL`.

```c
PyModule_AddObject(m, "Noddy", (PyObject *)&noddy_NoddyType);
```

This adds the type to the module dictionary. This allows us to create Noddy instances by calling the Noddy class:

```python
>>> import noddy
>>> mynoddy = noddy.Noddy()
```

That’s it! All that remains is to build it; put the above code in a file called `noddy.c` and

```python
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
```
ext_modules=[Extension("nодdy", ["nодdy.c"])]

in a file called setup.py; then typing

```
$ python setup.py build
```

at a shell should produce a file noddy.so in a subdirectory; move to that directory and fire up Python — you should be able to import noddy and play around with Noddy objects.

That wasn't so hard, was it?

Of course, the current Noddy type is pretty uninteresting. It has no data and doesn't do anything. It can't even be subclassed.

### 2.1.1. Adding data and methods to the Basic example

Let's extend the basic example to add some data and methods. Let's also make the type usable as a base class. We'll create a new module, noddy2 that adds these capabilities:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last; /* last name */
    int number;
} Noddy;

static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *
{
    Noddy *self;

    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
    }

    self->last = PyUnicode_FromString("");
    if (self->last == NULL) {
        Py_DECREF(self);
        return NULL;
    }

    self->number = 0;
}

    return (PyObject *)self;
}

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kw
{
    PyObject *first=NULL, *last=NULL, *tmp;
static char *kwlist[] = {
"first", "last", "number"
};

if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
    &first, &last,
    &self->number))
    return -1;

if (first) {
    tmp = self->first;
    Py_INCREF(first);
    self->first = first;
    Py_XDECREF(tmp);
}

if (last) {
    tmp = self->last;
    Py_INCREF(last);
    self->last = last;
    Py_XDECREF(tmp);
}

return 0;

}

static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0,
        "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0,  
        "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0,
        "noddy number"},
    {NULL} /* Sentinel */
};

static PyObject *
Noddy_name(Noddy* self)
if (self->first == NULL) {
    PyErr_SetString(PyExc_AttributeError, "first
    return NULL;
}

if (self->last == NULL) {
    PyErr_SetString(PyExc_AttributeError, "last"
    return NULL;
}

return PyUnicode_FromFormat("%S %S", self->first

static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
        "Return the name, combining the first and last
    },
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyVarObject_HEAD_INIT(NULL, 0)
        "noddy.Noddy",
        sizeof(Noddy),
        0,
        (destructor)Noddy_dealloc,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        0,
        /* tp_name */
        /* tp_basicsize */
        /* tp_itemsize */
        /* tp_dealloc */
        /* tp_print */
        /* tp_getattr */
        /* tp_setattr */
        /* tp_reserved */
        /* tp_repr */
        /* tp_as_number */
        /* tp_as_sequence */
        /* tp_as_mapping */
        /* tp_hash */
        /* tp_call */
    }
```c
0, /* tp_str */
0, /* tp_getattro */
0, /* tp_setattro */
0, /* tp_as_buffer */
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,
"Noddy objects",
0, /* tp_flags */
0, /* tp_doc */
0, /* tp_traverse */
0, /* tp_clear */
0, /* tp_richcompare */
0, /* tp_weaklistoffset */
0, /* tp_iter */
0, /* tp_iternext */
Noddy_methods, /* tp_methods */
Noddy_members, /* tp_members */
0, /* tp_getset */
0, /* tp_base */
0, /* tp_dict */
0, /* tp_descr_get */
0, /* tp_descr_set */
0, /* tp_dictoffset */
Noddy_init, /* tp_init */
0, /* tp_alloc */
Noddy_new, /* tp_new */
};

static PyModuleDef noddy2module = {
    PyModuleDef_HEAD_INIT,
    "noddy2",
    "Example module that creates an extension type."
    -1,
    NULL, NULL, NULL, NULL, NULL
};

PyMODINIT_FUNC
PyInit_noddy2(void)
{
```
PyObject* m;

if (PyType_Ready(&NoddyType) < 0)
    return NULL;

m = PyModule_Create(&noddy2module);
if (m == NULL)
    return NULL;

Py_INCREF(&NoddyType);
PyModule_AddObject(m, "Noddy", (PyObject *)&NoddyType);
return m;

This version of the module has a number of changes.

We've added an extra include:

```
#include <structmember.h>
```

This include provides declarations that we use to handle attributes, as described a bit later.

The name of the Noddy object structure has been shortened to Noddy. The type object name has been shortened to NoddyType.

The Noddy type now has three data attributes, first, last, and number. The first and last variables are Python strings containing first and last names. The number attribute is an integer.

The object structure is updated accordingly:

```
typedef struct {
    PyObject_HEAD
    PyObject *first;
```
Because we now have data to manage, we have to be more careful about object allocation and deallocation. At a minimum, we need a deallocation method:

```c
static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject*)self);
}
```

which is assigned to the `tp_dealloc` member:

```c
(destructor)Noddy_dealloc, /*tp_dealloc*/
```

This method decrements the reference counts of the two Python attributes. We use `Py_XDECREF()` here because the first and last members could be `NULL`. It then calls the `tp_free` member of the object's type to free the object's memory. Note that the object's type might not be `NoddyType`, because the object may be an instance of a subclass.

We want to make sure that the first and last names are initialized to empty strings, so we provide a new method:

```c
static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObjec
```
self = (Noddy *)type->tp_alloc(type, 0);
if (self != NULL) {
    self->first = PyUnicode_FromString("");  
    if (self->first == NULL) {  
        Py_DECREF(self);  
        return NULL;
    }
    self->last = PyUnicode_FromString("");  
    if (self->last == NULL) {  
        Py_DECREF(self);  
        return NULL;
    }
    self->number = 0;
}

return (PyObject *)self;

and install it in the tp_new member:

Noddy_new, /* tp_new */

The new member is responsible for creating (as opposed to initializing) objects of the type. It is exposed in Python as the __new__() method. See the paper titled “Unifying types and classes in Python” for a detailed discussion of the __new__() method. One reason to implement a new method is to assure the initial values of instance variables. In this case, we use the new method to make sure that the initial values of the members first and last are not NULL. If we didn’t care whether the initial values were NULL, we could have used PyType_GenericNew() as our new method, as we did before.
PyType_GenericNew() initializes all of the instance variable members to NULL.

The new method is a static method that is passed the type being instantiated and any arguments passed when the type was called, and that returns the new object created. New methods always accept positional and keyword arguments, but they often ignore the arguments, leaving the argument handling to initializer methods. Note that if the type supports subclassing, the type passed may not be the type being defined. The new method calls the tp_alloc slot to allocate memory. We don’t fill the tp_alloc slot ourselves. Rather PyType_Ready() fills it for us by inheriting it from our base class, which is object by default. Most types use the default allocation.

**Note:** If you are creating a co-operative tp_new (one that calls a base type’s tp_new or __new__( ))), you must not try to determine what method to call using method resolution order at runtime. Always statically determine what type you are going to call, and call its tp_new directly, or via type->tp_base->tp_new. If you do not do this, Python subclasses of your type that also inherit from other Python-defined classes may not work correctly. (Specifically, you may not be able to create instances of such subclasses without getting a TypeError.)

We provide an initialization function:

```c
static int Noddy_init(Noddy *self, PyObject *args, PyObject *kw)
{
    PyObject *first=NULL, *last=NULL, *tmp;
    static char *kwlist[] = {"first", "last", "number"};
```
if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi", &first, &last, &self->number))

    return -1;

if (first) {
    tmp = self->first;
    Py_INCRREF(first);
    self->first = first;
    Py_XDECREF(tmp);
}

if (last) {
    tmp = self->last;
    Py_INCRREF(last);
    self->last = last;
    Py_XDECREF(tmp);
}

    return 0;
}

by filling the tp_init slot.

(initproc)Noddy_init,    /* tp_init */

The tp_init slot is exposed in Python as the __init__() method. It is used to initialize an object after it's created. Unlike the new method, we can't guarantee that the initializer is called. The initializer isn't called when unpickling objects and it can be overridden. Our initializer accepts arguments to provide initial values for our instance. Initializers always accept positional and keyword arguments.

Initializers can be called multiple times. Anyone can call the
Our `__init__()` method on our objects. For this reason, we have to be extra careful when assigning the new values. We might be tempted, for example to assign the first member like this:

```python
if (first) {
    Py_XDECREF(self->first);
    Py_INCREF(first);
    self->first = first;
}
```

But this would be risky. Our type doesn’t restrict the type of the first member, so it could be any kind of object. It could have a destructor that causes code to be executed that tries to access the first member. To be paranoid and protect ourselves against this possibility, we almost always reassign members before decrementing their reference counts. When don’t we have to do this?

- when we absolutely know that the reference count is greater than 1
- when we know that deallocation of the object [1] will not cause any calls back into our type’s code
- when decrementing a reference count in a `tp_dealloc` handler when garbage-collections is not supported [2]

We want to expose our instance variables as attributes. There are a number of ways to do that. The simplest way is to define member definitions:

```python
static PyMemberDef Noddy_members[] = {
    {"first", T_OBJECT_EX, offsetof(Noddy, first), 0, "first name"},
    {"last", T_OBJECT_EX, offsetof(Noddy, last), 0, "last name"},
    {"number", T_INT, offsetof(Noddy, number), 0, "number"},
```
and put the definitions in the `tp_members` slot:

```c
Noddy_members,   /* tp_members */
```

Each member definition has a member name, type, offset, access flags and documentation string. See the *Generic Attribute Management* section below for details.

A disadvantage of this approach is that it doesn’t provide a way to restrict the types of objects that can be assigned to the Python attributes. We expect the first and last names to be strings, but any Python objects can be assigned. Further, the attributes can be deleted, setting the C pointers to `NULL`. Even though we can make sure the members are initialized to non-`NULL` values, the members can be set to `NULL` if the attributes are deleted.

We define a single method, `name()`, that outputs the objects name as the concatenation of the first and last names.

```c
static PyObject *
Noddy_name(Noddy* self)
{
    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }

    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }
```
The method is implemented as a C function that takes a Noddy (or Noddy subclass) instance as the first argument. Methods always take an instance as the first argument. Methods often take positional and keyword arguments as well, but in this case we don’t take any and don’t need to accept a positional argument tuple or keyword argument dictionary. This method is equivalent to the Python method:

```python
def name(self):
    return "%s %s" % (self.first, self.last)
```

Note that we have to check for the possibility that our first and last members are `NULL`. This is because they can be deleted, in which case they are set to `NULL`. It would be better to prevent deletion of these attributes and to restrict the attribute values to be strings. We’ll see how to do that in the next section.

Now that we’ve defined the method, we need to create an array of method definitions:

```c
static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
        "Return the name, combining the first and last"},
    {NULL} /* Sentinel */
};
```

and assign them to the `tp_methods` slot:
Noddy_methods, /* tp_methods */

Note that we used the METH_NOARGS flag to indicate that the method is passed no arguments.

Finally, we'll make our type usable as a base class. We've written our methods carefully so far so that they don't make any assumptions about the type of the object being created or used, so all we need to do is to add the Py_TPFLAGS_BASETYPE to our class flag definition:

```
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE, /*tp_flags*/
```

We rename PyInit_noddy() to PyInit_noddy2() and update the module name in the PyModuleDef struct.

Finally, we update our setup.py file to build the new module:

```
from distutils.core import setup, Extension
setup(name="noddy", version="1.0",
      ext_modules=[
        Extension("noddy", ["noddy.c"]),
        Extension("noddy2", ["noddy2.c"]),
      ])
```

2.1.2. Providing finer control over data attributes

In this section, we'll provide finer control over how the first and last attributes are set in the Noddy example. In the previous version of our module, the instance variables first and last could be set to non-string values or even deleted. We want to make sure that these attributes always contain strings.
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static void
Noddy_dealloc(Noddy* self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kws);
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString(""");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString(""");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
    }

    return self;
}
self->number = 0;

return (PyObject *)self;

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number"};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi", 
                                       &first, &last, 
                                       &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }

    return 0;
}

static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
"noddy number",
{NULL} /* Sentinel */
};

static PyObject *
Noddy_getfirst(Noddy *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the first attribute");
        return -1;
    }

    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
"The first attribute value must be a string");
        return -1;
    }

    Py_DECREF(self->first);
    Py_INCREF(value);
    self->first = value;

    return 0;
}

static PyObject *
Noddy_getlast(Noddy *self, void *closure)
{
    Py_INCREF(self->last);
    return self->last;
}
static int Noddy_setlast(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete the last attribute");
        return -1;
    }

    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The last attribute value must be a string");
        return -1;
    }

    Py_DECREF(self->last);
    Py_INCREF(value);
    self->last = value;

    return 0;
}

static PyObject *Noddy_name(Noddy *self)
```c
{ 
    return PyUnicode_FromFormat("%S %S", self->first
}

static PyMethodDef Noddy_methods[] = {
    {"name", (PyCFunction)Noddy_name, METH_NOARGS,
        "Return the name, combining the first and last
    },
    {NULL} /* Sentinel */
};

static PyTypeObject NoddyType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    "noddy.Noddy",
    sizeof(Noddy), /* tp_name */
    /* tp_basicsize */
    0,
    /* tp_itemsize */
    (destructor)Noddy_dealloc, /* tp_dealloc */
    0,
    /* tp_print */
    0,
    /* tp_getattr */
    0,
    /* tp_setattr */
    0,
    /* tp_reserved */
    0,
    /* tp_repr */
    0,
    /* tp_as_number */
    0,
    /* tp_as_sequence */
    0,
    /* tp_as_mapping */
    0,
    /* tp_hash */
    0,
    /* tp_call */
    0,
    /* tp_str */
    0,
    /* tp_getattro */
    0,
    /* tp_setattro */
    0,
    /* tp_as_buffer */
    Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,
    "Noddy objects",
    /* tp_doc */
    0,
    /* tp_traverse */
    0,
    /* tp_clear */
    0,
    /* tp_richcompare */
    0,
};
```
0,    /* tp_weaklistoffset */
0,    /* tp_iter */
0,    /* tp_iternext */
Noddy_methods,    /* tp_methods */
Noddy_members,    /* tp_members */
Noddy_getseters,  /* tp_getset */
0,    /* tp_base */
0,    /* tp_dict */
0,    /* tp_descr_get */
0,    /* tp_descr_set */
0,    /* tp_dictoffset */
(initproc)Noddy_init,    /* tp_init */
0,    /* tp_alloc */
Noddy_new,  /* tp_new */
};

static PyModuleDef noddy3module = {
    PyModuleDef_HEAD_INIT,
    "noddy3",
    "Example module that creates an extension type."
    -1,
    NULL, NULL, NULL, NULL, NULL
};

PyMODINIT_FUNC
PyInit_noddy3(void)
{
    PyObject* m;

    if (PyType_Ready(&NoddyType) < 0)
        return NULL;

    m = PyModule_Create(&noddy3module);
    if (m == NULL)
        return NULL;

    Py_INCREF(&NoddyType);
PyModule_AddObject(m, "Noddy", (PyObject *)&NoddyType);

return m;

To provide greater control, over the first and last attributes, we'll use custom getter and setter functions. Here are the functions for getting and setting the first attribute:

Noddy_getfirst(Noddy *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int Noddy_setfirst(Noddy *self, PyObject *value, void *closure)
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete first attribute");
        return -1;
    }

    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError, "The first attribute value must be a str");
        return -1;
    }

    Py_DECREF(self->first);
    Py_INCREF(value);
    self->first = value;

    return 0;
}
The getter function is passed a Noddy object and a “closure”, which is void pointer. In this case, the closure is ignored. (The closure supports an advanced usage in which definition data is passed to the getter and setter. This could, for example, be used to allow a single set of getter and setter functions that decide the attribute to get or set based on data in the closure.)

The setter function is passed the Noddy object, the new value, and the closure. The new value may be NULL, in which case the attribute is being deleted. In our setter, we raise an error if the attribute is deleted or if the attribute value is not a string.

We create an array of PyGetSetDef structures:

```c
static PyGetSetDef Noddy_getseters[] = {
    {"first",
     (getter)Noddy_getfirst, (setter)Noddy_setfirst,
     "first name",
     NULL},
    {"last",
     (getter)Noddy_getlast, (setter)Noddy_setlast,
     "last name",
     NULL},
    {NULL} /* Sentinel */
};
```

and register it in the `tp_getset` slot:

```c
Noddy_getseters,    /* tp_getset */
```

to register our attribute getters and setters.

The last item in a PyGetSetDef structure is the closure mentioned above. In this case, we aren’t using the closure, so we just pass NULL.
We also remove the member definitions for these attributes:

```c
static PyMemberDef Noddy_members[] = {
    {"number", T_INT, offsetof(Noddy, number), 0,
     "noddy number"},
    {NULL} /* Sentinel */
};
```

We also need to update the `tp_init` handler to only allow strings [3] to be passed:

```c
static int Noddy_init(Noddy *self, PyObject *args, PyObject *kwds) {
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number"};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|SSi",
                                        &first, &last,
                                        &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }

    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }

    return 1;
}
```
With these changes, we can assure that the first and last members are never NULL so we can remove checks for NULL values in almost all cases. This means that most of the Py_XDECREF() calls can be converted to Py_DECREF() calls. The only place we can’t change these calls is in the deallocator, where there is the possibility that the initialization of these members failed in the constructor.

We also rename the module initialization function and module name in the initialization function, as we did before, and we add an extra definition to the setup.py file.

2.1.3. Supporting cyclic garbage collection

Python has a cyclic-garbage collector that can identify unneeded objects even when their reference counts are not zero. This can happen when objects are involved in cycles. For example, consider:

```python
>>> l = []
>>> l.append(l)
>>> del l
```

In this example, we create a list that contains itself. When we delete it, it still has a reference from itself. Its reference count doesn’t drop to zero. Fortunately, Python’s cyclic-garbage collector will eventually figure out that the list is garbage and free it.

In the second version of the Noddy example, we allowed any kind of object to be stored in the first or last attributes. [4] This means
that Noddy objects can participate in cycles:

```python
>>> import noddy2
>>> n = noddy2.Noddy()
>>> l = [n]
>>> n.first = l
```

This is pretty silly, but it gives us an excuse to add support for the cyclic-garbage collector to the Noddy example. To support cyclic garbage collection, types need to fill two slots and set a class flag that enables these slots:

```c
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first;
    PyObject *last;
    int number;
} Noddy;

static int
Noddy_traverse(Noddy *self, visitproc visit, void *arg) {
    int vret;

    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }
    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }
}
```
static int Noddy_clear(Noddy *self)
{
    PyObject *tmp;

    tmp = self->first;
    self->first = NULL;
    Py_XDECREF(tmp);

    tmp = self->last;
    self->last = NULL;
    Py_XDECREF(tmp);

    return 0;
}

static void Noddy_dealloc(Noddy* self)
{
    Noddy_clear(self);
    Py_TYPE(self)->tp_free((PyObject*)self);
}

static PyObject *
Noddy_new(PyTypeObject *type, PyObject *args, PyObject *kargs)
{
    Noddy *self;

    self = (Noddy *)type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
    }

    return self;
}
Py_DECREF(self);
    return NULL;
}

self->last = PyUnicode_FromString("");  
if (self->last == NULL) {
    Py_DECREF(self);
    return NULL;
}

self->number = 0;
}

return (PyObject *)self;
}

static int
Noddy_init(Noddy *self, PyObject *args, PyObject *kwds)
{
    PyObject *first=NULL, *last=NULL, *tmp;

    static char *kwlist[] = {"first", "last", "number"};

    if (! PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
                                        &first, &last,
                                        &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }

    if (last) {
        tmp = self->last;
    }

    return 0;
}
Py_INCREF(last);
    self->last = last;
    Py_XDECREF(tmp);

    return 0;
}

0,        /* tp_base */
0,        /* tp_dict */
0,        /* tp_descr_get */
0,        /* tp_descr_set */
0,        /* tp_dictoffset */
(initproc)Noddy_init,  /* tp_init */
0,        /* tp_alloc */
Noddy_new,  /* tp_new */
};

static PyModuleDef noddy4module = {
    PyModuleDef_HEAD_INIT,
    "noddy4",
    "Example module that creates an extension type."
-1,
    NULL, NULL, NULL, NULL, NULL
};

PyMODINIT_FUNC
PyInit_noddy4(void)
{
    PyObject* m;

    if (PyType_Ready(&NoddyType) < 0)
        return NULL;

    m = PyModule_Create(&noddy4module);
    if (m == NULL)
        return NULL;

    Py_INCREF(&NoddyType);
    PyModule_AddObject(m, "Noddy", (PyObject *)&NoddyType);
    return m;
}
The traversal method provides access to subobjects that could participate in cycles:

```c
static int
Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
    int vret;

    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }

    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }

    return 0;
}
```

For each subobject that can participate in cycles, we need to call the visit() function, which is passed to the traversal method. The visit() function takes as arguments the subobject and the extra argument arg passed to the traversal method. It returns an integer value that must be returned if it is non-zero.

Python provides a Py_VISIT() macro that automates calling visit functions. With Py_VISIT(), Noddy_traverse() can be simplified:

```c
static int
Noddy_traverse(Noddy *self, visitproc visit, void *arg)
{
```
Note:  Note that the \texttt{tp\_traverse} implementation must name its arguments exactly \textit{visit} and \textit{arg} in order to use \texttt{Py\_VISIT()}. This is to encourage uniformity across these boring implementations.

We also need to provide a method for clearing any subobjects that can participate in cycles. We implement the method and reimplement the deallocator to use it:

```c
static int
Noddy_clear(Noddy *self)
{
    PyObject *tmp;

    tmp = self->first;
    self->first = NULL;
    Py_XDECREF(tmp);

    tmp = self->last;
    self->last = NULL;
    Py_XDECREF(tmp);

    return 0;
}

static void
Noddy_dealloc(Noddy* self)
{
    Noddy_clear(self);
    Py_TYPE(self)->tp_free((PyObject*)self);
}
```
Notice the use of a temporary variable in \texttt{Noddy\_clear()}. We use the temporary variable so that we can set each member to \texttt{NULL} before decrementing its reference count. We do this because, as was discussed earlier, if the reference count drops to zero, we might cause code to run that calls back into the object. In addition, because we now support garbage collection, we also have to worry about code being run that triggers garbage collection. If garbage collection is run, our \texttt{tp\_traverse} handler could get called. We can’t take a chance of having \texttt{Noddy\_traverse()} called when a member’s reference count has dropped to zero and its value hasn’t been set to \texttt{NULL}.

Python provides a \texttt{Py\_CLEAR()} that automates the careful decrementing of reference counts. With \texttt{Py\_CLEAR()}, the \texttt{Noddy\_clear()} function can be simplified:

```c
static int Noddy_clear(Noddy *self) {
    Py\_CLEAR(self->first);
    Py\_CLEAR(self->last);
    return 0;
}
```

Finally, we add the \texttt{Py\_TPFLAGS\_HAVE\_GC} flag to the class flags:

```
Py\_TPFLAGS\_DEFAULT | Py\_TPFLAGS\_BASETYPE | Py\_TPFLAGS\_HAVE\_GC
```

That’s pretty much it. If we had written custom \texttt{tp\_alloc} or \texttt{tp\_free} slots, we’d need to modify them for cyclic-garbage collection. Most extensions will use the versions automatically provided.
2.1.4. Subclassing other types

It is possible to create new extension types that are derived from existing types. It is easiest to inherit from the built in types, since an extension can easily use the PyTypeObject it needs. It can be difficult to share these PyTypeObject structures between extension modules.

In this example we will create a Shoddy type that inherits from the built-in list type. The new type will be completely compatible with regular lists, but will have an additional increment() method that increases an internal counter.

```python
>>> import shoddy
>>> s = shoddy.Shoddy(range(3))
>>> s.extend(s)
>>> print(len(s))
6
>>> print(s.increment())
1
>>> print(s.increment())
2
```

```c
#include <Python.h>

typedef struct {
    PyListObject list;
    int state;
} Shoddy;

static PyObject *
Shoddy_increment(Shoddy *self, PyObject *unused)
{
```
self->state++;
return PyLong_FromLong(self->state);
}

static PyMethodDef Shoddy_methods[] = {
    {"increment", (PyCFunction)Shoddy_increment, METH_NOARGS,
        PyDoc_STR("increment state counter")},
    {NULL, NULL},
};

static int Shoddy_init(Shoddy *self, PyObject *args, PyObject *)
{
    if (PyList_Type.tp_init((PyObject *)self, args,)
        return -1;
    self->state = 0;
    return 0;
}

static PyTypeObject ShoddyType = {
    PyObject_HEAD_INIT(NULL)
    "shoddy.Shoddy", /* tp_name */
    sizeof(Shoddy), /* tp_basicsize */
    0, /* tp_itemsize */
    0, /* tp_dealloc */
    0, /* tp_print */
    0, /* tp_getattr */
    0, /* tp_setattr */
    0, /* tp_reserved */
    0, /* tp_repr */
    0, /* tp_as_number */
    0, /* tp_as_sequence */
    0, /* tp_as_mapping */
    0, /* tp_hash */
    0, /* tp_call */
0,        /* tp_str */
0,        /* tp_getattro */
0,        /* tp_setattro */
0,        /* tp_as_buffer */
Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,        /* tp_flags */
0,        /* tp_doc */
0,        /* tp_traverse */
0,        /* tp_clear */
0,        /* tp_richcompare */
0,        /* tp_weaklistoffset */
0,        /* tp_iter */
0,        /* tp_iternext */
Shoddy_methods,        /* tp_methods */
0,        /* tp_members */
0,        /* tp_getset */
0,        /* tp_base */
0,        /* tp_dict */
0,        /* tp_descr_get */
0,        /* tp_descr_set */
0,        /* tp_dictoffset */
(initproc)Shoddy_init,        /* tp_init */
0,        /* tp_alloc */
0,        /* tp_new */
};

static PyModuleDef shoddymodule = {
    PyModuleDef_HEAD_INIT,
    "shoddy",
    "Shoddy module",
    -1,
    NULL, NULL, NULL, NULL, NULL
};

PyMODINIT_FUNC
PyInit_shoddy(void)
{

As you can see, the source code closely resembles the Noddy examples in previous sections. We will break down the main differences between them.

The primary difference for derived type objects is that the base type's object structure must be the first value. The base type will already include the `PyObject_HEAD()` at the beginning of its structure.

When a Python object is a Shoddy instance, its `PyObject*` pointer can be safely cast to both `PyListObject*` and `Shoddy*`.

```c
typedef struct {
    PyListObject list;
    int state;
} Shoddy;
```
In the \_init\_ method for our type, we can see how to call through to the \_init\_ method of the base type.

This pattern is important when writing a type with custom new and dealloc methods. The new method should not actually create the memory for the object with \texttt{tp\_alloc}, that will be handled by the base class when calling its \texttt{tp\_new}.

When filling out the \texttt{PyTypeObject()} for the Shoddy type, you see a slot for \texttt{tp\_base()}. Due to cross platform compiler issues, you can't fill that field directly with the \texttt{PyList\_Type()}; it can be done later in the module's \texttt{init()} function.

```c
PyMODINIT_FUNC
PyInit_shoddy(void)
{
    PyObject *m;

    ShoddyType.tp_base = &PyList_Type;
    if (PyType_Ready(&ShoddyType) < 0)
        return NULL;

    m = PyModule_Create(&shoddymodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&ShoddyType);
    PyModule_AddObject(m, "Shoddy", (PyObject *) &ShoddyType);
    return m;
}
```
Before calling `PyType_Ready()`, the type structure must have the `tp_base` slot filled in. When we are deriving a new type, it is not necessary to fill out the `tp_alloc` slot with `PyObject_GenericNew()` – the allocate function from the base type will be inherited.

After that, calling `PyType_Ready()` and adding the type object to the module is the same as with the basic Noddy examples.
2.2. Type Methods

This section aims to give a quick fly-by on the various type methods you can implement and what they do.

Here is the definition of `PyTypeObject`, with some fields only used in debug builds omitted:

```c
typedef struct _typeobject {
    PyObject_VAR_HEAD
    char *tp_name; /* For printing, in format "<module>.<name>" */
    int tp_basicsize, tp_itemsize; /* For allocation */
    destructor tp_dealloc;
    printfunc tp_print;
    getattrofunc tp_getattr;
   setattrfunc tp_setattr;
    void *tp_reserved;
    reprfunc tp_repr;

    /* Method suites for standard classes */
    PyNumberMethods *tp_as_number;
    PySequenceMethods *tp_as_sequence;
    PyMappingMethods *tp_as_mapping;

    /* More standard operations (here for binary compatibility) */
    hashfunc tp_hash;
    ternaryfunc tp_call;
    reprfunc tp_str;
    getattrofunc tp_getattro;
    setattrofunc tp_setattro;
}
```
/* Functions to access object as input/output buffer */
PyBufferProcs *tp_as_buffer;

/* Flags to define presence of optional/expanded */
long tp_flags;

cchar *tp_doc; /* Documentation string */

/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
long tp_weaklistoffset;

/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;
descrsetfunc tp_descr_set;
long tp_dictoffset;
initproc tp_init;
allocfunc tp_alloc;
newfunc tp_new;
Now that's a lot of methods. Don't worry too much though - if you have a type you want to define, the chances are very good that you will only implement a handful of these.

As you probably expect by now, we’re going to go over this and give more information about the various handlers. We won't go in the order they are defined in the structure, because there is a lot of historical baggage that impacts the ordering of the fields; be sure your type initialization keeps the fields in the right order! It's often easiest to find an example that includes all the fields you need (even if they're initialized to 0) and then change the values to suit your new type.

The name of the type - as mentioned in the last section, this will appear in various places, almost entirely for diagnostic purposes. Try to choose something that will be helpful in such a situation!

These fields tell the runtime how much memory to allocate when new objects of this type are created. Python has some built-in support for variable length structures (think: strings, lists) which is where the
tp_itemsize field comes in. This will be dealt with later.

```c
char *tp_doc;
```

Here you can put a string (or its address) that you want returned when the Python script references `obj.__doc__` to retrieve the doc string.

Now we come to the basic type methods—the ones most extension types will implement.

### 2.2.1. Finalization and De-allocation

```c
destructor tp_dealloc;
```

This function is called when the reference count of the instance of your type is reduced to zero and the Python interpreter wants to reclaim it. If your type has memory to free or other clean-up to perform, put it here. The object itself needs to be freed here as well. Here is an example of this function:

```c
static void newdatatype_dealloc(newdatatypeobject * obj)
{
    free(obj->obj_UnderlyingDatatypePtr);
    Py_TYPE(obj)->tp_free(obj);
}
```

One important requirement of the deallocator function is that it leaves any pending exceptions alone. This is important since deallocators are frequently called as the interpreter unwinds the Python stack; when the stack is unwound due to an exception (rather than normal returns), nothing is done to protect the deallocators from seeing that an exception has already been set. Any actions which a deallocator
performs which may cause additional Python code to be executed may
detect that an exception has been set. This can lead to misleading
errors from the interpreter. The proper way to protect against this is to
save a pending exception before performing the unsafe action, and
restoring it when done. This can be done using the `PyErr_Fetch()`
and `PyErr_Restore()` functions:

```c
static void
my_dealloc(PyObject *obj)
{
    MyObject *self = (MyObject *) obj;
    PyObject *cbresult;

    if (self->my_callback != NULL) {
        PyObject *err_type, *err_value, *err_traceback;

        PyErr_Fetch(&err_type, &err_value, &err_traceback);

        cbresult = PyObject_CallObject(self->my_callback,
                                        NULL);
        if (cbresult == NULL)
            PyErr_WriteUnraisable(self->my_callback);
        else
            Py_DECREF(cbresult);

        PyErr_Restore(err_type, err_value, err_traceback);
        Py_DECREF(self->my_callback);
    }

    Py_TYPE(obj)->tp_free((PyObject*)self);
}
```

2.2.2. Object Presentation
In Python, there are two ways to generate a textual representation of an object: the `repr()` function, and the `str()` function. (The `print()` function just calls `str()`.) These handlers are both optional.

```c
reprfunc tp_repr;
reprfunc tp_str;
```

The `tp_repr` handler should return a string object containing a representation of the instance for which it is called. Here is a simple example:

```c
static PyObject *
newdatatype_repr(newdatatypeobject * obj)
{
    return PyUnicode_FromFormat("Repr-ified_newdatatype{{size:%d}}", 
        obj->obj_UnderlyingDatatypePtr);
}
```

If no `tp_repr` handler is specified, the interpreter will supply a representation that uses the type’s `tp_name` and a uniquely-identifying value for the object.

The `tp_str` handler is to `str()` what the `tp_repr` handler described above is to `repr()`; that is, it is called when Python code calls `str()` on an instance of your object. Its implementation is very similar to the `tp_repr` function, but the resulting string is intended for human consumption. If `tp_str` is not specified, the `tp_repr` handler is used instead.

Here is a simple example:

```c
static PyObject *
```
newdatatype_str(newdatatypeobject * obj)
{
    return PyUnicode_FromFormat("Stringified_newdatatype\n" obj->obj_UnderlyingDatatypePtr, obj);
}

2.2.3. Attribute Management

For every object which can support attributes, the corresponding type must provide the functions that control how the attributes are resolved. There needs to be a function which can retrieve attributes (if any are defined), and another to set attributes (if setting attributes is allowed). Removing an attribute is a special case, for which the new value passed to the handler is NULL.

Python supports two pairs of attribute handlers; a type that supports attributes only needs to implement the functions for one pair. The difference is that one pair takes the name of the attribute as a char*, while the other accepts a PyObject*. Each type can use whichever pair makes more sense for the implementation’s convenience.

getattrfunc tp_getattr; /* char * version */
setattrfunc tp_setattr;
/* ... */
getattrofunc tp_getattro; /* PyObject * version */
setattrofunc tp_setattro;

If accessing attributes of an object is always a simple operation (this will be explained shortly), there are generic implementations which can be used to provide the PyObject* version of the attribute management functions. The actual need for type-specific attribute handlers almost completely disappeared starting with Python 2.2,
though there are many examples which have not been updated to use some of the new generic mechanism that is available.

2.2.3.1. Generic Attribute Management

Most extension types only use simple attributes. So, what makes the attributes simple? There are only a couple of conditions that must be met:

1. The name of the attributes must be known when `PyType_Ready()` is called.
2. No special processing is needed to record that an attribute was looked up or set, nor do actions need to be taken based on the value.

Note that this list does not place any restrictions on the values of the attributes, when the values are computed, or how relevant data is stored.

When `PyType_Ready()` is called, it uses three tables referenced by the type object to create descriptors which are placed in the dictionary of the type object. Each descriptor controls access to one attribute of the instance object. Each of the tables is optional; if all three are `NULL`, instances of the type will only have attributes that are inherited from their base type, and should leave the `tp_getattro` and `tp_setattro` fields `NULL` as well, allowing the base type to handle attributes.

The tables are declared as three fields of the type object:

```
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
```
If `tp_methods` is not `NULL`, it must refer to an array of `PyMethodDef` structures. Each entry in the table is an instance of this structure:

```c
typedef struct PyMethodDef {
    char    *ml_name;   /* method name */
    PyCFunction ml_meth; /* implementation function */
    int     ml_flags;   /* flags */
    char    *ml_doc;    /* docstring */
} PyMethodDef;
```

One entry should be defined for each method provided by the type; no entries are needed for methods inherited from a base type. One additional entry is needed at the end; it is a sentinel that marks the end of the array. The `ml_name` field of the sentinel must be `NULL`.

The second table is used to define attributes which map directly to data stored in the instance. A variety of primitive C types are supported, and access may be read-only or read-write. The structures in the table are defined as:

```c
typedef struct PyMemberDef {
    char    *name;
    int     type;
    int     offset;
    int     flags;
    char    *doc;
} PyMemberDef;
```

For each entry in the table, a descriptor will be constructed and added to the type which will be able to extract a value from the instance structure. The `type` field should contain one of the type codes defined in the `structmember.h` header; the value will be used to determine
how to convert Python values to and from C values. The flags field is used to store flags which control how the attribute can be accessed.

The following flag constants are defined in `structmember.h`; they may be combined using bitwise-OR.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>READONLY</td>
<td>Never writable.</td>
</tr>
<tr>
<td>READ_RESTRICTED</td>
<td>Not readable in restricted mode.</td>
</tr>
<tr>
<td>WRITE_RESTRICTED</td>
<td>Not writable in restricted mode.</td>
</tr>
<tr>
<td>RESTRICTED</td>
<td>Not readable or writable in restricted mode.</td>
</tr>
</tbody>
</table>

An interesting advantage of using the `tp_members` table to build descriptors that are used at runtime is that any attribute defined this way can have an associated doc string simply by providing the text in the table. An application can use the introspection API to retrieve the descriptor from the class object, and get the doc string using its `__doc__` attribute.

As with the `tp_methods` table, a sentinel entry with a name value of `NULL` is required.

2.2.3.2. Type-specific Attribute Management

For simplicity, only the `char*` version will be demonstrated here; the type of the name parameter is the only difference between the `char*` and `PyObject*` flavors of the interface. This example effectively does the same thing as the generic example above, but does not use the generic support added in Python 2.2. It explains how the handler functions are called, so that if you do need to extend their functionality,
you'll understand what needs to be done.

The \texttt{tpgetattr} handler is called when the object requires an attribute look-up. It is called in the same situations where the \texttt{\_\_getattr\_()} method of a class would be called.

Here is an example:

\begin{verbatim}
static PyObject *
newdatatype_getattr(newdatatypeobject *obj, char *name)
{
  if (strcmp(name, "data") == 0)
  {
    return PyInt_FromLong(obj->data);
  }
  PyErr_Format(PyExc_AttributeError,
               "'%.50s' object has no attribute '%%%
               tp->tp_name, name);
  return NULL;
}
\end{verbatim}

The \texttt{tpsetattr} handler is called when the \texttt{\_\_setattr\_()} or \texttt{\_\_delattr\_()} method of a class instance would be called. When an attribute should be deleted, the third parameter will be \texttt{NULL}. Here is an example that simply raises an exception; if this were really all you wanted, the \texttt{tpsetattr} handler should be set to \texttt{NULL}.

\begin{verbatim}
static int
newdatatype_setattr(newdatatypeobject *obj, char *name)
{
  (void)PyErr_Format(PyExc_RuntimeError, "Read-only
return -1;
\end{verbatim}
2.2.4. Object Comparison

```c
richcmpfunc tp_richcompare;
```

The `tp_richcompare` handler is called when comparisons are needed. It is analogous to the *rich comparison methods*, like `__lt__`, and also called by `PyObject_RichCompare()` and `PyObject_RichCompareBool()`.

This function is called with two Python objects and the operator as arguments, where the operator is one of `Py_EQ`, `Py_NE`, `Py_LE`, `Py_GT`, `Py_LT` or `Py_GT`. It should compare the two objects with respect to the specified operator and return `Py_True` or `Py_False` if the comparison is successful, `Py_NotImplemented` to indicate that comparison is not implemented and the other object’s comparison method should be tried, or `NULL` if an exception was set.

Here is a sample implementation, for a datatype that is considered equal if the size of an internal pointer is equal:

```c
static PyObject *
newdatatype_richcmp(PyObject *obj1, PyObject *obj2, {
    PyObject *result;
    int c, size1, size2;

    /* code to make sure that both arguments are of newdatatype omitted */
    size1 = obj1->obj_UnderlyingDatatypePtr->size;
    size2 = obj2->obj_UnderlyingDatatypePtr->size;
```
2.2.5. Abstract Protocol Support

Python supports a variety of abstract ‘protocols;' the specific interfaces provided to use these interfaces are documented in Abstract Objects Layer.

A number of these abstract interfaces were defined early in the development of the Python implementation. In particular, the number, mapping, and sequence protocols have been part of Python since the beginning. Other protocols have been added over time. For protocols which depend on several handler routines from the type implementation, the older protocols have been defined as optional blocks of handlers referenced by the type object. For newer protocols there are additional slots in the main type object, with a flag bit being set to indicate that the slots are present and should be checked by the interpreter. (The flag bit does not indicate that the slot values are non-NULL. The flag may be set to indicate the presence of a slot, but a slot may still be unfilled.)
If you wish your object to be able to act like a number, a sequence, or a mapping object, then you place the address of a structure that implements the C type `PyNumberMethods`, `PySequenceMethods`, or `PyMappingMethods`, respectively. It is up to you to fill in this structure with appropriate values. You can find examples of the use of each of these in the `Objects` directory of the Python source distribution.

```c
static long
newdatatype_hash(newdatatypeobject *obj)
{
    long result;
    result = obj->obj_UnderlyingDatatypePtr->size;
    result = result * 3;
    return result;
}
```

This function is called when an instance of your data type is “called”, for example, if `obj1` is an instance of your data type and the Python script contains `obj1('hello')`, the `tp_call` handler is invoked.

This function takes three arguments:
1. \textit{arg1} is the instance of the data type which is the subject of the call. If the call is \texttt{obj1('hello')}, then \textit{arg1} is \texttt{obj1}.

2. \textit{arg2} is a tuple containing the arguments to the call. You can use \texttt{PyArg_ParseTuple()} to extract the arguments.

3. \textit{arg3} is a dictionary of keyword arguments that were passed. If this is non-\textit{NULL} and you support keyword arguments, use \texttt{PyArg_ParseTupleAndKeywords()} to extract the arguments. If you do not want to support keyword arguments and this is non-\textit{NULL}, raise a \texttt{TypeError} with a message saying that keyword arguments are not supported.

Here is a desultory example of the implementation of the call function.

```c
/* Implement the call function.
 * obj1 is the instance receiving the call.
 * obj2 is a tuple containing the arguments to the call, in this case 3 strings.
 */

static PyObject *
newdatatype_call(newdatatypeobject *obj, PyObject *args)
{
    PyObject *result;
    char *arg1;
    char *arg2;
    char *arg3;

    if (!PyArg_ParseTuple(args, "sss:call", &arg1, &arg2, &arg3))
        return NULL;

            obj->obj_UnderlyingDatatypePtr->size, arg1, arg2, arg3);
    return result;
}
```
These functions provide support for the iterator protocol. Any object which wishes to support iteration over its contents (which may be generated during iteration) must implement the `tp_iter` handler. Objects which are returned by a `tp_iter` handler must implement both the `tp_iter` and `tp_iternext` handlers. Both handlers take exactly one parameter, the instance for which they are being called, and return a new reference. In the case of an error, they should set an exception and return `NULL`.

For an object which represents an iterable collection, the `tp_iter` handler must return an iterator object. The iterator object is responsible for maintaining the state of the iteration. For collections which can support multiple iterators which do not interfere with each other (as lists and tuples do), a new iterator should be created and returned. Objects which can only be iterated over once (usually due to side effects of iteration) should implement this handler by returning a new reference to themselves, and should also implement the `tp_iternext` handler. File objects are an example of such an iterator.

Iterator objects should implement both handlers. The `tp_iter` handler should return a new reference to the iterator (this is the same as the `tp_iter` handler for objects which can only be iterated over destructively). The `tp_iternext` handler should return a new reference to the next object in the iteration if there is one. If the iteration has reached the end, it may return `NULL` without setting an exception or it may set `StopIteration`; avoiding the exception can yield slightly better performance. If an actual error occurs, it should set
an exception and return *NULL*.

### 2.2.6. Weak Reference Support

One of the goals of Python’s weak-reference implementation is to allow any type to participate in the weak reference mechanism without incurring the overhead on those objects which do not benefit by weak referencing (such as numbers).

For an object to be weakly referencable, the extension must include a `PyObject*` field in the instance structure for the use of the weak reference mechanism; it must be initialized to *NULL* by the object's constructor. It must also set the `tp_weaklistoffset` field of the corresponding type object to the offset of the field. For example, the instance type is defined with the following structure:

```c
typedef struct {
    PyObject_HEAD
    PyClassObject *in_class; /* The class object */
    PyObject *in_dict;      /* A dictionary */
    PyObject *in_weakreflist; /* List of weak references */
} PyInstanceObject;
```

The statically-declared type object for instances is defined this way:

```c
PyTypeObject PyInstance_Type = {
    PyVarObject_HEAD_INIT(&PyType_Type, 0)
    0,
    "module.instance",
    /* Lots of stuff omitted for brevity... */
    Py_TPFLAGS_DEFAULT,
};
```
The type constructor is responsible for initializing the weak reference list to `NULL`:

```c
static PyObject *
instance_new() {
    /* Other initialization stuff omitted for brevity */
    self->in_weakreflist = NULL;

    return (PyObject *) self;
}
```

The only further addition is that the destructor needs to call the weak reference manager to clear any weak references. This is only required if the weak reference list is non-`NULL`:

```c
static void
instance_dealloc(PyInstanceObject *inst) {
    /* Allocate temporaries if needed, but do not begin destruction just yet. */

    if (inst->in_weakreflist != NULL)
        PyObject_ClearWeakRefs((PyObject *) inst);

    /* Proceed with object destruction normally. */
}
```
2.2.7. More Suggestions

Remember that you can omit most of these functions, in which case you provide 0 as a value. There are type definitions for each of the functions you must provide. They are in object.h in the Python include directory that comes with the source distribution of Python.

In order to learn how to implement any specific method for your new data type, do the following: Download and unpack the Python source distribution. Go to the Objects directory, then search the C source files for tp_ plus the function you want (for example, tp_richcompare). You will find examples of the function you want to implement.

When you need to verify that an object is an instance of the type you are implementing, use the PyObject_TypeCheck() function. A sample of its use might be something like the following:

```c
if (!PyObject_TypeCheck(some_object, &MyType)) {
    PyErr_SetString(PyExc_TypeError, "arg #1 not a 
    return NULL;
}
```

Footnotes

[1] This is true when we know that the object is a basic type, like a string or a float.

We relied on this in the tp_dealloc handler in this example, because our type doesn't support garbage collection. Even if a type supports garbage collection, there are calls that can be

[2]
made to “untrack” the object from garbage collection, however, these calls are advanced and not covered here.

We now know that the first and last members are strings, so perhaps we could be less careful about decrementing their reference counts, however, we accept instances of string subclasses. Even though deallocating normal strings won’t call back into our objects, we can’t guarantee that deallocating an instance of a string subclass won’t call back into our objects.

Even in the third version, we aren’t guaranteed to avoid cycles. Instances of string subclasses are allowed and string subclasses could allow cycles even if normal strings don’t.
3. Building C and C++ Extensions with distutils

Starting in Python 1.4, Python provides, on Unix, a special make file for building make files for building dynamically-linked extensions and custom interpreters. Starting with Python 2.0, this mechanism (known as related to Makefile.pre.in, and Setup files) is no longer supported. Building custom interpreters was rarely used, and extension modules can be built using distutils.

Building an extension module using distutils requires that distutils is installed on the build machine, which is included in Python 2.x and available separately for Python 1.5. Since distutils also supports creation of binary packages, users don’t necessarily need a compiler and distutils to install the extension.

A distutils package contains a driver script, `setup.py`. This is a plain Python file, which, in the most simple case, could look like this:

```python
from distutils.core import setup, Extension

module1 = Extension('demo',
                     sources = ['demo.c'])

setup (name = 'PackageName',
        version = '1.0',
        description = 'This is a demo package',
        ext_modules = [module1])
```

With this `setup.py`, and a file `demo.c`, running

```
python setup.py build
```
will compile demo.c, and produce an extension module named demo in the build directory. Depending on the system, the module file will end up in a subdirectory build/lib.system, and may have a name like demo.so or demo.pyd.

In the setup.py, all execution is performed by calling the setup function. This takes a variable number of keyword arguments, of which the example above uses only a subset. Specifically, the example specifies meta-information to build packages, and it specifies the contents of the package. Normally, a package will contain of addition modules, like Python source modules, documentation, subpackages, etc. Please refer to the distutils documentation in Distributing Python Modules to learn more about the features of distutils; this section explains building extension modules only.

It is common to pre-compute arguments to setup(), to better structure the driver script. In the example above, the ext_modules argument to setup() is a list of extension modules, each of which is an instance of the Extension. In the example, the instance defines an extension named demo which is build by compiling a single source file, demo.c.

In many cases, building an extension is more complex, since additional preprocessor defines and libraries may be needed. This is demonstrated in the example below.

```python
from distutils.core import setup, Extension

module1 = Extension('demo',
    define_macros = [('MAJOR_VERSION', '1'),
                     ('MINOR_VERSION', '0')],
    include_dirs = ['/usr/local/include'],
)`
In this example, `setup()` is called with additional meta-information, which is recommended when distribution packages have to be built. For the extension itself, it specifies preprocessor defines, include directories, library directories, and libraries. Depending on the compiler, `distutils` passes this information in different ways to the compiler. For example, on Unix, this may result in the compilation commands

```
gcc -DNDEBUG -g -O3 -Wall -Wstrict-prototypes -fPIC
gcc -shared build/temp.linux-i686-2.2/demo.o -L/usr/
```

These lines are for demonstration purposes only; `distutils` users should trust that `distutils` gets the invocations right.
3.1. Distributing your extension modules

When an extension has been successfully build, there are three ways to use it.

End-users will typically want to install the module, they do so by running

```
python setup.py install
```

Module maintainers should produce source packages; to do so, they run

```
python setup.py sdist
```

In some cases, additional files need to be included in a source distribution; this is done through a `MANIFEST.in` file; see the distutils documentation for details.

If the source distribution has been build successfully, maintainers can also create binary distributions. Depending on the platform, one of the following commands can be used to do so.

```
python setup.py bdist_wininst
python setup.py bdist_rpm
python setup.py bdist_dumb
```
4. Building C and C++ Extensions on Windows

This chapter briefly explains how to create a Windows extension module for Python using Microsoft Visual C++, and follows with more detailed background information on how it works. The explanatory material is useful for both the Windows programmer learning to build Python extensions and the Unix programmer interested in producing software which can be successfully built on both Unix and Windows.

Module authors are encouraged to use the distutils approach for building extension modules, instead of the one described in this section. You will still need the C compiler that was used to build Python; typically Microsoft Visual C++.

**Note:** This chapter mentions a number of filenames that include an encoded Python version number. These filenames are represented with the version number shown as XY; in practice, 'X' will be the major version number and 'Y' will be the minor version number of the Python release you’re working with. For example, if you are using Python 2.2.1, XY will actually be 22.
4.1. A Cookbook Approach

There are two approaches to building extension modules on Windows, just as there are on Unix: use the distutils package to control the build process, or do things manually. The distutils approach works well for most extensions; documentation on using distutils to build and package extension modules is available in *Distributing Python Modules*. This section describes the manual approach to building Python extensions written in C or C++.

To build extensions using these instructions, you need to have a copy of the Python sources of the same version as your installed Python. You will need Microsoft Visual C++ “Developer Studio”; project files are supplied for VC++ version 7.1, but you can use older versions of VC++. Notice that you should use the same version of VC++ that was used to build Python itself. The example files described here are distributed with the Python sources in the `PC\example_nt` directory.

1. **Copy the example files** — The `example_nt` directory is a subdirectory of the `PC` directory, in order to keep all the PC-specific files under the same directory in the source distribution. However, the `example_nt` directory can’t actually be used from this location. You first need to copy or move it up one level, so that `example_nt` is a sibling of the `PC` and `Include` directories. Do all your work from within this new location.

2. **Open the project** — From VC++, use the *File ▶ Open Solution* dialog (not *File ▶ Open!*). Navigate to and select the file `example.sln`, in the *copy* of the `example_nt` directory you made above. Click Open.
3. **Build the example DLL** — In order to check that everything is set up right, try building:

4. Select a configuration. This step is optional. Choose *Build → Configuration Manager → Active Solution Configuration* and select either *Release* or *Debug*. If you skip this step, VC++ will use the Debug configuration by default.

5. Build the DLL. Choose *Build → Build Solution*. This creates all intermediate and result files in a subdirectory called either *Debug* or *Release*, depending on which configuration you selected in the preceding step.

6. **Testing the debug-mode DLL** — Once the Debug build has succeeded, bring up a DOS box, and change to the `example_nt\Debug` directory. You should now be able to repeat the following session (C> is the DOS prompt, >>> is the Python prompt; note that build information and various debug output from Python may not match this screen dump exactly):

```plaintext
C>..\..\PCbuild\python_d
Adding parser accelerators ...
Done.
Python 2.2 (#28, Dec 19 2001, 23:26:37) [MSC 32 bit (Intel)] on win32
Type "copyright", "credits" or "license" for more information.
>>> import example
[4897 refs]
>>> example.foo()
Hello, world
[4903 refs]
>>>
```

Congratulations! You've successfully built your first Python
extension module.

7. **Creating your own project** — Choose a name and create a directory for it. Copy your C sources into it. Note that the module source file name does not necessarily have to match the module name, but the name of the initialization function should match the module name — you can only import a module spam if its initialization function is called `initspam()`, and it should call `Py_InitModule()` with the string "spam" as its first argument (use the minimal example.c in this directory as a guide). By convention, it lives in a file called spam.c or spammodule.c. The output file should be called spam.pyd (in Release mode) or spam_d.pyd (in Debug mode). The extension .pyd was chosen to avoid confusion with a system library spam.dll to which your module could be a Python interface.

Now your options are:

8. Copy example.sln and example.vcproj, rename them to spam.*, and edit them by hand, or

9. Create a brand new project; instructions are below.

   In either case, copy example_nt\example.def to spam\spam.def, and edit the new spam.def so its second line contains the string ‘initspam’. If you created a new project yourself, add the file spam.def to the project now. (This is an annoying little file with only two lines. An alternative approach is to forget about the .def file, and add the option /export:initspam somewhere to the Link settings, by manually editing the setting in Project Properties dialog).
10. **Creating a brand new project** — Use the *File ▶ New ▶ Project* dialog to create a new Project Workspace. Select *Visual C++ Projects/Win32/ Win32 Project*, enter the name *(spam)*, and make sure the Location is set to parent of the spam directory you have created (which should be a direct subdirectory of the Python build tree, a sibling of `Include` and PC). Select Win32 as the platform (in my version, this is the only choice). Make sure the Create new workspace radio button is selected. Click OK.

You should now create the file `spam.def` as instructed in the previous section. Add the source files to the project, using *Project ▶ Add Existing Item*. Set the pattern to `*.*` and select both `spam.c` and `spam.def` and click OK. (Inserting them one by one is fine too.)

Now open the *Project ▶ spam properties* dialog. You only need to change a few settings. Make sure *All Configurations* is selected from the *Settings for:* dropdown list. Select the C/C++ tab. Choose the General category in the popup menu at the top. Type the following text in the entry box labeled *Additional Include Directories*:

```plaintext
..\include, ..\PC
```

Then, choose the General category in the Linker tab, and enter

```plaintext
..\PCbuild
```

in the text box labelled *Additional library Directories.*

Now you need to add some mode-specific settings:

Select *Release* in the *Configuration* dropdown list. Choose the
Link tab, choose the Input category, and append pythonXY.lib to the list in the Additional Dependencies box.

Select Debug in the Configuration dropdown list, and append pythonXY_d.lib to the list in the Additional Dependencies box. Then click the C/C++ tab, select Code Generation, and select Multi-threaded Debug DLL from the Runtime library dropdown list.

Select Release again from the Configuration dropdown list. Select Multi-threaded DLL from the Runtime library dropdown list.

If your module creates a new type, you may have trouble with this line:

```c
PyVarObject_HEAD_INIT(&PyType_Type, 0)
```

Static type object initializers in extension modules may cause compiles to fail with an error message like “initializer not a constant”. This shows up when building DLL under MSVC. Change it to:

```c
PyVarObject_HEAD_INIT(NULL, 0)
```

and add the following to the module initialization function:

```c
if (PyType_Ready(&MyObject_Type) < 0)
    return NULL;
```
4.2. Differences Between Unix and Windows

Unix and Windows use completely different paradigms for run-time loading of code. Before you try to build a module that can be dynamically loaded, be aware of how your system works.

In Unix, a shared object (.so) file contains code to be used by the program, and also the names of functions and data that it expects to find in the program. When the file is joined to the program, all references to those functions and data in the file's code are changed to point to the actual locations in the program where the functions and data are placed in memory. This is basically a link operation.

In Windows, a dynamic-link library (.dll) file has no dangling references. Instead, an access to functions or data goes through a lookup table. So the DLL code does not have to be fixed up at runtime to refer to the program's memory; instead, the code already uses the DLL's lookup table, and the lookup table is modified at runtime to point to the functions and data.

In Unix, there is only one type of library file (.a) which contains code from several object files (.o). During the link step to create a shared object file (.so), the linker may find that it doesn’t know where an identifier is defined. The linker will look for it in the object files in the libraries; if it finds it, it will include all the code from that object file.

In Windows, there are two types of library, a static library and an import library (both called .lib). A static library is like a Unix .a file; it contains code to be included as necessary. An import library is basically used only to reassure the linker that a certain identifier is
legal, and will be present in the program when the DLL is loaded. So the linker uses the information from the import library to build the lookup table for using identifiers that are not included in the DLL. When an application or a DLL is linked, an import library may be generated, which will need to be used for all future DLLs that depend on the symbols in the application or DLL.

Suppose you are building two dynamic-load modules, B and C, which should share another block of code A. On Unix, you would not pass A.a to the linker for B.so and C.so; that would cause it to be included twice, so that B and C would each have their own copy. In Windows, building A.dll will also build A.lib. You do pass A.lib to the linker for B and C. A.lib does not contain code; it just contains information which will be used at runtime to access A’s code.

In Windows, using an import library is sort of like using import spam; it gives you access to spam’s names, but does not create a separate copy. On Unix, linking with a library is more like from spam import *; it does create a separate copy.
4.3. Using DLLs in Practice

Windows Python is built in Microsoft Visual C++; using other compilers may or may not work (though Borland seems to). The rest of this section is MSVC++ specific.

When creating DLLs in Windows, you must pass \texttt{pythonXY.lib} to the linker. To build two DLLs, spam and ni (which uses C functions found in spam), you could use these commands:

\begin{verbatim}
cl /LD /I/python/include spam.c ../libs/pythonXY.lib
cl /LD /I/python/include ni.c spam.lib ../libs/pythonXY.lib
\end{verbatim}

The first command created three files: \texttt{spam.obj}, \texttt{spam.dll} and \texttt{spam.lib}. Spam.dll does not contain any Python functions (such as \texttt{PyArg_ParseTuple()}), but it does know how to find the Python code thanks to \texttt{pythonXY.lib}.

The second command created \texttt{ni.dll} (and .obj and .lib), which knows how to find the necessary functions from spam, and also from the Python executable.

Not every identifier is exported to the lookup table. If you want any other modules (including Python) to be able to see your identifiers, you have to say \texttt{\_declspec(dllexport)}, as in \texttt{void \_declspec(dllexport) initspam(void)} or \texttt{PyObject \_declspec(dllexport) *NiGetSpamData(void)}.

Developer Studio will throw in a lot of import libraries that you do not really need, adding about 100K to your executable. To get rid of them, use the Project Settings dialog, Link tab, to specify \textit{ignore default
libraries. Add the correct `msvcrtnn.lib` to the list of libraries.
5. Embedding Python in Another Application

The previous chapters discussed how to extend Python, that is, how to extend the functionality of Python by attaching a library of C functions to it. It is also possible to do it the other way around: enrich your C/C++ application by embedding Python in it. Embedding provides your application with the ability to implement some of the functionality of your application in Python rather than C or C++. This can be used for many purposes; one example would be to allow users to tailor the application to their needs by writing some scripts in Python. You can also use it yourself if some of the functionality can be written in Python more easily.

Embedding Python is similar to extending it, but not quite. The difference is that when you extend Python, the main program of the application is still the Python interpreter, while if you embed Python, the main program may have nothing to do with Python — instead, some parts of the application occasionally call the Python interpreter to run some Python code.

So if you are embedding Python, you are providing your own main program. One of the things this main program has to do is initialize the Python interpreter. At the very least, you have to call the function `Py_Initialize()`. There are optional calls to pass command line arguments to Python. Then later you can call the interpreter from any part of the application.

There are several different ways to call the interpreter: you can pass a string containing Python statements to `PyRun_SimpleString()`, or
you can pass a stdio file pointer and a file name (for identification in error messages only) to `PyRun_SimpleFile()`. You can also call the lower-level operations described in the previous chapters to construct and use Python objects.

**See also:**

*Python/C API Reference Manual*

The details of Python’s C interface are given in this manual. A great deal of necessary information can be found here.
5.1. Very High Level Embedding

The simplest form of embedding Python is the use of the very high level interface. This interface is intended to execute a Python script without needing to interact with the application directly. This can for example be used to perform some operation on a file.

```c
#include <Python.h>

int main(int argc, char *argv[]) {
    Py_SetProgramName(argv[0]); /* optional but recommended */
    Py_Initialize();
    PyRun_SimpleString("from time import time,ctime
    'print('Today is', ctime(time()))
    Py_Finalize();
    return 0;
}
```

The `Py_SetProgramName()` function should be called before `Py_Initialize()` to inform the interpreter about paths to Python run-time libraries. Next, the Python interpreter is initialized with `Py_Initialize()`, followed by the execution of a hard-coded Python script that prints the date and time. Afterwards, the `Py_Finalize()` call shuts the interpreter down, followed by the end of the program. In a real program, you may want to get the Python script from another source, perhaps a text-editor routine, a file, or a database. Getting the Python code from a file can better be done by using the `PyRun_SimpleFile()` function, which saves you the trouble of allocating memory space and loading the file contents.
5.2. Beyond Very High Level Embedding: An overview

The high level interface gives you the ability to execute arbitrary pieces of Python code from your application, but exchanging data values is quite cumbersome to say the least. If you want that, you should use lower level calls. At the cost of having to write more C code, you can achieve almost anything.

It should be noted that extending Python and embedding Python is quite the same activity, despite the different intent. Most topics discussed in the previous chapters are still valid. To show this, consider what the extension code from Python to C really does:

1. Convert data values from Python to C,
2. Perform a function call to a C routine using the converted values, and
3. Convert the data values from the call from C to Python.

When embedding Python, the interface code does:

1. Convert data values from C to Python,
2. Perform a function call to a Python interface routine using the converted values, and
3. Convert the data values from the call from Python to C.

As you can see, the data conversion steps are simply swapped to accommodate the different direction of the cross-language transfer. The only difference is the routine that you call between both data conversions. When extending, you call a C routine, when embedding, you call a Python routine.

This chapter will not discuss how to convert data from Python to C and
vice versa. Also, proper use of references and dealing with errors is assumed to be understood. Since these aspects do not differ from extending the interpreter, you can refer to earlier chapters for the required information.
5.3. Pure Embedding

The first program aims to execute a function in a Python script. Like in the section about the very high level interface, the Python interpreter does not directly interact with the application (but that will change in the next section).

The code to run a function defined in a Python script is:

```c
#include <Python.h>

int main(int argc, char *argv[])
{
    PyObject *pName, *pModule, *pDict, *pFunc;
    PyObject *pArgs, *pValue;
    int i;

    if (argc < 3) {
        fprintf(stderr,"Usage: call pythonfile funcname [args]
            return 1;
    }

    Py_Initialize();
    pName = PyUnicode_FromString(argv[1]);
    /* Error checking of pName left out */

    pModule = PyImport_Import(pName);
    Py_DECREF(pName);

    if (pModule != NULL) {
        pFunc = PyObject_GetAttrString(pModule, argv[1]);
        /* pFunc is a new reference */

        if (pFunc && PyCallable_Check(pFunc)) {
```
pArgs = PyTuple_New(argc - 3);
for (i = 0; i < argc - 3; ++i) {
    pValue = PyLong_FromLong(atoi(argv[i]);
    if (!pValue) {
        Py_DECREF(pArgs);
        Py_DECREF(pModule);
        fprintf(stderr, "Cannot convert return 1;
    }
    /* pValue reference stolen here: */
    PyTuple_SetItem(pArgs, i, pValue);
}
pValue = PyObject_CallObject(pFunc, pArgs);
Py_DECREF(pArgs);
if (pValue != NULL) {
    printf("Result of call: %ld\n", PyLong_AsLong(pValue);
    Py_DECREF(pValue);
}
else {
    Py_DECREF(pFunc);
    Py_DECREF(pModule);
    PyErr_Print();
    fprintf(stderr,"Call failed\n";
    return 1;
}
else {
    if (PyErr_Occurred())
        PyErr_Print();
    fprintf(stderr, "Cannot find function \";
}
Py_XDECREF(pFunc);
Py_DECREF(pModule);
}
else {
    PyErr_Print();
    fprintf(stderr, "Failed to load "%s"\n", a
This code loads a Python script using `argv[1]`, and calls the function named in `argv[2]`. Its integer arguments are the other values of the `argv` array. If you compile and link this program (let's call the finished executable `call`), and use it to execute a Python script, such as:

```python
def multiply(a, b):
    print("Will compute", a, "times", b)
    c = 0
    for i in range(0, a):
        c = c + b
    return c
```

then the result should be:

```
$ call multiply multiply 3 2
Will compute 3 times 2
Result of call: 6
```

Although the program is quite large for its functionality, most of the code is for data conversion between Python and C, and for error reporting. The interesting part with respect to embedding Python starts with

```c
Py_Initialize();
pName = PyUnicode_FromString(argv[1]);
/* Error checking of pName left out */
pModule = PyImport_Import(pName);
```
After initializing the interpreter, the script is loaded using `PyImport_Import()`. This routine needs a Python string as its argument, which is constructed using the `PyUnicode_FromString()` data conversion routine.

```c
pFunc = PyObject_GetAttrString(pModule, argv[2]); /* pFunc is a new reference */

if (pFunc && PyCallable_Check(pFunc)) {
    ...
}
Py_XDECREF(pFunc);
```

Once the script is loaded, the name we’re looking for is retrieved using `PyObject_GetAttrString()`. If the name exists, and the object returned is callable, you can safely assume that it is a function. The program then proceeds by constructing a tuple of arguments as normal. The call to the Python function is then made with:

```c
pValue = PyObject_CallObject(pFunc, pArgs);
```

Upon return of the function, `pValue` is either `NULL` or it contains a reference to the return value of the function. Be sure to release the reference after examining the value.
5.4. Extending Embedded Python

Until now, the embedded Python interpreter had no access to functionality from the application itself. The Python API allows this by extending the embedded interpreter. That is, the embedded interpreter gets extended with routines provided by the application. While it sounds complex, it is not so bad. Simply forget for a while that the application starts the Python interpreter. Instead, consider the application to be a set of subroutines, and write some glue code that gives Python access to those routines, just like you would write a normal Python extension. For example:

```c
static int numargs=0;

/* Return the number of arguments of the application command line */
static PyObject*
emb_numargs(PyObject *self, PyObject *args)
{
    if(!PyArg_ParseTuple(args, ":numargs"))
        return NULL;
    return PyLong_FromLong(numargs);
}

static PyMethodDef EmbMethods[] = {
    {"numargs", emb_numargs, METH_VARARGS,
     "Return the number of arguments received by the process.
     {NULL, NULL, 0, NULL}
    },

    static PyModuleDef EmbModule = {
        PyModuleDef_HEAD_INIT, "emb", NULL, -1, EmbMethods,
        NULL, NULL, NULL, NULL
    };
```
```c
static PyObject*
PyInit_emb(void) {
    return PyModule_Create(&EmbModule);
}
```

Insert the above code just above the `main()` function. Also, insert the following two statements before the call to `Py_Initialize()`:

```c
numargs = argc;
PyImport_AppendInittab("emb", &PyInit_emb);
```

These two lines initialize the `numargs` variable, and make the `emb.numargs()` function accessible to the embedded Python interpreter. With these extensions, the Python script can do things like:

```python
import emb
print("Number of arguments", emb.numargs())
```

In a real application, the methods will expose an API of the application to Python.
5.5. Embedding Python in C++

It is also possible to embed Python in a C++ program; precisely how this is done will depend on the details of the C++ system used; in general you will need to write the main program in C++, and use the C++ compiler to compile and link your program. There is no need to recompile Python itself using C++. 
5.6. Compiling and Linking under Unix-like systems

It is not necessarily trivial to find the right flags to pass to your compiler (and linker) in order to embed the Python interpreter into your application, particularly because Python needs to load library modules implemented as C dynamic extensions (.so files) linked against it.

To find out the required compiler and linker flags, you can execute the `pythonX.Y-config` script which is generated as part of the installation process (a `python3-config` script may also be available). This script has several options, of which the following will be directly useful to you:

- `pythonX.Y-config --cflags` will give you the recommended flags when compiling:

  ```bash
  /opt/bin/python3.3-config --cflags
  -I/opt/include/python3.3m -I/opt/include/python3
  ```

- `pythonX.Y-config --ldflags` will give you the recommended flags when linking:

  ```bash
  /opt/bin/python3.3-config --ldflags
  -L/opt/lib/python3.3/config-3.3m -lpthread -ldl
  ```

**Note:** To avoid confusion between several Python installations (and especially between the system Python and your own compiled Python), it is recommended that you use the absolute path to `pythonX.Y-config`, as in the above example.
If this procedure doesn’t work for you (it is not guaranteed to work for all Unix-like platforms; however, we welcome bug reports) you will have to read your system’s documentation about dynamic linking and/or examine Python’s Makefile (use sysconfig.get_makefile_filename() to find its location) and compilation options. In this case, the sysconfig module is a useful tool to programmatically extract the configuration values that you will want to combine together. For example:

```python
>>> import sysconfig

>>> sysconfig.get_config_var('LIBS')
'-lpthread -ldl -lutil'

>>> sysconfig.get_config_var('LINKFORSHARED')
'-Xlinker -export-dynamic'
```
Introduction

The Application Programmer’s Interface to Python gives C and C++ programmers access to the Python interpreter at a variety of levels. The API is equally usable from C++, but for brevity it is generally referred to as the Python/C API. There are two fundamentally different reasons for using the Python/C API. The first reason is to write extension modules for specific purposes; these are C modules that extend the Python interpreter. This is probably the most common use. The second reason is to use Python as a component in a larger application; this technique is generally referred to as embedding Python in an application.

Writing an extension module is a relatively well-understood process, where a “cookbook” approach works well. There are several tools that automate the process to some extent. While people have embedded Python in other applications since its early existence, the process of embedding Python is less straightforward than writing an extension.

Many API functions are useful independent of whether you’re embedding or extending Python; moreover, most applications that embed Python will need to provide a custom extension as well, so it’s probably a good idea to become familiar with writing an extension before attempting to embed Python in a real application.
Include Files

All function, type and macro definitions needed to use the Python/C API are included in your code by the following line:

```c
#include "Python.h"
```

This implies inclusion of the following standard headers: `<stdio.h>`, `<string.h>`, `<errno.h>`, `<limits.h>`, `<assert.h>` and `<stdlib.h>` (if available).

**Note:** Since Python may define some pre-processor definitions which affect the standard headers on some systems, you must include `Python.h` before any standard headers are included.

All user visible names defined by `Python.h` (except those defined by the included standard headers) have one of the prefixes `Py` or `_Py`. Names beginning with `_Py` are for internal use by the Python implementation and should not be used by extension writers. Structure member names do not have a reserved prefix.

**Important:** user code should never define names that begin with `Py` or `_Py`. This confuses the reader, and jeopardizes the portability of the user code to future Python versions, which may define additional names beginning with one of these prefixes.

The header files are typically installed with Python. On Unix, these are located in the directories `prefix/include/pythonversion/` and `exec_prefix/include/pythonversion/`, where `prefix` and `exec_prefix` are defined by the corresponding parameters to Python’s `configure` script and `version` is `sys.version[:3]`. On
Windows, the headers are installed in `prefix/include`, where `prefix` is the installation directory specified to the installer.

To include the headers, place both directories (if different) on your compiler’s search path for includes. Do *not* place the parent directories on the search path and then use `#include <pythonX.Y/Python.h>`; this will break on multi-platform builds since the platform independent headers under `prefix` include the platform specific headers from `exec_prefix`.

C++ users should note that though the API is defined entirely using C, the header files do properly declare the entry points to be `extern "C"`, so there is no need to do anything special to use the API from C++.
Objects, Types and Reference Counts

Most Python/C API functions have one or more arguments as well as a return value of type `PyObject*`. This type is a pointer to an opaque data type representing an arbitrary Python object. Since all Python object types are treated the same way by the Python language in most situations (e.g., assignments, scope rules, and argument passing), it is only fitting that they should be represented by a single C type. Almost all Python objects live on the heap: you never declare an automatic or static variable of type `PyObject`, only pointer variables of type `PyObject*` can be declared. The sole exception are the type objects; since these must never be deallocated, they are typically static `PyTypeObject` objects.

All Python objects (even Python integers) have a `type` and a `reference count`. An object's type determines what kind of object it is (e.g., an integer, a list, or a user-defined function; there are many more as explained in *The standard type hierarchy*). For each of the well-known types there is a macro to check whether an object is of that type; for instance, `PyList_Check(a)` is true if (and only if) the object pointed to by `a` is a Python list.

Reference Counts

The reference count is important because today's computers have a finite (and often severely limited) memory size; it counts how many different places there are that have a reference to an object. Such a place could be another object, or a global (or static) C variable, or a local variable in some C function. When an object's reference count becomes zero, the object is deallocated. If it contains references to other objects, their reference count is decremented. Those other
objects may be deallocated in turn, if this decrement makes their reference count become zero, and so on. (There's an obvious problem with objects that reference each other here; for now, the solution is “don’t do that.”)

Reference counts are always manipulated explicitly. The normal way is to use the macro \texttt{Py\_INCREFF()} to increment an object’s reference count by one, and \texttt{Py\_DECLRF()} to decrement it by one. The \texttt{Py\_DECLRF()} macro is considerably more complex than the incref one, since it must check whether the reference count becomes zero and then cause the object’s deallocator to be called. The deallocator is a function pointer contained in the object’s type structure. The type-specific deallocator takes care of decrementing the reference counts for other objects contained in the object if this is a compound object type, such as a list, as well as performing any additional finalization that’s needed. There's no chance that the reference count can overflow; at least as many bits are used to hold the reference count as there are distinct memory locations in virtual memory (assuming \texttt{sizeof(Py\_ssize\_t)} \texttt{\geq sizeof(void*)}). Thus, the reference count increment is a simple operation.

It is not necessary to increment an object’s reference count for every local variable that contains a pointer to an object. In theory, the object’s reference count goes up by one when the variable is made to point to it and it goes down by one when the variable goes out of scope. However, these two cancel each other out, so at the end the reference count hasn’t changed. The only real reason to use the reference count is to prevent the object from being deallocated as long as our variable is pointing to it. If we know that there is at least one other reference to the object that lives at least as long as our variable, there is no need to increment the reference count temporarily. An important situation where this arises is in objects that are passed as
arguments to C functions in an extension module that are called from Python; the call mechanism guarantees to hold a reference to every argument for the duration of the call.

However, a common pitfall is to extract an object from a list and hold on to it for a while without incrementing its reference count. Some other operation might conceivably remove the object from the list, decrementing its reference count and possible deallocating it. The real danger is that innocent-looking operations may invoke arbitrary Python code which could do this; there is a code path which allows control to flow back to the user from a `Py_DECREF()`, so almost any operation is potentially dangerous.

A safe approach is to always use the generic operations (functions whose name begins with `PyObject_`, `PyNumber_`, `PySequence_` or `PyMapping_`). These operations always increment the reference count of the object they return. This leaves the caller with the responsibility to call `Py_DECREF()` when they are done with the result; this soon becomes second nature.

Reference Count Details

The reference count behavior of functions in the Python/C API is best explained in terms of **ownership of references**. Ownership pertains to references, never to objects (objects are not owned: they are always shared). “Owning a reference” means being responsible for calling `Py_DECREF` on it when the reference is no longer needed. Ownership can also be transferred, meaning that the code that receives ownership of the reference then becomes responsible for eventually decref’ing it by calling `Py_DECREF()` or `Py_XDECREF()` when it’s no longer needed—or passing on this responsibility (usually to its caller). When a function passes ownership of a reference on to its caller, the
caller is said to receive a new reference. When no ownership is transferred, the caller is said to borrow the reference. Nothing needs to be done for a borrowed reference.

Conversely, when a calling function passes in a reference to an object, there are two possibilities: the function steals a reference to the object, or it does not. Stealing a reference means that when you pass a reference to a function, that function assumes that it now owns that reference, and you are not responsible for it any longer.

Few functions steal references; the two notable exceptions are PyList_SetItem() and PyTuple_SetItem(), which steal a reference to the item (but not to the tuple or list into which the item is put!). These functions were designed to steal a reference because of a common idiom for populating a tuple or list with newly created objects; for example, the code to create the tuple (1, 2, "three") could look like this (forgetting about error handling for the moment; a better way to code this is shown below):

```python
PyObject *t;
t = PyTuple_New(3);
PyTuple_SetItem(t, 0, PyLong_FromLong(1L));
PyTuple_SetItem(t, 1, PyLong_FromLong(2L));
PyTuple_SetItem(t, 2, PyUnicode_FromString("three"))
```

Here, PyLong_FromLong() returns a new reference which is immediately stolen by PyTuple_SetItem(). When you want to keep using an object although the reference to it will be stolen, use Py_INCREF() to grab another reference before calling the reference-stealing function.

Incidentally, PyTuple_SetItem() is the only way to set tuple items;
PySequence_SetItem() and PyObject_SetItem() refuse to do this since tuples are an immutable data type. You should only use PyTuple_SetItem() for tuples that you are creating yourself.

Equivalent code for populating a list can be written using PyList_New() and PyList_SetItem().

However, in practice, you will rarely use these ways of creating and populating a tuple or list. There's a generic function, Py_BuildValue(), that can create most common objects from C values, directed by a format string. For example, the above two blocks of code could be replaced by the following (which also takes care of the error checking):

```c
PyObject *tuple, *list;

tuple = Py_BuildValue("(iis)", 1, 2, "three");
list = Py_BuildValue("[iis]", 1, 2, "three");
```

It is much more common to use PyObject_SetItem() and friends with items whose references you are only borrowing, like arguments that were passed in to the function you are writing. In that case, their behaviour regarding reference counts is much saner, since you don't have to increment a reference count so you can give a reference away (“have it be stolen”). For example, this function sets all items of a list (actually, any mutable sequence) to a given item:

```c
int set_all(PyObject *target, PyObject *item)
{
    Py_ssize_t i, n;

    n = PyObject_Length(target);
    if (n < 0)
The situation is slightly different for function return values. While passing a reference to most functions does not change your ownership responsibilities for that reference, many functions that return a reference to an object give you ownership of the reference. The reason is simple: in many cases, the returned object is created on the fly, and the reference you get is the only reference to the object. Therefore, the generic functions that return object references, like `PyObject_GetItem()` and `PySequence_GetItem()`, always return a new reference (the caller becomes the owner of the reference).

It is important to realize that whether you own a reference returned by a function depends on which function you call only — the plumage (the type of the object passed as an argument to the function) doesn’t enter into it! Thus, if you extract an item from a list using `PyList_GetItem()`, you don’t own the reference — but if you obtain the same item from the same list using `PySequence_GetItem()` (which happens to take exactly the same arguments), you do own a reference to the returned object.
Here is an example of how you could write a function that computes the sum of the items in a list of integers; once using `PyList_GetItem()`, and once using `PySequence_GetItem()`.

```c
long sum_list(PyObject *list)
{
    Py_ssize_t i, n;
    long total = 0, value;
    PyObject *item;

    n = PyList_Size(list);
    if (n < 0)
        return -1; /* Not a list */
    for (i = 0; i < n; i++) {
        item = PyList_GetItem(list, i); /* Can't fail */
        if (!PyLong_Check(item)) continue; /* Skip non-integers */
        value = PyLong_AsLong(item);
        if (value == -1 && PyErr_Occurred())
            /* Integer too big to fit in a C long, bail out */
            return -1;
        total += value;
    }
    return total;
}
```

```c
long sum_sequence(PyObject *sequence)
{
    Py_ssize_t i, n;
    long total = 0, value;
    PyObject *item;
    n = PySequence_Length(sequence);
    if (n < 0)
        return -1; /* Has no length */
    ...  
}
```
for (i = 0; i < n; i++) {
    item = PySequence_GetItem(sequence, i);
    if (item == NULL)
        return -1; /* Not a sequence, or other failure */
    if (PyLong_Check(item)) {
        value = PyLong_AsLong(item);
        Py_XDECREF(item);
        if (value == -1 && PyErr_Occurred())
            /* Integer too big to fit in a C long */
            return -1;
        total += value;
    }
    else {
        Py_XDECREF(item); /* Discard reference ownership */
    }
}
return total;

Types

There are few other data types that play a significant role in the Python/C API; most are simple C types such as int, long, double and char*. A few structure types are used to describe static tables used to list the functions exported by a module or the data attributes of a new object type, and another is used to describe the value of a complex number. These will be discussed together with the functions that use them.
Exceptions

The Python programmer only needs to deal with exceptions if specific error handling is required; unhandled exceptions are automatically propagated to the caller, then to the caller’s caller, and so on, until they reach the top-level interpreter, where they are reported to the user accompanied by a stack traceback.

For C programmers, however, error checking always has to be explicit. All functions in the Python/C API can raise exceptions, unless an explicit claim is made otherwise in a function’s documentation. In general, when a function encounters an error, it sets an exception, discards any object references that it owns, and returns an error indicator. If not documented otherwise, this indicator is either `NULL` or `-1`, depending on the function’s return type. A few functions return a Boolean true/false result, with false indicating an error. Very few functions return no explicit error indicator or have an ambiguous return value, and require explicit testing for errors with `PyErr_Occurred()`. These exceptions are always explicitly documented.

Exception state is maintained in per-thread storage (this is equivalent to using global storage in an unthreaded application). A thread can be in one of two states: an exception has occurred, or not. The function `PyErr_Occurred()` can be used to check for this: it returns a borrowed reference to the exception type object when an exception has occurred, and `NULL` otherwise. There are a number of functions to set the exception state: `PyErr_SetString()` is the most common (though not the most general) function to set the exception state, and `PyErr_Clear()` clears the exception state.

The full exception state consists of three objects (all of which can be
**NULL): the exception type, the corresponding exception value, and the traceback. These have the same meanings as the Python result of `sys.exc_info()`; however, they are not the same: the Python objects represent the last exception being handled by a Python `try ... except` statement, while the C level exception state only exists while an exception is being passed on between C functions until it reaches the Python bytecode interpreter’s main loop, which takes care of transferring it to `sys.exc_info()` and friends.

Note that starting with Python 1.5, the preferred, thread-safe way to access the exception state from Python code is to call the function `sys.exc_info()`, which returns the per-thread exception state for Python code. Also, the semantics of both ways to access the exception state have changed so that a function which catches an exception will save and restore its thread's exception state so as to preserve the exception state of its caller. This prevents common bugs in exception handling code caused by an innocent-looking function overwriting the exception being handled; it also reduces the often unwanted lifetime extension for objects that are referenced by the stack frames in the traceback.

As a general principle, a function that calls another function to perform some task should check whether the called function raised an exception, and if so, pass the exception state on to its caller. It should discard any object references that it owns, and return an error indicator, but it should *not* set another exception — that would overwrite the exception that was just raised, and lose important information about the exact cause of the error.

A simple example of detecting exceptions and passing them on is shown in the `sum_sequence()` example above. It so happens that this example doesn’t need to clean up any owned references when it
detected an error. The following example function shows some error cleanup. First, to remind you why you like Python, we show the equivalent Python code:

```python
def incr_item(dict, key):
    
    try:
        item = dict[key]
    except KeyError:
        item = 0
    dict[key] = item + 1
```

Here is the corresponding C code, in all its glory:

```c
int incr_item(PyObject *dict, PyObject *key)
{
    /* Objects all initialized to NULL for Py_XDECREF */
    PyObject *item = NULL, *const_one = NULL, *incremented_item;
    int rv = -1; /* Return value initialized to -1 (failure) */

    item = PyObject_GetItem(dict, key);
    if (item == NULL) {
        /* Handle KeyError only: */
        if (!PyErr_ExceptionMatches(PyExc_KeyError))
            goto error;

        /* Clear the error and use zero: */
        PyErr_Clear();
        item = PyLong_FromLong(0L);
        if (item == NULL)
            goto error;
    }

    const_one = PyLong_FromLong(1L);
    if (const_one == NULL)
        goto error;
```
incremented_item = PyNumber_Add(item, const_one)
if (incremented_item == NULL)
    goto error;

if (PyObject_SetItem(dict, key, incremented_item)
    goto error;
rv = 0; /* Success */
/* Continue with cleanup code */

error:
    /* Cleanup code, shared by success and failure paths */
/* Use Py_XDECREF() to ignore NULL references */
    Py_XDECREF(item);
    Py_XDECREF(const_one);
    Py_XDECREF(incremented_item);

    return rv; /* -1 for error, 0 for success */
}

This example represents an endorsed use of the goto statement in C!
It illustrates the use of PyErr_ExceptionMatches() and PyErr_Clear() to handle specific exceptions, and the use of Py_XDECREF() to dispose of owned references that may be NULL (note the 'X' in the name; Py_DECREF() would crash when confronted with a NULL reference). It is important that the variables used to hold owned references are initialized to NULL for this to work; likewise, the proposed return value is initialized to -1 (failure) and only set to success after the final call made is successful.
Embedding Python

The one important task that only embedders (as opposed to extension writers) of the Python interpreter have to worry about is the initialization, and possibly the finalization, of the Python interpreter. Most functionality of the interpreter can only be used after the interpreter has been initialized.

The basic initialization function is `Py_Initialize()`. This initializes the table of loaded modules, and creates the fundamental modules `builtins, __main__, and sys`. It also initializes the module search path (`sys.path`).

`Py_Initialize()` does not set the “script argument list” (`sys.argv`). If this variable is needed by Python code that will be executed later, it must be set explicitly with a call to `PySys_SetArgvEx(argc, argv, updatepath)` after the call to `Py_Initialize()`.

On most systems (in particular, on Unix and Windows, although the details are slightly different), `Py_Initialize()` calculates the module search path based upon its best guess for the location of the standard Python interpreter executable, assuming that the Python library is found in a fixed location relative to the Python interpreter executable. In particular, it looks for a directory named `lib/pythonX.Y` relative to the parent directory where the executable named `python` is found on the shell command search path (the environment variable `PATH`).

For instance, if the Python executable is found in `/usr/local/bin/python`, it will assume that the libraries are in
/usr/local/lib/pythonX.Y. (In fact, this particular path is also the “fallback” location, used when no executable file named python is found along PATH.) The user can override this behavior by setting the environment variable PYTHONHOME, or insert additional directories in front of the standard path by setting PYTHONPATH.

The embedding application can steer the search by calling Py_SetProgramName(file) before calling Py_Initialize(). Note that PYTHONHOME still overrides this and PYTHONPATH is still inserted in front of the standard path. An application that requires total control has to provide its own implementation of Py_GetPath(), Py_GetPrefix(), Py_GetExecPrefix(), and Py_GetProgramFullPath() (all defined in Modules/getpath.c).

Sometimes, it is desirable to “uninitialize” Python. For instance, the application may want to start over (make another call to Py_Initialize()) or the application is simply done with its use of Python and wants to free memory allocated by Python. This can be accomplished by calling Py_Finalize(). The function Py_IsInitialized() returns true if Python is currently in the initialized state. More information about these functions is given in a later chapter. Notice that Py_Finalize() does not free all memory allocated by the Python interpreter, e.g. memory allocated by extension modules currently cannot be released.
Debugging Builds

Python can be built with several macros to enable extra checks of the interpreter and extension modules. These checks tend to add a large amount of overhead to the runtime so they are not enabled by default.

A full list of the various types of debugging builds is in the file Misc/SpecialBuilds.txt in the Python source distribution. Builds are available that support tracing of reference counts, debugging the memory allocator, or low-level profiling of the main interpreter loop. Only the most frequently-used builds will be described in the remainder of this section.

Compiling the interpreter with the Py_DEBUG macro defined produces what is generally meant by “a debug build” of Python. Py_DEBUG is enabled in the Unix build by adding --with-pydebug to the ./configure command. It is also implied by the presence of the not-Python-specific _DEBUG macro. When Py_DEBUG is enabled in the Unix build, compiler optimization is disabled.

In addition to the reference count debugging described below, the following extra checks are performed:

- Extra checks are added to the object allocator.
- Extra checks are added to the parser and compiler.
- Downcasts from wide types to narrow types are checked for loss of information.
- A number of assertions are added to the dictionary and set implementations. In addition, the set object acquires a test_c_api() method.
- Sanity checks of the input arguments are added to frame creation.
- The storage for ints is initialized with a known invalid pattern to
catch reference to uninitialized digits.
- Low-level tracing and extra exception checking are added to the runtime virtual machine.
- Extra checks are added to the memory arena implementation.
- Extra debugging is added to the thread module.

There may be additional checks not mentioned here.

Defining Py_TRACE_REFS enables reference tracing. When defined, a circular doubly linked list of active objects is maintained by adding two extra fields to every PyObject. Total allocations are tracked as well. Upon exit, all existing references are printed. (In interactive mode this happens after every statement run by the interpreter.) Implied by Py_DEBUG.

Please refer to Misc/SpecialBuilds.txt in the Python source distribution for more detailed information.
Stable Application Binary Interface

Traditionally, the C API of Python will change with every release. Most changes will be source-compatible, typically by only adding API, rather than changing existing API or removing API (although some interfaces do get removed after being deprecated first).

Unfortunately, the API compatibility does not extend to binary compatibility (the ABI). The reason is primarily the evolution of struct definitions, where addition of a new field, or changing the type of a field, might not break the API, but can break the ABI. As a consequence, extension modules need to be recompiled for every Python release (although an exception is possible on Unix when none of the affected interfaces are used). In addition, on Windows, extension modules link with a specific pythonXY.dll and need to be recompiled to link with a newer one.

Since Python 3.2, a subset of the API has been declared to guarantee a stable ABI. Extension modules wishing to use this API (called “limited API”) need to define `Py_LIMITED_API`. A number of interpreter details then become hidden from the extension module; in return, a module is built that works on any 3.x version (x>=2) without recompilation.

In some cases, the stable ABI needs to be extended with new functions. Extension modules wishing to use these new APIs need to set `Py_LIMITED_API` to the `PY_VERSION_HEX` value (see API and ABI Versioning) of the minimum Python version they want to support (e.g. `0x03030000` for Python 3.3). Such modules will work on all subsequent Python releases, but fail to load (because of missing symbols) on the older releases.
As of Python 3.2, the set of functions available to the limited API is documented in PEP 384. In the C API documentation, API elements that are not part of the limited API are marked as “Not part of the limited API.”
The Very High Level Layer

The functions in this chapter will let you execute Python source code given in a file or a buffer, but they will not let you interact in a more detailed way with the interpreter.

Several of these functions accept a start symbol from the grammar as a parameter. The available start symbols are Py_eval_input, Py_file_input, and Py_single_input. These are described following the functions which accept them as parameters.

Note also that several of these functions take FILE* parameters. One particular issue which needs to be handled carefully is that the FILE structure for different C libraries can be different and incompatible. Under Windows (at least), it is possible for dynamically linked extensions to actually use different libraries, so care should be taken that FILE* parameters are only passed to these functions if it is certain that they were created by the same library that the Python runtime is using.

```c
int Py_Main(int argc, wchar_t **argv)
```

The main program for the standard interpreter. This is made available for programs which embed Python. The `argc` and `argv` parameters should be prepared exactly as those which are passed to a C program’s `main()` function (converted to wchar_t according to the user’s locale). It is important to note that the argument list may be modified (but the contents of the strings pointed to by the argument list are not). The return value will be 0 if the interpreter exits normally (i.e., without an exception), 1 if the interpreter exits due to an exception, or 2 if the parameter list does not represent a
valid Python command line.

Note that if an otherwise unhandled `SystemExit` is raised, this function will not return 1, but exit the process, as long as `Py_InspectFlag` is not set.

```c
int PyRun_AnyFile(FILE *fp, const char *filename)
    This is a simplified interface to PyRun_AnyFileExFlags() below, leaving closeit set to 0 and flags set to NULL.
```

```c
int PyRun_AnyFileEx(FILE *fp, const char *filename, int closeit)
    This is a simplified interface to PyRun_AnyFileExFlags() below, leaving the flags argument set to NULL.
```

```c
int PyRun_AnyFileExFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)
    If fp refers to a file associated with an interactive device (console or terminal input or Unix pseudo-terminal), return the value of PyRun_InteractiveLoop(), otherwise return the result of PyRun_SimpleFile(). `filename` is decoded from the filesystem encoding (sys.getfilesystemencoding()). If `filename` is NULL, this function uses "??" as the filename.
```

```c
int PyRun_SimpleString(const char *command)
    This is a simplified interface to PyRun_SimpleStringFlags() below, leaving the PyCompilerFlags* argument set to NULL.
```
int PyRun_SimpleStringFlags(const char *command, PyCompilerFlags *flags)

Executes the Python source code from command in the __main__ module according to the flags argument. If __main__ does not already exist, it is created. Returns 0 on success or -1 if an exception was raised. If there was an error, there is no way to get the exception information. For the meaning of flags, see below.

Note that if an otherwise unhandled SystemExit is raised, this function will not return -1, but exit the process, as long as Py_InspectFlag is not set.

int PyRun_SimpleFile(FILE *fp, const char *filename)
This is a simplified interface to PyRun_SimpleFileExFlags() below, leaving closeit set to 0 and flags set to NULL.

int PyRun_SimpleFileEx(FILE *fp, const char *filename, int closeit)
This is a simplified interface to PyRun_SimpleFileExFlags() below, leaving flags set to NULL.

int PyRun_SimpleFileExFlags(FILE *fp, const char *filename, int closeit, PyCompilerFlags *flags)
Similar to PyRun_SimpleStringFlags(), but the Python source code is read from fp instead of an in-memory string. filename should be the name of the file, it is decoded from the filesystem encoding (sys.getfilesystemencoding()). If closeit is true, the file is closed before PyRun_SimpleFileExFlags returns.

int PyRun_InteractiveOne(FILE *fp, const char *filename)
This is a simplified interface to
PyRun_InteractiveOneFlags() below, leaving flags set to NULL.

int PyRun_InteractiveOneFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)

Read and execute a single statement from a file associated with an interactive device according to the flags argument. The user will be prompted using sys.ps1 and sys.ps2. filename is decoded from the filesystem encoding (sys.getfilesystemencoding()).

Returns 0 when the input was executed successfully, -1 if there was an exception, or an error code from the errcode.h include file distributed as part of Python if there was a parse error. (Note that errcode.h is not included by Python.h, so must be included specifically if needed.)

int PyRun_InteractiveLoop(FILE *fp, const char *filename)

This is a simplified interface to PyRun_InteractiveLoopFlags() below, leaving flags set to NULL.

int PyRun_InteractiveLoopFlags(FILE *fp, const char *filename, PyCompilerFlags *flags)

Read and execute statements from a file associated with an interactive device until EOF is reached. The user will be prompted using sys.ps1 and sys.ps2. filename is decoded from the filesystem encoding (sys.getfilesystemencoding()). Returns 0 at EOF.

struct _node* PyParser_SimpleParseString(const char *str, int start)

This is a simplified interface to
PyParser_SimpleParseStringFlagsFilename() below, leaving filename set to NULL and flags set to 0.

struct_node* PyParser_SimpleParseStringFlags(const char *str, int start, int flags)

This is a simplified interface to PyParser_SimpleParseStringFlagsFilename() below, leaving filename set to NULL.

struct_node* PyParser_SimpleParseStringFlagsFilename(const char *str, const char *filename, int start, int flags)

Parse Python source code from str using the start token start according to the flags argument. The result can be used to create a code object which can be evaluated efficiently. This is useful if a code fragment must be evaluated many times. filename is decoded from the filesystem encoding (sys.getfilesystemencoding()).

struct_node* PyParser_SimpleParseFile(FILE *fp, const char *filename, int start)

This is a simplified interface to PyParser_SimpleParseFileFlags() below, leaving flags set to 0.

struct_node* PyParser_SimpleParseFileFlags(FILE *fp, const char *filename, int start, int flags)

Similar to PyParser_SimpleParseStringFlagsFilename(), but the Python source code is read from fp instead of an in-memory string.

PyObject* PyRun_String(const char *str, int start,
PyObject *globals, PyObject *locals)

This is a simplified interface to PyRun_StringFlags() below, leaving flags set to NULL.

PyObject* PyRun_StringFlags(const char *str, int start,
PyObject *globals, PyObject *locals, PyCompilerFlags *flags)

Execute Python source code from str in the context specified by the dictionaries globals and locals with the compiler flags specified by flags. The parameter start specifies the start token that should be used to parse the source code.

Returns the result of executing the code as a Python object, or NULL if an exception was raised.

PyObject* PyRun_File(FILE *fp, const char *filename, int start,
PyObject *globals, PyObject *locals)

This is a simplified interface to PyRun_FileExFlags() below, leaving closeit set to 0 and flags set to NULL.

PyObject* PyRun_FileEx(FILE *fp, const char *filename, int start,
PyObject *globals, PyObject *locals, int closeit)

This is a simplified interface to PyRun_FileExFlags() below, leaving flags set to NULL.

PyObject* PyRun_FileFlags(FILE *fp, const char *filename,
int start, PyObject *globals, PyObject *locals, PyCompilerFlags *flags)

This is a simplified interface to PyRun_FileExFlags() below, leaving closeit set to 0.
PyObject* **PyRun_FileExFlags**(FILE *fp, const char *filename, int start, PyObject *globals, PyObject *locals, int closeit, PyCompilerFlags *flags)

Similar to **PyRun_StringFlags()**, but the Python source code is read from *fp* instead of an in-memory string. *filename* should be the name of the file, it is decoded from the filesystem encoding (**sys.getfilesystemencoding()**). If *closeit* is true, the file is closed before **PyRun_FileExFlags()** returns.

PyObject* **Py_CompileString**(const char *str, const char *filename, int start)

This is a simplified interface to **Py_ComPILEStringFlags()** below, leaving *flags* set to **NULL**.

PyObject* **Py_CompileStringFlags**(const char *str, const char *filename, int start, PyCompilerFlags *flags)

This is a simplified interface to **Py_CompileStringExFlags()** below, with optimize set to -1.

PyObject* **Py_CompileStringExFlags**(const char *str, const char *filename, int start, PyCompilerFlags *flags, int optimize)
Parse and compile the Python source code in *str*, returning the resulting code object. The start token is given by *start*; this can be used to constrain the code which can be compiled and should be **Py_eval_input**, **Py_file_input**, or **Py_single_input**. The filename specified by *filename* is used to construct the code object and may appear in tracebacks or **SyntaxError** exception messages, it is decoded from the filesystem encoding
(sys.getfilesystemencoding()). This returns NULL if the code cannot be parsed or compiled.

The integer optimize specifies the optimization level of the compiler; a value of -1 selects the optimization level of the interpreter as given by -O options. Explicit levels are 0 (no optimization; __debug__ is true), 1 (asserts are removed, __debug__ is false) or 2 (docstrings are removed too).

New in version 3.2.

**PyObject** **PyEval_EvalCode**(**PyObject***co, **PyObject***globals, **PyObject***locals)**

*Return value: New reference.*

This is a simplified interface to PyEval_EvalCodeEx(), with just the code object, and the dictionaries of global and local variables. The other arguments are set to NULL.

**PyObject** **PyEval_EvalCodeEx**(**PyObject***co, **PyObject***globals, **PyObject***locals, **PyObject** **args**, int argcount, **PyObject** **kws**, int kwcount, **PyObject** **defs**, int defcount, **PyObject***closure)**

Evaluate a precompiled code object, given a particular environment for its evaluation. This environment consists of dictionaries of global and local variables, arrays of arguments, keywords and defaults, and a closure tuple of cells.

**PyObject** **PyEval_EvalFrame**(**PyFrameObject***f)**

Evaluate an execution frame. This is a simplified interface to PyEval_EvalFrameEx, for backward compatibility.

**PyObject** **PyEval_EvalFrameEx**(**PyFrameObject***f, int throwflag)**
This is the main, unvarnished function of Python interpretation. It is literally 2000 lines long. The code object associated with the execution frame \( f \) is executed, interpreting bytecode and executing calls as needed. The additional \( \text{throwflag} \) parameter can mostly be ignored - if true, then it causes an exception to immediately be thrown; this is used for the \( \text{throw()} \) methods of generator objects.

\begin{verbatim}
int PyEval_MergeCompilerFlags(PyCompilerFlags *cf)
This function changes the flags of the current evaluation frame, and returns true on success, false on failure.
\end{verbatim}

\begin{verbatim}
int Py_eval_input
The start symbol from the Python grammar for isolated expressions; for use with \( \text{Py_CompileString()} \).
\end{verbatim}

\begin{verbatim}
int Py_file_input
The start symbol from the Python grammar for sequences of statements as read from a file or other source; for use with \( \text{Py_CompileString()} \). This is the symbol to use when compiling arbitrarily long Python source code.
\end{verbatim}

\begin{verbatim}
int Py_single_input
The start symbol from the Python grammar for a single statement; for use with \( \text{Py_CompileString()} \). This is the symbol used for the interactive interpreter loop.
\end{verbatim}

\begin{verbatim}
struct PyCompilerFlags
This is the structure used to hold compiler flags. In cases where code is only being compiled, it is passed as \( \text{int flags} \), and in cases where code is being executed, it is passed as \( \text{PyCompilerFlags *flags} \). In this case, \( \text{from __future__ import} \) can modify \( \text{flags} \).
\end{verbatim}
Whenever `PyCompilerFlags *flags` is `NULL`, `cf_flags` is treated as equal to 0, and any modification due to `from __future__ import` is discarded.

```c
struct PyCompilerFlags {
    int cf_flags;
}
```

`int CO_FUTURE_DIVISION`

This bit can be set in `flags` to cause division operator ` `/` to be interpreted as “true division” according to PEP 238.
Reference Counting

The macros in this section are used for managing reference counts of Python objects.

void **Py_INCRE**F(PyObject *o)
Increment the reference count for object o. The object must not be NULL; if you aren’t sure that it isn’t NULL, use **Py_XINCREF()**.

void **Py_XINCREF**(PyObject *o)
Increment the reference count for object o. The object may be NULL, in which case the macro has no effect.

void **Py_DECREF**(PyObject *o)
Decrement the reference count for object o. The object must not be NULL; if you aren’t sure that it isn’t NULL, use **Py_XDECREF()**. If the reference count reaches zero, the object’s type’s deallocation function (which must not be NULL) is invoked.

**Warning:** The deallocation function can cause arbitrary Python code to be invoked (e.g. when a class instance with a **__del__()** method is deallocated). While exceptions in such code are not propagated, the executed code has free access to all Python global variables. This means that any object that is reachable from a global variable should be in a consistent state before **Py_DECREF()** is invoked. For example, code to delete an object from a list should copy a reference to the deleted object in a temporary variable, update the list data structure, and then call **Py_DECREF()** for the temporary variable.
void **Py_XDECRE**F(PyObject *o)

Decrement the reference count for object o. The object may be *NULL*, in which case the macro has no effect; otherwise the effect is the same as for **Py_DECREF**(), and the same warning applies.

void **Py_CLEAR**(PyObject *o)

Decrement the reference count for object o. The object may be *NULL*, in which case the macro has no effect; otherwise the effect is the same as for **Py_DECREF**(), except that the argument is also set to *NULL*. The warning for **Py_DECREF**() does not apply with respect to the object passed because the macro carefully uses a temporary variable and sets the argument to *NULL* before decrementing its reference count.

It is a good idea to use this macro whenever decrementing the value of a variable that might be traversed during garbage collection.

The following functions are for runtime dynamic embedding of Python: **Py_IncRef**(PyObject *o), **Py_DecRef**(PyObject *o). They are simply exported function versions of **Py_XINCREF**() and **Py_XDECRE**F(), respectively.

The following functions or macros are only for use within the interpreter core: _Py_Dealloc(), _Py_ForgetReference(), _Py_NewReference(), as well as the global variable _Py_RefTotal.
Exception Handling

The functions described in this chapter will let you handle and raise Python exceptions. It is important to understand some of the basics of Python exception handling. It works somewhat like the Unix errno variable: there is a global indicator (per thread) of the last error that occurred. Most functions don’t clear this on success, but will set it to indicate the cause of the error on failure. Most functions also return an error indicator, usually NULL if they are supposed to return a pointer, or -1 if they return an integer (exception: the PyArg_*() functions return 1 for success and 0 for failure).

When a function must fail because some function it called failed, it generally doesn’t set the error indicator; the function it called already set it. It is responsible for either handling the error and clearing the exception or returning after cleaning up any resources it holds (such as object references or memory allocations); it should not continue normally if it is not prepared to handle the error. If returning due to an error, it is important to indicate to the caller that an error has been set. If the error is not handled or carefully propagated, additional calls into the Python/C API may not behave as intended and may fail in mysterious ways.

The error indicator consists of three Python objects corresponding to the result of sys.exc_info(). API functions exist to interact with the error indicator in various ways. There is a separate error indicator for each thread.

void PyErr_PrintEx(int set_sys_last_vars)
    Print a standard traceback to sys.stderr and clear the error indicator. Call this function only when the error indicator is set.
(Otherwise it will cause a fatal error!)

If `set_sys_last_vars` is nonzero, the variables `sys.last_type`, `sys.last_value` and `sys.last_traceback` will be set to the type, value and traceback of the printed exception, respectively.

```c
void PyErr_Print()
```

Alias for `PyErr_PrintEx(1)`.

```c
PyObject* PyErr_Occurred()
```

*Return value: Borrowed reference.*

Test whether the error indicator is set. If set, return the exception type (the first argument to the last call to one of the `PyErr_Set*` () functions or to `PyErr_Restore()`). If not set, return `NULL`. You do not own a reference to the return value, so you do not need to `Py_DECREF()` it.

**Note:** Do not compare the return value to a specific exception; use `PyErr_ExceptionMatches()` instead, shown below. (The comparison could easily fail since the exception may be an instance instead of a class, in the case of a class exception, or it may the a subclass of the expected exception.)

```c
int PyErr_ExceptionMatches(PyObject *exc)
```

Equivalent to `PyErr_GivenExceptionMatches(PyErr_Occurred(), exc)`. This should only be called when an exception is actually set; a memory access violation will occur if no exception has been raised.

```c
int PyErr_GivenExceptionMatches(PyObject *given, PyObject *exc)
```
Return true if the *given* exception matches the exception in *exc*. If *exc* is a class object, this also returns true when *given* is an instance of a subclass. If *exc* is a tuple, all exceptions in the tuple (and recursively in subtuples) are searched for a match.

```c
void PyErr_NormalizeException(PyObject** exc, PyObject** val, PyObject** tb)
```

Under certain circumstances, the values returned by `PyErr_Fetch()` below can be “unnormalized”, meaning that *exc* is a class object but *val* is not an instance of the same class. This function can be used to instantiate the class in that case. If the values are already normalized, nothing happens. The delayed normalization is implemented to improve performance.

```c
void PyErr_Clear()
```

Clear the error indicator. If the error indicator is not set, there is no effect.

```c
void PyErr_Fetch(PyObject **ptype, PyObject **pvalue, PyObject **ptraceback)
```

Retrieve the error indicator into three variables whose addresses are passed. If the error indicator is not set, set all three variables to `NULL`. If it is set, it will be cleared and you own a reference to each object retrieved. The value and traceback object may be `NULL` even when the type object is not.

**Note:** This function is normally only used by code that needs to handle exceptions or by code that needs to save and restore the error indicator temporarily.

```c
void PyErr_Restore(PyObject *type, PyObject *value, PyObject *traceback)
```
Set the error indicator from the three objects. If the error indicator is already set, it is cleared first. If the objects are NULL, the error indicator is cleared. Do not pass a NULL type and non-NULL value or traceback. The exception type should be a class. Do not pass an invalid exception type or value. (Violating these rules will cause subtle problems later.) This call takes away a reference to each object: you must own a reference to each object before the call and after the call you no longer own these references. (If you don’t understand this, don’t use this function. I warned you.)

**Note:** This function is normally only used by code that needs to save and restore the error indicator temporarily; use PyErr_Fetch() to save the current exception state.

```c
void PyErr_GetExcInfo(PyObject **ptype, PyObject **pvalue, PyObject **ptraceback)
```

Retrieve the exception info, as known from sys.exc_info(). This refers to an exception that was already caught, not to an exception that was freshly raised. Returns new references for the three objects, any of which may be NULL. Does not modify the exception info state.

**Note:** This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use PyErr_SetExcInfo() to restore or clear the exception state.

*New in version 3.3.*

```c
void PyErr_SetExcInfo(PyObject *type, PyObject *value, PyObject *traceback)
```

Set the exception info, as known from sys.exc_info(). This
refers to an exception that was already caught, not to an exception that was freshly raised. This function steals the references of the arguments. To clear the exception state, pass \texttt{NULL} for all three arguments. For general rules about the three arguments, see \texttt{PyErr_Restore()}.

\begin{quote}
\textbf{Note:} This function is not normally used by code that wants to handle exceptions. Rather, it can be used when code needs to save and restore the exception state temporarily. Use \texttt{PyErr_GetExcInfo()} to read the exception state.
\end{quote}

\textit{New in version 3.3.}

\begin{verbatim}
void PyErr_SetString(PyObject *type, const char *message)
\end{verbatim}

This is the most common way to set the error indicator. The first argument specifies the exception type; it is normally one of the standard exceptions, e.g. \texttt{PyExc_RuntimeError}. You need not increment its reference count. The second argument is an error message; it is decoded from \texttt{'utf-8'}.

\begin{verbatim}
void PyErr_SetObject(PyObject *type, PyObject *value)
\end{verbatim}

This function is similar to \texttt{PyErr_SetString()} but lets you specify an arbitrary Python object for the “value” of the exception.

\begin{verbatim}
PyObject* PyErr_Format(PyObject *exception, const char *format, ...)
\end{verbatim}

\textit{Return value: Always NULL.}

This function sets the error indicator and returns \texttt{NULL}. \texttt{exception} should be a Python exception class. The \texttt{format} and subsequent parameters help format the error message; they have the same meaning and values as in \texttt{PyUnicode_FromFormat()}. \texttt{format} is an ASCII-encoded string.
void PyErr_SetNone(PyObject *type)

This is a shorthand for PyErr_SetObject(type, Py_None).

int PyErr_BadArgument()

This is a shorthand for PyErr_SetString(PyExc_TypeError, message), where message indicates that a built-in operation was invoked with an illegal argument. It is mostly for internal use.

PyObject* PyErr_NoMemory()

Return value: Always NULL.

This is a shorthand for PyErr_SetNone(PyExc_MemoryError); it returns NULL so an object allocation function can write return PyErr_NoMemory(); when it runs out of memory.

PyObject* PyErr_SetFromErrno(PyObject *type)

Return value: Always NULL.

This is a convenience function to raise an exception when a C library function has returned an error and set the C variable errno. It constructs a tuple object whose first item is the integer errno value and whose second item is the corresponding error message (gotten from strerror()), and then calls PyErr_SetObject(type, object). On Unix, when the errno value is EINTR, indicating an interrupted system call, this calls PyErr_CheckSignals(), and if that set the error indicator, leaves it set to that. The function always returns NULL, so a wrapper function around a system call can write return PyErr_SetFromErrno(type); when the system call returns an error.

PyObject*
PyErr_SetFromErrnoWithFilenameObject(PyObject *type, PyObject *filenameObject)
Similar to `PyErr_SetFromErrno()`, with the additional behavior that if `filenameObject` is not `NULL`, it is passed to the constructor of `type` as a third parameter. In the case of exceptions such as `IOError` and `OSError`, this is used to define the filename attribute of the exception instance.

```
PyObject*
PyErr_SetFromErrnoWithFilenameType(PyObject *type, const char *filename)

Return value: Always NULL.
Similar to `PyErr_SetFromErrnoWithFilenameObject()`, but the filename is given as a C string. `filename` is decoded from the filesystem encoding (`sys.getfilesystemencoding()`).
```

```
PyObject* PyErr_SetFromWindowsErr(int ierr)

Return value: Always NULL.
This is a convenience function to raise `WindowsError`. If called with `ierr` of 0, the error code returned by a call to `GetLastError()` is used instead. It calls the Win32 function `FormatMessage()` to retrieve the Windows description of error code given by `ierr` or `GetLastError()`, then it constructs a tuple object whose first item is the `ierr` value and whose second item is the corresponding error message (gotten from `FormatMessage()`), and then calls `PyErr_SetObject(PyExc_WindowsError, object)`. This function always returns `NULL`. Availability: Windows.
```

```
PyObject* PyErr_SetExcFromWindowsErr(PyObject *type, int ierr)

Return value: Always NULL.
Similar to `PyErr_SetFromWindowsErr()`, with an additional parameter specifying the exception type to be raised. Availability:
```
Windows.

PyObject*
PyErr_SetFromWindowsErrWithFilenameObject(int ierr
PyObject *filenameObject)
    Similar to PyErr_SetFromWindowsErr(), with the additional behavior that if filenameObject is not NULL, it is passed to the constructor of WindowsError as a third parameter. Availability: Windows.

PyObject*
PyErr_SetFromWindowsErrWithFilename(int ierr, const char *filename)
    Return value: Always NULL.
    Similar to PyErr_SetFromWindowsErrWithFilenameObject(), but the filename is given as a C string. filename is decoded from the filesystem encoding (sys.getfilesystemencoding()). Availability: Windows.

PyObject*
PyErr_SetExcFromWindowsErrWithFilenameObject(PyObject *type
int ierr, PyObject *filename)
    Similar to PyErr_SetFromWindowsErrWithFilenameObject(), with an additional parameter specifying the exception type to be raised. Availability: Windows.

PyObject*
PyErr_SetExcFromWindowsErrWithFilename(PyObject *
int ierr, const char *filename)
    Return value: Always NULL.
    Similar to PyErr_SetFromWindowsErrWithFilenameObject(), with
an additional parameter specifying the exception type to be raised. Availability: Windows.

**PyObject** * `PyErr_SetImportError` (*PyObject* *msg*, *PyObject* *name*, *PyObject* *path*)

This is a convenience function to raise `ImportError`. *msg* will be set as the exception’s message string. *name* and *path*, both of which can be `NULL`, will be set as the `ImportError`’s respective *name* and *path* attributes.

*New in version 3.3.*

**void** `PyErr_SyntaxLocationEx` (char *filename*, int *lineno*, int *col_offset*)

Set file, line, and offset information for the current exception. If the current exception is not a `SyntaxError`, then it sets additional attributes, which make the exception printing subsystem think the exception is a `SyntaxError`. *filename* is decoded from the filesystem encoding (`sys.getfilesystemencoding()`).

*New in version 3.2.*

**void** `PyErr_SyntaxLocation` (char *filename*, int *lineno*)

Like `PyErr_SyntaxLocationExc()`, but the *col_offset* parameter is omitted.

**void** `PyErr_BadInternalCall()`

This is a shorthand for `PyErr_SetString(PyExc_SystemError, message)`, where *message* indicates that an internal operation (e.g. a Python/C API function) was invoked with an illegal argument. It is mostly for internal use.
int PyErr_WarnEx(PyObject *category, char *message, int stack_level)

Issue a warning message. The category argument is a warning category (see below) or NULL; the message argument is an UTF-8 encoded string. stack_level is a positive number giving a number of stack frames; the warning will be issued from the currently executing line of code in that stack frame. A stack_level of 1 is the function calling PyErr_WarnEx(), 2 is the function above that, and so forth.

This function normally prints a warning message to sys.stderr; however, it is also possible that the user has specified that warnings are to be turned into errors, and in that case this will raise an exception. It is also possible that the function raises an exception because of a problem with the warning machinery (the implementation imports the warnings module to do the heavy lifting). The return value is 0 if no exception is raised, or -1 if an exception is raised. (It is not possible to determine whether a warning message is actually printed, nor what the reason is for the exception; this is intentional.) If an exception is raised, the caller should do its normal exception handling (for example, Py_DECREF() owned references and return an error value).

Warning categories must be subclasses of Warning; the default warning category is RuntimeWarning. The standard Python warning categories are available as global variables whose names are PyExc_ followed by the Python exception name. These have the type PyObject*; they are all class objects. Their names are PyExc_Warning, PyExc_UserWarning, PyExc_UnicodeWarning, PyExc_DeprecationWarning, PyExc_SyntaxWarning, PyExc_RuntimeWarning, and
PyExc_FutureWarning. PyExc_Warning is a subclass of PyExc_Exception; the other warning categories are subclasses of PyExc_Warning.

For information about warning control, see the documentation for the warnings module and the -W option in the command line documentation. There is no C API for warning control.

```c
int PyErr_WarnExplicit(PyObject *category, const char *message, const char *filename, int lineno, const char *module, PyObject *registry)
```

Issue a warning message with explicit control over all warning attributes. This is a straightforward wrapper around the Python function `warnings.warn_explicit()`, see there for more information. The `module` and `registry` arguments may be set to NULL to get the default effect described there. `message` and `module` are UTF-8 encoded strings, `filename` is decoded from the filesystem encoding (sys.getfilesystemencoding()).

```c
int PyErr_WarnFormat(PyObject *category, Py_ssize_t stack_level, const char *format, ...)
```

Function similar to `PyErr_WarnEx()`, but use `PyUnicode_FromFormat()` to format the warning message. `format` is an ASCII-encoded string.

*New in version 3.2.*

```c
int PyErr_CheckSignals()
```

This function interacts with Python’s signal handling. It checks whether a signal has been sent to the processes and if so, invokes the corresponding signal handler. If the `signal` module is supported, this can invoke a signal handler written in Python. In all
cases, the default effect for SIGINT is to raise the `KeyboardInterrupt` exception. If an exception is raised the error indicator is set and the function returns `-1`; otherwise the function returns `0`. The error indicator may or may not be cleared if it was previously set.

**void PyErr_SetInterrupt()**

This function simulates the effect of a SIGINT signal arriving — the next time `PyErr_CheckSignals()` is called, `KeyboardInterrupt` will be raised. It may be called without holding the interpreter lock.

**int PySignal_SetWakeupFd(int fd)**

This utility function specifies a file descriptor to which a `'\0'` byte will be written whenever a signal is received. It returns the previous such file descriptor. The value `-1` disables the feature; this is the initial state. This is equivalent to `signal.set_wakeup_fd()` in Python, but without any error checking. `fd` should be a valid file descriptor. The function should only be called from the main thread.

**PyObject* PyErr_NewException(char *name, PyObject *base, PyObject *dict)**

*Return value: New reference.*

This utility function creates and returns a new exception class. The `name` argument must be the name of the new exception, a C string of the form `module.classname`. The `base` and `dict` arguments are normally `NULL`. This creates a class object derived from `Exception` (accessible in C as `PyExc_Exception`).

The `__module__` attribute of the new class is set to the first part (up to the last dot) of the `name` argument, and the class name is set to the last part (after the last dot). The `base` argument can be
used to specify alternate base classes; it can either be only one class or a tuple of classes. The dict argument can be used to specify a dictionary of class variables and methods.

\textbf{PyObject* \texttt{PyErr\_NewExceptionWithDoc}(char \*name, char \*doc, PyObject \*base, PyObject \*dict)}

\textit{Return value: New reference.}

Same as \texttt{PyErr\_NewException()}, except that the new exception class can easily be given a docstring: If \textit{doc} is non-\texttt{NULL}, it will be used as the docstring for the exception class.

\textit{New in version 3.2.}

\textbf{void \texttt{PyErr\_WriteUnraisable}(PyObject \*obj)}

This utility function prints a warning message to \texttt{sys.stderr} when an exception has been set but it is impossible for the interpreter to actually raise the exception. It is used, for example, when an exception occurs in an \texttt{__del__()} method.

The function is called with a single argument \textit{obj} that identifies the context in which the unraisable exception occurred. The repr of \textit{obj} will be printed in the warning message.
Exception Objects

PyObject* PyException_GetTraceback(PyObject *ex)

Return the traceback associated with the exception as a new reference, as accessible from Python through __traceback__. If there is no traceback associated, this returns NULL.

int PyException_SetTraceback(PyObject *ex, PyObject *tb)
Set the traceback associated with the exception to tb. Use Py_None to clear it.

PyObject* PyException_GetContext(PyObject *ex)
Return the context (another exception instance during whose handling ex was raised) associated with the exception as a new reference, as accessible from Python through __context__. If there is no context associated, this returns NULL.

void PyException_SetContext(PyObject *ex, PyObject *ctx)
Set the context associated with the exception to ctx. Use NULL to clear it. There is no type check to make sure that ctx is an exception instance. This steals a reference to ctx.

PyObject* PyException_GetCause(PyObject *ex)
Return the cause (either an exception instance, or None, set by raise ... from ...) associated with the exception as a new reference, as accessible from Python through __cause__.

void PyException_SetCause(PyObject *ex, PyObject *ctx)
Set the cause associated with the exception to ctx. Use NULL to clear it. There is no type check to make sure that ctx is either an
exception instance or **None**. This steals a reference to **ctx**.

___suppress_context___ is implicitly set to **True** by this function.
Unicode Exception Objects

The following functions are used to create and modify Unicode exceptions from C.

**PyObject** PyUnicodeDecodeError_Create(const char *encoding, const char *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeDecodeError` object with the attributes `encoding`, `object`, `length`, `start`, `end` and `reason`. `encoding` and `reason` are UTF-8 encoded strings.

**PyObject** PyUnicodeEncodeError_Create(const char *encoding, const Py_UNICODE *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeEncodeError` object with the attributes `encoding`, `object`, `length`, `start`, `end` and `reason`. `encoding` and `reason` are UTF-8 encoded strings.

**PyObject** PyUnicodeTranslateError_Create(const Py_UNICODE *object, Py_ssize_t length, Py_ssize_t start, Py_ssize_t end, const char *reason)

Create a `UnicodeTranslateError` object with the attributes `object`, `length`, `start`, `end` and `reason`. `reason` is an UTF-8 encoded string.

**PyObject** PyUnicodeDecodeError_GetEncoding(PyObject *exc)

**PyObject** PyUnicodeEncodeError_GetEncoding(PyObject *exc)

Return the `encoding` attribute of the given exception object.
PyUnicodeDecodeError_GetObject(PyObject *exc)
PyObject*
PyUnicodeEncodeError_GetObject(PyObject *exc)
PyObject*
PyUnicodeTranslateError_GetObject(PyObject *exc)

Return the object attribute of the given exception object.

int PyUnicodeDecodeError_GetStart(PyObject *exc, Py_ssize_t *start)
int PyUnicodeEncodeError_GetStart(PyObject *exc, Py_ssize_t *start)
int PyUnicodeTranslateError_GetStart(PyObject *exc, Py_ssize_t *start)

Get the start attribute of the given exception object and place it into *start. start must not be NULL. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_SetStart(PyObject *exc, Py_ssize_t start)
int PyUnicodeEncodeError_SetStart(PyObject *exc, Py_ssize_t start)
int PyUnicodeTranslateError_SetStart(PyObject *exc, Py_ssize_t start)

Set the start attribute of the given exception object to start. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_GetEnd(PyObject *exc, Py_ssize_t *end)
int PyUnicodeEncodeError_GetEnd(PyObject *exc, Py_ssize_t *end)
int PyUnicodeTranslateError_GetEnd(PyObject *exc, Py_ssize_t *end)

Get the end attribute of the given exception object and place it into
*end. end must not be NULL. Return 0 on success, -1 on failure.

int PyUnicodeDecodeError_SetEnd(PyObject *exc, Py_ssize_t end)
int PyUnicodeEncodeError_SetEnd(PyObject *exc, Py_ssize_t end)
int PyUnicodeTranslateError_SetEnd(PyObject *exc, Py_ssize_t end)
    Set the end attribute of the given exception object to end. Return 0 on success, -1 on failure.

PyObject* PyUnicodeDecodeError_GetReason(PyObject *exc)
PyObject* PyUnicodeEncodeError_GetReason(PyObject *exc)
PyObject* PyUnicodeTranslateError_GetReason(PyObject *exc)
    Return the reason attribute of the given exception object.

int PyUnicodeDecodeError_SetReason(PyObject *exc, const char *reason)
int PyUnicodeEncodeError_SetReason(PyObject *exc, const char *reason)
int PyUnicodeTranslateError_SetReason(PyObject *exc, const char *reason)
    Set the reason attribute of the given exception object to reason. Return 0 on success, -1 on failure.
Recursion Control

These two functions provide a way to perform safe recursive calls at the C level, both in the core and in extension modules. They are needed if the recursive code does not necessarily invoke Python code (which tracks its recursion depth automatically).

```c
int Py_EnterRecursiveCall(char *where)
```

Marks a point where a recursive C-level call is about to be performed.

If USE_STACKCHECK is defined, this function checks if the OS stack overflowed using `PyOS_CheckStack()`. In this case, it sets a `MemoryError` and returns a nonzero value.

The function then checks if the recursion limit is reached. If this is the case, a `RuntimeError` is set and a nonzero value is returned. Otherwise, zero is returned.

`where` should be a string such as "in instance check" to be concatenated to the `RuntimeError` message caused by the recursion depth limit.

```c
void Py_LeaveRecursiveCall()
```

Ends a `Py_EnterRecursiveCall()`. Must be called once for each successful invocation of `Py_EnterRecursiveCall()`.

Properly implementing `tp_repr` for container types requires special recursion handling. In addition to protecting the stack, `tp_repr` also needs to track objects to prevent cycles. The following two functions facilitate this functionality. Effectively, these are the C equivalent to
reprlib.recursive_repr().

int **Py_ReprEnter**(PyObject *object)
 Called at the beginning of the **tp_repr** implementation to detect cycles.

If the object has already been processed, the function returns a positive integer. In that case the **tp_repr** implementation should return a string object indicating a cycle. As examples, **dict** objects return `{...}` and **list** objects return `[...]`.

The function will return a negative integer if the recursion limit is reached. In that case the **tp_repr** implementation should typically return **NULL**.

Otherwise, the function returns zero and the **tp_repr** implementation can continue normally.

void **Py_ReprLeave**(PyObject *object)
 Ends a **Py_ReprEnter()**. Must be called once for each invocation of **Py_ReprEnter()** that returns zero.
Standard Exceptions

All standard Python exceptions are available as global variables whose names are `PyExc_` followed by the Python exception name. These have the type `PyObject*`; they are all class objects. For completeness, here are all the variables:

<table>
<thead>
<tr>
<th>C Name</th>
<th>Python Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyExc_BaseException</td>
<td>BaseException</td>
</tr>
<tr>
<td>PyExc_Exception</td>

</tbody>
</table>

*New in version 3.3:* PyExc_BlockingIOError, PyExc_BrokenPipeError, PyExc_ChildProcessError,
PyExc_ConnectionError, PyExc_ConnectionAbortedError, PyExc_ConnectionRefusedError, PyExc_ConnectionResetError, PyExc_FileExistsError, PyExc_FileNotFoundError, PyExc_InterruptedError, PyExc_IsADirectoryError, PyExc_NotADirectoryError, PyExc_PermissionError, PyExc_ProcessLookupError and PyExc_TimeoutError were introduced following PEP 3151.

These are compatibility aliases to PyExc_OSError:

<table>
<thead>
<tr>
<th>C Name</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyExc_EnvironmentError</td>
<td></td>
</tr>
<tr>
<td>PyExc_IOError</td>
<td></td>
</tr>
<tr>
<td>PyExc_WindowsError</td>
<td>(3)</td>
</tr>
</tbody>
</table>

*Changed in version 3.3:* These aliases used to be separate exception types.

Notes:

1. This is a base class for other standard exceptions.
2. This is the same as `weakref.ReferenceError`.
3. Only defined on Windows; protect code that uses this by testing that the preprocessor macro `MS_WINDOWS` is defined.
Utilities

The functions in this chapter perform various utility tasks, ranging from helping C code be more portable across platforms, using Python modules from C, and parsing function arguments and constructing Python values from C values.

- Operating System Utilities
- System Functions
- Process Control
- Importing Modules
- Data marshalling support
- Parsing arguments and building values
  - Parsing arguments
    - Strings and buffers
    - Numbers
    - Other objects
    - API Functions
  - Building values
- String conversion and formatting
- Reflection
- Codec registry and support functions
  - Codec lookup API
  - Registry API for Unicode encoding error handlers
### Operating System Utilities

**int Py_FdIsInteractive(FILE *fp, const char *filename)**

Return true (nonzero) if the standard I/O file fp with name filename is deemed interactive. This is the case for files for which `isatty(fileno(fp))` is true. If the global flag `Py_InteractiveFlag` is true, this function also returns true if the filename pointer is `NULL` or if the name is equal to one of the strings `'<stdin>'` or `'???'`.

**void PyOS_AfterFork()**

Function to update some internal state after a process fork; this should be called in the new process if the Python interpreter will continue to be used. If a new executable is loaded into the new process, this function does not need to be called.

**int PyOS_CheckStack()**

Return true when the interpreter runs out of stack space. This is a reliable check, but is only available when `USE_STACKCHECK` is defined (currently on Windows using the Microsoft Visual C++ compiler). `USE_STACKCHECK` will be defined automatically; you should never change the definition in your own code.

**PyOS_sighandler_t PyOS_getsig(int i)**

Return the current signal handler for signal i. This is a thin wrapper around either `sigaction()` or `signal()`. Do not call those functions directly! `PyOS_sighandler_t` is a typedef alias for `void (*)(int)`.

**PyOS_sighandler_t PyOS_setsig(int i, PyOS_sighandler_t h)**
Set the signal handler for signal \( i \) to be \( h \); return the old signal handler. This is a thin wrapper around either \texttt{sigaction()} or \texttt{signal()}. Do not call those functions directly! \texttt{PyOS_sighandler_t} is a typedef alias for \texttt{void (*)(int)}.
System Functions

These are utility functions that make functionality from the `sys` module accessible to C code. They all work with the current interpreter thread's `sys` module's dict, which is contained in the internal thread state structure.

```c
PyObject *PySys_GetObject(char *name)
```

*Return value: Borrowed reference.*
Return the object `name` from the `sys` module or `NULL` if it does not exist, without setting an exception.

```c
int PySys_SetObject(char *name, PyObject *v)
```
Set `name` in the `sys` module to `v` unless `v` is `NULL`, in which case `name` is deleted from the `sys` module. Returns `0` on success, `-1` on error.

```c
void PySys_ResetWarnOptions()
```
Reset `sys.warnoptions` to an empty list.

```c
void PySys_AddWarnOption(wchar_t *s)
```
Append `s` to `sys.warnoptions`.

```c
void PySys_AddWarnOptionUnicode(PyObject *unicode)
```
Append `unicode` to `sys.warnoptions`.

```c
void PySys_SetPath(wchar_t *path)
```
Set `sys.path` to a list object of paths found in `path` which should be a list of paths separated with the platform’s search path delimiter (`:` on Unix, `;` on Windows).
void **PySys_WriteStdout**(const char *format, ...)

Write the output string described by *format* to *sys.stdout*. No exceptions are raised, even if truncation occurs (see below).

*format* should limit the total size of the formatted output string to 1000 bytes or less – after 1000 bytes, the output string is truncated. In particular, this means that no unrestricted “%s” formats should occur; these should be limited using “%.<N>s” where \(<N>\) is a decimal number calculated so that \(<N>\) plus the maximum size of other formatted text does not exceed 1000 bytes. Also watch out for “%f”, which can print hundreds of digits for very large numbers.

If a problem occurs, or *sys.stdout* is unset, the formatted message is written to the real (C level) *stdout*.

void **PySys_WriteStderr**(const char *format, ...)

As **PySys_WriteStdout()**, but write to *sys.stderr* or *stderr* instead.

void **PySys_FormatStdout**(const char *format, ...)

Function similar to **PySys_WriteStdout()** but format the message using **PyUnicode_FromFormatV()** and don’t truncate the message to an arbitrary length.

*New in version 3.2.*

void **PySys_FormatStderr**(const char *format, ...)

As **PySys_FormatStdout()**, but write to *sys.stderr* or *stderr* instead.

*New in version 3.2.*
void PySys_AddXOption(const wchar_t *s)

Parse s as a set of -X options and add them to the current options mapping as returned by PySys_GetXOptions().

New in version 3.2.

PyObject *PySys_GetXOptions()

Return value: Borrowed reference.
Return the current dictionary of -X options, similarly to sys._xoptions. On error, NULL is returned and an exception is set.

New in version 3.2.
Process Control

**void Py_FatalError(const char *message)**

Print a fatal error message and kill the process. No cleanup is performed. This function should only be invoked when a condition is detected that would make it dangerous to continue using the Python interpreter; e.g., when the object administration appears to be corrupted. On Unix, the standard C library function `abort()` is called which will attempt to produce a core file.

**void Py_Exit(int status)**

Exit the current process. This calls `Py_Finalize()` and then calls the standard C library function `exit(status)`.

**int Py_AtExit(void (*func)())**

Register a cleanup function to be called by `Py_Finalize()`. The cleanup function will be called with no arguments and should return no value. At most 32 cleanup functions can be registered. When the registration is successful, `Py_AtExit()` returns 0; on failure, it returns -1. The cleanup function registered last is called first. Each cleanup function will be called at most once. Since Python's internal finalization will have completed before the cleanup function, no Python APIs should be called by `func`. 
Importing Modules

**PyObject**\* PyImport_ImportModule(const char *\*name)

*Return value: New reference.*

This is a simplified interface to PyImport_ImportModuleEx() below, leaving the *globals* and *locals* arguments set to *NULL* and *level* set to 0. When the *name* argument contains a dot (when it specifies a submodule of a package), the *fromlist* argument is set to the list `['*']` so that the return value is the named module rather than the top-level package containing it as would otherwise be the case. (Unfortunately, this has an additional side effect when *name* in fact specifies a subpackage instead of a submodule: the submodules specified in the package’s *__all__* variable are loaded.) Return a new reference to the imported module, or *NULL* with an exception set on failure. A failing import of a module doesn’t leave the module in sys.modules.

This function always uses absolute imports.

**PyObject**\* PyImport_ImportModuleNoBlock(const char *\*name)

This function is a deprecated alias of PyImport_ImportModule().

*Changed in version 3.3:* This function used to fail immediately when the import lock was held by another thread. In Python 3.3 though, the locking scheme switched to per-module locks for most purposes, so this function’s special behaviour isn’t needed anymore.

**PyObject**\* PyImport_ImportModuleEx(char *\*name,
PyObject *globals, PyObject *locals, PyObject *fromlist)

Import a module. This is best described by referring to the built-in Python function __import__().

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure. Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.

Failing imports remove incomplete module objects, like with PyImport_ImportModule().

PyObject *
PyImport_ImportModuleNameObject(PyObject *name,
PyObject *globals, PyObject *locals, PyObject *fromlist, int level)

Import a module. This is best described by referring to the built-in Python function __import__(), as the standard __import__() function calls this function directly.

The return value is a new reference to the imported module or top-level package, or NULL with an exception set on failure. Like for __import__(), the return value when a submodule of a package was requested is normally the top-level package, unless a non-empty fromlist was given.

New in version 3.3.

PyObject* PyImport_ImportModuleNameLevel(char *name,
PyObject *globals, PyObject *locals, PyObject *fromlist, int level)

Similar to PyImport_ImportModuleNameLevelObject(), but the
name is an UTF-8 encoded string instead of a Unicode object.

*Changed in version 3.3:* Negative values for `level` are no longer accepted.

**PyObject** `PyImport_Import(PyObject *name)`

*Return value: New reference.*

This is a higher-level interface that calls the current “import hook function” (with an explicit `level` of 0, meaning absolute import). It invokes the `__import__()` function from the `__builtins__` of the current globals. This means that the import is done using whatever import hooks are installed in the current environment.

This function always uses absolute imports.

**PyObject** `PyImport_ReloadModule(PyObject *m)`

*Return value: New reference.*

Reload a module. Return a new reference to the reloaded module, or `NULL` with an exception set on failure (the module still exists in this case).

**PyObject** `PyImport_AddModuleObject(PyObject *name)`

Return the module object corresponding to a module name. The `name` argument may be of the form `package.module`. First check the modules dictionary if there’s one there, and if not, create a new one and insert it in the modules dictionary. Return `NULL` with an exception set on failure.

**Note:** This function does not load or import the module; if the module wasn't already loaded, you will get an empty module object. Use `PyImport_ImportModule()` or one of its variants to import a module. Package structures implied by a dotted name for `name` are not created if not already present.
New in version 3.3.

**PyObject** `PyImport_AddModule(const char *name)`

*Return value: Borrowed reference.*
Similar to `PyImport_AddModuleObject()`, but the name is a UTF-8 encoded string instead of a Unicode object.

**PyObject** `PyImport_ExecCodeModule(char *name, PyObject *co)`

*Return value: New reference.*
Given a module name (possibly of the form `package.module`) and a code object read from a Python bytecode file or obtained from the built-in function `compile()`, load the module. Return a new reference to the module object, or `NULL` with an exception set if an error occurred. `name` is removed from `sys.modules` in error cases, even if `name` was already in `sys.modules` on entry to `PyImport_ExecCodeModule()`. Leaving incompletely initialized modules in `sys.modules` is dangerous, as imports of such modules have no way to know that the module object is an unknown (and probably damaged with respect to the module author’s intents) state.

The module’s `__file__` attribute will be set to the code object’s `co_filename`.

This function will reload the module if it was already imported. See `PyImport_ReloadModule()` for the intended way to reload a module.

If `name` points to a dotted name of the form `package.module`, any package structures not already created will still not be created.
See also `PyImport_ExecCodeModuleEx()` and `PyImport_ExecCodeModuleWithPathnames()`.

`PyObject* PyImport_ExecCodeModuleEx(char *name, PyObject *co, char *pathname)`

*Return value: New reference.*

Like `PyImport_ExecCodeModule()`, but the `__file__` attribute of the module object is set to `pathname` if it is non-NULL.

See also `PyImport_ExecCodeModuleWithPathnames()`.

`PyObject* PyImport_ExecCodeModuleObject(PyObject *name, PyObject *co, PyObject *pathname, PyObject *cpathname)`

Like `PyImport_ExecCodeModuleEx()`, but the `__cached__` attribute of the module object is set to `cpathname` if it is non-NULL.

Of the three functions, this is the preferred one to use.

*New in version 3.3.*

`PyObject* PyImport_ExecCodeModuleWithPathnames(char *name, PyObject *co, char *pathname, char *cpathname)`

Like `PyImport_ExecCodeModuleObject()`, but `name`, `pathname` and `cpathname` are UTF-8 encoded strings. Attempts are also made to figure out what the value for `pathname` should be from `cpathname` if the former is set to NULL.

*New in version 3.2.*

*Changed in version 3.3:* Uses `imp.source_from_cache()` in calculating the source path if only the bytecode path is provided.
long **PyImport_GetMagicNumber()**

Return the magic number for Python bytecode files (a.k.a. .pyc and .pyo files). The magic number should be present in the first four bytes of the bytecode file, in little-endian byte order. Returns -1 on error.

*Changed in version 3.3:* Return value of -1 upon failure.

const char **PyImport_GetMagicTag()**

Return the magic tag string for PEP 3147 format Python bytecode file names. Keep in mind that the value at `sys.implementation.cache_tag` is authoritative and should be used instead of this function.

*New in version 3.2.*

PyObject **PyImport_GetModuleDict()**

*Return value: Borrowed reference.*

Return the dictionary used for the module administration (a.k.a. `sys.modules`). Note that this is a per-interpreter variable.

PyObject **PyImport_GetImporter**(PyObject *path)

Return an importer object for a `sys.path/pkg.__path__` item `path`, possibly by fetching it from the `sys.path_importer_cache` dict. If it wasn't yet cached, traverse `sys.path_hooks` until a hook is found that can handle the path item. Return `None` if no hook could; this tells our caller it should fall back to the built-in import mechanism. Cache the result in `sys.path_importer_cache`. Return a new reference to the importer object.

void **_PyImport_Init()**
Initialize the import mechanism. For internal use only.

```c
void PyImport_Cleanup()
```

Empty the module table. For internal use only.

```c
void _PyImport_Fini()
```

Finalize the import mechanism. For internal use only.

```c
PyObject* _PyImport_FindExtension(char *, char *)
```

For internal use only.

```c
PyObject* _PyImport_FixupExtension(char *, char *)
```

For internal use only.

```c
int PyImport_ImportFrozenModuleObject(PyObject *name)
```

Load a frozen module named `name`. Return 1 for success, 0 if the module is not found, and -1 with an exception set if the initialization failed. To access the imported module on a successful load, use `PyImport_ImportModule()`. (Note the misnomer — this function would reload the module if it was already imported.)

*New in version 3.3.*

```c
int PyImport_ImportFrozenModule(char *name)
```

Similar to `PyImport_ImportFrozenModuleObject()`, but the name is a UTF-8 encoded string instead of a Unicode object.

```c
struct _frozen
```

This is the structure type definition for frozen module descriptors, as generated by the `freeze` utility (see `Tools/freeze/` in the Python source distribution). Its definition, found in `Include/import.h`, is:
struct _frozen {
    char *name;
    unsigned char *code;
    int size;
};

struct _frozen* PyImport_FrozenModules
This pointer is initialized to point to an array of struct _frozen records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

int PyImport_AppendInittab(const char *name, PyObject* (*initfunc)(void))
Add a single module to the existing table of built-in modules. This is a convenience wrapper around PyImport_ExtendInittab(), returning -1 if the table could not be extended. The new module can be imported by the name name, and uses the function initfunc as the initialization function called on the first attempted import. This should be called before Py_Initialize().

struct _inittab
Structure describing a single entry in the list of built-in modules. Each of these structures gives the name and initialization function for a module built into the interpreter. The name is an ASCII encoded string. Programs which embed Python may use an array of these structures in conjunction with PyImport_ExtendInittab() to provide additional built-in modules. The structure is defined in Include/import.h as:

struct _inittab {
```c
char *name; /* ASCII encoded
PyObject* (*initfunc)(void);
```

```c
int PyImport_ExtendInitTab(struct _inittab *newtab)
```

Add a collection of modules to the table of built-in modules. The `newtab` array must end with a sentinel entry which contains `NULL` for the name field; failure to provide the sentinel value can result in a memory fault. Returns `0` on success or `-1` if insufficient memory could be allocated to extend the internal table. In the event of failure, no modules are added to the internal table. This should be called before `Py_Initialize()`.
Data marshalling support

These routines allow C code to work with serialized objects using the same data format as the `marshal` module. There are functions to write data into the serialization format, and additional functions that can be used to read the data back. Files used to store marshalled data must be opened in binary mode.

Numeric values are stored with the least significant byte first.

The module supports two versions of the data format: version 0 is the historical version, version 1 shares interned strings in the file, and upon unmarshalling. Version 2 uses a binary format for floating point numbers. `Py_MARSHAL_VERSION` indicates the current file format (currently 2).

```c
void PyMarshal_WriteLongToFile(long value, FILE *file, int version)
    Marshal a long integer, value, to file. This will only write the least-significant 32 bits of value; regardless of the size of the native long type. version indicates the file format.

void PyMarshal_WriteObjectToFile(PyObject *value, FILE *file, int version)
    Marshal a Python object, value, to file. version indicates the file format.

PyObject* PyMarshal_WriteObjectToString(PyObject *value, int version)
    Return a string object containing the marshalled representation of
value.version indicates the file format.

The following functions allow marshalled values to be read back in.

XXX What about error detection? It appears that reading past the end of the file will always result in a negative numeric value (where that's relevant), but it's not clear that negative values won't be handled properly when there's no error. What's the right way to tell? Should only non-negative values be written using these routines?

long PyMarshal_ReadLongFromFile(FILE *file)

Return a C long from the data stream in a FILE* opened for reading. Only a 32-bit value can be read in using this function, regardless of the native size of long.

int PyMarshal_ReadShortFromFile(FILE *file)

Return a C short from the data stream in a FILE* opened for reading. Only a 16-bit value can be read in using this function, regardless of the native size of short.

PyObject* PyMarshal_ReadObjectFromFile(FILE *file)

Return a Python object from the data stream in a FILE* opened for reading. On error, sets the appropriate exception (EOFError or TypeError) and returns NULL.

PyObject*
PyMarshal_ReadLastObjectFromFile(FILE *file)

Return a Python object from the data stream in a FILE* opened for reading. Unlike PyMarshal_ReadObjectFromFile(), this function assumes that no further objects will be read from the file,
allowing it to aggressively load file data into memory so that the de-
serialization can operate from data in memory rather than reading a byte at a time from the file. Only use these variant if you are certain that you won’t be reading anything else from the file. On error, sets the appropriate exception (EOFError or TypeError) and returns NULL.

PyObject* PyMarshal_ReadObjectFromString(char *string, Py_ssize_t len)

Return a Python object from the data stream in a character buffer containing len bytes pointed to by string. On error, sets the appropriate exception (EOFError or TypeError) and returns NULL.
Parsing arguments and building values

These functions are useful when creating your own extensions functions and methods. Additional information and examples are available in *Extending and Embedding the Python Interpreter*.

The first three of these functions described, `PyArg_ParseTuple()`, `PyArg_ParseTupleAndKeywords()`, and `PyArg_Parse()`, all use *format strings* which are used to tell the function about the expected arguments. The format strings use the same syntax for each of these functions.
Parsing arguments

A format string consists of zero or more “format units.” A format unit describes one Python object; it is usually a single character or a parenthesized sequence of format units. With a few exceptions, a format unit that is not a parenthesized sequence normally corresponds to a single address argument to these functions. In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that matches the format unit; and the entry in [square] brackets is the type of the C variable(s) whose address should be passed.

Strings and buffers

These formats allow to access an object as a contiguous chunk of memory. You don’t have to provide raw storage for the returned unicode or bytes area. Also, you won’t have to release any memory yourself, except with the es, es#, et and et# formats.

However, when a Py_buffer structure gets filled, the underlying buffer is locked so that the caller can subsequently use the buffer even inside a Py_BEGIN_ALLOW_THREADS block without the risk of mutable data being resized or destroyed. As a result, you have to call PyBuffer_Release() after you have finished processing the data (or in any early abort case).

Unless otherwise stated, buffers are not NUL-terminated.

Note: For all # variants of formats (s#, y#, etc.), the type of the length argument (int or Py_ssize_t) is controlled by defining the macro PY_SSIZE_T_CLEAN before including Python.h. If the
A macro was defined, length is a Py_ssize_t rather than an int. This behavior will change in a future Python version to only support Py_ssize_t and drop int support. It is best to always define PY_SSIZE_T_CLEAN.

s (str) [const char *]

Convert a Unicode object to a C pointer to a character string. A pointer to an existing string is stored in the character pointer variable whose address you pass. The C string is NUL-terminated. The Python string must not contain embedded NUL bytes; if it does, a TypeError exception is raised. Unicode objects are converted to C strings using 'utf-8' encoding. If this conversion fails, a UnicodeError is raised.

Note: This format does not accept bytes-like objects. If you want to accept filesystem paths and convert them to C character strings, it is preferable to use the 0& format with PyUnicode_FSConverter() as converter.

s* (str, bytes, bytearray or buffer compatible object) [Py_buffer]

This format accepts Unicode objects as well as bytes-like objects. It fills a Py_buffer structure provided by the caller. In this case the resulting C string may contain embedded NUL bytes. Unicode objects are converted to C strings using 'utf-8' encoding.

s# (str, bytes or read-only buffer compatible object) [const char *, int or Py_ssize_t]

Like s*, except that it doesn’t accept mutable buffer-like objects such as bytearray. The result is stored into two C variables, the first one a pointer to a C string, the second one its length. The string may contain embedded null bytes. Unicode objects are converted to C strings using 'utf-8' encoding.
\(z\) (**str** or **None**) [const char **]*

Like **s**, but the Python object may also be **None**, in which case the C pointer is set to **NULL**.

\(z**\) (**str**, **bytes**, **bytearray**, buffer compatible object or **None**) [**Py_buffer**]

Like **s***, but the Python object may also be **None**, in which case the **buf** member of the **Py_buffer** structure is set to **NULL**.

\(z#\) (**str**, **bytes**, read-only buffer compatible object or **None**) [const char ***, int]

Like **s##**, but the Python object may also be **None**, in which case the C pointer is set to **NULL**.

\(y\) (**bytes**) [const char **]*

This format converts a bytes-like object to a C pointer to a character string; it does not accept Unicode objects. The bytes buffer must not contain embedded NUL bytes; if it does, a **TypeError** exception is raised.

\(y**\) (**bytes**, **bytearray** or **bytes-like object**) [**Py_buffer**]

This variant on **s** doesn’t accept Unicode objects, only **bytes-like objects**. **This is the recommended way to accept binary data.**

\(y#\) (**bytes**) [const char ***, int]

This variant on **s#** doesn’t accept Unicode objects, only **bytes-like objects**.

\(S\) (**bytes**) [**PyObject** **]*

Requires that the Python object is a **bytes** object, without attempting any conversion. Raises **TypeError** if the object is not a bytes object. The C variable may also be declared as **PyObject** ***.**

\(Y\) (**bytearray**) [**PyByteArrayObject** **]*

Requires that the Python object is a **bytearray** object, without attempting any conversion. Raises **TypeError** if the object is not
a **bytesarray** object. The C variable may also be declared as **PyObject**.

**u (str) [Py_UNICODE *]**

Convert a Python Unicode object to a C pointer to a NUL-terminated buffer of Unicode characters. You must pass the address of a **Py_UNICODE** pointer variable, which will be filled with the pointer to an existing Unicode buffer. Please note that the width of a **Py_UNICODE** character depends on compilation options (it is either 16 or 32 bits). The Python string must not contain embedded NUL characters; if it does, a **TypeError** exception is raised.

**Note:** Since **u** doesn’t give you back the length of the string, and it may contain embedded NUL characters, it is recommended to use **u#** or **U** instead.

**u# (str) [Py_UNICODE *, int]**

This variant on **u** stores into two C variables, the first one a pointer to a Unicode data buffer, the second one its length.

**Z (str or None) [Py_UNICODE *]**

Like **u**, but the Python object may also be None, in which case the **Py_UNICODE** pointer is set to **NULL**.

**Z# (str or None) [Py_UNICODE *, int]**

Like **u#**, but the Python object may also be None, in which case the **Py_UNICODE** pointer is set to **NULL**.

**U (str) [PyObject **]**

Requires that the Python object is a Unicode object, without attempting any conversion. Raises **TypeError** if the object is not a Unicode object. The C variable may also be declared as **PyObject**.

**w* (bytesarray or read-write byte-oriented buffer) [Py_buffer]**
This format accepts any object which implements the read-write buffer interface. It fills a `Py_buffer` structure provided by the caller. The buffer may contain embedded null bytes. The caller have to call `PyBuffer_Release()` when it is done with the buffer.

```
es (str) [const char *encoding, char **buffer]
```

This variant on `s` is used for encoding Unicode into a character buffer. It only works for encoded data without embedded NUL bytes.

This format requires two arguments. The first is only used as input, and must be a `const char*` which points to the name of an encoding as a NUL-terminated string, or `NULL`, in which case 'utf-8' encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a `char**`; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument.

`PyArg_ParseTuple()` will allocate a buffer of the needed size, copy the encoded data into this buffer and adjust `*buffer` to reference the newly allocated storage. The caller is responsible for calling `PyMem_Free()` to free the allocated buffer after use.

```
et (str, bytes or bytearray) [const char *encoding, char **buffer]
```

Same as `es` except that byte string objects are passed through without recoding them. Instead, the implementation assumes that the byte string object uses the encoding passed in as parameter.

```
es# (str) [const char *encoding, char **buffer, int *buffer_length]
```

This variant on `s#` is used for encoding Unicode into a character buffer. Unlike the `es` format, this variant allows input data which contains NUL characters.
It requires three arguments. The first is only used as input, and must be a `const char*` which points to the name of an encoding as a NUL-terminated string, or `NULL`, in which case encoding is used. An exception is raised if the named encoding is not known to Python. The second argument must be a `char**`; the value of the pointer it references will be set to a buffer with the contents of the argument text. The text will be encoded in the encoding specified by the first argument. The third argument must be a pointer to an integer; the referenced integer will be set to the number of bytes in the output buffer.

There are two modes of operation:

If `*buffer` points a `NULL` pointer, the function will allocate a buffer of the needed size, copy the encoded data into this buffer and set `*buffer` to reference the newly allocated storage. The caller is responsible for calling `PyMem_Free()` to free the allocated buffer after usage.

If `*buffer` points to a non-NULL pointer (an already allocated buffer), `PyArg_ParseTuple()` will use this location as the buffer and interpret the initial value of `*buffer_length` as the buffer size. It will then copy the encoded data into the buffer and NUL-terminate it. If the buffer is not large enough, a `ValueError` will be set.

In both cases, `*buffer_length` is set to the length of the encoded data without the trailing NUL byte.

```c
et# (str, bytes or bytearray) [const char *encoding, char **buffer, int *buffer_length]
```

Same as `es#` except that byte string objects are passed through without recoding them. Instead, the implementation assumes that the byte string object uses the encoding passed in as parameter.
Numbers

\textbf{b (int)} [unsigned char]

Convert a nonnegative Python integer to an unsigned tiny int, stored in a C unsigned char.

\textbf{B (int)} [unsigned char]

Convert a Python integer to a tiny int without overflow checking, stored in a C unsigned char.

\textbf{h (int)} [short int]

Convert a Python integer to a C short int.

\textbf{H (int)} [unsigned short int]

Convert a Python integer to a C unsigned short int, without overflow checking.

\textbf{i (int)} [int]

Convert a Python integer to a plain C int.

\textbf{I (int)} [unsigned int]

Convert a Python integer to a C unsigned int, without overflow checking.

\textbf{l (int)} [long int]

Convert a Python integer to a C long int.

\textbf{k (int)} [unsigned long]

Convert a Python integer to a C unsigned long without overflow checking.

\textbf{L (int)} [PY_LONG_LONG]

Convert a Python integer to a C long long. This format is only available on platforms that support long long (or _int64 on Windows).

\textbf{K (int)} [unsigned PY_LONG_LONG]

Convert a Python integer to a C unsigned long long without
overflow checking. This format is only available on platforms that support unsigned long long (or unsigned _int64 on Windows).

\[
\text{n (int) [Py_ssize_t]}
\]
Convert a Python integer to a C Py_ssize_t.

\[
\text{c (bytes or bytearray of length 1) [char]}
\]
Convert a Python byte, represented as a bytes or bytearray object of length 1, to a C char.

*Changed in version 3.3:* Allow bytearray objects.

\[
\text{C (str of length 1) [int]}
\]
Convert a Python character, represented as a str object of length 1, to a C int.

\[
\text{f (float) [float]}
\]
Convert a Python floating point number to a C float.

\[
\text{d (float) [double]}
\]
Convert a Python floating point number to a C double.

\[
\text{D (complex) [Py_complex]}
\]
Convert a Python complex number to a C Py_complex structure.

**Other objects**

\[
\text{O (object) [PyObject *]}
\]
Store a Python object (without any conversion) in a C object pointer. The C program thus receives the actual object that was passed. The object’s reference count is not increased. The pointer stored is not NULL.

\[
\text{O! (object) [typeobject, PyObject *}]
\]
Store a Python object in a C object pointer. This is similar to \text{O}, but takes two C arguments: the first is the address of a Python type
object, the second is the address of the C variable (of type \texttt{PyObject*}) into which the object pointer is stored. If the Python object does not have the required type, \texttt{TypeError} is raised.

\texttt{0\& (object) [converter, \textit{anything}]}

Convert a Python object to a C variable through a \texttt{converter} function. This takes two arguments: the first is a function, the second is the address of a C variable (of arbitrary type), converted to \texttt{void*}. The \texttt{converter} function in turn is called as follows:

\begin{verbatim}
status = converter(object, address);
\end{verbatim}

where \texttt{object} is the Python object to be converted and \texttt{address} is the \texttt{void*} argument that was passed to the \texttt{PyArg_Parse*()} function. The returned \texttt{status} should be \texttt{1} for a successful conversion and \texttt{0} if the conversion has failed. When the conversion fails, the \texttt{converter} function should raise an exception and leave the content of \texttt{address} unmodified.

If the \texttt{converter} returns \texttt{Py_CLEANUP_SUPPORTED}, it may get called a second time if the argument parsing eventually fails, giving the converter a chance to release any memory that it had already allocated. In this second call, the \texttt{object} parameter will be \texttt{NULL}; \texttt{address} will have the same value as in the original call.

\textit{Changed in version 3.1:} \texttt{Py_CLEANUP_SUPPORTED} was added.

\texttt{p (bool) [int]}

Tests the value passed in for truth (a boolean \texttt{predicate}) and converts the result to its equivalent C true/false integer value. Sets the int to \texttt{1} if the expression was true and \texttt{0} if it was false. This accepts any valid Python value. See \textit{Truth Value Testing} for more information about how Python tests values for truth.
New in version 3.3.

(\texttt{items}) (\texttt{tuple}) [\texttt{matching-items}]

The object must be a Python sequence whose length is the number of format units in \texttt{items}. The C arguments must correspond to the individual format units in \texttt{items}. Format units for sequences may be nested.

It is possible to pass “long” integers (integers whose value exceeds the platform’s \texttt{LONG_MAX}) however no proper range checking is done — the most significant bits are silently truncated when the receiving field is too small to receive the value (actually, the semantics are inherited from downcasts in C — your mileage may vary).

A few other characters have a meaning in a format string. These may not occur inside nested parentheses. They are:

\begin{itemize}
    \item \textバックslash{}
        Indicates that the remaining arguments in the Python argument list are optional. The C variables corresponding to optional arguments should be initialized to their default value — when an optional argument is not specified, \texttt{PyArg_ParseTuple()} does not touch the contents of the corresponding C variable(s).

    \item \textdollar{}
        \texttt{PyArg_ParseTupleAndKeywords()} only: Indicates that the remaining arguments in the Python argument list are keyword-only. Currently, all keyword-only arguments must also be optional arguments, so \textbackslash{} must always be specified before \textdollar{} in the format string.

\end{itemize}

New in version 3.3.

: The list of format units ends here; the string after the colon is used
as the function name in error messages (the “associated value” of the exception that `PyArg_ParseTuple()` raises).

The list of format units ends here; the string after the semicolon is used as the error message instead of the default error message. The `;` and `:` mutually exclude each other.

Note that any Python object references which are provided to the caller are *borrowed* references; do not decrement their reference count!

Additional arguments passed to these functions must be addresses of variables whose type is determined by the format string; these are used to store values from the input tuple. There are a few cases, as described in the list of format units above, where these parameters are used as input values; they should match what is specified for the corresponding format unit in that case.

For the conversion to succeed, the `arg` object must match the format and the format must be exhausted. On success, the `PyArg_Parse*()` functions return true, otherwise they return false and raise an appropriate exception. When the `PyArg_Parse*()` functions fail due to conversion failure in one of the format units, the variables at the addresses corresponding to that and the following format units are left untouched.

### API Functions

```c
int PyArg_ParseTuple(PyObject *args, const char *format, ...)  
```

Parse the parameters of a function that takes only positional parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.
int **PyArg_VaParse** (PyObject *args, const char *format, va_list vargs)

Identical to **PyArg_ParseTuple()**, except that it accepts a `va_list` rather than a variable number of arguments.

int **PyArg_ParseTupleAndKeywords** (PyObject *args, PyObject *kw, const char *format, char *keywords[], ...)

Parse the parameters of a function that takes both positional and keyword parameters into local variables. Returns true on success; on failure, it returns false and raises the appropriate exception.

int **PyArg_VaParseTupleAndKeywords** (PyObject *args, PyObject *kw, const char *format, char *keywords[], va_list vargs)

Identical to **PyArg_ParseTupleAndKeywords()**, except that it accepts a `va_list` rather than a variable number of arguments.

int **PyArg_ValidateKeywordArguments** (PyObject *)

Ensure that the keys in the keywords argument dictionary are strings. This is only needed if **PyArg_ParseTupleAndKeywords()** is not used, since the latter already does this check.

*New in version 3.2.*

int **PyArg_Parse** (PyObject *args, const char *format, ...)

Function used to deconstruct the argument lists of “old-style” functions — these are functions which use the METH_OLDARGS parameter parsing method. This is not recommended for use in parameter parsing in new code, and most code in the standard interpreter has been modified to no longer use this for that purpose. It does remain a convenient way to decompose other tuples, however, and may continue to be used for that purpose.
int PyArg_UnpackTuple(PyObject *args, const char *name, Py_ssize_t min, Py_ssize_t max, ...)

A simpler form of parameter retrieval which does not use a format string to specify the types of the arguments. Functions which use this method to retrieve their parameters should be declared as METH_VARARGS in function or method tables. The tuple containing the actual parameters should be passed as args; it must actually be a tuple. The length of the tuple must be at least min and no more than max; min and max may be equal. Additional arguments must be passed to the function, each of which should be a pointer to a PyObject* variable; these will be filled in with the values from args; they will contain borrowed references. The variables which correspond to optional parameters not given by args will not be filled in; these should be initialized by the caller. This function returns true on success and false if args is not a tuple or contains the wrong number of elements; an exception will be set if there was a failure.

This is an example of the use of this function, taken from the sources for the _weakref helper module for weak references:

```
static PyObject *
weakref_ref(PyObject *self, PyObject *args)
{
    PyObject *object;
    PyObject *callback = NULL;
    PyObject *result = NULL;

    if (PyArg_UnpackTuple(args, "ref", 1, 2, &object, &callback))
    {
        result = PyWeakref_NewRef(object, callback);
    }
    return result;
}
```
The call to `PyArg_UnpackTuple()` in this example is entirely equivalent to this call to `PyArg_ParseTuple()`:

```
PyArg_ParseTuple(args, "0|0:ref", &object, &callback)
```
Building values

`PyObject* Py_BuildValue(const char *format, ...)`

*Return value: New reference.*

Create a new value based on a format string similar to those accepted by the `PyArg_Parse*( )` family of functions and a sequence of values. Returns the value or `NULL` in the case of an error; an exception will be raised if `NULL` is returned.

`Py_BuildValue()` does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

When memory buffers are passed as parameters to supply data to build objects, as for the `s` and `s#` formats, the required data is copied. Buffers provided by the caller are never referenced by the objects created by `Py_BuildValue()`. In other words, if your code invokes `malloc()` and passes the allocated memory to `Py_BuildValue()`, your code is responsible for calling `free()` for that memory once `Py_BuildValue()` returns.

In the following description, the quoted form is the format unit; the entry in (round) parentheses is the Python object type that the format unit will return; and the entry in [square] brackets is the type of the C value(s) to be passed.

The characters space, tab, colon and comma are ignored in format strings (but not within format units such as `s#`). This can be used
to make long format strings a tad more readable.

s (str or None) [char *]
  Convert a null-terminated C string to a Python str object using
  'utf-8' encoding. If the C string pointer is NULL, None is
  used.

s# (str or None) [char *, int]
  Convert a C string and its length to a Python str object using
  'utf-8' encoding. If the C string pointer is NULL, the length is
  ignored and None is returned.

y (bytes) [char *]
  This converts a C string to a Python bytes() object. If the C
  string pointer is NULL, None is returned.

y# (bytes) [char *, int]
  This converts a C string and its lengths to a Python object. If the
  C string pointer is NULL, None is returned.

z (str or None) [char *]
  Same as s.

z# (str or None) [char *, int]
  Same as s#.

u (str) [Py_UNICODE *]
  Convert a null-terminated buffer of Unicode (UCS-2 or UCS-4)
  data to a Python Unicode object. If the Unicode buffer pointer is
  NULL, None is returned.

u# (str) [Py_UNICODE *, int]
  Convert a Unicode (UCS-2 or UCS-4) data buffer and its length
to a Python Unicode object. If the Unicode buffer pointer is
  NULL, the length is ignored and None is returned.

U (str or None) [char *]
Same as \texttt{s}.

\textbf{U\# (}\texttt{str} or \texttt{None}) [char *, int]

Same as \texttt{s\#}.

\textbf{i (}int\textbf{)[int]}

Convert a plain C \texttt{int} to a Python integer object.

\textbf{b (}int\textbf{)[char]}

Convert a plain C \texttt{char} to a Python integer object.

\textbf{h (}int\textbf{)[short int]}

Convert a plain C \texttt{short int} to a Python integer object.

\textbf{l (}int\textbf{)[long int]}

Convert a C \texttt{long int} to a Python integer object.

\textbf{B (}int\textbf{)[unsigned char]}

Convert a C unsigned \texttt{char} to a Python integer object.

\textbf{H (}int\textbf{)[unsigned short int]}

Convert a C unsigned \texttt{short int} to a Python integer object.

\textbf{I (}int\textbf{)[unsigned int]}

Convert a C unsigned \texttt{int} to a Python integer object.

\textbf{k (}int\textbf{)[unsigned long]}

Convert a C unsigned \texttt{long} to a Python integer object.

\textbf{L (}int\textbf{)[PY\_LONG\_LONG]}

Convert a C \texttt{long long} to a Python integer object. Only available on platforms that support \texttt{long long} (or \_int64 on Windows).

\textbf{K (}int\textbf{)[unsigned PY\_LONG\_LONG]}

Convert a C unsigned \texttt{long long} to a Python integer object. Only available on platforms that support unsigned
long long (or unsigned _int64 on Windows).

n (int)[Py_ssize_t]
Convert a C Py_ssize_t to a Python integer.

c (bytes of length 1)[char]
Convert a C int representing a byte to a Python bytes object of length 1.

C (str of length 1)[int]
Convert a C int representing a character to Python str object of length 1.

d (float)[double]
Convert a C double to a Python floating point number.

f (float)[float]
Convert a C float to a Python floating point number.

D (complex)[Py_complex *]
Convert a C Py_complex structure to a Python complex number.

O (object)[PyObject *]
Pass a Python object untouched (except for its reference count, which is incremented by one). If the object passed in is a NULL pointer, it is assumed that this was caused because the call producing the argument found an error and set an exception. Therefore, Py_BuildValue() will return NULL but won't raise an exception. If no exception has been raised yet, SystemError is set.

S (object)[PyObject *]
Same as O.

N (object)[PyObject *]
Same as O, except it doesn't increment the reference count on
the object. Useful when the object is created by a call to an object constructor in the argument list.

0& (object) [converter, anything]
Convert anything to a Python object through a converter function. The function is called with anything (which should be compatible with void *) as its argument and should return a "new" Python object, or NULL if an error occurred.

(items) (tuple) [matching-items]
Convert a sequence of C values to a Python tuple with the same number of items.

[items] (list) [matching-items]
Convert a sequence of C values to a Python list with the same number of items.

{items} (dict) [matching-items]
Convert a sequence of C values to a Python dictionary. Each pair of consecutive C values adds one item to the dictionary, serving as key and value, respectively.

If there is an error in the format string, the SystemError exception is set and NULL returned.

PyObject* Py_VaBuildValue(const char *format, va_list vargs)
Identical to Py_BuildValue(), except that it accepts a va_list rather than a variable number of arguments.
String conversion and formatting

Functions for number conversion and formatted string output.

```c
int PyOS_snprintf(char *str, size_t size, const char *format, ...) {
    Output not more than size bytes to str according to the format
    string format and the extra arguments. See the Unix man page
    snprintf(2).
}
```

```c
int PyOS_vsnprintf(char *str, size_t size, const char *format, va_list va) {
    Output not more than size bytes to str according to the format
    string format and the variable argument list va. Unix man page
    vsnprintf(2).
}
```

`PyOS_snprintf()` and `PyOS_vsnprintf()` wrap the Standard C library functions `snprintf()` and `vsnprintf()`. Their purpose is to guarantee consistent behavior in corner cases, which the Standard C functions do not.

The wrappers ensure that `str[\*size-1]` is always '\0' upon return. They never write more than `size` bytes (including the trailing '\0') into str. Both functions require that `str != NULL`, `size > 0` and `format != NULL`.

If the platform doesn’t have `vsnprintf()` and the buffer size needed to avoid truncation exceeds `size` by more than 512 bytes, Python aborts with a `Py_FatalError`.

The return value `(rv)` for these functions should be interpreted as follows:
When \( 0 \leq rv < size \), the output conversion was successful and \( rv \) characters were written to \( str \) (excluding the trailing '\0' byte at \( str[rv] \)).

- When \( rv \geq size \), the output conversion was truncated and a buffer with \( rv + 1 \) bytes would have been needed to succeed. \( str[\text{size-1}] \) is '\0' in this case.

- When \( rv < 0 \), "something bad happened." \( str[\text{size-1}] \) is '\0' in this case too, but the rest of \( str \) is undefined. The exact cause of the error depends on the underlying platform.

The following functions provide locale-independent string to number conversions.

```c
double PyOS_string_to_double(const char *s, char **endptr, PyObject *overflow_exception)
```

Convert a string \( s \) to a double, raising a Python exception on failure. The set of accepted strings corresponds to the set of strings accepted by Python's `float()` constructor, except that \( s \) must not have leading or trailing whitespace. The conversion is independent of the current locale.

If \( endptr \) is NULL, convert the whole string. Raise ValueError and return `-1.0` if the string is not a valid representation of a floating-point number.

If \( endptr \) is not NULL, convert as much of the string as possible and set \( *endptr \) to point to the first unconverted character. If no initial segment of the string is the valid representation of a floating-point number, set \( *endptr \) to point to the beginning of the string, raise ValueError, and return `-1.0`.

If \( s \) represents a value that is too large to store in a float (for
example, "1e500" is such a string on many platforms) then if
overflow_exception is NULL return Py_HUGE_VAL (with an
appropriate sign) and don’t set any exception. Otherwise,
overflow_exception must point to a Python exception object;
raise that exception and return -1.0. In both cases, set *endptr
to point to the first character after the converted value.

If any other error occurs during the conversion (for example an out-
of-memory error), set the appropriate Python exception and return
-1.0.

*New in version 3.1.*

```c
char* PyOS_double_to_string(double val, char format_code,
int precision, int flags, int *ptype)
```

Convert a double val to a string using supplied format_code,
precision, and flags.

format_code must be one of 'e', 'E', 'f', 'F', 'g', 'G' or
'r'. For 'r', the supplied precision must be 0 and is ignored.
The 'r' format code specifies the standard repr() format.

flags can be zero or more of the values Py_DTSF_SIGN,
Py_DTSF_ADD_DOT_0, or Py_DTSF_ALT, or-ed together:

- Py_DTSF_SIGN means to always precede the returned string
  with a sign character, even if val is non-negative.
- Py_DTSF_ADD_DOT_0 means to ensure that the returned
  string will not look like an integer.
- Py_DTSF_ALT means to apply “alternate” formatting rules.
  See the documentation for the PyOS_snprintf() '#'
specifier for details.

If ptype is non-NULL, then the value it points to will be set to one of
Py_DTST_FINITE, Py_DTST_INFINITE, or Py_DTST_NAN, signifying that val is a finite number, an infinite number, or not a number, respectively.

The return value is a pointer to buffer with the converted string or NULL if the conversion failed. The caller is responsible for freeing the returned string by calling PyMem_Free().

New in version 3.1.

int PyOS_stricmp(char *s1, char *s2)
Case insensitive comparison of strings. The function works almost identically to strcmp() except that it ignores the case.

int PyOS_strnicmp(char *s1, char *s2, Py_ssize_t size)
Case insensitive comparison of strings. The function works almost identically to strncmp() except that it ignores the case.
Reflection

PyObject* PyEval_GetBuiltins()

*Return value: Borrowed reference.*
Return a dictionary of the builtins in the current execution frame, or the interpreter of the thread state if no frame is currently executing.

PyObject* PyEval_GetLocals()

*Return value: Borrowed reference.*
Return a dictionary of the local variables in the current execution frame, or NULL if no frame is currently executing.

PyObject* PyEval_GetGlobals()

*Return value: Borrowed reference.*
Return a dictionary of the global variables in the current execution frame, or NULL if no frame is currently executing.

PyFrameObject* PyEval_GetFrame()

*Return value: Borrowed reference.*
Return the current thread state's frame, which is NULL if no frame is currently executing.

int PyFrame_GetLineNumber(PyFrameObject *frame)

Return the line number that frame is currently executing.

const char* PyEval_GetFuncName(PyObject *func)

Return the name of func if it is a function, class or instance object, else the name of funcs type.

const char* PyEval_GetFuncDesc(PyObject *func)

Return a description string, depending on the type of func. Return
values include “()” for functions and methods, ” constructor”, " instance”, and ” object”. Concatenated with the result of `PyEval_GetFuncName()`, the result will be a description of `func`. 
Codec registry and support functions

int **PyCodec_Register**(PyObject *search_function)

Register a new codec search function.

As side effect, this tries to load the encodings package, if not yet done, to make sure that it is always first in the list of search functions.

int **PyCodec_KnownEncoding**(const char *encoding)

Return 1 or 0 depending on whether there is a registered codec for the given encoding.

PyObject** PyCodec_Encode**(PyObject *object, const char *encoding, const char *errors)

Generic codec based encoding API.

object is passed through the encoder function found for the given encoding using the error handling method defined by errors. errors may be NULL to use the default method defined for the codec. Raises a LookupError if no encoder can be found.

PyObject** PyCodec_Decode**(PyObject *object, const char *encoding, const char *errors)

Generic codec based decoding API.

object is passed through the decoder function found for the given encoding using the error handling method defined by errors. errors may be NULL to use the default method defined for the codec. Raises a LookupError if no encoder can be found.
Codec lookup API

In the following functions, the *encoding* string is looked up converted to all lower-case characters, which makes encodings looked up through this mechanism effectively case-insensitive. If no codec is found, a *KeyError* is set and *NULL* returned.

**PyObject**\* *PyCodec_Encoder*(const char *encoding)  
Get an encoder function for the given *encoding*.

**PyObject**\* *PyCodec_Decoder*(const char *encoding)  
Get a decoder function for the given *encoding*.

**PyObject**\* *PyCodec_IncrementalEncoder*(const char *encoding, const char *errors)  
Get an *IncrementalEncoder* object for the given *encoding*.

**PyObject**\* *PyCodec_IncrementalDecoder*(const char *encoding, const char *errors)  
Get an *IncrementalDecoder* object for the given *encoding*.

**PyObject**\* *PyCodec_StreamReader*(const char *encoding, PyObject *stream, const char *errors)  
Get a *StreamReader* factory function for the given *encoding*.

**PyObject**\* *PyCodec_StreamWriter*(const char *encoding, PyObject *stream, const char *errors)  
Get a *StreamWriter* factory function for the given *encoding*. 
Registry API for Unicode encoding error handlers

```c
int PyCodec_RegisterError(const char *name, PyObject *error)
```

Register the error handling callback function `error` under the given `name`. This callback function will be called by a codec when it encounters unencodable characters/undecodable bytes and `name` is specified as the error parameter in the call to the encode/decode function.

The callback gets a single argument, an instance of `UnicodeEncodeError`, `UnicodeDecodeError` or `UnicodeTranslateError` that holds information about the problematic sequence of characters or bytes and their offset in the original string (see `Unicode Exception Objects` for functions to extract this information). The callback must either raise the given exception, or return a two-item tuple containing the replacement for the problematic sequence, and an integer giving the offset in the original string at which encoding/decoding should be resumed.

Return 0 on success, -1 on error.

```c
PyObject* PyCodec_LookupError(const char *name)
```

Lookup the error handling callback function registered under `name`. As a special case `NULL` can be passed, in which case the error handling callback for “strict” will be returned.

```c
PyObject* PyCodec_StrictErrors(PyObject *exc)
```

Raise `exc` as an exception.
**PyObject** *PyCodec_IgnoreErrors**(PyObject *exc)**

Ignore the unicode error, skipping the faulty input.

**PyObject** *PyCodec_ReplacErrors**(PyObject *exc)**

Replace the unicode encode error with ? or U+FFFD.

**PyObject** *
**PyCodec/XMLCharRefReplaceErrors**(PyObject *exc)**

Replace the unicode encode error with XML character references.

**PyObject** *
**PyCodec/BackslashReplaceErrors**(PyObject *exc)**

Replace the unicode encode error with backslash escapes (\x, \u and \U).
Abstract Objects Layer

The functions in this chapter interact with Python objects regardless of their type, or with wide classes of object types (e.g. all numerical types, or all sequence types). When used on object types for which they do not apply, they will raise a Python exception.

It is not possible to use these functions on objects that are not properly initialized, such as a list object that has been created by `PyList_New()`, but whose items have not been set to some non-NULL value yet.

- Object Protocol
- Number Protocol
- Sequence Protocol
- Mapping Protocol

- Buffer Protocol
  - Buffer structure
  - Buffer request types
    - request-independent fields
    - readonly, format
    - shape, strides, suboffsets
    - contiguity requests
    - compound requests
  - Complex arrays
    - NumPy-style: shape and strides
    - PIL-style: shape, strides and suboffsets
  - Buffer-related functions
- Old Buffer Protocol
Object Protocol

PyObject* Py_NotImplemented

The NotImplemented singleton, used to signal that an operation is not implemented for the given type combination.

Py_RETURN_NOTIMPLEMENTED

Properly handle returning Py_NotImplemented from within a C function (that is, increment the reference count of Not Implemented and return it).

int PyObject_Print(PyObject *o, FILE *fp, int flags)

Print an object o, on file fp. Returns -1 on error. The flags argument is used to enable certain printing options. The only option currently supported is Py_PRINT_RAW; if given, the str() of the object is written instead of the repr().

int PyObject_HasAttr(PyObject *o, PyObject *attr_name)

Returns 1 if o has the attribute attr_name, and 0 otherwise. This is equivalent to the Python expression hasattr(o, attr_name). This function always succeeds.

int PyObject_HasAttrString(PyObject *o, const char *attr_name)

Returns 1 if o has the attribute attr_name, and 0 otherwise. This is equivalent to the Python expression hasattr(o, attr_name). This function always succeeds.

PyObject* PyObject_GetAttr(PyObject *o, PyObject *attr_name)

Retrieve an attribute named \textit{attr\_name} from object \textit{o}. Returns the attribute value on success, or \textit{NULL} on failure. This is the equivalent of the Python expression \texttt{o.attr\_name}.

\textbf{PyObject*} \texttt{PyObject\_GetAttrString}(PyObject *\textit{o}, const char *\textit{attr\_name})

\textit{Return value: New reference.}
Retrieve an attribute named \textit{attr\_name} from object \textit{o}. Returns the attribute value on success, or \textit{NULL} on failure. This is the equivalent of the Python expression \texttt{o.attr\_name}.

\textbf{PyObject*} \texttt{PyObject\_GenericGetAttr}(PyObject *\textit{o}, PyObject *\textit{name})

Generic attribute getter function that is meant to be put into a type object's \texttt{tp\_getattro} slot. It looks for a descriptor in the dictionary of classes in the object's MRO as well as an attribute in the object's \texttt{__dict__} (if present). As outlined in \textbf{Implementing Descriptors}, data descriptors take preference over instance attributes, while non-data descriptors don't. Otherwise, an \textbf{AttributeError} is raised.

\textbf{int} \texttt{PyObject\_SetAttr}(PyObject *\textit{o}, PyObject *\textit{attr\_name}, PyObject *\textit{v})

Set the value of the attribute named \textit{attr\_name}, for object \textit{o}, to the value \textit{v}. Returns \texttt{-1} on failure. This is the equivalent of the Python statement \texttt{o.attr\_name = v}.

\textbf{int} \texttt{PyObject\_SetAttrString}(PyObject *\textit{o}, const char *\textit{attr\_name}, PyObject *\textit{v})

Set the value of the attribute named \textit{attr\_name}, for object \textit{o}, to the value \textit{v}. Returns \texttt{-1} on failure. This is the equivalent of the Python statement \texttt{o.attr\_name = v}.
int **PyObject_GenericSetAttr**(PyObject *o, PyObject *name, PyObject *value)

Generic attribute setter function that is meant to be put into a type object's `tp_setattro` slot. It looks for a data descriptor in the dictionary of classes in the object's MRO, and if found it takes preference over setting the attribute in the instance dictionary. Otherwise, the attribute is set in the object's `__dict__` (if present). Otherwise, an `AttributeError` is raised and `-1` is returned.

int **PyObject_DelAttr**(PyObject *o, PyObject *attr_name)

Delete attribute named `attr_name`, for object `o`. Returns `-1` on failure. This is the equivalent of the Python statement `del o.attr_name`.

int **PyObject_DelAttrString**(PyObject *o, const char *attr_name)

Delete attribute named `attr_name`, for object `o`. Returns `-1` on failure. This is the equivalent of the Python statement `del o.attr_name`.

PyObject* **PyType_GenericGetDict**(PyObject *o, void *context)

A generic implementation for the getter of a `__dict__` descriptor. It creates the dictionary if necessary.

*New in version 3.3.*

int **PyType_GenericSetDict**(PyObject *o, void *context)

A generic implementation for the setter of a `__dict__` descriptor. This implementation does not allow the dictionary to be deleted.
New in version 3.3.

**PyObject** PyObject\_RichCompare(PyObject *o1, PyObject *o2, int opid)

*Return value: New reference.*

Compare the values of o1 and o2 using the operation specified by opid, which must be one of Py\_LT, Py\_LE, Py\_EQ, Py\_NE, Py\_GT, or Py\_GE, corresponding to <, <=, ==, !=, >, or >= respectively. This is the equivalent of the Python expression `o1 op o2`, where op is the operator corresponding to opid. Returns the value of the comparison on success, or NULL on failure.

**int** PyObject\_RichCompareBool(PyObject *o1, PyObject *o2, int opid)

Compare the values of o1 and o2 using the operation specified by opid, which must be one of Py\_LT, Py\_LE, Py\_EQ, Py\_NE, Py\_GT, or Py\_GE, corresponding to <, <=, ==, !=, >, or >= respectively. Returns -1 on error, 0 if the result is false, 1 otherwise. This is the equivalent of the Python expression `o1 op o2`, where op is the operator corresponding to opid.

**Note:** If o1 and o2 are the same object, `PyObject\_RichCompareBool()` will always return 1 for Py\_EQ and 0 for Py\_NE.

**PyObject** PyObject\_Repr(PyObject *o)

*Return value: New reference.*

Compute a string representation of object o. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression `repr(o)`. Called by the repr() built-in function.
PyObject* **PyObject_ASCII** (PyObject *o)

As **PyObject_Repr()**, compute a string representation of object o, but escape the non-ASCII characters in the string returned by **PyObject_Repr()** with \x, \u or \U escapes. This generates a string similar to that returned by **PyObject_Repr()** in Python 2. Called by the **ascii()** built-in function.

PyObject* **PyObject_Str** (PyObject *o)

*Return value: New reference.*

Compute a string representation of object o. Returns the string representation on success, NULL on failure. This is the equivalent of the Python expression str(o). Called by the **str()** built-in function and, therefore, by the **print()** function.

PyObject* **PyObject_Bytes** (PyObject *o)

Compute a bytes representation of object o. NULL is returned on failure and a bytes object on success. This is equivalent to the Python expression bytes(o), when o is not an integer. Unlike bytes(o), a TypeError is raised when o is an integer instead of a zero-initialized bytes object.

int **PyObject_IsInstance** (PyObject *inst, PyObject *cls)

Returns 1 if *inst* is an instance of the class *cls* or a subclass of *cls*, or 0 if not. On error, returns -1 and sets an exception. If *cls* is a type object rather than a class object, **PyObject_IsInstance()** returns 1 if *inst* is of type *cls*. If *cls* is a tuple, the check will be done against every entry in *cls*. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0. If *inst* is not a class instance and *cls* is neither a type object, nor a class object, nor a tuple, *inst* must have a **__class__** attribute — the class relationship of the value of that attribute with *cls* will be used to
determine the result of this function.

Subclass determination is done in a fairly straightforward way, but includes a wrinkle that implementors of extensions to the class system may want to be aware of. If A and B are class objects, B is a subclass of A if it inherits from A either directly or indirectly. If either is not a class object, a more general mechanism is used to determine the class relationship of the two objects. When testing if B is a subclass of A, if A is B, PyObject_IsSubclass() returns true. If A and B are different objects, B's __bases__ attribute is searched in a depth-first fashion for A — the presence of the __bases__ attribute is considered sufficient for this determination.

int PyObject_IsSubclass(PyObject *derived, PyObject *cls)

Returns 1 if the class derived is identical to or derived from the class cls, otherwise returns 0. In case of an error, returns -1. If cls is a tuple, the check will be done against every entry in cls. The result will be 1 when at least one of the checks returns 1, otherwise it will be 0. If either derived or cls is not an actual class object (or tuple), this function uses the generic algorithm described above.

int PyCallable_Check(PyObject *o)

Determine if the object o is callable. Return 1 if the object is callable and 0 otherwise. This function always succeeds.

PyObject* PyObject_Call(PyObject *callable_object, 
PyObject *args, PyObject *kw)

Call a callable Python object callable_object, with arguments given by the tuple args, and named arguments given by the dictionary kw. If no named arguments are needed, kw may be NULL. args
must not be `NULL`, use an empty tuple if no arguments are needed. Returns the result of the call on success, or `NULL` on failure. This is the equivalent of the Python expression `callable_object(*args, **kw).

PyObject* `PyObject_CallObject` (PyObject *callable_object, PyObject *args)

*Return value: New reference.*
Call a callable Python object `callable_object`, with arguments given by the tuple `args`. If no arguments are needed, then `args` may be `NULL`. Returns the result of the call on success, or `NULL` on failure. This is the equivalent of the Python expression `callable_object(*args).

PyObject* `PyObject_CallFunction` (PyObject *callable, char *format, ...)

*Return value: New reference.*
Call a callable Python object `callable`, with a variable number of C arguments. The C arguments are described using a `Py_BuildValue()` style format string. The format may be `NULL`, indicating that no arguments are provided. Returns the result of the call on success, or `NULL` on failure. This is the equivalent of the Python expression `callable(*args)`. Note that if you only pass `PyObject * args`, `PyObject_CallFunctionObjArgs()` is a faster alternative.

PyObject* `PyObject_CallMethod` (PyObject *o, char *method, char *format, ...)

*Return value: New reference.*
Call the method named `method` of object `o` with a variable number of C arguments. The C arguments are described by a `Py_BuildValue()` format string that should produce a tuple. The
format may be *NULL*, indicating that no arguments are provided. Returns the result of the call on success, or *NULL* on failure. This is the equivalent of the Python expression `o.method(args)`. Note that if you only pass `PyObject * args`, `PyObject_CallMethodObjArgs()` is a faster alternative.

`PyObject*`  
`PyObject_CallFunctionObjArgs(PyObject *callable, ..., NULL)`  

*Return value: New reference.*  
Call a callable Python object `callable`, with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by *NULL*. Returns the result of the call on success, or *NULL* on failure.

`PyObject*`  
`PyObject_CallMethodObjArgs(PyObject *o, PyObject *name, ..., NULL)`  

*Return value: New reference.*  
Calls a method of the object `o`, where the name of the method is given as a Python string object in `name`. It is called with a variable number of `PyObject*` arguments. The arguments are provided as a variable number of parameters followed by *NULL*. Returns the result of the call on success, or *NULL* on failure.

`Py_hash_t`  
`PyObject_Hash(PyObject *o)`  

Compute and return the hash value of an object `o`. On failure, return `-1`. This is the equivalent of the Python expression `hash(o)`.

*Changed in version 3.2:* The return type is now `Py_hash_t`. This is a signed integer the same size as `Py_ssize_t`.

`Py_hash_t`  
`PyObject_HashNotImplemented(PyObject *o)`
Set a `TypeError` indicating that `type(o)` is not hashable and return `-1`. This function receives special treatment when stored in a `tp_hash` slot, allowing a type to explicitly indicate to the interpreter that it is not hashable.

```c
int PyObject_IsTrue(PyObject *o)
```

Returns `1` if the object `o` is considered to be true, and `0` otherwise. This is equivalent to the Python expression `not not o`. On failure, return `-1`.

```c
int PyObject_Not(PyObject *o)
```

Returns `0` if the object `o` is considered to be true, and `1` otherwise. This is equivalent to the Python expression `not o`. On failure, return `-1`.

```c
PyObject* PyObject_Type(PyObject *o)
```

When `o` is non-NULL, returns a type object corresponding to the object type of object `o`. On failure, raises `SystemError` and returns `NULL`. This is equivalent to the Python expression `type(o)`. This function increments the reference count of the return value. There's really no reason to use this function instead of the common expression `o->ob_type`, which returns a pointer of type `PyTypeObject*`, except when the incremented reference count is needed.

```c
int PyObject_TypeCheck(PyObject *o, PyTypeObject *type)
```

Return true if the object `o` is of type `type` or a subtype of `type`. Both parameters must be non-NULL.

```c
Py_ssize_t PyObject_Length(PyObject *o)
```
Py_ssize_t **PyObject_Size(PyObject *o)**
Return the length of object o. If the object o provides either the sequence and mapping protocols, the sequence length is returned. On error, -1 is returned. This is the equivalent to the Python expression `len(o)`.

**PyObject** PyObject**_**GetI**t**em**(PyObject *o, PyObject *key)**
_Return value: New reference._
Return element of o corresponding to the object key or NULL on failure. This is the equivalent of the Python expression `o[key]`.

int **PyObject_SetI**tem**(PyObject *o, PyObject *key, PyObject *v)**
Map the object key to the value v. Returns -1 on failure. This is the equivalent of the Python statement `o[key] = v`.

int **PyObject_DelI**tem**(PyObject *o, PyObject *key)**
Delete the mapping for key from o. Returns -1 on failure. This is the equivalent of the Python statement `del o[key]`.

**PyObject** **_**Py**Object**_**_**D**i**r**(PyObject *o)**
_Return value: New reference._
This is equivalent to the Python expression `dir(o)`, returning a (possibly empty) list of strings appropriate for the object argument, or NULL if there was an error. If the argument is NULL, this is like the Python `dir()`, returning the names of the current locals; in this case, if no execution frame is active then NULL is returned but PyErr_Occurred() will return false.

**PyObject** **_**Py**Object**_**_**GetIter**(PyObject *o)**
_Return value: New reference._
This is equivalent to the Python expression `iter(o)`. It returns a new iterator for the object argument, or the object itself if the object
is already an iterator. Raises TypeError and returns NULL if the object cannot be iterated.
Number Protocol

int PyNumber_Check(PyObject *o)

Returns 1 if the object o provides numeric protocols, and false otherwise. This function always succeeds.

PyObject* PyNumber_Add(PyObject *o1, PyObject *o2)

Returns the result of adding o1 and o2, or NULL on failure. This is the equivalent of the Python expression o1 + o2.

PyObject* PyNumber_Subtract(PyObject *o1, PyObject *o2)

Returns the result of subtracting o2 from o1, or NULL on failure. This is the equivalent of the Python expression o1 - o2.

PyObject* PyNumber_Multiply(PyObject *o1, PyObject *o2)

Returns the result of multiplying o1 and o2, or NULL on failure. This is the equivalent of the Python expression o1 * o2.

PyObject* PyNumber_FloorDivide(PyObject *o1, PyObject *o2)

Return the floor of o1 divided by o2, or NULL on failure. This is equivalent to the “classic” division of integers.

PyObject* PyNumber_TrueDivide(PyObject *o1, PyObject *o2)

Return a reasonable approximation for the mathematical value of o1 divided by o2, or NULL on failure. The return value is
approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers.

PyObject* PyNumber_Remainder(PyObject *o1, PyObject *o2)

Returns the remainder of dividing o1 by o2, or NULL on failure. This is the equivalent of the Python expression o1 % o2.

PyObject* PyNumber_Divmod(PyObject *o1, PyObject *o2)

See the built-in function divmod(). Returns NULL on failure. This is the equivalent of the Python expression divmod(o1, o2).

PyObject* PyNumber_Power(PyObject *o1, PyObject *o2, PyObject *o3)

See the built-in function pow(). Returns NULL on failure. This is the equivalent of the Python expression pow(o1, o2, o3), where o3 is optional. If o3 is to be ignored, pass Py_None in its place (passing NULL for o3 would cause an illegal memory access).

PyObject* PyNumber_Negative(PyObject *o)

Returns the negation of o on success, or NULL on failure. This is the equivalent of the Python expression -o.

PyObject* PyNumber_Positive(PyObject *o)

Returns o on success, or NULL on failure. This is the equivalent of
the Python expression `+o`.

PyObject* **PyNumber_Absolute**(PyObject *o)

*Return value: New reference.*
Returns the absolute value of `o`, or `NULL` on failure. This is the equivalent of the Python expression `abs(o)`.

PyObject* **PyNumber_Invert**(PyObject *o)

*Return value: New reference.*
Returns the bitwise negation of `o` on success, or `NULL` on failure. This is the equivalent of the Python expression `~o`.

PyObject* **PyNumber_Lshift**(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the result of left shifting `o1` by `o2` on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 << o2`.

PyObject* **PyNumber_Rshift**(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the result of right shifting `o1` by `o2` on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 >> o2`.

PyObject* **PyNumber_And**(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the “bitwise and” of `o1` and `o2` on success and `NULL` on failure. This is the equivalent of the Python expression `o1 & o2`.

PyObject* **PyNumber_Xor**(PyObject *o1, PyObject *o2)

*Return value: New reference.*
Returns the “bitwise exclusive or” of `o1` by `o2` on success, or `NULL` on failure. This is the equivalent of the Python expression `o1 ^ o2`.
PyObject* **PyNumber** _**Or** *(PyObject* o1, PyObject* o2)*

*Return value: New reference.*
Returns the “bitwise or” of o1 and o2 on success, or NULL on failure. This is the equivalent of the Python expression o1 | o2.

PyObject* **PyNumber** _**InPlaceAdd** *(PyObject* o1, PyObject* o2)*

*Return value: New reference.*
Returns the result of adding o1 and o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 += o2.

PyObject* **PyNumber** _**InPlaceSubtract** *(PyObject* o1, PyObject* o2)*

*Return value: New reference.*
Returns the result of subtracting o2 from o1, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 -= o2.

PyObject* **PyNumber** _**InPlaceMultiply** *(PyObject* o1, PyObject* o2)*

*Return value: New reference.*
Returns the result of multiplying o1 and o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 *= o2.

PyObject* **PyNumber** _**InPlaceFloorDivide** *(PyObject* o1, PyObject* o2)*

*Return value: New reference.*
Returns the mathematical floor of dividing o1 by o2, or NULL on failure. The operation is done *in-place* when o1 supports it. This is the equivalent of the Python statement o1 //= o2.
PyObject* PyNumber_InPlaceTrueDivide(PyObject *o1, PyObject *o2)

Return a reasonable approximation for the mathematical value of o1 divided by o2, or NULL on failure. The return value is “approximate” because binary floating point numbers are approximate; it is not possible to represent all real numbers in base two. This function can return a floating point value when passed two integers. The operation is done in-place when o1 supports it.

PyObject* PyNumber_InPlaceRemainder(PyObject *o1, PyObject *o2)

Returns the remainder of dividing o1 by o2, or NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 %= o2.

PyObject* PyNumber_InPlacePower(PyObject *o1, PyObject *o2, PyObject *o3)

See the built-in function pow(). Returns NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python statement o1 **= o2 when o3 is Py_None, or an in-place variant of pow(o1, o2, o3) otherwise. If o3 is to be ignored, pass Py_None in its place (passing NULL for o3 would cause an illegal memory access).

PyObject* PyNumber_InPlaceLshift(PyObject *o1, PyObject *o2)

Returns the result of left shifting o1 by o2 on success, or NULL on failure. The operation is done in-place when o1 supports it. This is
the equivalent of the Python statement $o1 \ll= o2$.

**PyObject**\* **PyNumber\_InPlaceRshift**(**PyObject** \*o1, **PyObject** \*o2)

*Rvalue: New reference.*
Returns the result of right shifting $o1$ by $o2$ on success, or *NULL* on failure. The operation is done *in-place* when $o1$ supports it. This is the equivalent of the Python statement $o1 \gg= o2$.

**PyObject**\* **PyNumber\_InPlaceAnd**(**PyObject** \*o1, **PyObject** \*o2)

*Rvalue: New reference.*
Returns the “bitwise and” of $o1$ and $o2$ on success and *NULL* on failure. The operation is done *in-place* when $o1$ supports it. This is the equivalent of the Python statement $o1 \&= o2$.

**PyObject**\* **PyNumber\_InPlaceXor**(**PyObject** \*o1, **PyObject** \*o2)

*Rvalue: New reference.*
Returns the “bitwise exclusive or” of $o1$ by $o2$ on success, or *NULL* on failure. The operation is done *in-place* when $o1$ supports it. This is the equivalent of the Python statement $o1 ^= o2$.

**PyObject**\* **PyNumber\_InPlaceOr**(**PyObject** \*o1, **PyObject** \*o2)

*Rvalue: New reference.*
Returns the “bitwise or” of $o1$ and $o2$ on success, or *NULL* on failure. The operation is done *in-place* when $o1$ supports it. This is the equivalent of the Python statement $o1 | = o2$.

**PyObject**\* **PyNumber\_Long**(**PyObject** \*o)

*Rvalue: New reference.*
Returns the $o$ converted to an integer object on success, or *NULL* on failure. This is the equivalent of the Python expression `int(o)`.

**PyObject**\* **PyNumber\_Float**(**PyObject** \*o)
Returns the o converted to a float object on success, or NULL on failure. This is the equivalent of the Python expression `float(o)`.

PyObject* PyNumber_Index(PyObject *o)
Returns the o converted to a Python int on success or NULL with a TypeError exception raised on failure.

PyObject* PyNumber_ToBase(PyObject *n, int base)
Returns the integer n converted to base base as a string. The base argument must be one of 2, 8, 10, or 16. For base 2, 8, or 16, the returned string is prefixed with a base marker of '0b', '0o', or '0x', respectively. If n is not a Python int, it is converted with PyNumber_Index() first.

Py_ssize_t PyNumber_AsSsize_t(PyObject *o, PyObject *exc)
Returns o converted to a Py_ssize_t value if o can be interpreted as an integer. If the call fails, an exception is raised and -1 is returned.

If o can be converted to a Python int but the attempt to convert to a Py_ssize_t value would raise an OverflowError, then the exc argument is the type of exception that will be raised (usually IndexError or OverflowError). If exc is NULL, then the exception is cleared and the value is clipped to PY_SSIZE_T_MIN for a negative integer or PY_SSIZE_T_MAX for a positive integer.

int PyIndex_Check(PyObject *o)
Returns True if o is an index integer (has the nb_index slot of the tp_as_number structure filled in).
Sequence Protocol

```c
int PySequence_Check(PyObject *o)
Return 1 if the object provides sequence protocol, and 0 otherwise. This function always succeeds.
```

```c
Py_ssize_t PySequence_Size(PyObject *o)
Py_ssize_t PySequence_Length(PyObject *o)
Returns the number of objects in sequence o on success, and -1 on failure. For objects that do not provide sequence protocol, this is equivalent to the Python expression len(o).
```

```c
PyObject* PySequence_Concat(PyObject *o1, PyObject *o2)
Return the concatenation of o1 and o2 on success, and NULL on failure. This is the equivalent of the Python expression o1 + o2.
```

```c
PyObject* PySequence_Repeat(PyObject *o, Py_ssize_t count)
Return the result of repeating sequence object o count times, or NULL on failure. This is the equivalent of the Python expression o * count.
```

```c
PyObject* PySequence_InPlaceConcat(PyObject *o1, PyObject *o2)
Return the concatenation of o1 and o2 on success, and NULL on failure. The operation is done in-place when o1 supports it. This is the equivalent of the Python expression o1 += o2.
```

```c
PyObject* PySequence_InPlaceRepeat(PyObject *o,
```
Py_ssize_t count)

    Return the result of repeating sequence object o count times, or NULL on failure. The operation is done in-place when o supports it. This is the equivalent of the Python expression o *= count.

PyObject* PySequence_GetItem(PyObject *o, Py_ssize_t i)

    Return the i\text{th} element of o, or NULL on failure. This is the equivalent of the Python expression o[i].

PyObject* PySequence_GetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)

    Return the slice of sequence object o between i1 and i2, or NULL on failure. This is the equivalent of the Python expression o[i1:i2].

int PySequence_SetItem(PyObject *o, Py_ssize_t i, PyObject *v)

    Assign object v to the i\text{th} element of o. Returns -1 on failure. This is the equivalent of the Python statement o[i] = v. This function does not steal a reference to v.

int PySequence_DelItem(PyObject *o, Py_ssize_t i)

    Delete the i\text{th} element of object o. Returns -1 on failure. This is the equivalent of the Python statement del o[i].

int PySequence_SetSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2, PyObject *v)

    Assign the sequence object v to the slice in sequence object o from i1 to i2. This is the equivalent of the Python statement o[i1:i2]
int PySequence_DelSlice(PyObject *o, Py_ssize_t i1, Py_ssize_t i2)
    Delete the slice in sequence object o from i1 to i2. Returns -1 on failure. This is the equivalent of the Python statement del o[i1:i2].

Py_ssize_t PySequence_Count(PyObject *o, PyObject *value)
    Return the number of occurrences of value in o, that is, return the number of keys for which o[key] == value. On failure, return -1. This is equivalent to the Python expression o.count(value).

int PySequence_Contains(PyObject *o, PyObject *value)
    Determine if o contains value. If an item in o is equal to value, return 1, otherwise return 0. On error, return -1. This is equivalent to the Python expression value in o.

Py_ssize_t PySequence_Index(PyObject *o, PyObject *value)
    Return the first index i for which o[i] == value. On error, return -1. This is equivalent to the Python expression o.index(value).

PyObject* PySequence_List(PyObject *o)
    Return a list object with the same contents as the arbitrary sequence o. The returned list is guaranteed to be new.

PyObject* PySequence_Tuple(PyObject *o)
    Return a tuple object with the same contents as the arbitrary
sequence \( o \) or \( NULL \) on failure. If \( o \) is a tuple, a new reference will be returned, otherwise a tuple will be constructed with the appropriate contents. This is equivalent to the Python expression \( \text{tuple}(o) \).

**PyObject** \( \text{PySequence} \_\text{Fast}(\text{PyObject} \ *o, \ \text{const} \ \text{char} \ *m) \)

*Return value: New reference.*

Returns the sequence \( o \) as a tuple, unless it is already a tuple or list, in which case \( o \) is returned. Use \( \text{PySequence} \_\text{Fast} \_\text{GET} \_\text{ITEM}() \) to access the members of the result. Returns \( NULL \) on failure. If the object is not a sequence, raises \( \text{TypeError} \) with \( m \) as the message text.

**PyObject** \( \text{PySequence} \_\text{Fast} \_\text{GET} \_\text{ITEM}(\text{PyObject} \ *o, \ \text{Py} \_\text{ssize} \_t \ i) \)

*Return value: Borrowed reference.*

Return the \( i \)th element of \( o \), assuming that \( o \) was returned by \( \text{PySequence} \_\text{Fast}() \), \( o \) is not \( NULL \), and that \( i \) is within bounds.

**PyObject** \( \text{PySequence} \_\text{Fast} \_\text{ITEMS}(\text{PyObject} \ *o) \)

Return the underlying array of \( \text{PyObject} \) pointers. Assumes that \( o \) was returned by \( \text{PySequence} \_\text{Fast}() \) and \( o \) is not \( NULL \).

Note, if a list gets resized, the reallocation may relocate the items array. So, only use the underlying array pointer in contexts where the sequence cannot change.

**PyObject** \( \text{PySequence} \_\text{ITEM}(\text{PyObject} \ *o, \ \text{Py} \_\text{ssize} \_t \ i) \)

*Return value: New reference.*

Return the \( i \)th element of \( o \) or \( NULL \) on failure. Macro form of \( \text{PySequence} \_\text{Get} \_\text{Item}() \) but without checking that \( \text{PySequence} \_\text{Check}() \) on \( o \) is true and without adjustment for
negative indices.

Py_ssize_t PySequence_Fast_GET_SIZE(PyObject *o)
Returns the length of o, assuming that o was returned by
PySequence_Fast() and that o is not NULL. The size can also
be gotten by calling PySequence_Size() on o, but
PySequence_Fast_GET_SIZE() is faster because it can
assume o is a list or tuple.
Mapping Protocol

int **PyMapping__Check**(PyObject *o)

Return 1 if the object provides mapping protocol, and 0 otherwise. This function always succeeds.

Py_ssize_t **PyMapping__Size**(PyObject *o)

Py_ssize_t **PyMapping__Length**(PyObject *o)

Returns the number of keys in object o on success, and -1 on failure. For objects that do not provide mapping protocol, this is equivalent to the Python expression `len(o)`.

int **PyMapping__DelItemString**(PyObject *o, char *key)

Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement `del o[key]`.

int **PyMapping__DelItem**(PyObject *o, PyObject *key)

Remove the mapping for object key from the object o. Return -1 on failure. This is equivalent to the Python statement `del o[key]`.

int **PyMapping__HasKeyString**(PyObject *o, char *key)

On success, return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to the Python expression `key in o`. This function always succeeds.

int **PyMapping__HasKey**(PyObject *o, PyObject *key)

Return 1 if the mapping object has the key key and 0 otherwise. This is equivalent to the Python expression `key in o`. This
function always succeeds.

PyObject* **PyMapping_Keys**(PyObject *o)

*Return value: New reference.*

On success, return a list of the keys in object o. On failure, return *NULL*. This is equivalent to the Python expression `list(o.keys())`.

PyObject* **PyMapping_Values**(PyObject *o)

*Return value: New reference.*

On success, return a list of the values in object o. On failure, return *NULL*. This is equivalent to the Python expression `list(o.values())`.

PyObject* **PyMapping_Items**(PyObject *o)

*Return value: New reference.*

On success, return a list of the items in object o, where each item is a tuple containing a key-value pair. On failure, return *NULL*. This is equivalent to the Python expression `list(o.items())`.

PyObject* **PyMapping_GetItemString**(PyObject *o, char *key)

*Return value: New reference.*

Return element of o corresponding to the object key or *NULL* on failure. This is the equivalent of the Python expression `o[key]`.

int **PyMapping_SetItemString**(PyObject *o, char *key, PyObject *v)

Map the object key to the value v in object o. Returns -1 on failure. This is the equivalent of the Python statement `o[key] = v`.
Iterator Protocol

There are two functions specifically for working with iterators.

```c
int PyIter_Check(PyObject *o)
    Return true if the object o supports the iterator protocol.

PyObject* PyIter_Next(PyObject *o)
    Return the next value from the iteration o. The object must be an iterator (it is up to the caller to check this). If there are no remaining values, returns NULL with no exception set. If an error occurs while retrieving the item, returns NULL and passes along the exception.
```

To write a loop which iterates over an iterator, the C code should look something like this:

```c
PyObject *iterator = PyObject_GetIter(obj);
PyObject *item;

if (iterator == NULL) {
    /* propagate error */
}

while (item = PyIter_Next(iterator)) {
    /* do something with item */
    ...
    /* release reference when done */
    Py_DECREF(item);
}

Py_DECREF(iterator);

if (PyErr_Occurred()) {
```
/* propagate error */
}
else {
    /* continue doing useful work */
}
Buffer Protocol

Certain objects available in Python wrap access to an underlying memory array or buffer. Such objects include the built-in bytes and bytearray, and some extension types like array.array. Third-party libraries may define their own types for special purposes, such as image processing or numeric analysis.

While each of these types have their own semantics, they share the common characteristic of being backed by a possibly large memory buffer. It is then desirable, in some situations, to access that buffer directly and without intermediate copying.

Python provides such a facility at the C level in the form of the buffer protocol. This protocol has two sides:

- on the producer side, a type can export a “buffer interface” which allows objects of that type to expose information about their underlying buffer. This interface is described in the section Buffer Object Structures;
- on the consumer side, several means are available to obtain a pointer to the raw underlying data of an object (for example a method parameter).

Simple objects such as bytes and bytearray expose their underlying buffer in byte-oriented form. Other forms are possible; for example, the elements exposed by a array.array can be multi-byte values.

An example consumer of the buffer interface is the write() method of file objects: any object that can export a series of bytes through the buffer interface can be written to a file. While write() only needs
read-only access to the internal contents of the object passed to it, other methods such as `readinto()` need write access to the contents of their argument. The buffer interface allows objects to selectively allow or reject exporting of read-write and read-only buffers.

There are two ways for a consumer of the buffer interface to acquire a buffer over a target object:

- call `PyObject_GetBuffer()` with the right parameters;
- call `PyArg_ParseTuple()` (or one of its siblings) with one of the `y*`, `w*` or `s*` format codes.

In both cases, `PyBuffer_Release()` must be called when the buffer isn’t needed anymore. Failure to do so could lead to various issues such as resource leaks.
Buffer structure

Buffer structures (or simply “buffers”) are useful as a way to expose the binary data from another object to the Python programmer. They can also be used as a zero-copy slicing mechanism. Using their ability to reference a block of memory, it is possible to expose any data to the Python programmer quite easily. The memory could be a large, constant array in a C extension, it could be a raw block of memory for manipulation before passing to an operating system library, or it could be used to pass around structured data in its native, in-memory format.

Contrary to most data types exposed by the Python interpreter, buffers are not PyObject pointers but rather simple C structures. This allows them to be created and copied very simply. When a generic wrapper around a buffer is needed, a memoryview object can be created.

For short instructions how to write an exporting object, see Buffer Object Structures. For obtaining a buffer, see PyObject_GetBuffer().

Py_buffer

void *obj

A new reference to the exporting object. The reference is owned by the consumer and automatically decremented and set to NULL by PyBuffer_Release(). The field is the equivalent of the return value of any standard C-API function.

As a special case, for temporary buffers that are wrapped by PyMemoryView_FromBuffer() or PyBuffer_FillInfo() this field is NULL. In general, exporting objects MUST NOT use this scheme.
void *buf

A pointer to the start of the logical structure described by the buffer fields. This can be any location within the underlying physical memory block of the exporter. For example, with negative strides the value may point to the end of the memory block.

For contiguous arrays, the value points to the beginning of the memory block.

Py_ssize_t len

product(shape) * itemsize. For contiguous arrays, this is the length of the underlying memory block. For non-contiguous arrays, it is the length that the logical structure would have if it were copied to a contiguous representation.

Accessing ((char *)buf)[0] up to ((char *)buf)[len-1] is only valid if the buffer has been obtained by a request that guarantees contiguity. In most cases such a request will be PyBUF_SIMPLE or PyBUF_WRITABLE.

int readonly

An indicator of whether the buffer is read-only. This field is controlled by the PyBUF_WRITABLE flag.

Py_ssize_t itemsize

Item size in bytes of a single element. Same as the value of struct.calcsize() called on non-NULL format values.

Important exception: If a consumer requests a buffer without the PyBUF_FORMAT flag, format will be set to NULL, but itemsize still has the value for the original format.
If shape is present, the equality \( \text{product(\(shape\))} \times \text{itemsize} == \text{len} \) still holds and the consumer can use \text{itemsize} to navigate the buffer.

If shape is \textit{NULL} as a result of a \texttt{PyBUF_SIMPLE} or a \texttt{PyBUF_WRITABLE} request, the consumer must disregard \text{itemsize} and assume \text{itemsize} == 1.

**const char **\texttt{format}**

A \texttt{NULL} terminated string in \texttt{struct} module style syntax describing the contents of a single item. If this is \texttt{NULL}, "B" (unsigned bytes) is assumed.

This field is controlled by the \texttt{PyBUF_FORMAT} flag.

**int **\texttt{ndim}**

The number of dimensions the memory represents as an n-dimensional array. If it is 0, \texttt{buf} points to a single item representing a scalar. In this case, \texttt{shape}, \texttt{strides} and \texttt{suboffsets} MUST be \texttt{NULL}.

The macro \texttt{PyBUF_MAX_NDIM} limits the maximum number of dimensions to 64. Exporters MUST respect this limit, consumers of multi-dimensional buffers SHOULD be able to handle up to \texttt{PyBUF_MAX_NDIM} dimensions.

**Py_ssize_t **\texttt{shape}**

An array of \texttt{Py_ssize_t} of length \texttt{ndim} indicating the shape of the memory as an n-dimensional array. Note that \texttt{shape[0]} * ... * \texttt{shape[ndim-1]} * \texttt{itemsize} MUST be equal to \texttt{len}. 

Shape values are restricted to \( \text{shape}[n] \geq 0 \). The case \( \text{shape}[n] = 0 \) requires special attention. See complex arrays for further information.

The shape array is read-only for the consumer.

Py_ssize_t* \textbf{strides}

An array of Py_ssize_t of length \( \text{ndim} \) giving the number of bytes to skip to get to a new element in each dimension.

Stride values can be any integer. For regular arrays, strides are usually positive, but a consumer MUST be able to handle the case \( \text{strides}[n] \leq 0 \). See complex arrays for further information.

The strides array is read-only for the consumer.

Py_ssize_t* \textbf{suboffsets}

An array of Py_ssize_t of length \( \text{ndim} \). If \( \text{suboffsets}[n] \geq 0 \), the values stored along the nth dimension are pointers and the suboffset value dictates how many bytes to add to each pointer after de-referencing. A suboffset value that is negative indicates that no de-referencing should occur (striding in a contiguous memory block).

This type of array representation is used by the Python Imaging Library (PIL). See complex arrays for further information how to access elements of such an array.

The suboffsets array is read-only for the consumer.

void* \textbf{internal}

This is for use internally by the exporting object. For example,
this might be re-cast as an integer by the exporter and used to store flags about whether or not the shape, strides, and suboffsets arrays must be freed when the buffer is released. The consumer MUST NOT alter this value.
Buffer request types

Buffers are usually obtained by sending a buffer request to an exporting object via `PyObject_GetBuffer()`. Since the complexity of the logical structure of the memory can vary drastically, the consumer uses the *flags* argument to specify the exact buffer type it can handle.

All *Py_buffer* fields are unambiguously defined by the request type.

request-independent fields

The following fields are not influenced by *flags* and must always be filled in with the correct values: *obj*, *buf*, *len*, *itemsize*, *ndim*.

readonly, format

**PyBUF_WRITABLE**

Controls the *readonly* field. If set, the exporter MUST provide a writable buffer or else report failure. Otherwise, the exporter MAY provide either a read-only or writable buffer, but the choice MUST be consistent for all consumers.

**PyBUF_FORMAT**

Controls the *format* field. If set, this field MUST be filled in correctly. Otherwise, this field MUST be *NULL*.

*PyBUF_WRITABLE* can be |'d to any of the flags in the next section. Since *PyBUF_SIMPLE* is defined as 0, *PyBUF_WRITABLE* can be used as a stand-alone flag to request a simple writable buffer.
PyBUF_FORMAT can be |’d to any of the flags except PyBUF_SIMPLE. The latter already implies format B (unsigned bytes).

shape, strides, suboffsets

The flags that control the logical structure of the memory are listed in decreasing order of complexity. Note that each flag contains all bits of the flags below it.

<table>
<thead>
<tr>
<th>Request</th>
<th>shape</th>
<th>strides</th>
<th>suboffsets</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyBUF_INDIRECT</td>
<td>yes</td>
<td>yes</td>
<td>if needed</td>

<td>NULL</td>
</tr>
<tr>
<td>PyBUF_SIMPLE</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

contiguity requests

C or Fortran contiguity can be explicitly requested, with and without stride information. Without stride information, the buffer must be C-contiguous.

<table>
<thead>
<tr>
<th>Request</th>
<th>shape</th>
<th>strides</th>
<th>suboffsets</th>
<th>cont</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyBUF_C_CONTIGUOUS</td>
<td>yes</td>
<td>yes</td>
<td>NULL</td>
<td>C</td>
</tr>
<tr>
<td>PyBUF_F_CONTIGUOUS</td>
<td>yes</td>
<td>yes</td>
<td>NULL</td>
<td>F</td>
</tr>
<tr>
<td>PyBUF_ANY_CONTIGUOUS</td>
<td>yes</td>
<td>yes</td>
<td>NULL</td>
<td>C,F</td>
</tr>
</tbody>
</table>
compound requests

All possible requests are fully defined by some combination of the flags in the previous section. For convenience, the buffer protocol provides frequently used combinations as single flags.

In the following table $U$ stands for undefined contiguity. The consumer would have to call `PyBuffer_IsContiguous()` to determine contiguity.

<table>

</table>
Complex arrays

NumPy-style: shape and strides

The logical structure of NumPy-style arrays is defined by `itemsize`, `ndim`, `shape` and `strides`.

If `ndim == 0`, the memory location pointed to by `buf` is interpreted as a scalar of size `itemsize`. In that case, both `shape` and `strides` are `NULL`.

If `strides` is `NULL`, the array is interpreted as a standard n-dimensional C-array. Otherwise, the consumer must access an n-dimensional array as follows:

```c
ptr = (char *)buf + indices[0] * strides[0] + ... + indices[n-1] * strides[n-1] item = *((typeof(item) *)ptr);
```

As noted above, `buf` can point to any location within the actual memory block. An exporter can check the validity of a buffer with this function:

```python
def verify_structure(memlen, itemsize, ndim, shape, shape, strides):
    """Verify that the parameters represent a valid the bounds of the allocated memory:
    char *mem: start of the physical memory b
    memlen: length of the physical memory block
    offset: (char *)buf - mem
    """
    if offset % itemsize:
        return False
    if offset < 0 or offset+itemsize > memlen:
        return False
```
if any(v % itemsize for v in strides):
    return False

if ndim <= 0:
    return ndim == 0 and not shape and not strides
if 0 in shape:
    return True

imin = sum(strides[j]*(shape[j]-1) for j in range
            if strides[j] <= 0)
imax = sum(strides[j]*(shape[j]-1) for j in range
            if strides[j] > 0)

return 0 <= offset+imin and offset+imax+itemsize

PIL-style: shape, strides and suboffsets

In addition to the regular items, PIL-style arrays can contain pointers
that must be followed in order to get to the next element in a
dimension. For example, the regular three-dimensional C-array char
v[2][2][3] can also be viewed as an array of 2 pointers to 2 two-
dimensional arrays: char (*v[2])[2][3]. In suboffsets
representation, those two pointers can be embedded at the start of
buf, pointing to two char x[2][3] arrays that can be located
anywhere in memory.

Here is a function that returns a pointer to the element in an N-D array
pointed to by an N-dimensional index when there are both non-NULL
strides and suboffsets:

void *get_item_pointer(int ndim, void *buf, Py_ssize_t *suboffsets, Py_ssize_t *shape, Py_ssize_t *strides):
    char *pointer = (char*)buf;
int i;
for (i = 0; i < ndim; i++) {
    pointer += strides[i] * indices[i];
    if (suboffsets[i] >= 0) {
        pointer = *((char**)pointer) + suboffsets[i];
    }
}
return (void*)pointer;
Buffer-related functions

```c
int PyObject_CheckBuffer(PyObject *obj)
```

Return 1 if `obj` supports the buffer interface otherwise 0. When 1 is returned, it doesn’t guarantee that `PyObject_GetBuffer()` will succeed.

```c
int PyObject_GetBuffer(PyObject *exporter, Py_buffer *view, int flags)
```

Send a request to `exporter` to fill in `view` as specified by `flags`. If the exporter cannot provide a buffer of the exact type, it MUST raise `PyExc_BufferError`, set `view->obj` to NULL and return -1.

On success, fill in `view`, set `view->obj` to a new reference to `exporter` and return 0. In the case of chained buffer providers that redirect requests to a single object, `view->obj` MAY refer to this object instead of `exporter` (See Buffer Object Structures).

Successful calls to `PyObject_GetBuffer()` must be paired with calls to `PyBuffer_Release()`, similar to `malloc()` and `free()`. Thus, after the consumer is done with the buffer, `PyBuffer_Release()` must be called exactly once.

```c
void PyBuffer_Release(Py_buffer *view)
```

Release the buffer `view` and decrement the reference count for `view->obj`. This function MUST be called when the buffer is no longer being used, otherwise reference leaks may occur.

It is an error to call this function on a buffer that was not obtained via `PyObject_GetBuffer()`.
Py_ssize_t **PyBuffer_SizeFromFormat**(*const char * )

Return the implied *itemsize* from *format*. This function is not yet implemented.

int **PyBuffer_IsContiguous**(*Py_buffer *view, char order*)

Return 1 if the memory defined by the *view* is C-style (*order* is 'C') or Fortran-style (*order* is 'F') contiguous or either one (*order* is 'A'). Return 0 otherwise.

void **PyBuffer_FillContiguousStrides**(int *ndim, Py_ssize_t *shape, Py_ssize_t *strides, Py_ssize_t *itemsize, char order)

Fill the *strides* array with byte-strides of a contiguous (C-style if *order* is 'C' or Fortran-style if *order* is 'F') array of the given shape with the given number of bytes per element.

int **PyBuffer_FillInfo**(*Py_buffer *view, PyObject *exporter, void *buf, Py_ssize_t len, int readonly, int flags*)

Handle buffer requests for an exporter that wants to expose *buf* of size *len* with writability set according to *readonly*. *buf* is interpreted as a sequence of unsigned bytes.

The *flags* argument indicates the request type. This function always fills in *view* as specified by flags, unless *buf* has been designated as read-only and *PyBUF_WRITABLE* is set in *flags*.

On success, set *view*->obj to a new reference to *exporter* and return 0. Otherwise, raise *PyExc_BufferError*, set *view*->obj to *NULL* and return -1;.

If this function is used as part of a *getbufferproc*, *exporter* MUST be set to the exporting object. Otherwise, *exporter* MUST be *NULL*. 
Old Buffer Protocol

*Deprecated since version 3.0.*

These functions were part of the “old buffer protocol” API in Python 2. In Python 3, this protocol doesn’t exist anymore but the functions are still exposed to ease porting 2.x code. They act as a compatibility wrapper around the *new buffer protocol*, but they don’t give you control over the lifetime of the resources acquired when a buffer is exported.

Therefore, it is recommended that you call `PyObject_GetBuffer()` (or the `y*` or `w*` format codes with the `PyArg_ParseTuple()` family of functions) to get a buffer view over an object, and `PyBuffer_Release()` when the buffer view can be released.

```c
int PyObject_AsCharBuffer(PyObject *obj, const char **buffer, Py_ssize_t *buffer_len)

    Returns a pointer to a read-only memory location usable as character-based input. The *obj* argument must support the single-segment character buffer interface. On success, returns 0, sets *buffer* to the memory location and *buffer_len* to the buffer length. Returns -1 and sets a `TypeError` on error.
```

```c
int PyObject_AsReadBuffer(PyObject *obj, const void **buffer, Py_ssize_t *buffer_len)

    Returns a pointer to a read-only memory location containing arbitrary data. The *obj* argument must support the single-segment readable buffer interface. On success, returns 0, sets *buffer* to the memory location and *buffer_len* to the buffer length. Returns -1 and sets a `TypeError` on error.
```
int **PyObject_CheckReadBuffer(*PyObject *o)

Returns 1 if o supports the single-segment readable buffer interface. Otherwise returns 0.

int PyObject_AsWriteBuffer(*PyObject *obj, void **buffer, Py_ssize_t *buffer_len)

Returns a pointer to a writable memory location. The obj argument must support the single-segment, character buffer interface. On success, returns 0, sets buffer to the memory location and buffer_len to the buffer length. Returns -1 and sets a TypeError on error.
Concrete Objects Layer

The functions in this chapter are specific to certain Python object types. Passing them an object of the wrong type is not a good idea; if you receive an object from a Python program and you are not sure that it has the right type, you must perform a type check first; for example, to check that an object is a dictionary, use `PyDict_Check()`. The chapter is structured like the “family tree” of Python object types.

**Warning:** While the functions described in this chapter carefully check the type of the objects which are passed in, many of them do not check for `NULL` being passed instead of a valid object. Allowing `NULL` to be passed in can cause memory access violations and immediate termination of the interpreter.
Fundamental Objects

This section describes Python type objects and the singleton object None.

- Type Objects
- The None Object
Numeric Objects

- Integer Objects
- Boolean Objects
- Floating Point Objects
- Complex Number Objects
  - Complex Numbers as C Structures
  - Complex Numbers as Python Objects
Sequence Objects

Generic operations on sequence objects were discussed in the previous chapter; this section deals with the specific kinds of sequence objects that are intrinsic to the Python language.

- **Bytes Objects**
- **Byte Array Objects**
  - Type check macros
  - Direct API functions
  - Macros
- **Unicode Objects and Codecs**
  - Unicode Objects
    - Unicode Type
    - Unicode Character Properties
    - Creating and accessing Unicode strings
    - Deprecated Py_UNICODE APIs
    - Locale Encoding
    - File System Encoding
    - wchar_t Support
    - UCS4 Support
  - Built-in Codecs
    - Generic Codecs
    - UTF-8 Codecs
    - UTF-32 Codecs
    - UTF-16 Codecs
    - UTF-7 Codecs
    - Unicode-Escape Codecs
    - Raw-Unicode-Escape Codecs
    - Latin-1 Codecs
    - ASCII Codecs
    - Character Map Codecs
    - MBCS codecs for Windows

  - Methods and Slot Functions
- Tuple Objects
- Struct Sequence Objects
- List Objects
Mapping Objects

- Dictionary Objects
Other Objects

- Set Objects
- Function Objects
- Instance Method Objects
- Method Objects
- File Objects
- Module Objects
  - Initializing C modules
- Iterator Objects
- Descriptor Objects
- Slice Objects
- MemoryView objects
- Weak Reference Objects
- Capsules
- Cell Objects
- Generator Objects
- DateTime Objects
- Code Objects
Type Objects

PyTypeObject
The C structure of the objects used to describe built-in types.

PyObject* PyType_Type
This is the type object for type objects; it is the same object as type in the Python layer.

int PyType_Check(PyObject *o)
Return true if the object o is a type object, including instances of types derived from the standard type object. Return false in all other cases.

int PyType_CheckExact(PyObject *o)
Return true if the object o is a type object, but not a subtype of the standard type object. Return false in all other cases.

unsigned int PyType_ClearCache()
Clear the internal lookup cache. Return the current version tag.

long PyType_GetFlags(PyTypeObject* type)
Return the tp_flags member of type. This function is primarily meant for use with Py_LIMITED_API; the individual flag bits are guaranteed to be stable across Python releases, but access to tp_flags itself is not part of the limited API.

New in version 3.2.

void PyType_Modified(PyTypeObject *type)
Invalidate the internal lookup cache for the type and all of its
subtypes. This function must be called after any manual modification of the attributes or base classes of the type.

```c
int PyType_HasFeature(PyTypeObject *o, int feature)
```

Return true if the type object `o` sets the feature `feature`. Type features are denoted by single bit flags.

```c
int PyType_IS_GC(PyTypeObject *o)
```

Return true if the type object includes support for the cycle detector; this tests the type flag `Py_TPFLAGS_HAVE_GC`.

```c
int PyType_IsSubtype(PyTypeObject *a, PyTypeObject *b)
```

Return true if `a` is a subtype of `b`.

```c
PyObject* PyType_GenericAlloc(PyTypeObject *type, Py_ssize_t nitems)
```

*Return value: New reference.*

Generic handler for the `tp_alloc` slot of a type object. Use Python's default memory allocation mechanism to allocate a new instance and initialize all its contents to `NULL`.

```c
PyObject* PyType_GenericNew(PyTypeObject *type, PyObject *args, PyObject *kwds)
```

*Return value: New reference.*

Generic handler for the `tp_new` slot of a type object. Create a new instance using the type's `tp_alloc` slot.

```c
int PyType_Ready(PyTypeObject *type)
```

Finalize a type object. This should be called on all type objects to finish their initialization. This function is responsible for adding inherited slots from a type's base class. Return `0` on success, or return `-1` and sets an exception on error.
PyObject* PyType_FromSpec(PyType_Spec* spec)

Creates and returns a heap type object from the `spec` passed to the function.

PyObject* PyType_FromSpecWithBases(PyType_Spec* spec, PyObject* bases)

Creates and returns a heap type object from the `spec`. In addition to that, the created heap type contains all types contained by the `bases` tuple as base types. This allows the caller to reference other heap types as base types.

New in version 3.3.
The None Object

Note that the `PyTypeObject` for None is not directly exposed in the Python/C API. Since None is a singleton, testing for object identity (using `==` in C) is sufficient. There is no `PyNone_Check()` function for the same reason.

**PyObject* Py_None**

The Python None object, denoting lack of value. This object has no methods. It needs to be treated just like any other object with respect to reference counts.

**Py_RETURN_NONE**

Properly handle returning `Py_None` from within a C function (that is, increment the reference count of None and return it.)
Integer Objects

All integers are implemented as “long” integer objects of arbitrary size.

PyLongObject
This subtype of PyObject represents a Python integer object.

PyTypeObject PyLong_Type
This instance of PyTypeObject represents the Python integer type. This is the same object as int in the Python layer.

int PyLong_Check(PyObject *p)
Return true if its argument is a PyLongObject or a subtype of PyLongObject.

int PyLong_CheckExact(PyObject *p)
Return true if its argument is a PyLongObject, but not a subtype of PyLongObject.

PyObject* PyLong_FromLong(long v)
Return a new PyLongObject object from v, or NULL on failure.

The current implementation keeps an array of integer objects for all integers between -5 and 256, when you create an int in that range you actually just get back a reference to the existing object. So it should be possible to change the value of 1. I suspect the behaviour of Python in this case is undefined. :-)

PyObject* PyLong_FromUnsignedLong(unsigned long v)
Return a new *PyLongObject* object from a C `unsigned long`, or *NULL* on failure.

*PyObject* `PyLong_FromSsize_t(Py_ssize_t v)`
Return a new *PyLongObject* object from a C `Py_ssize_t`, or *NULL* on failure.

*PyObject* `PyLong_FromSize_t(size_t v)`
Return a new *PyLongObject* object from a C `size_t`, or *NULL* on failure.

*PyObject* `PyLong_FromLongLong(PY_LONG_LONG v)`
*Return value: New reference.*
Return a new *PyLongObject* object from a C `long long`, or *NULL* on failure.

*PyObject* `PyLong_FromUnsignedLongLong(unsigned PY_LONG_LONG v)`
*Return value: New reference.*
Return a new *PyLongObject* object from a C `unsigned long long`, or *NULL* on failure.

*PyObject* `PyLong_FromDouble(double v)`
*Return value: New reference.*
Return a new *PyLongObject* object from the integer part of `v`, or *NULL* on failure.

*PyObject* `PyLong_FromString(char *str, char **pend, int base)`
*Return value: New reference.*
Return a new *PyLongObject* based on the string value in `str`, which is interpreted according to the radix in `base`. If `pend` is non-*NULL*, `*pend` will point to the first character in `str` which follows the
representation of the number. If base is 0, the radix will be
determined based on the leading characters of str: if str starts with
'0x' or '0X', radix 16 will be used; if str starts with '0o' or
'0O', radix 8 will be used; if str starts with '0b' or '0B', radix 2
will be used; otherwise radix 10 will be used. If base is not 0, it
must be between 2 and 36, inclusive. Leading spaces are ignored.
If there are no digits, ValueError will be raised.

PyObject* PyLong_FromUnicode(Py_UNICODE *u,
Py_ssize_t length, int base)

Convert a sequence of Unicode digits to a Python integer value.
The Unicode string is first encoded to a byte string using
PyUnicode_EncodeDecimal() and then converted using
PyLong_FromString().

Deprecated since version 3.3, will be removed in version 4.0:
Part of the old-style Py_UNICODE API; please migrate to using
PyLong_FromUnicodeObject().

PyObject* PyLong_FromUnicodeObject(PyObject *u,
int base)

Convert a sequence of Unicode digits in the string u to a Python
integer value. The Unicode string is first encoded to a byte string
using PyUnicode_EncodeDecimal() and then converted using
PyLong_FromString().

New in version 3.3.

PyObject* PyLong_FromVoidPtr(void *p)

Create a Python integer from the pointer $p$. The pointer value can be retrieved from the resulting value using `PyLong_AsVoidPtr()`.

**long PyLong_AsLong** *(PyObject *obj)*
Return a C `long` representation of `obj`. If `obj` is not an instance of `PyLongObject`, first call its `__int__() method (if present) to convert it to a `PyLongObject`.

Raise `OverflowError` if the value of `obj` is out of range for a `long`.

**long PyLong_AsLongAndOverflow** *(PyObject *obj, int *overflow)*
Return a C `long` representation of `obj`. If `obj` is not an instance of `PyLongObject`, first call its `__int__() method (if present) to convert it to a `PyLongObject`.

If the value of `obj` is greater than `LONG_MAX` or less than `LONG_MIN`, set `*overflow` to 1 or -1, respectively, and return -1; otherwise, set `*overflow` to 0. If any other exception occurs set `*overflow` to 0 and return -1 as usual.

**PY_LONG_LONG PyLong_AsLongLong** *(PyObject *obj)*
Return a C `long long` representation of `obj`. If `obj` is not an instance of `PyLongObject`, first call its `__int__() method (if present) to convert it to a `PyLongObject`.

Raise `OverflowError` if the value of `obj` is out of range for a `long`.

**PY_LONG_LONG**
PyLong_AsLongLongAndOverflow(PyObject *obj, int *overflow)

Return a C long long representation of obj. If obj is not an instance of PyLongObject, first call its __int__() method (if present) to convert it to a PyLongObject.

If the value of obj is greater than PY_LLONG_MAX or less than PY_LLONG_MIN, set *overflow to 1 or -1, respectively, and return -1; otherwise, set *overflow to 0. If any other exception occurs set *overflow to 0 and return -1 as usual.

*New in version 3.2.*

Py_ssize_t PyLong_AsSsize_t(PyObject *pylong)

Return a C Py_ssize_t representation of pylong. pylong must be an instance of PyLongObject.

Raise OverflowError if the value of pylong is out of range for a Py_ssize_t.

unsigned long PyLong_AsUnsignedLong(PyObject *pylong)

Return a C unsigned long representation of pylong. pylong must be an instance of PyLongObject.

Raise OverflowError if the value of pylong is out of range for a unsigned long.

size_t PyLong_AsSize_t(PyObject *pylong)

Return a C size_t representation of pylong. pylong must be an instance of PyLongObject.

Raise OverflowError if the value of pylong is out of range for a
size_t.

unsigned PY_LONG_LONG
PyLong_AsUnsignedLongLong(PyObject *pylong)

Return a C unsigned PY_LONG_LONG representation of pylong. pylong must be an instance of PyLongObject.

Raise OverflowError if the value of pylong is out of range for an unsigned PY_LONG_LONG.

Changed in version 3.1: A negative pylong now raises OverflowError, not TypeError.

unsigned long PyLong_AsUnsignedLongMask(PyObject *obj)

Return a C unsigned long representation of obj. If obj is not an instance of PyLongObject, first call its __int__() method (if present) to convert it to a PyLongObject.

If the value of obj is out of range for an unsigned long, return the reduction of that value modulo ULONG_MAX + 1.

unsigned PY_LONG_LONG
PyLong_AsUnsignedLongLongMask(PyObject *obj)

Return a C unsigned long long representation of obj. If obj is not an instance of PyLongObject, first call its __int__() method (if present) to convert it to a PyLongObject.

If the value of obj is out of range for an unsigned long long, return the reduction of that value modulo PY_ULLONG_MAX + 1.

double PyLong_AsDouble(PyObject *pylong)

Return a C double representation of pylong. pylong must be an
instance of `PyLongObject`.

Raise `OverflowError` if the value of `pylong` is out of range for a double.

```c
void* PyLong_AsVoidPtr(PyObject *pylong)
```

Convert a Python integer `pylong` to a C void pointer. If `pylong` cannot be converted, an `OverflowError` will be raised. This is only assured to produce a usable void pointer for values created with `PyLong_FromVoidPtr()`.
Boolean Objects

Booleans in Python are implemented as a subclass of integers. There are only two booleans, Py_False and Py_True. As such, the normal creation and deletion functions don’t apply to booleans. The following macros are available, however.

```c
int PyBool_Check(PyObject *o)
```

Return true if `o` is of type PyBool_Type.

```c
PyObject* Py_False
```
The Python False object. This object has no methods. It needs to be treated just like any other object with respect to reference counts.

```c
PyObject* Py_True
```
The Python True object. This object has no methods. It needs to be treated just like any other object with respect to reference counts.

```c
Py_RETURN_FALSE
```
Return Py_False from a function, properly incrementing its reference count.

```c
Py_RETURN_TRUE
```
Return Py_True from a function, properly incrementing its reference count.

```c
PyObject* PyBool_FromLong(long v)
```

*Return value: New reference.*

Return a new reference to Py_True or Py_False depending on
the truth value of \( v \).
Floating Point Objects

**PyFloatObject**
This subtype of *PyObject* represents a Python floating point object.

**PyTypeObject PyFloat_Type**
This instance of *PyTypeObject* represents the Python floating point type. This is the same object as *float* in the Python layer.

```c
int PyFloat_Check(PyObject *p)
```
Return true if its argument is a *PyFloatObject* or a subtype of *PyFloatObject*.

```c
int PyFloat_CheckExact(PyObject *p)
```
Return true if its argument is a *PyFloatObject*, but not a subtype of *PyFloatObject*.

```c
PyObject* PyFloat_FromString(PyObject *str)
```
*Return value: New reference.*
Create a *PyFloatObject* object based on the string value in *str*, or *NULL* on failure.

```c
PyObject* PyFloat_FromDouble(double v)
```
*Return value: New reference.*
Create a *PyFloatObject* object from *v*, or *NULL* on failure.

```c
double PyFloat_AsDouble(PyObject *pyfloat)
```
Return a C double representation of the contents of *pyfloat*. If *pyfloat* is not a Python floating point object but has a **__float__()** method, this method will first be called to convert
*pyfloat* into a float. This method returns -1.0 upon failure, so one should call *PyErr_Occurred()* to check for errors.

double **PyFloat_AS_DOUBLE**(*PyObject *pyfloat*)
Return a C double representation of the contents of *pyfloat*, but without error checking.

*PyObject* **PyFloat_GetInfo**(void)
Return a structseq instance which contains information about the precision, minimum and maximum values of a float. It's a thin wrapper around the header file *float.h*.

double **PyFloat_GetMax**(void)
Return the maximum representable finite float *DBL_MAX* as C double.

double **PyFloat_GetMin**(void)
Return the minimum normalized positive float *DBL_MIN* as C double.

int **PyFloat_ClearFreeList**(void)
Clear the float free list. Return the number of items that could not be freed.
Complex Number Objects

Python’s complex number objects are implemented as two distinct types when viewed from the C API: one is the Python object exposed to Python programs, and the other is a C structure which represents the actual complex number value. The API provides functions for working with both.
Complex Numbers as C Structures

Note that the functions which accept these structures as parameters and return them as results do so by value rather than dereferencing them through pointers. This is consistent throughout the API.

**Py_complex**

The C structure which corresponds to the value portion of a Python complex number object. Most of the functions for dealing with complex number objects use structures of this type as input or output values, as appropriate. It is defined as:

```c
typedef struct {
    double real;
    double imag;
} Py_complex;
```

**Py_complex _Py_c_sum(Py_complex left, Py_complex right)**

Return the sum of two complex numbers, using the C `Py_complex` representation.

**Py_complex _Py_c_diff(Py_complex left, Py_complex right)**

Return the difference between two complex numbers, using the C `Py_complex` representation.

**Py_complex _Py_c_neg(Py_complex complex)**

Return the negation of the complex number `complex`, using the C `Py_complex` representation.

**Py_complex _Py_c_prod(Py_complex left, Py_complex right)**

Return the product of two complex numbers, using the C `Py_complex` representation.
Py_complex _Py_c_quot(Py_complex dividend, 
Py_complex divisor)
    Return the quotient of two complex numbers, using the C 
Py_complex representation.

    If divisor is null, this method returns zero and sets errno to EDOM.

Py_complex _Py_c_pow(Py_complex num, Py_complex exp)
    Return the exponentiation of num by exp, using the C 
Py_complex representation.

    If num is null and exp is not a positive real number, this method 
returns zero and sets errno to EDOM.
Complex Numbers as Python Objects

**PyComplexObject**
This subtype of PyObject represents a Python complex number object.

**PyTypeObject PyComplex_Type**
This instance of PyTypeObject represents the Python complex number type. It is the same object as complex in the Python layer.

```c
int PyComplex_Check(PyObject *p)
```
Return true if its argument is a PyComplexObject or a subtype of PyComplexObject.

```c
int PyComplex_CheckExact(PyObject *p)
```
Return true if its argument is a PyComplexObject, but not a subtype of PyComplexObject.

```c
PyObject* PyComplex_FromCComplex(Py_complex v)
```
*Return value: New reference.*
Create a new Python complex number object from a C Py_complex value.

```c
PyObject* PyComplex_FromDoubles(double real, double imag)
```
*Return value: New reference.*
Return a new PyComplexObject object from real and imag.

```c
double PyComplex_RealAsDouble(PyObject *op)
```
Return the real part of op as a C double.

```c
double PyComplex_ImagAsDouble(PyObject *op)
```
Return the imaginary part of \( op \) as a C double.

\[
\text{Py_complex } \text{PyComplex_AsCComplex}(\text{PyObject } *op)
\]

Return the \text{Py_complex} value of the complex number \( op \).

If \( op \) is not a Python complex number object but has a \texttt{\_\_complex\_\_} method, this method will first be called to convert \( op \) to a Python complex number object. Upon failure, this method returns \(-1.0\) as a real value.
Bytes Objects

These functions raise `TypeError` when expecting a bytes parameter and are called with a non-bytes parameter.

**PyBytesObject**

This subtype of `PyObject` represents a Python bytes object.

**PyTypeObject PyBytes_Type**

This instance of `PyTypeObject` represents the Python bytes type; it is the same object as `bytes` in the Python layer.

int `PyBytes_Check(PyObject *o)`

Return true if the object `o` is a bytes object or an instance of a subtype of the bytes type.

int `PyBytes_CheckExact(PyObject *o)`

Return true if the object `o` is a bytes object, but not an instance of a subtype of the bytes type.

`PyObject* PyBytes_FromString(const char *v)`

Return a new bytes object with a copy of the string `v` as value on success, and `NULL` on failure. The parameter `v` must not be `NULL`; it will not be checked.

`PyObject* PyBytes_FromStringAndSize(const char *v, Py_ssize_t len)`

Return a new bytes object with a copy of the string `v` as value and length `len` on success, and `NULL` on failure. If `v` is `NULL`, the contents of the bytes object are uninitialized.
PyObject* PyBytes_FromFormat(const char *format, ...)  
Take a C printf()-style format string and a variable number of arguments, calculate the size of the resulting Python bytes object and return a bytes object with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the format string. The following format characters are allowed:

<table>
<thead>
<tr>
<th>Format Characters</th>
<th>Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>n/a</td>
<td>The literal % character.</td>
</tr>
<tr>
<td>%c</td>
<td>int</td>
<td>A single character, represented as an C int.</td>
</tr>
<tr>
<td>%d</td>
<td>int</td>
<td>Exactly equivalent to printf(&quot;%d&quot;).</td>
</tr>
<tr>
<td>%u</td>
<td>unsigned int</td>
<td>Exactly equivalent to printf(&quot;%u&quot;).</td>
</tr>
<tr>
<td>%ld</td>
<td>long</td>
<td>Exactly equivalent to printf(&quot;%ld&quot;).</td>
</tr>
<tr>
<td>%lu</td>
<td>unsigned long</td>
<td>Exactly equivalent to printf(&quot;%lu&quot;).</td>
</tr>
<tr>
<td>%zd</td>
<td>Py_ssize_t</td>
<td>Exactly equivalent to printf(&quot;%zd&quot;).</td>
</tr>
<tr>
<td>%zu</td>
<td>size_t</td>
<td>Exactly equivalent to printf(&quot;%zu&quot;).</td>
</tr>
<tr>
<td>%i</td>
<td>int</td>
<td>Exactly equivalent to printf(&quot;%i&quot;).</td>
</tr>
<tr>
<td>%x</td>
<td>int</td>
<td>Exactly equivalent to printf(&quot;%x&quot;).</td>
</tr>
<tr>
<td>%s</td>
<td>char*</td>
<td>A null-terminated C character</td>
</tr>
</tbody>
</table>

The hex representation of a C pointer. Mostly equivalent to `printf("%p")` except that it is guaranteed to start with the literal `0x` regardless of what the platform’s `printf` yields.

An unrecognized format character causes all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

**PyObject**\* `PyBytes_FromFormatV`(const char *`format`, va_list `vargs`)

Identical to `PyBytes_FromFormat()` except that it takes exactly two arguments.

**PyObject**\* `PyBytes_FromObject`(PyObject *`o`)

Return the bytes representation of object `o` that implements the buffer protocol.

**Py_ssize_t** `PyBytes_Size`(PyObject *`o`)

Return the length of the bytes in bytes object `o`.

**Py_ssize_t** `PyBytes_GET_SIZE`(PyObject *`o`)

Macro form of `PyBytes_Size()` but without error checking.

**char**\* `PyBytes_AsString`(PyObject *`o`)

Return a NUL-terminated representation of the contents of `o`. The pointer refers to the internal buffer of `o`, not a copy. The data must not be modified in any way, unless the string was just created using `PyBytes_FromStringAndSize(NULL, size)`. It must not be
deallocated. If o is not a string object at all, PyBytes_AsString() returns NULL and raises TypeError.

char* PyBytes_AS_STRING(PyObject *string)
Macro form of PyBytes_AsString() but without error checking.

int PyBytes_AsStringAndSize(PyObject *obj, char **buffer, Py_ssize_t *length)
Return a NUL-terminated representation of the contents of the object obj through the output variables buffer and length.

If length is NULL, the resulting buffer may not contain NUL characters; if it does, the function returns -1 and a TypeError is raised.

The buffer refers to an internal string buffer of obj, not a copy. The data must not be modified in any way, unless the string was just created using PyBytes_FromStringAndSize(NULL, size). It must not be deallocated. If string is not a string object at all, PyBytes_AsStringAndSize() returns -1 and raises TypeError.

void PyBytes_Concat(PyObject **bytes, PyObject *newpart)
Create a new bytes object in *bytes containing the contents of newpart appended to bytes; the caller will own the new reference. The reference to the old value of bytes will be stolen. If the new string cannot be created, the old reference to bytes will still be discarded and the value of *bytes will be set to NULL; the appropriate exception will be set.

void PyBytes_ConcatAndDel(PyObject **bytes, PyObject *newpart)
Create a new string object in *bytes containing the contents of newpart appended to bytes. This version decrements the reference count of newpart.

```c
int _PyBytes_Resize(PyObject **bytes, Py_ssize_t newsize)
```

A way to resize a bytes object even though it is “immutable”. Only use this to build up a brand new bytes object; don’t use this if the bytes may already be known in other parts of the code. It is an error to call this function if the refcount on the input bytes object is not one. Pass the address of an existing bytes object as an lvalue (it may be written into), and the new size desired. On success, *bytes holds the resized bytes object and 0 is returned; the address in *bytes may differ from its input value. If the reallocation fails, the original bytes object at *bytes is deallocated, *bytes is set to NULL, a memory exception is set, and -1 is returned.
Byte Array Objects

**PyByteArrayObject**
This subtype of *PyObject* represents a Python bytearray object.

**PyTypeObject** *PyByteArray_Type*
This instance of *PyTypeObject* represents the Python bytearray type; it is the same object as *bytearray* in the Python layer.
Type check macros

int `PyByteArray_Check`(`PyObject *o`)
   Return true if the object \( o \) is a bytearray object or an instance of a subtype of the bytearray type.

int `PyByteArray_CheckExact`(`PyObject *o`)
   Return true if the object \( o \) is a bytearray object, but not an instance of a subtype of the bytearray type.
Direct API functions

**PyObject**\* **PyByteArray_FromObject**(**PyObject** \*o)

Return a new bytearray object from any object, \( o \), that implements the *buffer protocol*.

**PyObject**\* **PyByteArray_FromStringAndSize**(const char \*string, Py_ssize_t \*len)

Create a new bytearray object from *string* and its length, \( \text{len} \). On failure, \( \text{NULL} \) is returned.

**PyObject**\* **PyByteArray_Concat**(**PyObject** \*a, **PyObject** \*b)

Concat bytearrays \( a \) and \( b \) and return a new bytearray with the result.

Py_ssize_t **PyByteArray_Size**(**PyObject** \*bytearray)

Return the size of *bytearray* after checking for a *NULL* pointer.

char\* **PyByteArray_AsString**(**PyObject** \*bytearray)

Return the contents of *bytearray* as a char array after checking for a *NULL* pointer.

int **PyByteArray_Resize**(**PyObject** \*bytearray, Py_ssize_t \*len)

Resize the internal buffer of *bytearray* to \( \text{len} \).
Macros

These macros trade safety for speed and they don’t check pointers.

```c
char* PyByteArray_AS_STRING(PyObject *bytearray)
Macro version of PyByteArray_AsString().
```

```c
Py_ssize_t PyByteArray_GET_SIZE(PyObject *bytearray)
Macro version of PyByteArray_Size().
```
Unicode Objects and Codecs
Unicode Objects

Since the implementation of PEP 393 in Python 3.3, Unicode objects internally use a variety of representations, in order to allow handling the complete range of Unicode characters while staying memory efficient. There are special cases for strings where all code points are below 128, 256, or 65536; otherwise, code points must be below 1114112 (which is the full Unicode range).

Py_UNICODE* and UTF-8 representations are created on demand and cached in the Unicode object. The Py_UNICODE* representation is deprecated and inefficient; it should be avoided in performance- or memory-sensitive situations.

Due to the transition between the old APIs and the new APIs, unicode objects can internally be in two states depending on how they were created:

- “canonical” unicode objects are all objects created by a non-deprecated unicode API. They use the most efficient representation allowed by the implementation.
- “legacy” unicode objects have been created through one of the deprecated APIs (typically PyUnicode_FromUnicode()) and only bear the Py_UNICODE* representation; you will have to call PyUnicode_READY() on them before calling any other API.

Unicode Type

These are the basic Unicode object types used for the Unicode implementation in Python:

Py_UCS4
**Py_UCS2**
**Py_UCS1**

These types are typedefs for unsigned integer types wide enough to contain characters of 32 bits, 16 bits and 8 bits, respectively. When dealing with single Unicode characters, use Py_UCS4.

*New in version 3.3.*

**Py_UNICODE**

This is a typedef of wchar_t, which is a 16-bit type or 32-bit type depending on the platform.

*Changed in version 3.3:* In previous versions, this was a 16-bit type or a 32-bit type depending on whether you selected a “narrow” or “wide” Unicode version of Python at build time.

**PyASCIIObject**
**PyCompactUnicodeObject**
**PyUnicodeObject**

These subtypes of PyObject represent a Python Unicode object. In almost all cases, they shouldn’t be used directly, since all API functions that deal with Unicode objects take and return PyObject pointers.

*New in version 3.3.*

**PyTypeObject** **PyUnicode_Type**

This instance of PyTypeObject represents the Python Unicode type. It is exposed to Python code as str.

The following APIs are really C macros and can be used to do fast checks and to access internal read-only data of Unicode objects:
int PyUnicode_Check(PyObject *o)
    Return true if the object o is a Unicode object or an instance of a Unicode subtype.

int PyUnicode_CheckExact(PyObject *o)
    Return true if the object o is a Unicode object, but not an instance of a subtype.

int PyUnicode_READY(PyObject *o)
    Ensure the string object o is in the “canonical” representation. This is required before using any of the access macros described below.

    Returns 0 on success and -1 with an exception set on failure, which in particular happens if memory allocation fails.

    New in version 3.3.

Py_ssize_t PyUnicode_GET_LENGTH(PyObject *o)
    Return the length of the Unicode string, in code points. o has to be a Unicode object in the “canonical” representation (not checked).

    New in version 3.3.

Py_UCS1* PyUnicode_1BYTE_DATA(PyObject *o)
Py_UCS2* PyUnicode_2BYTE_DATA(PyObject *o)
Py_UCS4* PyUnicode_4BYTE_DATA(PyObject *o)
    Return a pointer to the canonical representation cast to UCS1, UCS2 or UCS4 integer types for direct character access. No checks are performed if the canonical representation has the correct character size; use PyUnicode_KIND() to select the right macro. Make sure PyUnicode_READY() has been called before accessing this.
New in version 3.3.

PyUnicode WCHAR_KIND
PyUnicode 1BYTE_KIND
PyUnicode 2BYTE_KIND
PyUnicode 4BYTE_KIND
Return values of the PyUnicode_KIND() macro.

New in version 3.3.

int PyUnicode_KIND(PyObject *o)
Return one of the PyUnicode kind constants (see above) that indicate how many bytes per character this Unicode object uses to store its data. o has to be a Unicode object in the “canonical” representation (not checked).

New in version 3.3.

void* PyUnicode_DATA(PyObject *o)
Return a void pointer to the raw unicode buffer. o has to be a Unicode object in the “canonical” representation (not checked).

New in version 3.3.

void PyUnicode_WRITE(int kind, void *data, Py_ssize_t index, Py_UCS4 value)
Write into a canonical representation data (as obtained with PyUnicode_DATA()). This macro does not do any sanity checks and is intended for usage in loops. The caller should cache the kind value and data pointer as obtained from other macro calls. index is the index in the string (starts at 0) and value is the new code point value which should be written to that location.
New in version 3.3.

**Py_UCS4 PyUnicode_READ**(int kind, void *data, Py_ssize_t index)

Read a code point from a canonical representation data (as obtained with `PyUnicode_DATA()`). No checks or ready calls are performed.

New in version 3.3.

**Py_UCS4 PyUnicode_READ_CHAR**(PyObject *o, Py_ssize_t index)

Read a character from a Unicode object o, which must be in the “canonical” representation. This is less efficient than `PyUnicode_READ()` if you do multiple consecutive reads.

New in version 3.3.

**PyUnicode_MAX_CHAR_VALUE**(PyObject *o)

Return the maximum code point that is suitable for creating another string based on o, which must be in the “canonical” representation. This is always an approximation but more efficient than iterating over the string.

New in version 3.3.

int **PyUnicode_ClearFreeList**()

Clear the free list. Return the total number of freed items.

Py_ssize_t **PyUnicode_GET_SIZE**(PyObject *o)

Return the size of the deprecated **Py_UNICODE** representation, in code units (this includes surrogate pairs as 2 units). o has to be a Unicode object (not checked).
Py_ssize_t **PyUnicode_GET_DATA_SIZE**(PyObject \*o)

Return the size of the deprecated Py_UNICODE representation in bytes. o has to be a Unicode object (not checked).

**Py_UNICODE**\* **PyUnicode_AS_UNICODE**(PyObject \*o)

const char\* **PyUnicode_AS_DATA**(PyObject \*o)

Return a pointer to a Py_UNICODE representation of the object. The AS_DATA form casts the pointer to const char \*. o has to be a Unicode object (not checked).

*Changed in version 3.3:* This macro is now inefficient – because in many cases the Py_UNICODE representation does not exist and needs to be created – and can fail (return NULL with an exception set). Try to port the code to use the new PyUnicode_nBYTE_DATA() macros or use PyUnicode_WRITE() or PyUnicode_READ().

**Deprecation Notice:**

*Deprecated since version 3.3, will be removed in version 4.0:*
Part of the old-style Unicode API, please migrate to using the PyUnicode_nBYTE_DATA() family of macros.

**Unicode Character Properties**
Unicode provides many different character properties. The most often needed ones are available through these macros which are mapped to C functions depending on the Python configuration.

```c
int Py_UNICODE_ISSPACE(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a whitespace character.

int Py_UNICODE_ISLOWER(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a lowercase character.

int Py_UNICODE_ISUPPER(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an uppercase character.

int Py_UNICODE_ISTITLE(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a titlecase character.

int Py_UNICODE_ISLINEBREAK(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a linebreak character.

int Py_UNICODE_ISDECIMAL(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a decimal character.

int Py_UNICODE_ISDIGIT(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a digit character.

int Py_UNICODE_ISNUMERIC(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is a numeric character.

int Py_UNICODE_ISALPHA(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an alphabetic character.

int Py_UNICODE_ISALNUM(Py_UNICODE ch)
    Return 1 or 0 depending on whether ch is an alphanumeric
character.

int Py_UNICODE_ISPRINTABLE(Py_UNICODE ch)
Return 1 or 0 depending on whether ch is a printable character. Nonprintable characters are those characters defined in the Unicode character database as “Other” or “Separator”, excepting the ASCII space (0x20) which is considered printable. (Note that printable characters in this context are those which should not be escaped when repr() is invoked on a string. It has no bearing on the handling of strings written to sys.stdout or sys.stderr.)

These APIs can be used for fast direct character conversions:

Py_UNICODE Py_UNICODE_TOLOWER(Py_UNICODE ch)
Return the character ch converted to lower case.

Deprecated since version 3.3: This function uses simple case mappings.

Py_UNICODE Py_UNICODE_TOUPPER(Py_UNICODE ch)
Return the character ch converted to upper case.

Deprecated since version 3.3: This function uses simple case mappings.

Py_UNICODE Py_UNICODE_TOTITLE(Py_UNICODE ch)
Return the character ch converted to title case.

Deprecated since version 3.3: This function uses simple case mappings.

int Py_UNICODE_TODECIMAL(Py_UNICODE ch)
Return the character \( ch \) converted to a decimal positive integer. Return \(-1\) if this is not possible. This macro does not raise exceptions.

```c
int Py_UNICODE_TODIGIT(Py_UNICODE ch)
```

Return the character \( ch \) converted to a single digit integer. Return \(-1\) if this is not possible. This macro does not raise exceptions.

```c
double Py_UNICODE_TONUMERIC(Py_UNICODE ch)
```

Return the character \( ch \) converted to a double. Return \(-1.0\) if this is not possible. This macro does not raise exceptions.

These APIs can be used to work with surrogates:

```c
Py_UNICODE_IS_SURROGATE(ch)
```

Check if \( ch \) is a surrogate (0xD800 \( \leq \) \( ch \) \( \leq \) 0xDFFF).

```c
Py_UNICODE_IS_HIGH_SURROGATE(ch)
```

Check if \( ch \) is an high surrogate (0xD800 \( \leq \) \( ch \) \( \leq \) 0xDBFF).

```c
Py_UNICODE_IS_LOW_SURROGATE(ch)
```

Check if \( ch \) is a low surrogate (0xDC00 \( \leq \) \( ch \) \( \leq \) 0xDFFF).

```c
Py_UNICODE_JOIN_SURROGATES(high, low)
```

Join two surrogate characters and return a single Py_UCS4 value. \( high \) and \( low \) are respectively the leading and trailing surrogates in a surrogate pair.

### Creating and accessing Unicode strings

To create Unicode objects and access their basic sequence properties, use these APIs:
PyObject* PyUnicode_New(Py_ssize_t size, Py_UCS4 maxchar)
Create a new Unicode object. maxchar should be the true maximum code point to be placed in the string. As an approximation, it can be rounded up to the nearest value in the sequence 127, 255, 65535, 1114111.

This is the recommended way to allocate a new Unicode object. Objects created using this function are not resizable.

New in version 3.3.

PyObject* PyUnicode_FromKindAndData(int kind, const void *buffer, Py_ssize_t size)
Create a new Unicode object with the given kind (possible values are PyUnicode_1BYTE_KIND etc., as returned by PyUnicode_KIND()). The buffer must point to an array of size units of 1, 2 or 4 bytes per character, as given by the kind.

New in version 3.3.

PyObject* PyUnicode_FromStringAndSize(const char *u, Py_ssize_t size)
Create a Unicode object from the char buffer u. The bytes will be interpreted as being UTF-8 encoded. The buffer is copied into the new object. If the buffer is not NULL, the return value might be a shared object, i.e. modification of the data is not allowed.

If u is NULL, this function behaves like PyUnicode_FromUnicode() with the buffer set to NULL. This usage is deprecated in favor of PyUnicode_New().

PyObject *PyUnicode_FromString(const char *u)
Create a Unicode object from an UTF-8 encoded null-terminated
char buffer \textit{u}.

\textbf{PyObject*} \textbf{PyUnicode\_FromFormat}(\textbf{const char*} \textit{format}, ...)

Take a C printf()-style \textit{format} string and a variable number of arguments, calculate the size of the resulting Python unicode string and return a string with the values formatted into it. The variable arguments must be C types and must correspond exactly to the format characters in the \textit{format} ASCII-encoded string. The following format characters are allowed:

<table>
<thead>
<tr>
<th>Format Characters</th>
<th>Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>\textit{n/a}</td>
<td>The literal % character.</td>
</tr>
<tr>
<td>%c</td>
<td>int</td>
<td>A single character, represented as an C int.</td>
</tr>
<tr>
<td>%d</td>
<td>int</td>
<td>Exactly equivalent to printf(&quot;%d&quot;).</td>
</tr>
<tr>
<td>%u</td>
<td>unsigned int</td>
<td>Exactly equivalent to printf(&quot;%u&quot;).</td>
</tr>
<tr>
<td>%ld</td>
<td>long</td>
<td>Exactly equivalent to printf(&quot;%ld&quot;).</td>
</tr>
<tr>
<td>%li</td>
<td>long</td>
<td>Exactly equivalent to printf(&quot;%li&quot;).</td>
</tr>
<tr>
<td>%lu</td>
<td>unsigned long</td>
<td>Exactly equivalent to printf(&quot;%lu&quot;).</td>
</tr>
<tr>
<td>%lld</td>
<td>long long</td>
<td>Exactly equivalent to printf(&quot;%lld&quot;).</td>
</tr>
<tr>
<td>%lll</td>
<td>long long</td>
<td>Exactly equivalent to printf(&quot;%lli&quot;).</td>
</tr>
<tr>
<td>%llu</td>
<td>unsigned long long</td>
<td>Exactly equivalent to printf(&quot;%llu&quot;).</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Notes</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>-------</td>
</tr>
</tbody>
</table>
| `%zd`  | `Py_ssize_t` | Exactly equivalent to `printf("%zd")`.
| `%zi`  | `Py_ssize_t` | Exactly equivalent to `printf("%zi")`.
| `%zu`  | `size_t`    | Exactly equivalent to `printf("%zu")`.
| `%i`   | `int`       | Exactly equivalent to `printf("%i")`.
| `%x`   | `int`       | Exactly equivalent to `printf("%x")`.
| `%s`   | `char*`     | A null-terminated C character array.
| `%p`   | `void*`     | The hex representation of a C pointer. Mostly equivalent to `printf("%p")` except that it is guaranteed to start with the literal `0x` regardless of what the platform's `printf` yields.
| `%A`   | `PyObject*` | The result of calling `ascii()`.
| `%U`   | `PyObject*` | A unicode object.
| `%V`   | `PyObject*, char*` | A unicode object (which may be `NULL`) and a null-terminated C character array as a second parameter (which will be used, if the first parameter is `NULL`).
| `%S`   | `PyObject*` | The result of calling `PyObject_Str()`.
An unrecognized format character causes all the rest of the format string to be copied as-is to the result string, and any extra arguments discarded.

**Note:** The “%lld” and “%llu” format specifiers are only available when HAVE_LONG_LONG is defined.

*Changed in version 3.2:* Support for "%lld" and "%llu" added.

*Changed in version 3.3:* Support for "%li", "%lli" and "%zi" added.

**PyObject** PyUnicode_FromFormatV(const char *format, va_list vargs)

Identical to PyUnicode_FromFormat() except that it takes exactly two arguments.

**PyObject** PyUnicode_FromEncodedObject(PyObject *obj, const char *encoding, const char *errors)

*Return value: New reference.*

Coerce an encoded object *obj* to a Unicode object and return a reference with incremented refcount.

*bytes, bytearray* and other char buffer compatible objects are decoded according to the given *encoding* and using the error handling defined by *errors*. Both can be NULL to have the interface use the default values (see the next section for details).

All other objects, including Unicode objects, cause a *TypeError* to be set.
The API returns `NULL` if there was an error. The caller is responsible for deref'ing the returned objects.

Py_ssize_t **PyUnicode_GetLength**(PyObject *unicode)

Return the length of the Unicode object, in code points.

*New in version 3.3.*

int **PyUnicode_CopyCharacters**(PyObject *to,
Py_ssize_t to_start, PyObject *from, Py_ssize_t from_start,
Py_ssize_t how_many)

Copy characters from one Unicode object into another. This function performs character conversion when necessary and falls back to `memcpy()` if possible. Returns `-1` and sets an exception on error, otherwise returns `0`.

*New in version 3.3.*

Py_ssize_t **PyUnicode_Fill**(PyObject *unicode,
Py_ssize_t start, Py_ssize_t length, Py_UCS4 fill_char)

Fill a string with a character: write `fill_char` into `unicode[start:start+length]`.

Fail if `fill_char` is bigger than the string maximum character, or if the string has more than 1 reference.

Return the number of written character, or return `-1` and raise an exception on error.

*New in version 3.3.*

int **PyUnicode_WriteChar**(PyObject *unicode,
Py_ssize_t index, Py_UCS4 character)

Write a character to a string. The string must have been created
through `PyUnicode_New()`. Since Unicode strings are supposed to be immutable, the string must not be shared, or have been hashed yet.

This function checks that `unicode` is a Unicode object, that the index is not out of bounds, and that the object can be modified safely (i.e. that it its reference count is one), in contrast to the macro version `PyUnicode_WRITE_CHAR()`.

*New in version 3.3.*

**Py_UCS4** `PyUnicode_ReadChar(PyObject *unicode, Py_ssize_t index)`

Read a character from a string. This function checks that `unicode` is a Unicode object and the index is not out of bounds, in contrast to the macro version `PyUnicode_READ_CHAR()`.

*New in version 3.3.*

**PyObject** `*` `PyUnicode_Substring(PyObject *str, Py_ssize_t start, Py_ssize_t end)`

Return a substring of `str`, from character index `start` (included) to character index `end` (excluded). Negative indices are not supported.

*New in version 3.3.*

**Py_UCS4** `*` `PyUnicode_AsUCS4(PyObject *u, Py_UCS4 *buffer, Py_ssize_t buflen, int copy_null)`

Copy the string `u` into a UCS4 buffer, including a null character, if `copy_null` is set. Returns `NULL` and sets an exception on error (in particular, a `ValueError` if `buflen` is smaller than the length of `u`). `buffer` is returned on success.
New in version 3.3.

**Py_UCS4** *PyUnicode_AsUCS4Copy*(PyObject *u)

Copy the string u into a new UCS4 buffer that is allocated using `PyMem_Malloc()`. If this fails, NULL is returned with a `MemoryError` set.

New in version 3.3.

### Deprecated Py_UNICODE APIs

*Deprecated since version 3.3, will be removed in version 4.0.*

These API functions are deprecated with the implementation of [PEP 393](https://www.python.org/dev/peps/pep-0393/). Extension modules can continue using them, as they will not be removed in Python 3.x, but need to be aware that their use can now cause performance and memory hits.

**PyObject** *PyUnicode_FromUnicode*(const Py_UNICODE *u, Py_ssize_t size)

*Return value: New reference.*

Create a Unicode object from the Py_UNICODE buffer u of the given size. u may be NULL which causes the contents to be undefined. It is the user’s responsibility to fill in the needed data. The buffer is copied into the new object.

If the buffer is not NULL, the return value might be a shared object. Therefore, modification of the resulting Unicode object is only allowed when u is NULL.

If the buffer is NULL, `PyUnicode_READY()` must be called once the string content has been filled before using any of the access
macros such as `PyUnicode_KIND()`.

Please migrate to using `PyUnicode_FromKindAndData()` or `PyUnicode_New()`.

**Py_UNICODE**

**Py_UNICODE* PyUnicode_AsUnicode**(PyObject *unicode)

Return a read-only pointer to the Unicode object’s internal `Py_UNICODE` buffer, or `NULL` on error. This will create the `Py_UNICODE*` representation of the object if it is not yet available. Note that the resulting `Py_UNICODE` string may contain embedded null characters, which would cause the string to be truncated when used in most C functions.

Please migrate to using `PyUnicode_AsUCS4()`, `PyUnicode_Substring()`, `PyUnicode_ReadChar()` or similar new APIs.

**PyObject**

**Py_UNICODE* PyUnicode_TransformDecimalToASCII**(Py_UNICODE *s, Py_ssize_t size)

Create a Unicode object by replacing all decimal digits in `Py_UNICODE` buffer of the given size by ASCII digits 0–9 according to their decimal value. Return `NULL` if an exception occurs.

**Py_UNICODE**

**Py_UNICODE* PyUnicode_AsUnicodeAndSize**(PyObject *unicode, Py_ssize_t *size)

Like `PyUnicode_AsUnicode()`, but also saves the `Py_UNICODE()` array length in `size`. Note that the resulting `Py_UNICODE*` string may contain embedded null characters, which would cause the string to be truncated when used in most C functions.
New in version 3.3.

**Py_UNICODE***

**PyUnicode_AsUnicodeCopy**(PyObject *unicode)

Create a copy of a Unicode string ending with a nul character. Return `NULL` and raise a `MemoryError` exception on memory allocation failure, otherwise return a new allocated buffer (use `PyMem_Free()` to free the buffer). Note that the resulting **Py_UNICODE*** string may contain embedded null characters, which would cause the string to be truncated when used in most C functions.

New in version 3.2.

Please migrate to using `PyUnicode_AsUCS4Copy()` or similar new APIs.

**Py_ssize_t** **PyUnicode_GetSize**(PyObject *unicode)

Return the size of the deprecated **Py_UNICODE*** representation, in code units (this includes surrogate pairs as 2 units).

Please migrate to using `PyUnicode_GetLength()`.

**PyObject*** **PyUnicode_FromObject**(PyObject *obj)

Shortcut for `PyUnicode_FromEncodedObject(obj, NULL, "strict")` which is used throughout the interpreter whenever coercion to Unicode is needed.

**Locale Encoding**

The current locale encoding can be used to decode text from the
operating system.

PyObject* **PyUnicode_DecodeLocaleAndSize**(const char *str, Py_ssize_t len, const char *errors)

Decode a string from the current locale encoding. The supported error handlers are "strict" and "surrogateescape" (PEP 383). The decoder uses "strict" error handler if *errors* is NULL. *str* must end with a null character but cannot contain embedded null characters.

**See also:** Use **PyUnicode_DecodeFSDefaultAndSize()** to decode a string from Py_FileSystemDefaultEncoding (the locale encoding read at Python startup).

*New in version 3.3.*

PyObject* **PyUnicode_DecodeLocale**(const char *str, const char *errors)

Similar to **PyUnicode_DecodeLocaleAndSize()**, but compute the string length using strlen().

*New in version 3.3.*

PyObject* **PyUnicode_EncodeLocale**(PyObject *unicode, const char *errors)

Encode a Unicode object to the current locale encoding. The supported error handlers are "strict" and "surrogateescape" (PEP 383). The encoder uses "strict" error handler if *errors* is NULL. Return a bytes object. *str* cannot contain embedded null characters.

**See also:** Use **PyUnicode_EncodeFSDefault()** to encode
a string to Py_FileSystemDefaultEncoding (the locale encoding read at Python startup).

New in version 3.3.

File System Encoding

To encode and decode file names and other environment strings, Py_FileSystemEncoding should be used as the encoding, and "surrogateescape" should be used as the error handler (PEP 383). To encode file names during argument parsing, the "O&E" converter should be used, passing PyUnicode_FSConverter() as the conversion function:

```c
int PyUnicode_FSConverter(PyObject* obj, void* result)
    ParseTuple converter: encode str objects to bytes using
    PyUnicode_EncodeFSDefault(); bytes objects are output as-is. result must be a PyBytesObject* which must be released when it is no longer used.
```

New in version 3.1.

To decode file names during argument parsing, the "O&E" converter should be used, passing PyUnicode_FSDecoder() as the conversion function:

```c
int PyUnicode_FSDecoder(PyObject* obj, void* result)
    ParseTuple converter: decode bytes objects to str using
    PyUnicode_DecodeFSDefaultAndSize(); str objects are output as-is. result must be a PyUnicodeObject* which must be released when it is no longer used.
```
New in version 3.2.

PyObject* `PyUnicode_DecodeFSDefaultAndSize`(const char *s, Py_ssize_t size)

Decode a string using `Py_FileSystemDefaultEncoding` and the "surrogateescape" error handler, or "strict" on Windows.

If `Py_FileSystemDefaultEncoding` is not set, fall back to the locale encoding.

**See also:** `Py_FileSystemDefaultEncoding` is initialized at startup from the locale encoding and cannot be modified later. If you need to decode a string from the current locale encoding, use `PyUnicode_DecodeLocaleAndSize()`.

*Changed in version 3.2:* Use "strict" error handler on Windows.

PyObject* `PyUnicode_DecodeFSDefault`(const char *s)

Decode a null-terminated string using `Py_FileSystemDefaultEncoding` and the "surrogateescape" error handler, or "strict" on Windows.

If `Py_FileSystemDefaultEncoding` is not set, fall back to the locale encoding.

Use `PyUnicode_DecodeFSDefaultAndSize()` if you know the string length.

*Changed in version 3.2:* Use "strict" error handler on Windows.

PyObject* `PyUnicode_EncodeFSDefault`(PyObject *unicode)

Encode a Unicode object to `Py_FileSystemDefaultEncoding`
with the "surrogateescape" error handler, or "strict" on Windows, and return bytes. Note that the resulting bytes object may contain null bytes.

If Py_FileSystemDefaultEncoding is not set, fall back to the locale encoding.

See also: Py_FileSystemDefaultEncoding is initialized at startup from the locale encoding and cannot be modified later. If you need to encode a string to the current locale encoding, use PyUnicode_EncodeLocale().

New in version 3.2.

wchar_t Support

wchar_t support for platforms which support it:

PyObject* PyUnicode_FromWideChar(const wchar_t *w, Py_ssize_t size)

Create a Unicode object from the wchar_t buffer w of the given size. Passing -1 as the size indicates that the function must itself compute the length, using wcslen. Return NULL on failure.

Py_ssize_t
PyUnicode_AsWideChar(PyUnicodeObject *unicode, wchar_t *w, Py_ssize_t size)

Copy the Unicode object contents into the wchar_t buffer w. At most size wchar_t characters are copied (excluding a possibly trailing 0-termination character). Return the number of wchar_t characters copied or -1 in case of an error. Note that the resulting
wchar_t* string may or may not be 0-terminated. It is the responsibility of the caller to make sure that the wchar_t* string is 0-terminated in case this is required by the application. Also, note that the wchar_t* string might contain null characters, which would cause the string to be truncated when used with most C functions.

wchar_t* **PyUnicode_AsWideCharString**(PyObject *unicode, Py_ssize_t *size)

Convert the Unicode object to a wide character string. The output string always ends with a null character. If *size* is not NULL, write the number of wide characters (excluding the trailing 0-termination character) into *size.

Returns a buffer allocated by PyMem_Alloc() (use PyMem_Free() to free it) on success. On error, returns NULL, *size* is undefined and raises a MemoryError. Note that the resulting wchar_t string might contain null characters, which would cause the string to be truncated when used with most C functions.

*New in version 3.2.*

**UCS4 Support**

*New in version 3.3.*

double **Py_UCS4_strlen**(const Py_UCS4 *u)

Py_UCS4* **Py_UCS4_strcpy**(Py_UCS4 *s1, const Py_UCS4 *s2)

Py_UCS4* **Py_UCS4_strncpy**(Py_UCS4 *s1, const Py_UCS4 *s2, size_t n)

Py_UCS4* **Py_UCS4_strcat**(Py_UCS4 *s1, const Py_UCS4 *s2)
int Py_UCS4_strcmp(const Py_UCS4 *s1, const Py_UCS4 *s2)
int Py_UCS4_strncmp(const Py_UCS4 *s1, const Py_UCS4 *s2, size_t n)
Py_UCS4* Py_UCS4_strchr(const Py_UCS4 *s, Py_UCS4 c)
Py_UCS4* Py_UCS4_strrchr(const Py_UCS4 *s, Py_UCS4 c)

These utility functions work on strings of Py_UCS4 characters and otherwise behave like the C standard library functions with the same name.
Built-in Codecs

Python provides a set of built-in codecs which are written in C for speed. All of these codecs are directly usable via the following functions.

Many of the following APIs take two arguments encoding and errors, and they have the same semantics as the ones of the built-in \texttt{str()} string object constructor.

Setting encoding to \texttt{NULL} causes the default encoding to be used which is ASCII. The file system calls should use \texttt{PyUnicode_FSCConverter()} for encoding file names. This uses the variable \texttt{Py_FileSystemDefaultEncoding} internally. This variable should be treated as read-only: on some systems, it will be a pointer to a static string, on others, it will change at run-time (such as when the application invokes setlocale).

Error handling is set by errors which may also be set to \texttt{NULL} meaning to use the default handling defined for the codec. Default error handling for all built-in codecs is “strict” (\texttt{ValueError} is raised).

The codecs all use a similar interface. Only deviation from the following generic ones are documented for simplicity.

Generic Codecs

These are the generic codec APIs:

\begin{verbatim}
PyObject* PyUnicode_Decode(const char *s, Py_ssize_t size, const char *encoding, const char *errors)
\end{verbatim}

\textit{Return value: New reference.}
Create a Unicode object by decoding size bytes of the encoded string s. *encoding* and *errors* have the same meaning as the parameters of the same name in the *str()* built-in function. The codec to be used is looked up using the Python codec registry. Return *NULL* if an exception was raised by the codec.

### PyObject* PyUnicode_AsEncodedString(PyObject *unicode, const char *encoding, const char *errors)

*Return value: New reference.*

Encode a Unicode object and return the result as Python bytes object. *encoding* and *errors* have the same meaning as the parameters of the same name in the Unicode *encode()* method. The codec to be used is looked up using the Python codec registry. Return *NULL* if an exception was raised by the codec.

### PyObject* PyUnicode_Encode(const Py_UNICODE *s, Py_ssize_t size, const char *encoding, const char *errors)

*Return value: New reference.*

Encode the Py_UNICODE buffer s of the given size and return a Python bytes object. *encoding* and *errors* have the same meaning as the parameters of the same name in the Unicode *encode()* method. The codec to be used is looked up using the Python codec registry. Return *NULL* if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:* Part of the old-style Py_UNICODE API; please migrate to using PyUnicode_AsEncodedString().

## UTF-8 Codecs

These are the UTF-8 codec APIs:
PyObject* **PyUnicode_DecodeUTF8**(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*
Create a Unicode object by decoding size bytes of the UTF-8 encoded string s. Return *NULL* if an exception was raised by the codec.

PyObject* **PyUnicode_DecodeUTF8Stateful**(const char *s, Py_ssize_t size, const char *errors, Py_ssize_t *consumed)

*Return value: New reference.*
If consumed is *NULL*, behave like **PyUnicode_DecodeUTF8()**. If consumed is not *NULL*, trailing incomplete UTF-8 byte sequences will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in consumed.

PyObject* **PyUnicode_AsUTF8String**(PyObject *unicode)

*Return value: New reference.*
Encode a Unicode object using UTF-8 and return the result as Python bytes object. Error handling is “strict”. Return *NULL* if an exception was raised by the codec.

char* **PyUnicode_AsUTF8AndSize**(PyObject *unicode, Py_ssize_t *size)

Return a pointer to the default encoding (UTF-8) of the Unicode object, and store the size of the encoded representation (in bytes) in size. size can be *NULL*, in this case no size will be stored.

In the case of an error, *NULL* is returned with an exception set and no size is stored.

This caches the UTF-8 representation of the string in the Unicode object, and subsequent calls will return a pointer to the same
buffer. The caller is not responsible for deallocating the buffer.

*New in version 3.3.*

char* `PyUnicode_AsUTF8(PyObject *unicode)`

As `PyUnicode_AsUTF8AndSize()`, but does not store the size.

*New in version 3.3.*

PyObject* `PyUnicode_EncodeUTF8(const Py_UNICODE *s, Py_ssize_t size, const char *errors)`

*Return value: New reference.*

Encode the `Py_UNICODE` buffer `s` of the given `size` using UTF-8 and return a Python bytes object. Return `NULL` if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:* Part of the old-style `Py_UNICODE` API; please migrate to using `PyUnicode_AsUTF8String()` or `PyUnicode_AsUTF8AndSize()`.

**UTF-32 Codecs**

These are the UTF-32 codec APIs:

PyObject* `PyUnicode_DecodeUTF32(const char *s, Py_ssize_t size, const char *errors, int *byteorder)`

Decode `size` bytes from a UTF-32 encoded buffer string and return the corresponding Unicode object. `errors` (if non-`NULL`) defines the error handling. It defaults to “strict”.

If `byteorder` is non-`NULL`, the decoder starts decoding using the
given byte order:

```
*byteorder == -1: little endian
*byteorder == 0: native order
*byteorder == 1: big endian
```

If `byteorder` is zero, and the first four bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If `byteorder` is `-1` or `1`, any byte order mark is copied to the output.

After completion, `byteorder` is set to the current byte order at the end of input data.

If `byteorder` is `NULL`, the codec starts in native order mode.

Return `NULL` if an exception was raised by the codec.

**PyObject* PyUnicode_DecodeUTF32Stateful** (const char *s, Py_ssize_t size, const char *errors, int *byteorder, Py_ssize_t *consumed)

If `consumed` is `NULL`, behave like `PyUnicode_DecodeUTF32()`. If `consumed` is not `NULL`, `PyUnicode_DecodeUTF32Stateful()` will not treat trailing incomplete UTF-32 byte sequences (such as a number of bytes not divisible by four) as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in `consumed`.

**PyObject* PyUnicode_AsUTF32String** (PyObject *unicode)

Return a Python byte string using the UTF-32 encoding in native byte order. The string always starts with a BOM mark. Error
handling is “strict”. Return \texttt{NULL} if an exception was raised by the codec.

\textbf{PyObject* \texttt{PyUnicode\_EncodeUTF32}}(const \texttt{Py\_UNICODE }*s, \texttt{Py\_ssize\_t size}, const char *errors, int \texttt{byteorder})

Return a Python bytes object holding the UTF-32 encoded value of the Unicode data in \texttt{s}. Output is written according to the following byte order:

\begin{center}
\begin{tabular}{ll}
byteorder == \texttt{-1}: little endian \\
byteorder == \texttt{0}: native byte order (writes a BOM) \\
byteorder == \texttt{1}: big endian
\end{tabular}
\end{center}

If byteorder is \texttt{0}, the output string will always start with the Unicode BOM mark (U+FEFF). In the other two modes, no BOM mark is prepended.

If \texttt{Py\_UNICODE\_WIDE} is not defined, surrogate pairs will be output as a single codepoint.

Return \texttt{NULL} if an exception was raised by the codec.

\textbf{Deprecated since version 3.3, will be removed in version 4.0:} Part of the old-style \texttt{Py\_UNICODE} API; please migrate to using \texttt{PyUnicode\_AsUTF32String}( ).

\section*{UTF-16 Codecs}

These are the UTF-16 codec APIs:

\textbf{PyObject* \texttt{PyUnicode\_DecodeUTF16}}(const char *\texttt{s}, \texttt{Py\_ssize\_t size}, const char *\texttt{errors}, int *\texttt{byteorder})
**Return value:** New reference.
Decide \( \text{size} \) bytes from a UTF-16 encoded buffer string and return the corresponding Unicode object. \textit{errors} (if non-\texttt{NULL}) defines the error handling. It defaults to “strict”.

If \textit{byteorder} is non-\texttt{NULL}, the decoder starts decoding using the given byte order:

\begin{verbatim}
*byteorder == -1: little endian
*byteorder == 0: native order
*byteorder == 1: big endian
\end{verbatim}

If \texttt{*byteorder} is zero, and the first two bytes of the input data are a byte order mark (BOM), the decoder switches to this byte order and the BOM is not copied into the resulting Unicode string. If \texttt{*byteorder} is \texttt{-1} or \texttt{1}, any byte order mark is copied to the output (where it will result in either a \texttt{\ufffe} or a \texttt{\ufeff} character).

After completion, \texttt{*byteorder} is set to the current byte order at the end of input data.

If \textit{byteorder} is \texttt{NULL}, the codec starts in native order mode.

Return \texttt{NULL} if an exception was raised by the codec.

\texttt{PyObject* \textbf{PyUnicode_DecodeUTF16Stateful}(const char *s, Py_ssize_t \texttt{size}, const char *errors, int \texttt{*byteorder}, Py_ssize_t \texttt{*consumed})}

**Return value:** New reference.

If \texttt{consumed} is \texttt{NULL}, behave like \texttt{PyUnicode_DecodeUTF16()}. If \texttt{consumed} is not \texttt{NULL}, \texttt{PyUnicode_DecodeUTF16Stateful()} will not treat trailing incomplete UTF-16 byte sequences (such as an odd number of
bytes or a split surrogate pair) as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in consumed.

PyObject* **PyUnicode_AsUTF16String**(PyObject *unicode)

Return a Python byte string using the UTF-16 encoding in native byte order. The string always starts with a BOM mark. Error handling is “strict”. Return NULL if an exception was raised by the codec.

PyObject* **PyUnicode_EncodeUTF16**(const Py_UNICODE *s, Py_ssize_t size, const char *errors, int byteorder)

Return a Python bytes object holding the UTF-16 encoded value of the Unicode data in s. Output is written according to the following byte order:

- `byteorder == -1`: little endian
- `byteorder == 0`: native byte order (writes a BOM mark)
- `byteorder == 1`: big endian

If byteorder is 0, the output string will always start with the Unicode BOM mark (U+FEFF). In the other two modes, no BOM mark is prepended.

If `Py_UNICODE_WIDE` is defined, a single `Py_UNICODE` value may get represented as a surrogate pair. If it is not defined, each `Py_UNICODE` values is interpreted as an UCS-2 character.

Return NULL if an exception was raised by the codec.
UTF-7 Codecs

These are the UTF-7 codec APIs:

**PyObject* **PyUnicode_DecodeUTF7**(const char *s, Py_ssize_t size, const char *errors)

Create a Unicode object by decoding size bytes of the UTF-7 encoded string s. Return NULL if an exception was raised by the codec.

**PyObject* **PyUnicode_DecodeUTF7Stateful**(const char *s, Py_ssize_t size, const char *errors, Py_ssize_t *consumed)

If consumed is NULL, behave like PyUnicode_DecodeUTF7(). If consumed is not NULL, trailing incomplete UTF-7 base-64 sections will not be treated as an error. Those bytes will not be decoded and the number of bytes that have been decoded will be stored in consumed.

**PyObject* **PyUnicode_EncodeUTF7**(const Py_UNICODE *s, Py_ssize_t size, int base64SetO, int base64WhiteSpace, const char *errors)

Encode the Py_UNICODE buffer of the given size using UTF-7 and return a Python bytes object. Return NULL if an exception was raised by the codec.

If base64SetO is nonzero, “Set O” (punctuation that has no otherwise special meaning) will be encoded in base-64. If base64WhiteSpace is nonzero, whitespace will be encoded in
base-64. Both are set to zero for the Python “utf-7” codec.

*Deprecated since version 3.3, will be removed in version 4.0:*
Part of the old-style *Py_UNICODE* API.

**Unicode-Escape Codecs**

These are the “Unicode Escape” codec APIs:

**PyObject**

**PyUnicode_DecodeUnicodeEscape**(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Create a Unicode object by decoding size bytes of the Unicode-Escape encoded string s. Return *NULL* if an exception was raised by the codec.

**PyObject**

**PyUnicode_AsUnicodeEscapeString**(PyObject *unicode)

*Return value: New reference.*

Encode a Unicode object using Unicode-Escape and return the result as Python string object. Error handling is “strict”. Return *NULL* if an exception was raised by the codec.

**PyObject**

**PyUnicode_EncodeUnicodeEscape**(const Py_UNICODE *s, Py_ssize_t size)

*Return value: New reference.*

Encode the *Py_UNICODE* buffer of the given size using Unicode-Escape and return a Python string object. Return *NULL* if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:*
Part of the old-style *Py_UNICODE* API; please migrate to using
Raw-Unicode-Escape Codecs

These are the “Raw Unicode Escape” codec APIs:

**PyObject**\* **PyUnicode.DecodeRawUnicodeEscape**(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*
Create a Unicode object by decoding size bytes of the Raw-Unicode-Escape encoded string s. Return NULL if an exception was raised by the codec.

**PyObject**\* **PyUnicode.AsRawUnicodeEscapeString**(PyObject *unicode)

*Return value: New reference.*
Encode a Unicode object using Raw-Unicode-Escape and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

**PyObject**\* **PyUnicode.EncodeRawUnicodeEscape**(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*
Encode the Py_UNICODE buffer of the given size using Raw-Unicode-Escape and return a Python string object. Return NULL if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:* Part of the old-style Py_UNICODE API; please migrate to using PyUnicode.AsRawUnicodeEscapeString().
Latin-1 Codecs

These are the Latin-1 codec APIs: Latin-1 corresponds to the first 256 Unicode ordinals and only these are accepted by the codecs during encoding.

PyObject* PyUnicode_DecodeLatin1(const char *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*
Create a Unicode object by decoding size bytes of the Latin-1 encoded string s. Return NULL if an exception was raised by the codec.

PyObject* PyUnicode_AsLatin1String(PyObject *unicode)

*Return value: New reference.*
Encode a Unicode object using Latin-1 and return the result as Python bytes object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

PyObject* PyUnicode_EncodeLatin1(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*
Encode the Py_UNICODE buffer of the given size using Latin-1 and return a Python bytes object. Return NULL if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:* Part of the old-style Py_UNICODE API; please migrate to using PyUnicode_AsLatin1String().

ASCII Codecs
These are the ASCII codec APIs. Only 7-bit ASCII data is accepted. All other codes generate errors.

**PyObject** `PyUnicode_DecodeASCII` *(const char *s, Py_ssize_t size, const char *errors)*

*Return value: New reference.*

Create a Unicode object by decoding size bytes of the ASCII encoded string s. Return *NULL* if an exception was raised by the codec.

**PyObject** `PyUnicode_AsASCIIString` *(PyObject *unicode)*

*Return value: New reference.*

Encode a Unicode object using ASCII and return the result as Python bytes object. Error handling is “strict”. Return *NULL* if an exception was raised by the codec.

**PyObject** `PyUnicode_EncodeASCII` *(const Py_UNICODE *s, Py_ssize_t size, const char *errors)*

*Return value: New reference.*

Encode the Py_UNICODE buffer of the given size using ASCII and return a Python bytes object. Return *NULL* if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0: Part of the old-style Py_UNICODE API; please migrate to using PyUnicode_AsASCIIString().*

**Character Map Codecs**

This codec is special in that it can be used to implement many different codecs (and this is in fact what was done to obtain most of the standard codecs included in the encodings package). The codec
uses mapping to encode and decode characters.

Decoding mappings must map single string characters to single Unicode characters, integers (which are then interpreted as Unicode ordinals) or None (meaning “undefined mapping” and causing an error).

Encoding mappings must map single Unicode characters to single string characters, integers (which are then interpreted as Latin-1 ordinals) or None (meaning “undefined mapping” and causing an error).

The mapping objects provided must only support the \_getitem\_ mapping interface.

If a character lookup fails with a LookupError, the character is copied as-is meaning that its ordinal value will be interpreted as Unicode or Latin-1 ordinal resp. Because of this, mappings only need to contain those mappings which map characters to different code points.

These are the mapping codec APIs:

PyObject* PyUnicode\_DecodeCharmap(const char *s, Py_ssize_t size, PyObject *mapping, const char *errors)

Create a Unicode object by decoding size bytes of the encoded string s using the given mapping object. Return NULL if an exception was raised by the codec. If mapping is NULL latin-1 decoding will be done. Else it can be a dictionary mapping byte or a unicode string, which is treated as a lookup table. Byte values greater that the length of the string and U+FFFE “characters” are treated as “undefined mapping”.

PyObject* PyUnicode\_AsCharmapString(PyObject *unicode,
PyObject *mapping)

Encode a Unicode object using the given mapping object and return the result as Python string object. Error handling is “strict”. Return NULL if an exception was raised by the codec.

The following codec API is special in that maps Unicode to Unicode.

PyObject* PyUnicode_TranslateCharmap(const Py_UNICODE *s, Py_ssize_t size, PyObject *table, const char *errors)

Translate a Py_UNICODE buffer of the given size by applying a character mapping table to it and return the resulting Unicode object. Return NULL when an exception was raised by the codec.

The mapping table must map Unicode ordinal integers to Unicode ordinal integers or None (causing deletion of the character).

Mapping tables need only provide the __getitem__() interface; dictionaries and sequences work well. Unmapped character ordinals (ones which cause a LookupError) are left untouched and are copied as-is.

Deprecated since version 3.3, will be removed in version 4.0: Part of the old-style Py_UNICODE API.

PyObject* PyUnicode_EncodeCharmap(const Py_UNICODE *s, Py_ssize_t size, PyObject *mapping, const char *errors)

Encode the Py_UNICODE buffer of the given size using the given mapping object and return a Python string object. Return NULL if an exception was raised by the codec.
Deprecated since version 3.3, will be removed in version 4.0: Part of the old-style Py_UNICODE API; please migrate to using PyUnicode_AsCharmapString().

MBCS codecs for Windows

These are the MBCS codec APIs. They are currently only available on Windows and use the Win32 MBCS converters to implement the conversions. Note that MBCS (or DBCS) is a class of encodings, not just one. The target encoding is defined by the user settings on the machine running the codec.

PyObject* PyUnicode_DecodeMBCS(const char *s, Py_ssize_t size, const char *errors)

Create a Unicode object by decoding size bytes of the MBCS encoded string s. Return NULL if an exception was raised by the codec.

PyObject* PyUnicode_DecodeMBCSStateful(const char *s, int size, const char *errors, int *consumed)

If consumed is NULL, behave like PyUnicode_DecodeMBCS(). If consumed is not NULL, PyUnicode_DecodeMBCSStateful() will not decode trailing lead byte and the number of bytes that have been decoded will be stored in consumed.

PyObject* PyUnicode_AsMBCSString(PyObject *unicode)

Encode a Unicode object using MBCS and return the result as Python bytes object. Error handling is “strict”. Return NULL if an exception was raised by the codec.
PyObject* PyUnicode_EncodeCodePage(int code_page, PyObject *unicode, const char *errors)

Encode the Unicode object using the specified code page and return a Python bytes object. Return NULL if an exception was raised by the codec. Use CP_ACP code page to get the MBCS encoder.

*New in version 3.3.*

PyObject* PyUnicode_EncodeMBCS(const Py_UNICODE *s, Py_ssize_t size, const char *errors)

*Return value: New reference.*

Encode the Py_UNICODE buffer of the given size using MBCS and return a Python bytes object. Return NULL if an exception was raised by the codec.

*Deprecated since version 3.3, will be removed in version 4.0:* Part of the old-style Py_UNICODE API; please migrate to using PyUnicode_AsMBCSString() or PyUnicode_EncodeCodePage().

Methods & Slots
Methods and Slot Functions

The following APIs are capable of handling Unicode objects and strings on input (we refer to them as strings in the descriptions) and return Unicode objects or integers as appropriate.

They all return \texttt{NULL} or \texttt{-1} if an exception occurs.

\textbf{PyObject* PyUnicode\_Concat(PyObject *left, PyObject *right)}

\textit{Return value: New reference.}
Concat two strings giving a new Unicode string.

\textbf{PyObject* PyUnicode\_Split(PyObject *s, PyObject *sep, Py\_ssize\_t maxsplit)}

\textit{Return value: New reference.}
Split a string giving a list of Unicode strings. If \texttt{sep} is \texttt{NULL}, splitting will be done at all whitespace substrings. Otherwise, splits occur at the given separator. At most \texttt{maxsplit} splits will be done. If negative, no limit is set. Separators are not included in the resulting list.

\textbf{PyObject* PyUnicode\_Splitlines(PyObject *s, int keepend)}

\textit{Return value: New reference.}
Split a Unicode string at line breaks, returning a list of Unicode strings. CRLF is considered to be one line break. If \texttt{keepend} is 0, the Line break characters are not included in the resulting strings.

\textbf{PyObject* PyUnicode\_Translate(PyObject *str, PyObject *table, const char *errors)}

\textit{Return value: New reference.}
Translate a string by applying a character mapping table to it and return the resulting Unicode object.
The mapping table must map Unicode ordinal integers to Unicode ordinal integers or None (causing deletion of the character).

Mapping tables need only provide the `__getitem__()` interface; dictionaries and sequences work well. Unmapped character ordinals (ones which cause a `LookupError`) are left untouched and are copied as-is.

`errors` has the usual meaning for codecs. It may be `NULL` which indicates to use the default error handling.

```c
PyObject* PyUnicode_Join(PyObject *separator, PyObject *seq)
```

*Return value: New reference.*

Join a sequence of strings using the given `separator` and return the resulting Unicode string.

```c
int PyUnicode_Tailmatch(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end, int direction)
```

Return 1 if `substr` matches `str[start:end]` at the given tail end (`direction` == -1 means to do a prefix match, `direction` == 1 a suffix match), 0 otherwise. Return -1 if an error occurred.

```c
Py_ssize_t PyUnicode_Find(PyObject *str, PyObject *substr, Py_ssize_t start, Py_ssize_t end, int direction)
```

Return the first position of `substr` in `str[start:end]` using the given `direction` (`direction` == 1 means to do a forward search, `direction` == -1 a backward search). The return value is the index of the first match; a value of -1 indicates that no match was found, and -2 indicates that an error occurred and an exception has been set.

```c
Py_ssize_t PyUnicode_FindChar(PyObject *str, Py_UCS4 ch, Py_ssize_t start, Py_ssize_t end, int direction)
```
Return the first position of the character \texttt{ch} in \texttt{str[start:end]} using the given \texttt{direction} (\texttt{direction} == 1 means to do a forward search, \texttt{direction} == -1 a backward search). The return value is the index of the first match; a value of \texttt{-1} indicates that no match was found, and \texttt{-2} indicates that an error occurred and an exception has been set.

\textit{New in version 3.3.}

\texttt{Py_ssize_t PyUnicode_Count(PyObject \*str, PyObject \*substr, Py_ssize_t start, Py_ssize_t end)}

Return the number of non-overlapping occurrences of \texttt{substr} in \texttt{str[start:end]}. Return \texttt{-1} if an error occurred.

\texttt{PyObject\* PyUnicode_Replace(PyObject \*str, PyObject \*substr, PyObject \*replstr, Py_ssize_t maxcount)}

\textit{Return value: New reference.}

Replace at most \texttt{maxcount} occurrences of \texttt{substr} in \texttt{str} with \texttt{replstr} and return the resulting Unicode object. \texttt{maxcount} == -1 means replace all occurrences.

\texttt{int PyUnicode_Compare(PyObject \*left, PyObject \*right)}

Compare two strings and return -1, 0, 1 for less than, equal, and greater than, respectively.

\texttt{int PyUnicode_CompareWithASCIIString(PyObject \*uni, char \*string)}

Compare a unicode object, \texttt{uni}, with \texttt{string} and return -1, 0, 1 for less than, equal, and greater than, respectively. It is best to pass only ASCII-encoded strings, but the function interprets the input string as ISO-8859-1 if it contains non-ASCII characters”.

\texttt{PyObject\* PyUnicode_RichCompare(PyObject \*left,}
Rich compare two unicode strings and return one of the following:

- NULL in case an exception was raised
- Py_True or Py_False for successful comparisons
- Py_NotImplemented in case the type combination is unknown

Note that Py_EQ and Py_NE comparisons can cause a UnicodeWarning in case the conversion of the arguments to Unicode fails with a UnicodeDecodeError.

Possible values for op are Py_GT, Py_GE, Py_EQ, Py_NE, Py_LT, and Py_LE.

Return a new string object from format and args; this is analogous to format % args. The args argument must be a tuple.

Check whether element is contained in container and return true or false accordingly.

element has to coerce to a one element Unicode string. -1 is returned if there was an error.

Intern the argument *string in place. The argument must be the address of a pointer variable pointing to a Python unicode string object. If there is an existing interned string that is the same as
*string, it sets *string to it (decrementing the reference count of the old string object and incrementing the reference count of the interned string object), otherwise it leaves *string alone and interns it (incrementing its reference count). (Clarification: even though there is a lot of talk about reference counts, think of this function as reference-count-neutral; you own the object after the call if and only if you owned it before the call.)

**PyObject**` PyUnicode_InternFromString`((const char *v))
A combination of **PyUnicode_FromString()** and **PyUnicode_InternInPlace()**, returning either a new unicode string object that has been interned, or a new (“owned”) reference to an earlier interned string object with the same value.
Tuple Objects

**PyTupleObject**
This subtype of `PyObject` represents a Python tuple object.

**PyTypeObject** **PyTuple_Type**
This instance of `PyTypeObject` represents the Python tuple type; it is the same object as `tuple` in the Python layer.

**int PyTuple_Check(PyObject *p)**
Return true if `p` is a tuple object or an instance of a subtype of the tuple type.

**int PyTuple_CheckExact(PyObject *p)**
Return true if `p` is a tuple object, but not an instance of a subtype of the tuple type.

**PyObject* PyTuple_New(Py_ssize_t len)**
*Return value: New reference.*
Return a new tuple object of size `len`, or `NULL` on failure.

**PyObject* PyTuple_Pack(Py_ssize_t n, ...)**
*Return value: New reference.*
Return a new tuple object of size `n`, or `NULL` on failure. The tuple values are initialized to the subsequent `n` C arguments pointing to Python objects. `PyTuple_Pack(2, a, b)` is equivalent to `Py_BuildValue("(OO)", a, b)`.

**Py_ssize_t PyTuple_Size(PyObject *p)**
Take a pointer to a tuple object, and return the size of that tuple.
Py_ssize_t PyTuple_GET_SIZE(PyObject *p)

Return the size of the tuple p, which must be non-NULL and point to a tuple; no error checking is performed.

PyObject* PyTuple_GetItem(PyObject *p, Py_ssize_t pos)

Return value: Borrowed reference.

Return the object at position pos in the tuple pointed to by p. If pos is out of bounds, return NULL and sets an IndexError exception.

PyObject* PyTuple_GET_ITEM(PyObject *p, Py_ssize_t pos)

Return value: Borrowed reference.

Like PyTuple_GetItem(), but does no checking of its arguments.

PyObject* PyTuple_GetSlice(PyObject *p, Py_ssize_t low, Py_ssize_t high)

Take a slice of the tuple pointed to by p from low to high and return it as a new tuple.

int PyTuple_SetItem(PyObject *p, Py_ssize_t pos, PyObject *o)

Insert a reference to object o at position pos of the tuple pointed to by p. Return 0 on success.

Note: This function “steals” a reference to o.

void PyTuple_SET_ITEM(PyObject *p, Py_ssize_t pos, PyObject *o)

Like PyTuple_SetItem(), but does no error checking, and should only be used to fill in brand new tuples.

Note: This function “steals” a reference to o.
int _PyTuple_Resize(PyObject **p, Py_ssize_t newsize)

Can be used to resize a tuple. newsize will be the new length of the tuple. Because tuples are supposed to be immutable, this should only be used if there is only one reference to the object. Do not use this if the tuple may already be known to some other part of the code. The tuple will always grow or shrink at the end. Think of this as destroying the old tuple and creating a new one, only more efficiently. Returns 0 on success. Client code should never assume that the resulting value of *p will be the same as before calling this function. If the object referenced by *p is replaced, the original *p is destroyed. On failure, returns -1 and sets *p to NULL, and raises MemoryError or SystemError.

int PyTuple_ClearFreeList()

Clear the free list. Return the total number of freed items.
Struct Sequence Objects

Struct sequence objects are the C equivalent of `namedtuple()` objects, i.e. a sequence whose items can also be accessed through attributes. To create a struct sequence, you first have to create a specific struct sequence type.

```c
PyTypeObject* PyStructSequence_NewType(PyStructSequence_Desc *desc)

Create a new struct sequence type from the data in `desc`, described below. Instances of the resulting type can be created with `PyStructSequence_New()`.
```

```c
void PyStructSequence_InitType(PyTypeObject *type, PyStructSequence_Desc *desc)

Initializes a struct sequence type `type` from `desc` in place.
```

`PyStructSequence_Desc`

Contains the meta information of a struct sequence type to create.

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>char *</td>
<td>name of the struct sequence type</td>
</tr>
<tr>
<td>doc</td>
<td>char *</td>
<td>pointer to docstring for the type or NULL to omit</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>pointer to <code>NULL</code></td>
</tr>
</tbody>
</table>
PyStructSequence_Field

Describes a field of a struct sequence. As a struct sequence is modeled as a tuple, all fields are typed as PyObject*. The index in the fields array of the PyStructSequence_Desc determines which field of the struct sequence is described.

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>char *</td>
<td>name for the field or NULL to end the list of named fields, set to PyStructSequence_UnnamedField to leave unnamed</td>
</tr>
<tr>
<td>doc</td>
<td>char *</td>
<td>field docstring or NULL to omit</td>
</tr>
</tbody>
</table>

char* PyStructSequence_UnnamedField

Special value for a field name to leave it unnamed.

PyObject* PyStructSequence_New(PyTypeObject *type)

Creates an instance of type, which must have been created with PyStructSequence_NewType().

PyObject* PyStructSequence_GetItem(PyObject *p,
Py_ssize_t pos)
    Return the object at position pos in the struct sequence pointed to by p. No bounds checking is performed.

PyObject* PyStructSequence_GET_ITEM(PyObject *p, Py_ssize_t pos)
    Macro equivalent of PyStructSequence_GetItem().

void PyStructSequence_SET_ITEM(PyObject *p, Py_ssize_t pos, PyObject *o)
    Sets the field at index pos of the struct sequence p to value o. Like PyTuple_SET_ITEM(), this should only be used to fill in brand new instances.

    Note: This function “steals” a reference to o.

PyObject* PyStructSequence_SET_ITEM(PyObject *p, Py_ssize_t *pos, PyObject *o)
    Macro equivalent of PyStructSequence_SetItem().

    Note: This function “steals” a reference to o.
List Objects

**PyListObject**
This subtype of PyObjec
t represents a Python list object.

**PyTypeObject PyList_Type**
This instance of PyTypeObject represents the Python list type. This is the same object as list in the Python layer.

int **PyList_Check**(PyObject *p)
Return true if p is a list object or an instance of a subtype of the list type.

int **PyList_CheckExact**(PyObject *p)
Return true if p is a list object, but not an instance of a subtype of the list type.

**PyObject** PyList_New(Py_ssize_t len)

*Return value: New reference.*
Return a new list of length len on success, or NULL on failure.

**Note:** If len is greater than zero, the returned list object’s items are set to NULL. Thus you cannot use abstract API functions such as PySequence_SetItem() or expose the object to Python code before setting all items to a real object with PyList_SetItem().

Py_ssize_t **PyList_Size**(PyObject *list)
Return the length of the list object in list; this is equivalent to len(list) on a list object.
Py_ssize_t **PyList_GET_SIZE** *(PyObject *list)*  
Macro form of **PyList_Size()** without error checking.

**PyObject** **PyList_GetItem** *(PyObject *list, Py_ssize_t index)*  
*Return value: Borrowed reference.*  
Return the object at position *index* in the list pointed to by *list*. The position must be positive, indexing from the end of the list is not supported. If *index* is out of bounds, return *NULL* and set an **IndexError** exception.

**PyObject** **PyList_GET_ITEM** *(PyObject *list, Py_ssize_t i)*  
*Return value: Borrowed reference.*  
Macro form of **PyList_GetItem()** without error checking.

int **PyList_SetItem** *(PyObject *list, Py_ssize_t index, PyObject *item)*  
Set the item at index *index* in list to *item*. Return 0 on success or -1 on failure.

**Note:** This function “steals” a reference to *item* and discards a reference to an item already in the list at the affected position.

void **PyList_SET_ITEM** *(PyObject *list, Py_ssize_t i, PyObject *o)*  
Macro form of **PyList_SetItem()** without error checking. This is normally only used to fill in new lists where there is no previous content.

**Note:** This macro “steals” a reference to *item*, and, unlike **PyList_SetItem()**, does not discard a reference to any item that is being replaced; any reference in *list* at position *i* will be leaked.
int PyList_Insert(PyObject *list, Py_ssize_t index, PyObject *item)
   Insert the item item into list list in front of index index. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to list.insert(index, item).

int PyList_Append(PyObject *list, PyObject *item)
   Append the object item at the end of list list. Return 0 if successful; return -1 and set an exception if unsuccessful. Analogous to list.append(item).

PyObject* PyList_GetSlice(PyObject *list, Py_ssize_t low, Py_ssize_t high)
   Return a list of the objects in list containing the objects between low and high. Return NULL and set an exception if unsuccessful. Analogous to list[low:high]. Negative indices, as when slicing from Python, are not supported.

int PyList_SetSlice(PyObject *list, Py_ssize_t low, Py_ssize_t high, PyObject *itemlist)
   Set the slice of list between low and high to the contents of itemlist. Analogous to list[low:high] = itemlist. The itemlist may be NULL, indicating the assignment of an empty list (slice deletion). Return 0 on success, -1 on failure. Negative indices, as when slicing from Python, are not supported.

int PyList_Sort(PyObject *list)
   Sort the items of list in place. Return 0 on success, -1 on failure. This is equivalent to list.sort().

int PyList_Reverse(PyObject *list)
Reverse the items of *list* in place. Return 0 on success, -1 on failure. This is the equivalent of *list*.reverse().

**PyObject** PyList_AsTuple(PyObject *list)

*Return value: New reference.*

Return a new tuple object containing the contents of *list*; equivalent to *tuple(list)*.

**int PyList_ClearFreeList()**

Clear the free list. Return the total number of freed items.

*New in version 3.3.*
Dictionary Objects

**PyDictObject**

This subtype of `PyObject` represents a Python dictionary object.

**PyTypeObject PyDict_Type**

This instance of `PyTypeObject` represents the Python dictionary type. This is the same object as `dict` in the Python layer.

```c
int PyDict_Check(PyObject *p)
```

Return true if `p` is a dict object or an instance of a subtype of the dict type.

```c
int PyDict_CheckExact(PyObject *p)
```

Return true if `p` is a dict object, but not an instance of a subtype of the dict type.

```c
PyObject* PyDict_New()
```

*Return value: New reference.*

Return a new empty dictionary, or `NULL` on failure.

```c
PyObject* PyDictProxy_New(PyObject *mapping)
```

*Return value: New reference.*

Return a `types.MappingProxyType` object for a mapping which enforces read-only behavior. This is normally used to create a view to prevent modification of the dictionary for non-dynamic class types.

```c
void PyDict_Clear(PyObject *p)
```

Empty an existing dictionary of all key-value pairs.
int PyDict_Contains(PyObject *p, PyObject *key)

Determine if dictionary p contains key. If an item in p is matches key, return 1, otherwise return 0. On error, return -1. This is equivalent to the Python expression key in p.

PyObject* PyDict_Copy(PyObject *p)

Return a new dictionary that contains the same key-value pairs as p.

int PyDict_SetItem(PyObject *p, PyObject *key, PyObject *val)

Insert value into the dictionary p with a key of key. key must be hashable; if it isn't, TypeError will be raised. Return 0 on success or -1 on failure.

int PyDict_SetItemString(PyObject *p, const char *key, PyObject *val)

Insert value into the dictionary p using key as a key. key should be a char*. The key object is created using PyUnicode_FromString(key). Return 0 on success or -1 on failure.

int PyDict_DelItem(PyObject *p, PyObject *key)

Remove the entry in dictionary p with key key. key must be hashable; if it isn't, TypeError is raised. Return 0 on success or -1 on failure.

int PyDict_DelItemString(PyObject *p, char *key)

Remove the entry in dictionary p which has a key specified by the string key. Return 0 on success or -1 on failure.

PyObject* PyDict_GetItem(PyObject *p, PyObject *key)
Return value: Borrowed reference.
Return the object from dictionary \( p \) which has a key \( \texttt{key} \). Return NULL if the key \( \texttt{key} \) is not present, but without setting an exception.

**PyObject** \( \texttt{PyDict\_GetItemWithError}(...) \)

Variant of \( \texttt{PyDict\_GetItem()} \) that does not suppress exceptions. Return NULL with an exception set if an exception occurred. Return NULL without an exception set if the key wasn’t present.

**PyObject** \( \texttt{PyDict\_GetItemString}(...) \)

Return value: Borrowed reference.
This is the same as \( \texttt{PyDict\_GetItem()} \), but \( \texttt{key} \) is specified as a char*, rather than a PyObject*.

**PyObject** \( \texttt{PyDict\_Items}(...) \)

Return a PyListObject containing all the items from the dictionary.

**PyObject** \( \texttt{PyDict\_Keys}(...) \)

Return a PyListObject containing all the keys from the dictionary.

**PyObject** \( \texttt{PyDict\_Values}(...) \)

Return a PyListObject containing all the values from the dictionary \( p \).

**Py\_ssize\_t** \( \texttt{PyDict\_Size}(...) \)
Return the number of items in the dictionary. This is equivalent to 
\texttt{len(p)} on a dictionary.

\begin{verbatim}
int PyDict_Next(PyObject *p, Py_ssize_t *ppos, PyObject **pkey, 
PyObject **pvalue)
\end{verbatim}

Iterate over all key-value pairs in the dictionary \texttt{p}. The Py\_ssize\_t referred to by \texttt{ppos} must be initialized to 0 prior to the first call to this function to start the iteration; the function returns true for each pair in the dictionary, and false once all pairs have been reported. The parameters \texttt{pkey} and \texttt{pvalue} should either point to \texttt{PyObject*} variables that will be filled in with each key and value, respectively, or may be \texttt{NULL}. Any references returned through them are borrowed. \texttt{ppos} should not be altered during iteration. Its value represents offsets within the internal dictionary structure, and since the structure is sparse, the offsets are not consecutive.

For example:

\begin{verbatim}
PyObject *key, *value;
Py_ssize_t pos = 0;

while (PyDict_Next(self->dict, &pos, &key, &value
    /* do something interesting with the values.. 
    ... 
})
\end{verbatim}

The dictionary \texttt{p} should not be mutated during iteration. It is safe to modify the values of the keys as you iterate over the dictionary, but only so long as the set of keys does not change. For example:

\begin{verbatim}
PyObject *key, *value;
Py_ssize_t pos = 0;
\end{verbatim}
while (PyDict_Next(self->dict, &pos, &key, &value)) {
    long i = PyLong_AsLong(value);
    if (i == -1 && PyErr_Occurred()) {
        return -1;
    }
    PyObject *o = PyLong_FromLong(i + 1);
    if (o == NULL)
        return -1;
    if (PyDict_SetItem(self->dict, key, o) < 0) {
        Py_DECREF(o);
        return -1;
    }
}
Py_DECREF(o);

int PyDict_Merge(PyObject *a, PyObject *b, int override)
Iterate over mapping object b adding key-value pairs to dictionary a. b may be a dictionary, or any object supporting PyMapping_Keys() and PyObject_GetItem(). If override is true, existing pairs in a will be replaced if a matching key is found in b, otherwise pairs will only be added if there is not a matching key in a. Return 0 on success or -1 if an exception was raised.

int PyDict_Update(PyObject *a, PyObject *b)
This is the same as PyDict_Merge(a, b, 1) in C, or a.update(b) in Python. Return 0 on success or -1 if an exception was raised.

int PyDict_MergeFromSeq2(PyObject *a, PyObject *seq2, int override)
Update or merge into dictionary a, from the key-value pairs in seq2. seq2 must be an iterable object producing iterable objects of length
2, viewed as key-value pairs. In case of duplicate keys, the last wins if `override` is true, else the first wins. Return 0 on success or -1 if an exception was raised. Equivalent Python (except for the return value):

```python
def PyDict_MergeFromSeq2(a, seq2, override):
    for key, value in seq2:
        if override or key not in a:
            a[key] = value
```

```
int PyDict_ClearFreeList()
Clear the free list. Return the total number of freed items.

New in version 3.3.
```
Set Objects

This section details the public API for set and frozenset objects. Any functionality not listed below is best accessed using the either the abstract object protocol (including PyObject_CallMethod(), PyObject_RichCompareBool(), PyObject_Hash(), PyObject_Repr(), PyObject_IsTrue(), PyObject_Print(), and PyObject_GetIter()) or the abstract number protocol (including PyNumber_And(), PyNumber_Subtract(), PyNumber_Or(), PyNumber_Xor(), PyNumber_InPlaceAnd(), PyNumber_InPlaceSubtract(), PyNumber_InPlaceOr(), and PyNumber_InPlaceXor()).

PySetObject

This subtype of PyObject is used to hold the internal data for both set and frozenset objects. It is like a PyDictObject in that it is a fixed size for small sets (much like tuple storage) and will point to a separate, variable sized block of memory for medium and large sized sets (much like list storage). None of the fields of this structure should be considered public and are subject to change. All access should be done through the documented API rather than by manipulating the values in the structure.

PyTypeObject PySet_Type

This is an instance of PyTypeObject representing the Python set type.

PyTypeObject PyFrozenSet_Type

This is an instance of PyTypeObject representing the Python frozenset type.
The following type check macros work on pointers to any Python object. Likewise, the constructor functions work with any iterable Python object.

```c
int PySet_Check(PyObject *p)
    Return true if p is a set object or an instance of a subtype.

int PyFrozenSet_Check(PyObject *p)
    Return true if p is a frozenset object or an instance of a subtype.

int PyAnySet_Check(PyObject *p)
    Return true if p is a set object, a frozenset object, or an instance of a subtype.

int PyAnySet_CheckExact(PyObject *p)
    Return true if p is a set object or a frozenset object but not an instance of a subtype.

int PyFrozenSet_CheckExact(PyObject *p)
    Return true if p is a frozenset object but not an instance of a subtype.
```

```c
PyObject* PySet_New(PyObject *iterable)
    Return a new set containing objects returned by the iterable. The iterable may be NULL to create a new empty set. Return the new set on success or NULL on failure. Raise TypeError if iterable is not actually iterable. The constructor is also useful for copying a set (c=set(s)).

PyObject* PyFrozenSet_New(PyObject *iterable)
```
Return a new `frozenset` containing objects returned by the `iterable`. The `iterable` may be `NULL` to create a new empty `frozenset`. Return the new set on success or `NULL` on failure. Raise `TypeError` if `iterable` is not actually iterable.

The following functions and macros are available for instances of `set` or `frozenset` or instances of their subtypes.

**Py_ssize_t PySet_Size(PyObject *anyset)**

Return the length of a `set` or `frozenset` object. Equivalent to `len(anyset)`. Raises a `PyExc_SystemError` if `anyset` is not a `set`, `frozenset`, or an instance of a subtype.

**Py_ssize_t PySet_GET_SIZE(PyObject *anyset)**

Macro form of `PySet_Size()` without error checking.

**int PySet_Contains(PyObject *anyset, PyObject *key)**

Return 1 if found, 0 if not found, and -1 if an error is encountered. Unlike the Python `__contains__()` method, this function does not automatically convert unhashable sets into temporary `frozensets`. Raise a `TypeError` if the `key` is unhashable. Raise `PyExc_SystemError` if `anyset` is not a `set`, `frozenset`, or an instance of a subtype.

**int PySet_Add(PyObject *set, PyObject *key)**

Add `key` to a `set` instance. Also works with `frozenset` instances (like `PyTuple_SetItem()` it can be used to fill-in the values of brand new `frozensets` before they are exposed to other code). Return 0 on success or -1 on failure. Raise a `TypeError` if the `key` is unhashable. Raise a `MemoryError` if there is no room to grow. Raise a `SystemError` if `set` is an not an instance of `set` or
its subtype.

The following functions are available for instances of `set` or its subtypes but not for instances of `frozenset` or its subtypes.

```c
int PySet_Discard(PyObject *set, PyObject *key)
```

Return 1 if found and removed, 0 if not found (no action taken), and -1 if an error is encountered. Does not raise `KeyError` for missing keys. Raise a `TypeError` if the `key` is unhashable. Unlike the Python `discard()` method, this function does not automatically convert unhashable sets into temporary frozensets. Raise `PyExc_SystemError` if `set` is not an instance of `set` or its subtype.

```c
PyObject* PySet_Pop(PyObject *set)
```

*Return value: New reference.*

Return a new reference to an arbitrary object in the `set`, and removes the object from the `set`. Return `NULL` on failure. Raise `KeyError` if the set is empty. Raise a `SystemError` if `set` is not an instance of `set` or its subtype.

```c
int PySet_Clear(PyObject *set)
```

Empty an existing set of all elements.

```c
int PySet_ClearFreeList()
```

Clear the free list. Return the total number of freed items.

*New in version 3.3.*

Created using Sphinx 1.0.7.
Function Objects

There are a few functions specific to Python functions.

**PyFunctionObject**

The C structure used for functions.

**PyTypeObject PyFunction_Type**

This is an instance of `PyTypeObject` and represents the Python function type. It is exposed to Python programmers as `types.FunctionType`.

```c
int PyFunction_Check(PyObject *o)
```

Return true if `o` is a function object (has type `PyFunction_Type`). The parameter must not be `NULL`.

```c
PyObject* PyFunction_New(PyObject *code, PyObject *globals)
```

*Return value: New reference.*

Return a new function object associated with the code object `code`. `globals` must be a dictionary with the global variables accessible to the function.

The function's docstring, name and `__module__` are retrieved from the code object, the argument defaults and closure are set to `NULL`.

```c
PyObject* PyFunction_NewWithQualName(PyObject *code, PyObject *globals, PyObject *qualname)
```

*Return value: New reference.*

As `PyFunction_New()`, but also allows to set the function object's `__qualname__` attribute. `qualname` should be a unicode
object or NULL; if NULL, the __qualname__ attribute is set to the same value as its __name__ attribute.

*New in version 3.3.*

**PyObject* `PyFunction_GetCode`** (**PyObject** *op*)

*Return value: Borrowed reference.*

Return the code object associated with the function object *op*.

**PyObject* `PyFunction_GetGlobals`** (**PyObject** *op*)

*Return value: Borrowed reference.*

Return the globals dictionary associated with the function object *op*.

**PyObject* `PyFunction_GetModule`** (**PyObject** *op*)

*Return value: Borrowed reference.*

Return the __module__ attribute of the function object *op*. This is normally a string containing the module name, but can be set to any other object by Python code.

**PyObject* `PyFunction_GetDefaults`** (**PyObject** *op*)

*Return value: Borrowed reference.*

Return the argument default values of the function object *op*. This can be a tuple of arguments or NULL.

**int `PyFunction_SetDefaults`** (**PyObject** *op*, **PyObject** *defaults*)

Set the argument default values for the function object *op*. *defaults* must be *Py_None* or a tuple.

Raises SystemError and returns −1 on failure.

**PyObject* `PyFunction_GetClosure`** (**PyObject** *op*)
Return value: Borrowed reference.
Return the closure associated with the function object `op`. This can be `NULL` or a tuple of cell objects.

```c
int PyFunction_SetClosure(PyObject *op, PyObject *closure)
```

Set the closure associated with the function object `op`. `closure` must be `Py_None` or a tuple of cell objects.

Raises `SystemError` and returns `-1` on failure.

```c
PyObject *PyFunction_GetAnnotations(PyObject *op)
```

Return the annotations of the function object `op`. This can be a mutable dictionary or `NULL`.

```c
int PyFunction_SetAnnotations(PyObject *op, PyObject *annotations)
```

Set the annotations for the function object `op`. `annotations` must be a dictionary or `Py_None`.

Raises `SystemError` and returns `-1` on failure.
Instance Method Objects

An instance method is a wrapper for a `PyCFunction` and the new way to bind a `PyCFunction` to a class object. It replaces the former call `PyMethod_New(func, NULL, class).

**PyTypeObject PyInstanceMethod_Type**
This instance of `PyTypeObject` represents the Python instance method type. It is not exposed to Python programs.

**int PyInstanceMethod_Check(PyObject *o)**
Return true if `o` is an instance method object (has type `PyInstanceMethod_Type`). The parameter must not be `NULL`.

**PyObject* PyInstanceMethod_New(PyObject *func)**
Return a new instance method object, with `func` being any callable object. `func` is the function that will be called when the instance method is called.

**PyObject* PyInstanceMethod_Function(PyObject *im)**
Return the function object associated with the instance method `im`.

**PyObject**

**PyInstanceMethod_GET_FUNCTION(PyObject *im)**
Macro version of `PyInstanceMethod_Function()` which avoids error checking.
Method Objects

Methods are bound function objects. Methods are always bound to an instance of an user-defined class. Unbound methods (methods bound to a class object) are no longer available.

**PyTypeObject PyMethod_Type**
This instance of `PyTypeObject` represents the Python method type. This is exposed to Python programs as `types.MethodType`.

```c
int PyMethod_Check(PyObject *o)
```
Return true if `o` is a method object (has type `PyMethod_Type`). The parameter must not be `NULL`.

```c
PyObject* PyMethod_New(PyObject *func, PyObject *self)
```
*Return value: New reference.*
Return a new method object, with `func` being any callable object and `self` the instance the method should be bound. `func` is the function that will be called when the method is called. `self` must not be `NULL`.

```c
PyObject* PyMethod_Function(PyObject *meth)
```
*Return value: Borrowed reference.*
Return the function object associated with the method `meth`.

```c
PyObject* PyMethod_GET_FUNCTION(PyObject *meth)
```
*Return value: Borrowed reference.*
Macro version of `PyMethod_Function()` which avoids error checking.
PyObject* **PyMethod**\_**Self**(PyObject *meth)

*Return value: Borrowed reference.*
Return the instance associated with the method *meth*.

PyObject* **PyMethod**\_**GET**\_**SELF**(PyObject *meth)

*Return value: Borrowed reference.*
Macro version of **PyMethod**\_**Self**( ) which avoids error checking.

int **PyMethod**\_**ClearFreeList**( )

Clear the free list. Return the total number of freed items.
File Objects

These APIs are a minimal emulation of the Python 2 C API for built-in file objects, which used to rely on the buffered I/O (FILE*) support from the C standard library. In Python 3, files and streams use the new `io` module, which defines several layers over the low-level unbuffered I/O of the operating system. The functions described below are convenience C wrappers over these new APIs, and meant mostly for internal error reporting in the interpreter; third-party code is advised to access the `io` APIs instead.

**PyFile_FromFd** (int *fd*, char **name**, char **mode**, int *buffering*, char **encoding**, char **errors**, char **newline**, int *closefd*)

Create a Python file object from the file descriptor of an already opened file *fd*. The arguments *name*, *encoding*, *errors* and *newline* can be NULL to use the defaults; *buffering* can be -1 to use the default. *name* is ignored and kept for backward compatibility. Return NULL on failure. For a more comprehensive description of the arguments, please refer to the `io.open()` function documentation.

**Warning:** Since Python streams have their own buffering layer, mixing them with OS-level file descriptors can produce various issues (such as unexpected ordering of data).

*Changed in version 3.2:* Ignore *name* attribute.

int **PyObject_AsFileDescriptor** (PyObject *p)

Return the file descriptor associated with *p* as an int. If the object is an integer, its value is returned. If not, the object's *fileno()* method is called if it exists; the method must return an integer,
which is returned as the file descriptor value. Sets an exception and returns -1 on failure.

**PyObject* PyFile_GetLine(PyObject *p, int n)**

*Return value: New reference.*

Equivalent to `p.readline([n])`, this function reads one line from the object `p`. `p` may be a file object or any object with a `readline()` method. If `n` is 0, exactly one line is read, regardless of the length of the line. If `n` is greater than 0, no more than `n` bytes will be read from the file; a partial line can be returned. In both cases, an empty string is returned if the end of the file is reached immediately. If `n` is less than 0, however, one line is read regardless of length, but **EOFError** is raised if the end of the file is reached immediately.

**int PyFile_WriteObject(PyObject *obj, PyObject *p, int flags)**

Write object `obj` to file object `p`. The only supported flag for `flags` is `Py_PRINT_RAW`; if given, the `str()` of the object is written instead of the `repr()`. Return 0 on success or -1 on failure; the appropriate exception will be set.

**int PyFile_WriteString(const char *s, PyObject *p)**

Write string `s` to file object `p`. Return 0 on success or -1 on failure; the appropriate exception will be set.
Module Objects

There are only a few functions special to module objects.

**PyTypeObject PyModule_Type**

This instance of *PyTypeObject* represents the Python module type. This is exposed to Python programs as *types.ModuleType*.

```c
int PyModule_Check(PyObject *p)
```

Return true if *p* is a module object, or a subtype of a module object.

```c
int PyModule_CheckExact(PyObject *p)
```

Return true if *p* is a module object, but not a subtype of *PyModule_Type*.

**PyObject* PyModule_NewObject(PyObject *name)**

Return a new module object with the *__name__* attribute set to *name*. Only the module’s *__doc__* and *__name__* attributes are filled in; the caller is responsible for providing a *__file__* attribute.

*New in version 3.3.*

**PyObject* PyModule_New(const char *name)**

*Return value: New reference.*

Similar to *PyImport_NewObject()*), but the name is an UTF-8 encoded string instead of a Unicode object.

**PyObject* PyModule_GetDict(PyObject *module)**

*Return value: Borrowed reference.*
Return the dictionary object that implements module's namespace; this object is the same as the __dict__ attribute of the module object. This function never fails. It is recommended extensions use other PyModule_*( ) and PyObject_*( ) functions rather than directly manipulate a module's __dict__.

PyObject* **PyModule_GetNameObject**(PyObject *module)

Return module's __name__ value. If the module does not provide one, or if it is not a string, SystemError is raised and NULL is returned.

*New in version 3.3.*

char* **PyModule_GetName**(PyObject *module)

Similar to PyModule_GetNameObject() but return the name encoded to 'utf-8'.

PyObject* **PyModule_GetFilenameObject**(PyObject *module)

Return the name of the file from which module was loaded using module's __file__ attribute. If this is not defined, or if it is not a unicode string, raise SystemError and return NULL; otherwise return a reference to a Unicode object.

*New in version 3.2.*

char* **PyModule_GetFilename**(PyObject *module)

Similar to PyModule_GetFilenameObject() but return the filename encoded to ‘utf-8’.

*Deprecated since version 3.2: PyModule_GetFilename() raises UnicodeEncodeError on unencodable filenames, use*
void* **PyModule_GetState**(PyObject *module)

Return the “state” of the module, that is, a pointer to the block of memory allocated at module creation time, or *NULL*. See `PyModuleDef.m_size`.

**PyModuleDef** Py**Module_GetDef**(PyObject *module)

Return a pointer to the `PyModuleDef` struct from which the module was created, or *NULL* if the module wasn’t created with `PyModule_Create()`.

**PyObject** Py**State_FindModule**(PyModuleDef *def)

Returns the module object that was created from *def* for the current interpreter. This method requires that the module object has been attached to the interpreter state with `PyState_AddModule()` beforehand. In case the corresponding module object is not found or has not been attached to the interpreter state yet, it returns *NULL*.

**int** Py**State_AddModule**(PyObject *module, PyModuleDef *def)

Attaches the module object passed to the function to the interpreter state. This allows the module object to be accessible via `PyState_FindModule()`.

*New in version 3.3.*

**int** Py**State_RemoveModule**(PyModuleDef *def)

Removes the module object created from *def* from the interpreter state.

*New in version 3.3.*
Initializing C modules

These functions are usually used in the module initialization function.

**PyObject**\* **PyModule_Create**(PyModuleDef \*module)

Create a new module object, given the definition in module. This behaves like **PyModule_Create2()** with module_api_version set to PYTHON_API_VERSION.

**PyObject**\* **PyModule_Create2**(PyModuleDef \*module, int module_api_version)

Create a new module object, given the definition in module, assuming the API version module_api_version. If that version does not match the version of the running interpreter, a RuntimeWarning is emitted.

**Note:** Most uses of this function should be using PyModule_Create() instead; only use this if you are sure you need it.

**PyModuleDef**

This struct holds all information that is needed to create a module object. There is usually only one static variable of that type for each module, which is statically initialized and then passed to **PyModule_Create()** in the module initialization function.

PyModuleDef\_Base **m\_base**

Always initialize this member to PyModuleDef\_HEAD\_INIT.

char* **m\_name**

Name for the new module.
char* m_doc

Docstring for the module; usually a docstring variable created with PyDoc_STRVAR() is used.

Py_ssize_t m_size

Some modules allow re-initialization (calling their PyInit_* function more than once). These modules should keep their state in a per-module memory area that can be retrieved with PyModule_GetState().

This memory should be used, rather than static globals, to hold per-module state, since it is then safe for use in multiple sub-interpreters. It is freed when the module object is deallocated, after the m_free function has been called, if present.

Setting m_size to -1 means that the module can not be re-initialized because it has global state. Setting it to a non-negative value means that the module can be re-initialized and specifies the additional amount of memory it requires for its state.

See PEP 3121 for more details.

PyMethodDef* m_methods

A pointer to a table of module-level functions, described by PyMethodDef values. Can be NULL if no functions are present.

inquiry m_reload

Currently unused, should be NULL.

traverseproc m_traverse

A traversal function to call during GC traversal of the module
object, or \texttt{NULL} if not needed.

\textbf{inquiry m\_clear}

A clear function to call during GC clearing of the module object, or \texttt{NULL} if not needed.

\textbf{freefunc m\_free}

A function to call during deallocation of the module object, or \texttt{NULL} if not needed.

\begin{verbatim}
int PyModule_AddObject(PyObject *module, const char *name, PyObject *value)
    Add an object to \texttt{module} as \texttt{name}. This is a convenience function which can be used from the module's initialization function. This steals a reference to \texttt{value}. Return -1 on error, 0 on success.

int PyModule_AddIntConstant(PyObject *module, const char *name, long value)
    Add an integer constant to \texttt{module} as \texttt{name}. This convenience function can be used from the module's initialization function. Return -1 on error, 0 on success.

int PyModule_AddStringConstant(PyObject *module, const char *name, const char *value)
    Add a string constant to \texttt{module} as \texttt{name}. This convenience function can be used from the module's initialization function. The string \texttt{value} must be null-terminated. Return -1 on error, 0 on success.

int PyModule_AddIntMacro(PyObject *module, macro)
    Add an int constant to \texttt{module}. The name and the value are taken from \texttt{macro}. For example PyModule_AddIntMacro(module,
AF_INET) adds the int constant AF_INET with the value of AF_INET to module. Return -1 on error, 0 on success.

int PyModule_AddStringMacro(PyObject *module, macro)
Add a string constant to module.
Iterator Objects

Python provides two general-purpose iterator objects. The first, a sequence iterator, works with an arbitrary sequence supporting the \_\_getitem\_\_() method. The second works with a callable object and a sentinel value, calling the callable for each item in the sequence, and ending the iteration when the sentinel value is returned.

**PyTypeObject PySeqIter\_Type**

Type object for iterator objects returned by PySeqIter\_New() and the one-argument form of the iter() built-in function for built-in sequence types.

```
int PySeqIter\_Check(op)
    Return true if the type of \textit{op} is \texttt{PySeqIter\_Type}.
```

**PyObject\* PySeqIter\_New(PyObject \*seq)**

*Return value: New reference.*

Return an iterator that works with a general sequence object, \textit{seq}. The iteration ends when the sequence raises IndexError for the subscripting operation.

**PyTypeObject PyCallIter\_Type**

Type object for iterator objects returned by PyCallIter\_New() and the two-argument form of the iter() built-in function.

```
int PyCallIter\_Check(op)
    Return true if the type of \textit{op} is \texttt{PyCallIter\_Type}.
```

**PyObject\* PyCallIter\_New(PyObject \*callable, PyObject \*sentinel)**
Return a new iterator. The first parameter, `callable`, can be any Python callable object that can be called with no parameters; each call to it should return the next item in the iteration. When `callable` returns a value equal to `sentinel`, the iteration will be terminated.
Descriptor Objects

“Descriptors” are objects that describe some attribute of an object. They are found in the dictionary of type objects.

**PyTypeObject PyProperty_Type**
The type object for the built-in descriptor types.

**PyObject* PyDescr_NewGetSet**(PyTypeObject *type, struct PyGetSetDef *getset)
   *Return value: New reference.*

**PyObject* PyDescr_NewMember**(PyTypeObject *type, struct PyMemberDef *meth)
   *Return value: New reference.*

**PyObject* PyDescr_NewMethod**(PyTypeObject *type, struct PyMethodDef *meth)
   *Return value: New reference.*

**PyObject* PyDescr_NewWrapper**(PyTypeObject *type, struct wrapperbase *wrapper, void *wrapped)
   *Return value: New reference.*

**PyObject* PyDescr_NewClassMethod**(PyTypeObject *type, PyMethodDef *method)
   *Return value: New reference.*

int **PyDescr_IsData**(PyObject *descr)
   Return true if the descriptor objects descr describes a data attribute, or false if it describes a method. descr must be a descriptor object; there is no error checking.
PyObject* PyWrapper_New(PyObject *, PyObject *)

Slice Objects

PyTypeObject PySlice_Type
   The type object for slice objects. This is the same as slice in the Python layer.

int PySlice_Check(PyObject *ob)
   Return true if ob is a slice object; ob must not be NULL.

PyObject* PySlice_New(PyObject *start, PyObject *stop, PyObject *step)
   Return a new slice object with the given values. The start, stop, and step parameters are used as the values of the slice object attributes of the same names. Any of the values may be NULL, in which case the None will be used for the corresponding attribute. Return NULL if the new object could not be allocated.

int PySlice_GetIndices(PyObject *slice, Py_ssize_t length, Py_ssize_t *start, Py_ssize_t *stop, Py_ssize_t *step)
   Retrieve the start, stop and step indices from the slice object slice, assuming a sequence of length length. Treats indices greater than length as errors.

   Returns 0 on success and -1 on error with no exception set (unless one of the indices was not None and failed to be converted to an integer, in which case -1 is returned with an exception set).

   You probably do not want to use this function.

   Changed in version 3.2: The parameter type for the slice parameter
int **PySlice_GetIndicesEx**(**PyObject** *slice, **Py_ssize_t** length,
**Py_ssize_t** *start, **Py_ssize_t** *stop, **Py_ssize_t** *step,
**Py_ssize_t** *slicelength)

Usable replacement for **PySlice_GetIndices()**. Retrieve the
start, stop, and step indices from the slice object *slice* assuming a
sequence of length *length*, and store the length of the slice in
*slicelength*. Out of bounds indices are clipped in a manner
consistent with the handling of normal slices.

Returns 0 on success and -1 on error with exception set.

*Changed in version 3.2:* The parameter type for the *slice* parameter
was **PySliceObject** before.
MemoryView objects

A memoryview object exposes the C level buffer interface as a Python object which can then be passed around like any other object.

PyObject *PyMemoryView_FromObject(PyObject *obj)

Create a memoryview object from an object that provides the buffer interface. If obj supports writable buffer exports, the memoryview object will be read/write, otherwise it may be either read-only or read/write at the discretion of the exporter.

PyObject *PyMemoryView_FromMemory(char *mem, Py_ssize_t size, int flags)

Create a memoryview object using mem as the underlying buffer. flags can be one of PyBUF_READ or PyBUF_WRITE.

New in version 3.3.

PyObject *PyMemoryView_FromBuffer(Py_buffer *view)

Create a memoryview object wrapping the given buffer structure view. For simple byte buffers, PyMemoryView_FromMemory() is the preferred function.

PyObject *PyMemoryView_GetContiguous(PyObject *obj, int buffertype, char order)

Create a memoryview object to a contiguous chunk of memory (in either ‘C’ or ‘F’ortran order) from an object that defines the buffer interface. If memory is contiguous, the memoryview object points to the original memory. Otherwise, a copy is made and the memoryview points to a new bytes object.
int PyMemoryView_Check(PyObject *obj)

Return true if the object obj is a memoryview object. It is not currently allowed to create subclasses of memoryview.

Py_buffer *PyMemoryView_GET_BUFFER(PyObject *mview)

Return a pointer to the memoryview's private copy of the exporter's buffer. mview must be a memoryview instance; this macro doesn't check its type, you must do it yourself or you will risk crashes.

Py_buffer *PyMemoryView_GET_BASE(PyObject *mview)

Return either a pointer to the exporting object that the memoryview is based on or NULL if the memoryview has been created by one of the functions PyMemoryView_FromMemory() or PyMemoryView_FromBuffer(). mview must be a memoryview instance.
Weak Reference Objects

Python supports *weak references* as first-class objects. There are two specific object types which directly implement weak references. The first is a simple reference object, and the second acts as a proxy for the original object as much as it can.

```c
int PyWeakref_Check(ob)
    return true if ob is either a reference or proxy object.
```

```c
int PyWeakref_CheckRef(ob)
    return true if ob is a reference object.
```

```c
int PyWeakref_CheckProxy(ob)
    return true if ob is a proxy object.
```

```c
PyObject* PyWeakref_NewRef(PyObject *ob,
PyObject *callback)
    Return a weak reference object for the object ob. This will always return a new reference, but is not guaranteed to create a new object; an existing reference object may be returned. The second parameter, callback, can be a callable object that receives notification when ob is garbage collected; it should accept a single parameter, which will be the weak reference object itself. callback may also be None or NULL. If ob is not a weakly-referencable object, or if callback is not callable, None, or NULL, this will return NULL and raise TypeError.
```

```c
PyObject* PyWeakref_NewProxy(PyObject *ob,
PyObject *callback)
```
Return a weak reference proxy object for the object `ob`. This will always return a new reference, but is not guaranteed to create a new object; an existing proxy object may be returned. The second parameter, `callback`, can be a callable object that receives notification when `ob` is garbage collected; it should accept a single parameter, which will be the weak reference object itself. `callback` may also be None or `NULL`. If `ob` is not a weakly-referencable object, or if `callback` is not callable, None, or `NULL`, this will return `NULL` and raise `TypeError`.

```c
PyObject* PyWeakref_GetObject(PyObject *ref)
```

Return value: Borrowed reference.
Return the referenced object from a weak reference, `ref`. If the referent is no longer live, returns `Py_None`.

Note: This function returns a borrowed reference to the referenced object. This means that you should always call `Py_INCREF()` on the object except if you know that it cannot be destroyed while you are still using it.

```c
PyObject* PyWeakref_GET_OBJECT(PyObject *ref)
```

Return value: Borrowed reference.
Similar to `PyWeakref_GetObject()`, but implemented as a macro that does no error checking.
Capsules

Refer to *Providing a C API for an Extension Module* for more information on using these objects.

**PyCapsule**

This subtype of PyObject represents an opaque value, useful for C extension modules who need to pass an opaque value (as a void* pointer) through Python code to other C code. It is often used to make a C function pointer defined in one module available to other modules, so the regular import mechanism can be used to access C APIs defined in dynamically loaded modules.

**PyCapsuleDestructor**

The type of a destructor callback for a capsule. Defined as:

```c
typedef void (*PyCapsule_Destructor)(PyObject *);
```

See `PyCapsule_New()` for the semantics of PyCapsuleDestructor callbacks.

```c
int PyCapsule_CheckExact(PyObject *p)
```

Return true if its argument is a PyCapsule.

```c
PyObject* PyCapsule_New(void *pointer, const char *name, PyCapsule_Destructor destructor)
```

*Return value: New reference.*

Create a PyCapsule encapsulating the pointer. The pointer argument may not be NULL.

On failure, set an exception and return NULL.
The *name* string may either be *NULL* or a pointer to a valid C string. If non-*NULL*, this string must outlive the capsule. (Though it is permitted to free it inside the *destructor*.)

If the *destructor* argument is not *NULL*, it will be called with the capsule as its argument when it is destroyed.

If this capsule will be stored as an attribute of a module, the *name* should be specified as `modulename.attributename`. This will enable other modules to import the capsule using `PyCapsule_Import()`.

```c
void* PyCapsule_GetPointer(PyObject *capsule, const char *name)
```

Retrieve the *pointer* stored in the capsule. On failure, set an exception and return *NULL*.

The *name* parameter must compare exactly to the name stored in the capsule. If the name stored in the capsule is *NULL*, the *name* passed in must also be *NULL*. Python uses the C function `strcmp()` to compare capsule names.

```c
PyCapsule_Destructor
PyCapsule_GetDestructor(PyObject *capsule)
```

Return the current destructor stored in the capsule. On failure, set an exception and return *NULL*.

It is legal for a capsule to have a *NULL* destructor. This makes a *NULL* return code somewhat ambiguous; use `PyCapsule_IsValid()` or `PyErr_Occurred()` to disambiguate.

```c
void* PyCapsule_GetContext(PyObject *capsule)
```
Return the current context stored in the capsule. On failure, set an exception and return *NULL*.

It is legal for a capsule to have a *NULL* context. This makes a *NULL* return code somewhat ambiguous; use *PyCapsule_IsValid()* or *PyErr_Occurred()* to disambiguate.

```c
const char* PyCapsule_GetName(PyObject *capsule)
```

Return the current name stored in the capsule. On failure, set an exception and return *NULL*.

It is legal for a capsule to have a *NULL* name. This makes a *NULL* return code somewhat ambiguous; use *PyCapsule_IsValid()* or *PyErr_Occurred()* to disambiguate.

```c
void* PyCapsule_Import(const char *name, int no_block)
```

Import a pointer to a C object from a capsule attribute in a module. The *name* parameter should specify the full name to the attribute, as in module.attribute. The *name* stored in the capsule must match this string exactly. If *no_block* is true, import the module without blocking (using *PyImport_ImportModuleNoBlock()*). If *no_block* is false, import the module conventionally (using *PyImport_ImportModule()*).

Return the capsule’s internal *pointer* on success. On failure, set an exception and return *NULL*. However, if *PyCapsule_Import()* failed to import the module, and *no_block* was true, no exception is set.

```c
int PyCapsule_IsValid(PyObject *capsule, const char *name)
```

Determines whether or not *capsule* is a valid capsule. A valid
capsule is non-

\texttt{NULL}, passes \texttt{PyCapsule\_CheckExact()} , has a non-

\texttt{NULL} pointer stored in it, and its internal name matches the

\textit{name} parameter. (See \texttt{PyCapsule\_GetPointer()} for

information on how capsule names are compared.)

In other words, if \texttt{PyCapsule\_IsValid()} returns a true value,
calls to any of the accessors (any function starting with

\texttt{PyCapsule\_Get()}) are guaranteed to succeed.

Return a nonzero value if the object is valid and matches the name

passed in. Return 0 otherwise. This function will not fail.

\begin{verbatim}
int \texttt{PyCapsule\_SetContext}(\texttt{PyObject *capsule}, void *context)
  \texttt{Set the context pointer inside capsule to context.}

  Return 0 on success. Return nonzero and set an exception on
  failure.

int \texttt{PyCapsule\_SetDestructor}(\texttt{PyObject *capsule},
  \texttt{PyCapsule\_Destructor destructor})
  \texttt{Set the destructor inside capsule to destructor.}

  Return 0 on success. Return nonzero and set an exception on
  failure.

int \texttt{PyCapsule\_SetName}(\texttt{PyObject *capsule}, const char *name)
  \texttt{Set the name inside capsule to name. If non-
  NULL, the name must outlive the capsule. If the previous name stored in
  the capsule was not NULL, no attempt is made to free it.}

  Return 0 on success. Return nonzero and set an exception on
  failure.

int \texttt{PyCapsule\_SetPointer}(\texttt{PyObject *capsule, void *pointer})
\end{verbatim}
Set the void pointer inside `capsule` to `pointer`. The pointer may not be `NULL`.

Return 0 on success. Return nonzero and set an exception on failure.
Cell Objects

“Cell” objects are used to implement variables referenced by multiple scopes. For each such variable, a cell object is created to store the value; the local variables of each stack frame that references the value contains a reference to the cells from outer scopes which also use that variable. When the value is accessed, the value contained in the cell is used instead of the cell object itself. This de-referencing of the cell object requires support from the generated byte-code; these are not automatically de-referenced when accessed. Cell objects are not likely to be useful elsewhere.

**PyCellObject**

The C structure used for cell objects.

**PyTypeObject PyCell_Type**

The type object corresponding to cell objects.

```c
int PyCell_Check(PyObject *ob)
    Return true if ob is a cell object; ob must not be NULL.
```

```c
PyObject* PyCell_New(PyObject *ob)
    Create and return a new cell object containing the value ob. The parameter may be NULL.
```

```c
PyObject* PyCell_Get(PyObject *cell)
    Return the contents of the cell cell.
```

```c
PyObject* PyCell_GET(PyObject *cell)
    Return value: Borrowed reference.
```
Return the contents of the cell `cell`, but without checking that `cell` is non-`NULL` and a cell object.

```c
int PyCell_Set(PyObject *cell, PyObject *value)
```

Set the contents of the cell object `cell` to `value`. This releases the reference to any current content of the cell. `value` may be `NULL`. `cell` must be non-`NULL`; if it is not a cell object, `-1` will be returned. On success, `0` will be returned.

```c
void PyCell_SET(PyObject *cell, PyObject *value)
```

Sets the value of the cell object `cell` to `value`. No reference counts are adjusted, and no checks are made for safety; `cell` must be non-`NULL` and must be a cell object.
Generator Objects

Generator objects are what Python uses to implement generator iterators. They are normally created by iterating over a function that yields values, rather than explicitly calling `PyGen_New()`.

**PyGenObject**

The C structure used for generator objects.

**PyTypeObject** *PyGen_Type*

The type object corresponding to generator objects

```c
int PyGen_Check(ob)

Return true if ob is a generator object; ob must not be NULL.
```

```c
int PyGen_CheckExact(ob)

Return true if ob's type is PyGen_Type is a generator object; ob must not be NULL.
```

**PyObject* PyGen_New(PyFrameObject *frame)**

*Return value: New reference.*

Create and return a new generator object based on the `frame` object. A reference to `frame` is stolen by this function. The parameter must not be `NULL`.

Last updated on Nov 11, 2013. Found a bug?

Created using Sphinx 1.0.7.
DateTime Objects

Various date and time objects are supplied by the `datetime` module. Before using any of these functions, the header file `datetime.h` must be included in your source (note that this is not included by `Python.h`), and the macro `PyDateTime_IMPORT` must be invoked, usually as part of the module initialisation function. The macro puts a pointer to a C structure into a static variable, `PyDateTimeAPI`, that is used by the following macros.

Type-check macros:

```c
int PyDate_Check(PyObject *ob)
    Return true if `ob` is of type PyDateTime_DateType or a subtype of PyDateTime_DateType. `ob` must not be `NULL`.
```

```c
int PyDate_CheckExact(PyObject *ob)
    Return true if `ob` is of type PyDateTime_DateType. `ob` must not be `NULL`.
```

```c
int PyDateTime_Check(PyObject *ob)
    Return true if `ob` is of type PyDateTime_DateTimeType or a subtype of PyDateTime_DateTimeType. `ob` must not be `NULL`.
```

```c
int PyDateTime_CheckExact(PyObject *ob)
    Return true if `ob` is of type PyDateTime_DateTimeType. `ob` must not be `NULL`.
```

```c
int PyTime_Check(PyObject *ob)
    Return true if `ob` is of type PyDateTime_TimeType or a subtype of PyDateTime_TimeType. `ob` must not be `NULL`.
```
int PyTime_CheckExact(PyObject *ob)
    Return true if ob is of type PyDateTime_TimeType. ob must not be NULL.

int PyDelta_Check(PyObject *ob)
    Return true if ob is of type PyDateTime_DeltaType or a subtype of PyDateTime_DeltaType. ob must not be NULL.

int PyDelta_CheckExact(PyObject *ob)
    Return true if ob is of type PyDateTime_DeltaType. ob must not be NULL.

int PyTZInfo_Check(PyObject *ob)
    Return true if ob is of type PyDateTime_TZInfoType or a subtype of PyDateTime_TZInfoType. ob must not be NULL.

int PyTZInfo_CheckExact(PyObject *ob)
    Return true if ob is of type PyDateTime_TZInfoType. ob must not be NULL.

Macros to create objects:

PyObject* PyDate_FromDate(int year, int month, int day)
    Return a datetime.date object with the specified year, month and day.

PyObject* PyDateTime_FromDateAndTime(int year, int month, int day, int hour, int minute, int second, int usecond)
    Return a datetime.datetime object with the specified year,
month, day, hour, minute, second and microsecond.

**PyObject** `PyObject* PyTime_FromTime(int hour, int minute, int second, int usecond)`

*Return value: New reference.*

Return a `datetime.time` object with the specified hour, minute, second and microsecond.

**PyObject** `PyObject* PyDelta_FromDSU(int days, int seconds, int useconds)`

*Return value: New reference.*

Return a `datetime.timedelta` object representing the given number of days, seconds and microseconds. Normalization is performed so that the resulting number of microseconds and seconds lie in the ranges documented for `datetime.timedelta` objects.

Macros to extract fields from date objects. The argument must be an instance of `PyDateTime_Date`, including subclasses (such as `PyDateTime_DateTime`). The argument must not be `NULL`, and the type is not checked:

```
int int PyDateTime_GET_YEAR(PyDateTime_Date *o)
   Return the year, as a positive int.

int int PyDateTime_GET_MONTH(PyDateTime_Date *o)
   Return the month, as an int from 1 through 12.

int int PyDateTime_GET_DAY(PyDateTime_Date *o)
   Return the day, as an int from 1 through 31.
```

Macros to extract fields from datetime objects. The argument must be an instance of `PyDateTime_DateTime`, including subclasses. The argument must not be `NULL`, and the type is not checked:
int PyDateTime_DATE_GET_HOUR(PyDateTime_DateTime *o)
   Return the hour, as an int from 0 through 23.

int PyDateTime_DATE_GET_MINUTE(PyDateTime_DateTime *o)
   Return the minute, as an int from 0 through 59.

int PyDateTime_DATE_GET_SECOND(PyDateTime_DateTime *o)
   Return the second, as an int from 0 through 59.

int PyDateTime_DATE_GET_MICROSECOND(PyDateTime_DateTime *o)
   Return the microsecond, as an int from 0 through 999999.

Macros to extract fields from time objects. The argument must be an
instance of PyDateTime_Time, including subclasses. The argument
must not be NULL, and the type is not checked:

int PyDateTime_TIME_GET_HOUR(PyDateTime_Time *o)
   Return the hour, as an int from 0 through 23.

int PyDateTime_TIME_GET_MINUTE(PyDateTime_Time *o)
   Return the minute, as an int from 0 through 59.

int PyDateTime_TIME_GET_SECOND(PyDateTime_Time *o)
   Return the second, as an int from 0 through 59.

int PyDateTime_TIME_GET_MICROSECOND(PyDateTime_Time *o)
   Return the microsecond, as an int from 0 through 999999.

Macros to extract fields from time delta objects. The argument must be
an instance of PyDateTime_Delta, including subclasses. The
argument must not be *NULL*, and the type is not checked:

```c
int PyDateTime_DELTA_GET_DAYS(PyDateTime_Delta *o)
    Return the number of days, as an int from -999999999 to 999999999.

    New in version 3.3.
```

```c
int PyDateTime_DELTA_GET_SECONDS(PyDateTime_Delta *o)
    Return the number of seconds, as an int from 0 through 86399.

    New in version 3.3.
```

```c
int PyDateTime_DELTA_GET_MICROSECOND(PyDateTime_Delta *o)
    Return the number of microseconds, as an int from 0 through 999999.

    New in version 3.3.
```

Macros for the convenience of modules implementing the DB API:

```c
PyObject* PyDateTime_FromTimestamp(PyObject *args)
    Create and return a new *datetime.datetime* object given an argument tuple suitable for passing to *datetime.datetime.fromtimestamp()*.

PyObject* PyDate_FromTimestamp(PyObject *args)
    Create and return a new *datetime.date* object given an argument tuple suitable for passing to *datetime.date.fromtimestamp()*.
Code Objects

Code objects are a low-level detail of the CPython implementation. Each one represents a chunk of executable code that hasn’t yet been bound into a function.

**PyCodeObject**

The C structure of the objects used to describe code objects. The fields of this type are subject to change at any time.

**PyTypeObject** `PyCode_Type`

This is an instance of `PyTypeObject` representing the Python code type.

```c
int PyCode_Check(PyObject *co)
Return true if co is a code object
```

```c
int PyCode_GetNumFree(PyCodeObject *co)
Return the number of free variables in co.
```

```c
PyCodeObject* PyCode_New(int argcount, int kwonlyargcount,
int nlocals, int stacksize, int flags, PyObject *code, PyObject *consts,
PyObject *names, PyObject *varnames, PyObject *freevars,
PyObject *cellvars, PyObject *filename, PyObject *name,
int firstlineno, PyObject *lnotab)
Return a new code object. If you need a dummy code object to
create a frame, use PyCode_NewEmpty() instead. Calling
PyCode_New() directly can bind you to a precise Python version
since the definition of the bytecode changes often.
```

```c
PyCodeObject* PyCode_NewEmpty(const char *filename, const char *funcname, int firstlineno)
```
Return a new empty code object with the specified filename, function name, and first line number. It is illegal to exec() or eval() the resulting code object.
Initialization, Finalization, and Threads
Initializing and finalizing the interpreter

void **Py_InitAll**

Initialize the Python interpreter. In an application embedding Python, this should be called before using any other Python/C API functions; with the exception of **Py_SetProgramName()**, **Py_SetPythonHome()** and **Py_SetPath()**. This initializes the table of loaded modules (sys.modules), and creates the fundamental modules `builtins`, `__main__` and `sys`. It also initializes the module search path (sys.path). It does not set `sys.argv`; use `PySys_SetArgvEx()` for that. This is a no-op when called for a second time (without calling **Py_Finalize()** first). There is no return value; it is a fatal error if the initialization fails.

void **Py_InitAllEx**(int initargs)

This function works like **Py_InitAll()** if `initargs` is 1. If `initargs` is 0, it skips initialization registration of signal handlers, which might be useful when Python is embedded.

int **Py_IsInitialized**

Return true (nonzero) when the Python interpreter has been initialized, false (zero) if not. After **Py_Finalize()** is called, this returns false until **Py_InitAll()** is called again.

void **Py_Finalize**

Undo all initializations made by **Py_InitAll()** and subsequent use of Python/C API functions, and destroy all sub-interpreters (see **Py_NewInterpreter()** below) that were created and not yet destroyed since the last call to
Py_Initialize(). Ideally, this frees all memory allocated by the Python interpreter. This is a no-op when called for a second time (without calling Py_Initialize() again first). There is no return value; errors during finalization are ignored.

This function is provided for a number of reasons. An embedding application might want to restart Python without having to restart the application itself. An application that has loaded the Python interpreter from a dynamically loadable library (or DLL) might want to free all memory allocated by Python before unloading the DLL. During a hunt for memory leaks in an application a developer might want to free all memory allocated by Python before exiting from the application.

**Bugs and caveats:** The destruction of modules and objects in modules is done in random order; this may cause destructors (__del__() methods) to fail when they depend on other objects (even functions) or modules. Dynamically loaded extension modules loaded by Python are not unloaded. Small amounts of memory allocated by the Python interpreter may not be freed (if you find a leak, please report it). Memory tied up in circular references between objects is not freed. Some memory allocated by extension modules may not be freed. Some extensions may not work properly if their initialization routine is called more than once; this can happen if an application calls Py_Initialize() and Py_Finalize() more than once.
Process-wide parameters

void Py_SetProgramName(wchar_t *name)

This function should be called before Py_Initialize() is called for the first time, if it is called at all. It tells the interpreter the value of the argv[0] argument to the main() function of the program (converted to wide characters). This is used by Py_GetPath() and some other functions below to find the Python run-time libraries relative to the interpreter executable. The default value is 'python'. The argument should point to a zero-terminated wide character string in static storage whose contents will not change for the duration of the program’s execution. No code in the Python interpreter will change the contents of this storage.

wchar* Py_GetProgramName()

Return the program name set with Py_SetProgramName(), or the default. The returned string points into static storage; the caller should not modify its value.

wchar_t* Py_GetPrefix()

Return the prefix for installed platform-independent files. This is derived through a number of complicated rules from the program name set with Py_SetProgramName() and some environment variables; for example, if the program name is '/usr/local/bin/python', the prefix is '/usr/local'. The returned string points into static storage; the caller should not modify its value. This corresponds to the prefix variable in the top-level Makefile and the --prefix argument to the configure script at build time. The value is available to Python code as sys.prefix. It is only useful on Unix. See also the next function.
Return the *exec-prefix* for installed *platform-dependent* files. This is derived through a number of complicated rules from the program name set with *Py_SetProgramName()* and some environment variables; for example, if the program name is "/usr/local/bin/python", the exec-prefix is "/usr/local". The returned string points into static storage; the caller should not modify its value. This corresponds to the *exec_prefix* variable in the top-level *Makefile* and the *--exec-prefix* argument to the *configure* script at build time. The value is available to Python code as *sys.exec_prefix*. It is only useful on Unix.

Background: The exec-prefix differs from the prefix when platform dependent files (such as executables and shared libraries) are installed in a different directory tree. In a typical installation, platform dependent files may be installed in the /usr/local/plat subtree while platform independent may be installed in /usr/local.

Generally speaking, a platform is a combination of hardware and software families, e.g. Sparc machines running the Solaris 2.x operating system are considered the same platform, but Intel machines running Solaris 2.x are another platform, and Intel machines running Linux are yet another platform. Different major revisions of the same operating system generally also form different platforms. Non-Unix operating systems are a different story; the installation strategies on those systems are so different that the prefix and exec-prefix are meaningless, and set to the empty string. Note that compiled Python bytecode files are platform independent (but not independent from the Python version by which they were compiled!).
System administrators will know how to configure the mount or automount programs to share /usr/local between platforms while having /usr/local/plat be a different filesystem for each platform.

`wchar_t* Py_GetProgramFullPath()`

Return the full program name of the Python executable; this is computed as a side-effect of deriving the default module search path from the program name (set by `Py_SetProgramName()` above). The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.executable`.

`wchar_t* Py_GetPath()`

Return the default module search path; this is computed from the program name (set by `Py_SetProgramName()` above) and some environment variables. The returned string consists of a series of directory names separated by a platform dependent delimiter character. The delimiter character is `':'` on Unix and Mac OS X, `';'` on Windows. The returned string points into static storage; the caller should not modify its value. The list `sys.path` is initialized with this value on interpreter startup; it can be (and usually is) modified later to change the search path for loading modules.

`void Py_SetPath(const wchar_t *)`  

Set the default module search path. If this function is called before `Py_Initialize()`, then `Py_GetPath()` won’t attempt to compute a default search path but uses the one provided instead. This is useful if Python is embedded by an application that has full knowledge of the location of all modules. The path components should be separated by semicolons.
This also causes `sys.executable` to be set only to the raw program name (see `Py_SetProgramName()`) and for `sys.prefix` and `sys.exec_prefix` to be empty. It is up to the caller to modify these if required after calling `Py_Initialize()`.

**const char* Py_GetVersion()**

Return the version of this Python interpreter. This is a string that looks something like

```
"3.0a5+ (py3k:63103M, May 12 2008, 00:53:55) \n[GCC 4.2.3]"
```

The first word (up to the first space character) is the current Python version; the first three characters are the major and minor version separated by a period. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.version`.

**const char* Py_GetPlatform()**

Return the platform identifier for the current platform. On Unix, this is formed from the “official” name of the operating system, converted to lower case, followed by the major revision number; e.g., for Solaris 2.x, which is also known as SunOS 5.x, the value is 'sunos5'. On Mac OS X, it is 'darwin'. On Windows, it is 'win'. The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.platform`.

**const char* Py_GetCopyright()**

Return the official copyright string for the current Python version, for example

```
'Copyright 1991-1995 Stichting Mathematisch
```
The returned string points into static storage; the caller should not modify its value. The value is available to Python code as `sys.copyright`.

`const char* Py_GetCompiler()`  
Return an indication of the compiler used to build the current Python version, in square brackets, for example:

```
"[GCC 2.7.2.2]"
```

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

`const char* Py_GetBuildInfo()`  
Return information about the sequence number and build date and time of the current Python interpreter instance, for example

```
"#67, Aug 1 1997, 22:34:28"
```

The returned string points into static storage; the caller should not modify its value. The value is available to Python code as part of the variable `sys.version`.

`void PySys_SetArgvEx(int argc, wchar_t **argv, int updatepath)`  
Set `sys.argv` based on `argc` and `argv`. These parameters are similar to those passed to the program’s `main()` function with the difference that the first entry should refer to the script file to be executed rather than the executable hosting the Python interpreter. If there isn’t a script that will be run, the first entry in `argv` can be an empty string. If this function fails to initialize `sys.argv`, a fatal
condition is signalled using `Py_FatalError()`.

If `updatepath` is zero, this is all the function does. If `updatepath` is non-zero, the function also modifies `sys.path` according to the following algorithm:

- If the name of an existing script is passed in `argv[0]`, the absolute path of the directory where the script is located is prepended to `sys.path`.
- Otherwise (that is, if `argc` is 0 or `argv[0]` doesn’t point to an existing file name), an empty string is prepended to `sys.path`, which is the same as prepending the current working directory (`"."`).

**Note:** It is recommended that applications embedding the Python interpreter for purposes other than executing a single script pass 0 as `updatepath`, and update `sys.path` themselves if desired. See [CVE-2008-5983](https://github.com/python/cpython/commit/8db8bda5a7f507cf37555d0b224521c699b7e0e7).

On versions before 3.1.3, you can achieve the same effect by manually popping the first `sys.path` element after having called `PySys_SetArgv()`, for example using:

```python
PyRun_SimpleString("import sys; sys.path.pop(0)\n")
```

*New in version 3.1.3.*

void **PySys_SetArgv**(int `argc`, wchar_t **`argv`)**

This function works like `PySys_SetArgvEx()` with `updatepath` set to 1.

void **Py_SetPythonHome**(wchar_t *`home`)**

Set the default “home” directory, that is, the location of the standard
Python libraries. See `PYTHONHOME` for the meaning of the argument string.

The argument should point to a zero-terminated character string in static storage whose contents will not change for the duration of the program's execution. No code in the Python interpreter will change the contents of this storage.

```
w_char* Py_GetPythonHome()
```

Return the default “home”, that is, the value set by a previous call to `Py_SetPythonHome()`, or the value of the `PYTHONHOME` environment variable if it is set.
Thread State and the Global Interpreter Lock

The Python interpreter is not fully thread-safe. In order to support multi-threaded Python programs, there's a global lock, called the *global interpreter lock* or GIL, that must be held by the current thread before it can safely access Python objects. Without the lock, even the simplest operations could cause problems in a multi-threaded program: for example, when two threads simultaneously increment the reference count of the same object, the reference count could end up being incremented only once instead of twice.

Therefore, the rule exists that only the thread that has acquired the GIL may operate on Python objects or call Python/C API functions. In order to emulate concurrency of execution, the interpreter regularly tries to switch threads (see `sys.setswitchinterval()`). The lock is also released around potentially blocking I/O operations like reading or writing a file, so that other Python threads can run in the meantime.

The Python interpreter keeps some thread-specific bookkeeping information inside a data structure called `PyThreadState`. There's also one global variable pointing to the current `PyThreadState`: it can be retrieved using `PyThreadState_Get()`.

Releasing the GIL from extension code

Most extension code manipulating the GIL has the following simple structure:

```
Save the thread state in a local variable.
Release the global interpreter lock.
```
... Do some blocking I/O operation ...
Reacquire the global interpreter lock.
Restore the thread state from the local variable.

This is so common that a pair of macros exists to simplify it:

```python
Py_BEGIN_ALLOW_THREADS
... Do some blocking I/O operation ...
Py_END_ALLOW_THREADS
```

The `Py_BEGIN_ALLOW_THREADS` macro opens a new block and declares a hidden local variable; the `Py_END_ALLOW_THREADS` macro closes the block. These two macros are still available when Python is compiled without thread support (they simply have an empty expansion).

When thread support is enabled, the block above expands to the following code:

```python
PyThreadState *_save;
_save = PyEval_SaveThread();
...Do some blocking I/O operation...
PyEval_RestoreThread(_save);
```

Here is how these functions work: the global interpreter lock is used to protect the pointer to the current thread state. When releasing the lock and saving the thread state, the current thread state pointer must be retrieved before the lock is released (since another thread could immediately acquire the lock and store its own thread state in the global variable). Conversely, when acquiring the lock and restoring the thread state, the lock must be acquired before storing the thread state pointer.
Note: Calling system I/O functions is the most common use case for releasing the GIL, but it can also be useful before calling long-running computations which don’t need access to Python objects, such as compression or cryptographic functions operating over memory buffers. For example, the standard zlib and hashlib modules release the GIL when compressing or hashing data.

Non-Python created threads

When threads are created using the dedicated Python APIs (such as the threading module), a thread state is automatically associated to them and the code showed above is therefore correct. However, when threads are created from C (for example by a third-party library with its own thread management), they don’t hold the GIL, nor is there a thread state structure for them.

If you need to call Python code from these threads (often this will be part of a callback API provided by the aforementioned third-party library), you must first register these threads with the interpreter by creating a thread state data structure, then acquiring the GIL, and finally storing their thread state pointer, before you can start using the Python/C API. When you are done, you should reset the thread state pointer, release the GIL, and finally free the thread state data structure.

The PyGILState_Ensure() and PyGILState_Release() functions do all of the above automatically. The typical idiom for calling into Python from a C thread is:

```c
PyGILState_STATE gstate;
gstate = PyGILState_Ensure();
```
Perform Python actions here. /*
result = CallSomeFunction();
/* evaluate result or handle exception */
/* Release the thread. No Python API allowed beyond
PyGILState_Release(gstate);

Note that the PyGILState_*() functions assume there is only one
global interpreter (created automatically by Py_Initialize()).
Python supports the creation of additional interpreters (using
Py_NewInterpreter()), but mixing multiple interpreters and the
PyGILState_*() API is unsupported.

Another important thing to note about threads is their behaviour in the
face of the C fork() call. On most systems with fork(), after a
process forks only the thread that issued the fork will exist. That also
means any locks held by other threads will never be released. Python
solves this for os.fork() by acquiring the locks it uses internally
before the fork, and releasing them afterwards. In addition, it resets
any Lock Objects in the child. When extending or embedding Python,
there is no way to inform Python of additional (non-Python) locks that
need to be acquired before or reset after a fork. OS facilities such as
pthread_atfork() would need to be used to accomplish the same
thing. Additionally, when extending or embedding Python, calling
fork() directly rather than through os.fork() (and returning to or
calling into Python) may result in a deadlock by one of Python’s
internal locks being held by a thread that is defunct after the fork.
PyOS_AfterFork() tries to reset the necessary locks, but is not
always able to.

High-level API
These are the most commonly used types and functions when writing C extension code, or when embedding the Python interpreter:

**PyInterpreterState**

This data structure represents the state shared by a number of cooperating threads. Threads belonging to the same interpreter share their module administration and a few other internal items. There are no public members in this structure.

Threads belonging to different interpreters initially share nothing, except process state like available memory, open file descriptors and such. The global interpreter lock is also shared by all threads, regardless of to which interpreter they belong.

**PyThreadState**

This data structure represents the state of a single thread. The only public data member is `PyInterpreterState * interp`, which points to this thread’s interpreter state.

```c
void PyEval_InitThreads()
```

Initialize and acquire the global interpreter lock. It should be called in the main thread before creating a second thread or engaging in any other thread operations such as `PyEval_ReleaseThread(tstate)`. It is not needed before calling `PyEval_SaveThread()` or `PyEval_RestoreThread()`.

This is a no-op when called for a second time.

*Changed in version 3.2:* This function cannot be called before `Py_Initialize()` anymore.

**Note:** When only the main thread exists, no GIL operations are needed. This is a common situation (most Python programs do
not use threads), and the lock operations slow the interpreter down a bit. Therefore, the lock is not created initially. This situation is equivalent to having acquired the lock: when there is only a single thread, all object accesses are safe. Therefore, when this function initializes the global interpreter lock, it also acquires it. Before the Python _thread module creates a new thread, knowing that either it has the lock or the lock hasn’t been created yet, it calls PyEval_InitThreads(). When this call returns, it is guaranteed that the lock has been created and that the calling thread has acquired it.

It is **not** safe to call this function when it is unknown which thread (if any) currently has the global interpreter lock. This function is not available when thread support is disabled at compile time.

```c
int PyEval_ThreadsInitialized()

Returns a non-zero value if PyEval_InitThreads() has been called. This function can be called without holding the GIL, and therefore can be used to avoid calls to the locking API when running single-threaded. This function is not available when thread support is disabled at compile time.

```c
PyThreadState* PyEval_SaveThread()

Release the global interpreter lock (if it has been created and thread support is enabled) and reset the thread state to NULL, returning the previous thread state (which is not NULL). If the lock has been created, the current thread must have acquired it. (This function is available even when thread support is disabled at compile time.)

```c
void PyEval_RestoreThread(PyThreadState *tstate)

```
Acquire the global interpreter lock (if it has been created and thread support is enabled) and set the thread state to tstate, which must not be NULL. If the lock has been created, the current thread must not have acquired it, otherwise deadlock ensues. (This function is available even when thread support is disabled at compile time.)

**PyThreadState**

*PyThreadState_Get()*

Return the current thread state. The global interpreter lock must be held. When the current thread state is NULL, this issues a fatal error (so that the caller needn't check for NULL).

**PyThreadState**

*PyThreadState_Swap(PyThreadState *tstate)*

Swap the current thread state with the thread state given by the argument tstate, which may be NULL. The global interpreter lock must be held and is not released.

**void**

*PyEval_ReInitThreads()*

This function is called from PyOS_AfterFork() to ensure that newly created child processes don't hold locks referring to threads which are not running in the child process.

The following functions use thread-local storage, and are not compatible with sub-interpreters:

**PyGILState_STATE**

*PyGILState_Ensure()*

Ensure that the current thread is ready to call the Python C API regardless of the current state of Python, or of the global interpreter lock. This may be called as many times as desired by a thread as long as each call is matched with a call to PyGILState_Release(). In general, other thread-related APIs may be used between PyGILState_Ensure() and
PyGILState_Release() calls as long as the thread state is restored to its previous state before the Release(). For example, normal usage of the Py_BEGIN_ALLOW_THREADS and Py_END_ALLOW_THREADS macros is acceptable.

The return value is an opaque “handle” to the thread state when PyGILState_Ensure() was called, and must be passed to PyGILState_Release() to ensure Python is left in the same state. Even though recursive calls are allowed, these handles cannot be shared - each unique call to PyGILState_Ensure() must save the handle for its call to PyGILState_Release().

When the function returns, the current thread will hold the GIL and be able to call arbitrary Python code. Failure is a fatal error.

void PyGILState_Release(PyGILState_STATE)
Release any resources previously acquired. After this call, Python's state will be the same as it was prior to the corresponding PyGILState_Ensure() call (but generally this state will be unknown to the caller, hence the use of the GILState API).

Every call to PyGILState_Ensure() must be matched by a call to PyGILState_Release() on the same thread.

PyThreadState* PyGILState_GetThisThreadState()
Get the current thread state for this thread. May return NULL if no GILState API has been used on the current thread. Note that the main thread always has such a thread-state, even if no auto-thread-state call has been made on the main thread. This is mainly a helper/diagnostic function.

The following macros are normally used without a trailing semicolon;
look for example usage in the Python source distribution.

**Py_BEGIN_ALLOW_THREADS**

This macro expands to `{ PyThreadState *__save; __save = PyEval_SaveThread(); };` Note that it contains an opening brace; it must be matched with a following **Py_END_ALLOW_THREADS** macro. See above for further discussion of this macro. It is a no-op when thread support is disabled at compile time.

**Py_END_ALLOW_THREADS**

This macro expands to `PyEval_RestoreThread(__save); }`. Note that it contains a closing brace; it must be matched with an earlier **Py_BEGIN_ALLOW_THREADS** macro. See above for further discussion of this macro. It is a no-op when thread support is disabled at compile time.

**Py_BLOCK_THREADS**

This macro expands to `PyEval_RestoreThread(__save);`: it is equivalent to **Py_END_ALLOW_THREADS** without the closing brace. It is a no-op when thread support is disabled at compile time.

**Py_UNBLOCK_THREADS**

This macro expands to `__save = PyEval_SaveThread();`: it is equivalent to **Py_BEGIN_ALLOW_THREADS** without the opening brace and variable declaration. It is a no-op when thread support is disabled at compile time.

**Low-level API**

All of the following functions are only available when thread support is enabled at compile time, and must be called only when the global interpreter lock has been created.
PyInterpreterState* PyInterpreterState_New()

Create a new interpreter state object. The global interpreter lock need not be held, but may be held if it is necessary to serialize calls to this function.

void PyInterpreterState_Clear(PyInterpreterState *interp)

Reset all information in an interpreter state object. The global interpreter lock must be held.

void PyInterpreterState_Delete(PyInterpreterState *interp)

Destroy an interpreter state object. The global interpreter lock need not be held. The interpreter state must have been reset with a previous call to PyInterpreterState_Clear().

PyThreadState* PyThreadState_New(PyInterpreterState *interp)

Create a new thread state object belonging to the given interpreter object. The global interpreter lock need not be held, but may be held if it is necessary to serialize calls to this function.

void PyThreadState_Clear(PyThreadState *tstate)

Reset all information in a thread state object. The global interpreter lock must be held.

void PyThreadState_Delete(PyThreadState *tstate)

Destroy a thread state object. The global interpreter lock need not be held. The thread state must have been reset with a previous call to PyThreadState_Clear().

PyObject* PyThreadState_GetDict()

Return value: Borrowed reference.
Return a dictionary in which extensions can store thread-specific
state information. Each extension should use a unique key to use to store state in the dictionary. It is okay to call this function when no current thread state is available. If this function returns NULL, no exception has been raised and the caller should assume no current thread state is available.

```c
int PyThreadState_SetAsyncExc(long id, PyObject *exc)
```

Asynchronously raise an exception in a thread. The `id` argument is the thread id of the target thread; `exc` is the exception object to be raised. This function does not steal any references to `exc`. To prevent naive misuse, you must write your own C extension to call this. Must be called with the GIL held. Returns the number of thread states modified; this is normally one, but will be zero if the thread id isn’t found. If `exc` is NULL, the pending exception (if any) for the thread is cleared. This raises no exceptions.

```c
void PyEval_AcquireThread(PyThreadState *tstate)
```

Acquire the global interpreter lock and set the current thread state to `tstate`, which should not be NULL. The lock must have been created earlier. If this thread already has the lock, deadlock ensues.

```c
PyEval_RestoreThread()
```

is a higher-level function which is always available (even when thread support isn’t enabled or when threads have not been initialized).

```c
void PyEval_ReleaseThread(PyThreadState *tstate)
```

Reset the current thread state to NULL and release the global interpreter lock. The lock must have been created earlier and must be held by the current thread. The `tstate` argument, which must not be NULL, is only used to check that it represents the current thread state — if it isn’t, a fatal error is reported.
PyEval_SaveThread() is a higher-level function which is always available (even when thread support isn't enabled or when threads have not been initialized).

void PyEval_AcquireLock()
Acquire the global interpreter lock. The lock must have been created earlier. If this thread already has the lock, a deadlock ensues.

*Deprecated since version 3.2:* This function does not update the current thread state. Please use PyEval_RestoreThread() or PyEval_AcquireThread() instead.

void PyEval_ReleaseLock()
Release the global interpreter lock. The lock must have been created earlier.

*Deprecated since version 3.2:* This function does not update the current thread state. Please use PyEval_SaveThread() or PyEval_ReleaseThread() instead.
Sub-interpreter support

While in most uses, you will only embed a single Python interpreter, there are cases where you need to create several independent interpreters in the same process and perhaps even in the same thread. Sub-interpreters allow you to do that. You can switch between sub-interpreters using the `PyThreadState_Swap()` function. You can create and destroy them using the following functions:

```
PyThreadState* Py_NewInterpreter()
```

Create a new sub-interpreter. This is an (almost) totally separate environment for the execution of Python code. In particular, the new interpreter has separate, independent versions of all imported modules, including the fundamental modules `builtins`, `__main__` and `sys`. The table of loaded modules (`sys.modules`) and the module search path (`sys.path`) are also separate. The new environment has no `sys.argv` variable. It has new standard I/O stream file objects `sys.stdin`, `sys.stdout` and `sys.stderr` (however these refer to the same underlying file descriptors).

The return value points to the first thread state created in the new sub-interpreter. This thread state is made in the current thread state. Note that no actual thread is created; see the discussion of thread states below. If creation of the new interpreter is unsuccessful, `NULL` is returned; no exception is set since the exception state is stored in the current thread state and there may not be a current thread state. (Like all other Python/C API functions, the global interpreter lock must be held before calling this function and is still held when it returns; however, unlike most other Python/C API functions, there needn’t be a current thread
Extension modules are shared between (sub-)interpreters as follows: the first time a particular extension is imported, it is initialized normally, and a (shallow) copy of its module's dictionary is squirreled away. When the same extension is imported by another (sub-)interpreter, a new module is initialized and filled with the contents of this copy; the extension's `init` function is not called. Note that this is different from what happens when an extension is imported after the interpreter has been completely re-initialized by calling `Py_Finalize()` and `Py_Initialize()`; in that case, the extension's `init` module function is called again.

```c
void Py_EndInterpreter(PyThreadState *tstate)
```

Destroy the (sub-)interpreter represented by the given thread state. The given thread state must be the current thread state. See the discussion of thread states below. When the call returns, the current thread state is `NULL`. All thread states associated with this interpreter are destroyed. (The global interpreter lock must be held before calling this function and is still held when it returns.) `Py_Finalize()` will destroy all sub-interpreters that haven’t been explicitly destroyed at that point.

Bugs and caveats

Because sub-interpreters (and the main interpreter) are part of the same process, the insulation between them isn't perfect — for example, using low-level file operations like `os.close()` they can (accidentally or maliciously) affect each other's open files. Because of the way extensions are shared between (sub-)interpreters, some extensions may not work properly; this is especially likely when the extension makes use of (static) global variables, or when the
extension manipulates its module's dictionary after its initialization. It is possible to insert objects created in one sub-interpreter into a namespace of another sub-interpreter; this should be done with great care to avoid sharing user-defined functions, methods, instances or classes between sub-interpreters, since import operations executed by such objects may affect the wrong (sub-)interpreter’s dictionary of loaded modules.

Also note that combining this functionality with PyGILState_*( ) APIs is delicate, because these APIs assume a bijection between Python thread states and OS-level threads, an assumption broken by the presence of sub-interpreters. It is highly recommended that you don’t switch sub-interpreters between a pair of matching PyGILState_Ensure() and PyGILState_Release() calls. Furthermore, extensions (such as ctypes) using these APIs to allow calling of Python code from non-Python created threads will probably be broken when using sub-interpreters.
Asynchronous Notifications

A mechanism is provided to make asynchronous notifications to the main interpreter thread. These notifications take the form of a function pointer and a void pointer argument.

```c
int Py_AddPendingCall(int (*func)(void *), void *arg)
```

Schedule a function to be called from the main interpreter thread. On success, 0 is returned and `func` is queued for being called in the main thread. On failure, -1 is returned without setting any exception.

When successfully queued, `func` will be eventually called from the main interpreter thread with the argument `arg`. It will be called asynchronously with respect to normally running Python code, but with both these conditions met:

- on a `bytecode` boundary;
- with the main thread holding the `global interpreter lock` (`func` can therefore use the full C API).

`func` must return 0 on success, or -1 on failure with an exception set. `func` won’t be interrupted to perform another asynchronous notification recursively, but it can still be interrupted to switch threads if the global interpreter lock is released.

This function doesn’t need a current thread state to run, and it doesn’t need the global interpreter lock.

**Warning:** This is a low-level function, only useful for very special cases. There is no guarantee that `func` will be called as quick as possible. If the main thread is busy executing a system call, `func` won’t be called before the system call returns. This
function is generally **not** suitable for calling Python code from arbitrary C threads. Instead, use the *PyGILState API*.

*New in version 3.1.*
Profiling and Tracing

The Python interpreter provides some low-level support for attaching profiling and execution tracing facilities. These are used for profiling, debugging, and coverage analysis tools.

This C interface allows the profiling or tracing code to avoid the overhead of calling through Python-level callable objects, making a direct C function call instead. The essential attributes of the facility have not changed; the interface allows trace functions to be installed per-thread, and the basic events reported to the trace function are the same as had been reported to the Python-level trace functions in previous versions.

```c
int (*Py_tracefunc)(PyObject *obj, PyFrameObject *frame, int what, PyObject *arg)
```

The type of the trace function registered using `PyEval_SetProfile()` and `PyEval_SetTrace()`. The first parameter is the object passed to the registration function as `obj`, `frame` is the frame object to which the event pertains, `what` is one of the constants `PyTrace_CALL`, `PyTrace_EXCEPTION`, `PyTrace_LINE`, `PyTrace_RETURN`, `PyTrace_C_CALL`, `PyTrace_C_EXCEPTION`, or `PyTrace_C_RETURN`, and `arg` depends on the value of `what`:

<table>
<thead>
<tr>
<th>Value of what</th>
<th>Meaning of arg</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyTrace_CALL</td>
<td>Always <code>NULL</code>.</td>
</tr>
<tr>
<td>PyTrace_EXCEPTION</td>
<td>Exception information as returned by <code>sys.exc_info()</code>.</td>
</tr>
<tr>
<td>PyTrace_LINE</td>
<td>Always <code>NULL</code>.</td>
</tr>
<tr>
<td>PyTrace_RETURN</td>
<td>Value being returned to the caller, or NULL if caused by an exception.</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PyTrace_C_CALL</td>
<td>Function object being called.</td>
</tr>
<tr>
<td>PyTrace_C_EXCEPTION</td>
<td>Function object being called.</td>
</tr>
<tr>
<td>PyTrace_C_RETURN</td>
<td>Function object being called.</td>
</tr>
</tbody>
</table>

int **PyTrace_CALL**

The value of the *what* parameter to a `Py_tracefunc` function when a new call to a function or method is being reported, or a new entry into a generator. Note that the creation of the iterator for a generator function is not reported as there is no control transfer to the Python bytecode in the corresponding frame.

int **PyTrace_EXCEPTION**

The value of the *what* parameter to a `Py_tracefunc` function when an exception has been raised. The callback function is called with this value for *what* when after any bytecode is processed after which the exception becomes set within the frame being executed. The effect of this is that as exception propagation causes the Python stack to unwind, the callback is called upon return to each frame as the exception propagates. Only trace functions receives these events; they are not needed by the profiler.

int **PyTrace_LINE**

The value passed as the *what* parameter to a trace function (but not a profiling function) when a line-number event is being reported.

int **PyTrace_RETURN**

The value for the *what* parameter to `Py_tracefunc` functions when a call is returning without propagating an exception.
int **PyTrace_C_CALL**

The value for the *what* parameter to *Py_tracefunc* functions when a C function is about to be called.

int **PyTrace_C_EXCEPTION**

The value for the *what* parameter to *Py_tracefunc* functions when a C function has raised an exception.

int **PyTrace_C_RETURN**

The value for the *what* parameter to *Py_tracefunc* functions when a C function has returned.

```c
void PyEval_SetProfile(Py_tracefunc func, PyObject *obj)
```

Set the profiler function to `func`. The `obj` parameter is passed to the function as its first parameter, and may be any Python object, or `NULL`. If the profile function needs to maintain state, using a different value for `obj` for each thread provides a convenient and thread-safe place to store it. The profile function is called for all monitored events except the line-number events.

```c
void PyEval_SetTrace(Py_tracefunc func, PyObject *obj)
```

Set the tracing function to `func`. This is similar to `PyEval_SetProfile()`, except the tracing function does receive line-number events.

```c
PyObject* PyEval_GetCallStats(PyObject *self)
```

Return a tuple of function call counts. There are constants defined for the positions within the tuple:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCALL_ALL</td>
<td>0</td>
</tr>
<tr>
<td>PCALL_FUNCTION</td>
<td>1</td>
</tr>
<tr>
<td>PCALL_FAST_FUNCTION</td>
<td>2</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---</td>
</tr>
<tr>
<td>PCALL_FASTER_FUNCTION</td>
<td>3</td>
</tr>
<tr>
<td>PCALL_METHOD</td>
<td>4</td>
</tr>
<tr>
<td>PCALL_BOUND_METHOD</td>
<td>5</td>
</tr>
<tr>
<td>PCALL_CFUNCTION</td>
<td>6</td>
</tr>
<tr>
<td>PCALL_TYPE</td>
<td>7</td>
</tr>
<tr>
<td>PCALL_GENERATOR</td>
<td>8</td>
</tr>
<tr>
<td>PCALL_OTHER</td>
<td>9</td>
</tr>
<tr>
<td>PCALL_POP</td>
<td>10</td>
</tr>
</tbody>
</table>

PCALL_FAST_FUNCTION means no argument tuple needs to be created. PCALL_FASTER_FUNCTION means that the fast-path frame setup code is used.

If there is a method call where the call can be optimized by changing the argument tuple and calling the function directly, it gets recorded twice.

This function is only present if Python is compiled with CALL_PROFILE defined.
Advanced Debugger Support

These functions are only intended to be used by advanced debugging tools.

**PyInterpreterState** `PyInterpreterState_Head()`
Return the interpreter state object at the head of the list of all such objects.

**PyInterpreterState**
**PyInterpreterState** `PyInterpreterState_Next(PyInterpreterState *interp)`
Return the next interpreter state object after `interp` from the list of all such objects.

**PyThreadState**
**PyInterpreterState** `PyInterpreterState_ThreadHead(PyInterpreterState *interp)`
Return the a pointer to the first `PyThreadState` object in the list of threads associated with the interpreter `interp`.

**PyThreadState**
**PyInterpreterState** `PyThreadState_Next(PyThreadState *tstate)`
Return the next thread state object after `tstate` from the list of all such objects belonging to the same `PyInterpreterState` object.
Memory Management
Overview

Memory management in Python involves a private heap containing all Python objects and data structures. The management of this private heap is ensured internally by the *Python memory manager*. The Python memory manager has different components which deal with various dynamic storage management aspects, like sharing, segmentation, preallocation or caching.

At the lowest level, a raw memory allocator ensures that there is enough room in the private heap for storing all Python-related data by interacting with the memory manager of the operating system. On top of the raw memory allocator, several object-specific allocators operate on the same heap and implement distinct memory management policies adapted to the peculiarities of every object type. For example, integer objects are managed differently within the heap than strings, tuples or dictionaries because integers imply different storage requirements and speed/space tradeoffs. The Python memory manager thus delegates some of the work to the object-specific allocators, but ensures that the latter operate within the bounds of the private heap.

It is important to understand that the management of the Python heap is performed by the interpreter itself and that the user has no control over it, even if she regularly manipulates object pointers to memory blocks inside that heap. The allocation of heap space for Python objects and other internal buffers is performed on demand by the Python memory manager through the Python/C API functions listed in this document.

To avoid memory corruption, extension writers should never try to operate on Python objects with the functions exported by the C library:
malloc(), calloc(), realloc() and free(). This will result in mixed calls between the C allocator and the Python memory manager with fatal consequences, because they implement different algorithms and operate on different heaps. However, one may safely allocate and release memory blocks with the C library allocator for individual purposes, as shown in the following example:

```c
PyObject *res;
char *buf = (char *) malloc(BUFSIZ); /* for I/O */

if (buf == NULL)  
    return PyErr_NoMemory();
...
Do some I/O operation involving buf...
res = PyBytes_FromString(buf);
free(buf); /* malloc'ed */
return res;
```

In this example, the memory request for the I/O buffer is handled by the C library allocator. The Python memory manager is involved only in the allocation of the string object returned as a result.

In most situations, however, it is recommended to allocate memory from the Python heap specifically because the latter is under control of the Python memory manager. For example, this is required when the interpreter is extended with new object types written in C. Another reason for using the Python heap is the desire to inform the Python memory manager about the memory needs of the extension module. Even when the requested memory is used exclusively for internal, highly-specific purposes, delegating all memory requests to the Python memory manager causes the interpreter to have a more accurate image of its memory footprint as a whole. Consequently, under certain circumstances, the Python memory manager may or may not trigger appropriate actions, like garbage collection, memory compaction or
other preventive procedures. Note that by using the C library allocator as shown in the previous example, the allocated memory for the I/O buffer escapes completely the Python memory manager.
Memory Interface

The following function sets, modeled after the ANSI C standard, but specifying behavior when requesting zero bytes, are available for allocating and releasing memory from the Python heap:

```c
void* PyMem_Malloc(size_t n)
```

Allocates $n$ bytes and returns a pointer of type `void*` to the allocated memory, or `NULL` if the request fails. Requesting zero bytes returns a distinct non-`NULL` pointer if possible, as if `PyMem_Malloc(1)` had been called instead. The memory will not have been initialized in any way.

```c
void* PyMem_Realloc(void *p, size_t n)
```

Resizes the memory block pointed to by $p$ to $n$ bytes. The contents will be unchanged to the minimum of the old and the new sizes. If $p$ is `NULL`, the call is equivalent to `PyMem_Malloc(n)`; else if $n$ is equal to zero, the memory block is resized but is not freed, and the returned pointer is non-`NULL`. Unless $p$ is `NULL`, it must have been returned by a previous call to `PyMem_Malloc()` or `PyMem_Realloc()`. If the request fails, `PyMem_Realloc()` returns `NULL` and $p$ remains a valid pointer to the previous memory area.

```c
void PyMem_Free(void *p)
```

Frees the memory block pointed to by $p$, which must have been returned by a previous call to `PyMem_Malloc()` or `PyMem_Realloc()`. Otherwise, or if `PyMem_Free(p)` has been called before, undefined behavior occurs. If $p$ is `NULL`, no operation is performed.
The following type-oriented macros are provided for convenience. Note that \texttt{TYPE} refers to any C type.

\textbf{TYPE* \texttt{PyMem\_New}(TYPE, size\_t \textit{n})}

Same as \texttt{PyMem\_Malloc()}, but allocates \((n \times \text{sizeof}(\text{TYPE}))\) bytes of memory. Returns a pointer cast to TYPE*. The memory will not have been initialized in any way.

\textbf{TYPE* \texttt{PyMem\_Resize}(void *\textit{p}, TYPE, size\_t \textit{n})}

Same as \texttt{PyMem\_Realloc()}, but the memory block is resized to \((n \times \text{sizeof}(\text{TYPE}))\) bytes. Returns a pointer cast to TYPE*. On return, \textit{p} will be a pointer to the new memory area, or \textsc{null} in the event of failure. This is a C preprocessor macro; \textit{p} is always reassigned. Save the original value of \textit{p} to avoid losing memory when handling errors.

\textbf{\textit{void} \texttt{PyMem\_Del}(void *\textit{p})}

Same as \texttt{PyMem\_Free()}.

In addition, the following macro sets are provided for calling the Python memory allocator directly, without involving the C API functions listed above. However, note that their use does not preserve binary compatibility across Python versions and is therefore deprecated in extension modules.

\texttt{PyMem\_MALLOC()}, \texttt{PyMem\_REALLOC()}, \texttt{PyMem\_FREE()}.

\texttt{PyMem\_NEW()}, \texttt{PyMem\_RESIZE()}, \texttt{PyMem\_DEL()}. 
Examples

Here is the example from section *Overview*, rewritten so that the I/O buffer is allocated from the Python heap by using the first function set:

```python
PyObject *res;
char *buf = (char *) PyMem_Malloc(BUFSIZ); /* for I/O */

if (buf == NULL)
    return PyErr_NoMemory();
/* ...Do some I/O operation involving buf... */
res = PyBytes_FromString(buf);
PyMem_Free(buf); /* allocated with PyMem_Malloc */
return res;
```

The same code using the type-oriented function set:

```python
PyObject *res;
char *buf = PyMem_New(char, BUFSIZ); /* for I/O */

if (buf == NULL)
    return PyErr_NoMemory();
/* ...Do some I/O operation involving buf... */
res = PyBytes_FromString(buf);
PyMem_Del(buf); /* allocated with PyMem_New */
return res;
```

Note that in the two examples above, the buffer is always manipulated via functions belonging to the same set. Indeed, it is required to use the same memory API family for a given memory block, so that the risk of mixing different allocators is reduced to a minimum. The following code sequence contains two errors, one of which is labeled as *fatal* because it mixes two different allocators operating on different heaps.
In addition to the functions aimed at handling raw memory blocks from the Python heap, objects in Python are allocated and released with `PyObject_New()`, `PyObject_NewVar()` and `PyObject_Del()`.

These will be explained in the next chapter on defining and implementing new object types in C.
Object Implementation Support

This chapter describes the functions, types, and macros used when defining new object types.

- Allocating Objects on the Heap
- Common Object Structures
- Type Objects
- Number Object Structures
- Mapping Object Structures
- Sequence Object Structures
- Buffer Object Structures
- Supporting Cyclic Garbage Collection
Allocating Objects on the Heap

PyObject* _PyObject_New(PyTypeObject *type)

*Return value: New reference.*

PyVarObject* _PyObject_NewVar(PyTypeObject *type, Py_ssize_t size)

*Return value: New reference.*

PyObject* PyObject_Init(PyObject *op, PyTypeObject *type)

*Return value: Borrowed reference.*

Initialize a newly-allocated object op with its type and initial reference. Returns the initialized object. If type indicates that the object participates in the cyclic garbage detector, it is added to the detector's set of observed objects. Other fields of the object are not affected.

PyVarObject* PyObject_InitVar(PyVarObject *op, PyTypeObject *type, Py_ssize_t size)

*Return value: Borrowed reference.*

This does everything PyObject_Init() does, and also initializes the length information for a variable-size object.

TYPE* PyObject_New(TYPE, PyTypeObject *type)

*Return value: New reference.*

Allocate a new Python object using the C structure type TYPE and the Python type object type. Fields not defined by the Python object header are not initialized; the object's reference count will be one. The size of the memory allocation is determined from the tp_basicsize field of the type object.
TYPE* **PyObject_NewVar** (TYPE, PyTypeObject *type, Py_ssize_t size)

*Return value: New reference.*
Allocate a new Python object using the C structure type `TYPE` and the Python type object `type`. Fields not defined by the Python object header are not initialized. The allocated memory allows for the `TYPE` structure plus `size` fields of the size given by the `tp_itemsize` field of `type`. This is useful for implementing objects like tuples, which are able to determine their size at construction time. Embedding the array of fields into the same allocation decreases the number of allocations, improving the memory management efficiency.

```c
void **PyObject_Del** (PyObject *op)
```
Releases memory allocated to an object using `PyObject_New()` or `PyObject_NewVar()`. This is normally called from the `tp_dealloc` handler specified in the object's type. The fields of the object should not be accessed after this call as the memory is no longer a valid Python object.

**PyObject _Py_NoneStruct**
Object which is visible in Python as `None`. This should only be accessed using the `Py_None` macro, which evaluates to a pointer to this object.

**See also:**

**PyModule_Create()**
To allocate and create extension modules.
Common Object Structures

There are a large number of structures which are used in the definition of object types for Python. This section describes these structures and how they are used.

All Python objects ultimately share a small number of fields at the beginning of the object's representation in memory. These are represented by the `PyObject` and `PyVarObject` types, which are defined, in turn, by the expansions of some macros also used, whether directly or indirectly, in the definition of all other Python objects.

**PyObject**

All object types are extensions of this type. This is a type which contains the information Python needs to treat a pointer to an object as an object. In a normal “release” build, it contains only the object's reference count and a pointer to the corresponding type object. It corresponds to the fields defined by the expansion of the `PyObject_HEAD` macro.

**PyVarObject**

This is an extension of `PyObject` that adds the `ob_size` field. This is only used for objects that have some notion of `length`. This type does not often appear in the Python/C API. It corresponds to the fields defined by the expansion of the `PyObject_VAR_HEAD` macro.

These macros are used in the definition of `PyObject` and `PyVarObject`:

**PyObject_HEAD**
This is a macro which expands to the declarations of the fields of the `PyObject` type; it is used when declaring new types which represent objects without a varying length. The specific fields it expands to depend on the definition of Py_TRACE_REFS. By default, that macro is not defined, and `PyObject_HEAD` expands to:

```c
Py_ssize_t ob_refcnt;
PyTypeObject *ob_type;
```

When Py_TRACE_REFS is defined, it expands to:

```c
PyObject *__ob_next, *__ob_prev;
Py_ssize_t ob_refcnt;
PyTypeObject *ob_type;
```

**PyObject_VAR_HEAD**

This is a macro which expands to the declarations of the fields of the `PyVarObject` type; it is used when declaring new types which represent objects with a length that varies from instance to instance. This macro always expands to:

```c
PyObject_HEAD
Py_ssize_t ob_size;
```

Note that `PyObject_HEAD` is part of the expansion, and that its own expansion varies depending on the definition of Py_TRACE_REFS.

**PyObject_HEAD_INIT**(type)

This is a macro which expands to initialization values for a new `PyObject` type. This macro expands to:
_PyObject_EXTRA_INIT
1, type,

\textbf{PyVarObject\_HEAD\_INIT}(\text{type, size})

This is a macro which expands to initialization values for a new \textbf{PyVarObject} type, including the ob\_size field. This macro expands to:

_PyObject_EXTRA_INIT
1, type, size,

\textbf{PyCFunction}

Type of the functions used to implement most Python callables in C. Functions of this type take two \texttt{PyObject*} parameters and return one such value. If the return value is \textit{NULL}, an exception shall have been set. If not \textit{NULL}, the return value is interpreted as the return value of the function as exposed in Python. The function must return a new reference.

\textbf{PyCFunctionWithKeywords}

Type of the functions used to implement Python callables in C that take keyword arguments: they take three \texttt{PyObject*} parameters and return one such value. See \textbf{PyCFunction} above for the meaning of the return value.

\textbf{PyMethodDef}

Structure used to describe a method of an extension type. This structure has four fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_name</td>
<td>char *</td>
<td>name of the method</td>
</tr>
<tr>
<td>ml_meth</td>
<td>PyCFunction</td>
<td>pointer to the C</td>
</tr>
</tbody>
</table>
The `ml_meth` is a C function pointer. The functions may be of different types, but they always return `PyObject*`. If the function is not of the `PyCFunction`, the compiler will require a cast in the method table. Even though `PyCFunction` defines the first parameter as `PyObject*`, it is common that the method implementation uses a the specific C type of the `self` object.

The `ml_flags` field is a bitfield which can include the following flags. The individual flags indicate either a calling convention or a binding convention. Of the calling convention flags, only `METH_VARARGS` and `METH_KEYWORDS` can be combined (but note that `METH_KEYWORDS` alone is equivalent to `METH_VARARGS | METH_KEYWORDS`). Any of the calling convention flags can be combined with a binding flag.

**METH_VARARGS**

This is the typical calling convention, where the methods have the type `PyCFunction`. The function expects two `PyObject*` values. The first one is the `self` object for methods; for module functions, it is the module object. The second parameter (often called `args`) is a tuple object representing all arguments. This parameter is typically processed using `PyArg_ParseTuple()` or `PyArg_UnpackTuple()`.

**METH_KEYWORDS**

Methods with these flags must be of type

<table>
<thead>
<tr>
<th>ml_flags</th>
<th>int</th>
<th>flag bits indicating how the call should be constructed</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_doc</td>
<td>char *</td>
<td>points to the contents of the docstring</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ml_flags</th>
<th>int</th>
<th>flag bits indicating how the call should be constructed</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_doc</td>
<td>char *</td>
<td>points to the contents of the docstring</td>
</tr>
</tbody>
</table>
PyCFunctionWithKeywords. The function expects three parameters: \texttt{self}, \texttt{args}, and a dictionary of all the keyword arguments. The flag is typically combined with \texttt{METH\_VARARGS}, and the parameters are typically processed using \texttt{PyArg\_ParseTupleAndKeywords()}.

**METH\_NOARGS**

Methods without parameters don’t need to check whether arguments are given if they are listed with the \texttt{METH\_NOARGS} flag. They need to be of type \texttt{PyCFunction}. The first parameter is typically named \texttt{self} and will hold a reference to the module or object instance. In all cases the second parameter will be \texttt{NULL}.

**METH\_O**

Methods with a single object argument can be listed with the \texttt{METH\_O} flag, instead of invoking \texttt{PyArg\_ParseTuple()} with a "0" argument. They have the type \texttt{PyCFunction}, with the \texttt{self} parameter, and a \texttt{PyObject*} parameter representing the single argument.

These two constants are not used to indicate the calling convention but the binding when use with methods of classes. These may not be used for functions defined for modules. At most one of these flags may be set for any given method.

**METH\_CLASS**

The method will be passed the type object as the first parameter rather than an instance of the type. This is used to create class methods, similar to what is created when using the \texttt{classmethod()} built-in function.

**METH\_STATIC**
The method will be passed `NULL` as the first parameter rather than an instance of the type. This is used to create static methods, similar to what is created when using the `staticmethod()` built-in function.

One other constant controls whether a method is loaded in place of another definition with the same method name.

**METH_COEXIST**

The method will be loaded in place of existing definitions. Without `METH_COEXIST`, the default is to skip repeated definitions. Since slot wrappers are loaded before the method table, the existence of a `sq_contains` slot, for example, would generate a wrapped method named `__contains__()` and preclude the loading of a corresponding `PyCFunction` with the same name. With the flag defined, the `PyCFunction` will be loaded in place of the wrapper object and will co-exist with the slot. This is helpful because calls to `PyCFunctions` are optimized more than wrapper object calls.

**PyMemberDef**

Structure which describes an attribute of a type which corresponds to a C struct member. Its fields are:

<table>
<thead>
<tr>
<th>Field</th>
<th>C Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>char *</td>
<td>name of the member</td>
</tr>
<tr>
<td>type</td>
<td>int</td>
<td>the type of the member in the C struct</td>
</tr>
<tr>
<td>offset</td>
<td>Py_ssize_t</td>
<td>the offset in bytes that the member is located on the type's object struct</td>
</tr>
<tr>
<td>flags</td>
<td>int</td>
<td>flag bits indicating if the field should be read-only or writable</td>
</tr>
</tbody>
</table>
**type** can be one of many `T_` macros corresponding to various C types. When the member is accessed in Python, it will be converted to the equivalent Python type.

<table>
<thead>
<tr>
<th>Macro name</th>
<th>C type</th>
</tr>
</thead>
<tbody>
<tr>
<td>T_SHORT</td>
<td>short</td>
</tr>
<tr>
<td>T_INT</td>
<td>int</td>
</tr>
<tr>
<td>T_LONG</td>
<td>long</td>
</tr>
<tr>
<td>T_FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>T_DOUBLE</td>
<td>double</td>
</tr>
<tr>
<td>T_STRING</td>
<td>char *</td>
</tr>
<tr>
<td>T_OBJECT</td>
<td>PyObject *</td>
</tr>
<tr>
<td>T_OBJECT_EX</td>
<td>PyObject *</td>
</tr>
<tr>
<td>T_CHAR</td>
<td>char</td>
</tr>
<tr>
<td>T_BYTE</td>
<td>char</td>
</tr>
<tr>
<td>T_UBYTE</td>
<td>unsigned char</td>
</tr>
<tr>
<td>T_UINT</td>
<td>unsigned int</td>
</tr>
<tr>
<td>T_USHORT</td>
<td>unsigned short</td>
</tr>
<tr>
<td>T_ULONG</td>
<td>unsigned long</td>
</tr>
<tr>
<td>T_BOOL</td>
<td>char</td>
</tr>
<tr>
<td>T_LONGLONG</td>
<td>long long</td>
</tr>
<tr>
<td>T_ULONGLONG</td>
<td>unsigned long long</td>
</tr>
<tr>
<td>T_PYSSIZET</td>
<td>Py_ssize_t</td>
</tr>
</tbody>
</table>

`T_OBJECT` and `T_OBJECT_EX` differ in that `T_OBJECT` returns
None if the member is NULL and T_OBJECT_EX raises an AttributeError. Try to use T_OBJECT_EX over T_OBJECT because T_OBJECT_EX handles use of the del statement on that attribute more correctly than T_OBJECT.

flags can be 0 for write and read access or READONLY for read-only access. Using T_STRING for type implies READONLY. Only T_OBJECT and T_OBJECT_EX members can be deleted. (They are set to NULL).
Type Objects

Perhaps one of the most important structures of the Python object system is the structure that defines a new type: the PyTypeObject structure. Type objects can be handled using any of the PyObject_*( ) or PyType_*( ) functions, but do not offer much that's interesting to most Python applications. These objects are fundamental to how objects behave, so they are very important to the interpreter itself and to any extension module that implements new types.

Type objects are fairly large compared to most of the standard types. The reason for the size is that each type object stores a large number of values, mostly C function pointers, each of which implements a small part of the type's functionality. The fields of the type object are examined in detail in this section. The fields will be described in the order in which they occur in the structure.

Typedefs: unaryfunc, binaryfunc, ternaryfunc, inquiry, intargfunc, intintargfunc, intobjargproc, intintobjargproc, objobjargproc, destructor, freefunc, printfunc, getattrfunc, getattrofunc,setattrfunc, setattrofunc, reprfunc, hashfunc

The structure definition for PyTypeObject can be found in Include/object.h. For convenience of reference, this repeats the definition found there:

```c
typedef struct __typeobject {
    PyObject_VAR_HEAD
    char  *tp_name; /* For printing, in format "<module>"*/
    int    tp_basicsize, tp_itemsize; /* For allocation */
    
    /* Methods to implement standard operations */
```
destructor tp_dealloc;
printfunc tp_print;
getattrfunc tp_getattr;
setattrfunc tp_setattr;
void *tp_reserved;
reprfunc tp_repr;

/* Method suites for standard classes */

PyNumberMethods *tp_as_number;
PySequenceMethods *tp_as_sequence;
PyMappingMethods *tp_as_mapping;

/* More standard operations (here for binary compatibility) */

hashfunc tp_hash;
ternaryfunc tp_call;
reprfunc tp_str;
getattrfunc tp_getattro;
setattrfunc tp_setattro;

/* Functions to access object as input/output buffer */
PyBufferProcs *tp_as_buffer;

/* Flags to define presence of optional/expanded features */

long tp_flags;

char *tp_doc; /* Documentation string */

/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
long tp_weaklistoffset;

/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;
descrsetfunc tp_descr_set;
long tp_dictoffset;
initproc tp_init;
allocfunc tp_alloc;
newfunc tp_new;
freefunc tp_free; /* Low-level free-memory routine */
inquiry tp_is_gc; /* For PyObject_IS_GC */
PyObject *tp_bases;
PyObject *tp_mro; /* method resolution order */
PyObject *tp_cache;
PyObject *tp_subclasses;
PyObject *tp_weaklist;

} PyTypeObject;

The type object structure extends the PyVarObject structure. The ob_size field is used for dynamic types (created by type_new(), usually called from a class statement). Note that PyType_Type (the metatype) initializes tp_itemsize, which means that its instances
(i.e. type objects) must have the ob_size field.

**PyObject** PyObject._ob_next
**PyObject** PyObject._ob_prev
These fields are only present when the macro Py_TRACE_REFS is defined. Their initialization to *NULL* is taken care of by the PyObject_HEAD_INIT macro. For statically allocated objects, these fields always remain *NULL*. For dynamically allocated objects, these two fields are used to link the object into a doubly-linked list of all live objects on the heap. This could be used for various debugging purposes; currently the only use is to print the objects that are still alive at the end of a run when the environment variable PYTHONDUMPREFS is set.

These fields are not inherited by subtypes.

**Py_ssize_t** PyObject.ob_refcnt
This is the type object's reference count, initialized to 1 by the PyObject_HEAD_INIT macro. Note that for statically allocated type objects, the type's instances (objects whose ob_type points back to the type) do not count as references. But for dynamically allocated type objects, the instances do count as references.

This field is not inherited by subtypes.

**PyTypeObject** PyObject.ob_type
This is the type's type, in other words its metatype. It is initialized by the argument to the PyObject_HEAD_INIT macro, and its value should normally be &PyType_Type. However, for dynamically loadable extension modules that must be usable on Windows (at least), the compiler complains that this is not a valid initializer. Therefore, the convention is to pass *NULL* to the
PyObject\_HEAD\_INIT macro and to initialize this field explicitly at the start of the module’s initialization function, before doing anything else. This is typically done like this:

```
Foo\_Type.\_ob\_type = &PyType\_Type;
```

This should be done before any instances of the type are created. `PyType\_Ready()` checks if `\_ob\_type` is `NULL`, and if so, initializes it to the `\_ob\_type` field of the base class. `PyType\_Ready()` will not change this field if it is non-zero.

This field is inherited by subtypes.

`Py\_ssize\_t PyVarObject.\_ob\_size`

For statically allocated type objects, this should be initialized to zero. For dynamically allocated type objects, this field has a special internal meaning.

This field is not inherited by subtypes.

`char* PyTypeObject.\_tp\_name`

Pointer to a NUL-terminated string containing the name of the type. For types that are accessible as module globals, the string should be the full module name, followed by a dot, followed by the type name; for built-in types, it should be just the type name. If the module is a submodule of a package, the full package name is part of the full module name. For example, a type named T defined in module M in subpackage Q in package P should have the `\_tp\_name` initializer "P.Q.M.T".

For dynamically allocated type objects, this should just be the type name, and the module name explicitly stored in the type dict as the value for key '__module__'.

For statically allocated type objects, the tp_name field should contain a dot. Everything before the last dot is made accessible as the __module__ attribute, and everything after the last dot is made accessible as the __name__ attribute.

If no dot is present, the entire tp_name field is made accessible as the __name__ attribute, and the __module__ attribute is undefined (unless explicitly set in the dictionary, as explained above). This means your type will be impossible to pickle.

This field is not inherited by subtypes.

Py_ssize_t PyTypeObject.tp_basicsize
Py_ssize_t PyTypeObject.tp_itemsize

These fields allow calculating the size in bytes of instances of the type.

There are two kinds of types: types with fixed-length instances have a zero tp_itemsize field, types with variable-length instances have a non-zero tp_itemsize field. For a type with fixed-length instances, all instances have the same size, given in tp_basicsize.

For a type with variable-length instances, the instances must have an ob_size field, and the instance size is tp_basicsize plus N times tp_itemsize, where N is the “length” of the object. The value of N is typically stored in the instance’s ob_size field. There are exceptions: for example, ints use a negative ob_size to indicate a negative number, and N is abs(ob_size) there. Also, the presence of an ob_size field in the instance layout doesn’t mean that the instance structure is variable-length (for example, the structure for the list type has fixed-length instances, yet those
instances have a meaningful ob_size field).

The basic size includes the fields in the instance declared by the macro `PyObject_HEAD` or `PyObject_VAR_HEAD` (whichever is used to declare the instance struct) and this in turn includes the _ob_prev and _ob_next fields if they are present. This means that the only correct way to get an initializer for the `tp_basicsize` is to use the `sizeof` operator on the struct used to declare the instance layout. The basic size does not include the GC header size.

These fields are inherited separately by subtypes. If the base type has a non-zero `tp_itemsize`, it is generally not safe to set `tp_itemsize` to a different non-zero value in a subtype (though this depends on the implementation of the base type).

A note about alignment: if the variable items require a particular alignment, this should be taken care of by the value of `tp_basicsize`. Example: suppose a type implements an array of double. `tp_itemsize` is `sizeof(double)`. It is the programmer's responsibility that `tp_basicsize` is a multiple of `sizeof(double)` (assuming this is the alignment requirement for double).

destructor `PyTypeObject.tp_dealloc`

A pointer to the instance destructor function. This function must be defined unless the type guarantees that its instances will never be deallocated (as is the case for the singletons None and Ellipsis).

The destructor function is called by the `Py_DECREF()` and `Py_XDECREF()` macros when the new reference count is zero. At
At this point, the instance is still in existence, but there are no references to it. The destructor function should free all references which the instance owns, free all memory buffers owned by the instance (using the freeing function corresponding to the allocation function used to allocate the buffer), and finally (as its last action) call the type's `tp_free` function. If the type is not subtypable (doesn't have the `Py_TPFLAGS_BASETYPE` flag bit set), it is permissible to call the object deallocator directly instead of via `tp_free`. The object deallocator should be the one used to allocate the instance; this is normally `PyObject_Del()` if the instance was allocated using `PyObject_New()` or `PyObject_VarNew()`, or `PyObject_GC_Del()` if the instance was allocated using `PyObject_GC_New()` or `PyObject_GC_NewVar()`.

This field is inherited by subtypes.

**printfunc** `PyTypeObject.tp_print`

An optional pointer to the instance print function.

The print function is only called when the instance is printed to a *real* file; when it is printed to a pseudo-file (like a `io.StringIO` instance), the instance’s `tp_repr` or `tp_str` function is called to convert it to a string. These are also called when the type's `tp_print` field is `NULL`. A type should never implement `tp_print` in a way that produces different output than `tp_repr` or `tp_str` would.

The print function is called with the same signature as `PyObject_Print()`:

```c
int tp_print(PyObject *self, FILE *file, int flags)
```

The `self` argument is the instance to be printed. The `file` argument is the stdio file to which it is to be
The flags argument is composed of flag bits. The only flag bit currently defined is Py_PRINT_RAW. When the Py_PRINT_RAW flag bit is set, the instance should be printed the same way as \texttt{tp\_str} would format it; when the Py_PRINT_RAW flag bit is clear, the instance should be printed the same was as \texttt{tp\_repr} would format it. It should return -1 and set an exception condition when an error occurred during the comparison.

It is possible that the \texttt{tp\_print} field will be deprecated. In any case, it is recommended not to define \texttt{tp\_print}, but instead to rely on \texttt{tp\_repr} and \texttt{tp\_str} for printing.

This field is inherited by subtypes.

\textbf{getattrfunc} \texttt{PyTypeObject\_tp\_getattr}  
An optional pointer to the get-attribute-string function.

This field is deprecated. When it is defined, it should point to a function that acts the same as the \texttt{tp\_getattro} function, but taking a C string instead of a Python string object to give the attribute name. The signature is the same as for \texttt{PyObject\_GetAttrString()}.  

This field is inherited by subtypes together with \texttt{tp\_getattro}: a subtype inherits both \texttt{tp\_getattr} and \texttt{tp\_getattro} from its base type when the subtype's \texttt{tp\_getattr} and \texttt{tp\_getattro} are both \texttt{NULL}.

\textbf{setattrfunc} \texttt{PyTypeObject\_tp\_setattr}  
An optional pointer to the set-attribute-string function.

This field is deprecated. When it is defined, it should point to a function that acts the same as the \texttt{tp\_setattro} function, but
taking a C string instead of a Python string object to give the attribute name. The signature is the same as for PyObject_SetAttrString().

This field is inherited by subtypes together with tp_setattro: a subtype inherits both tp_setattr and tp_setattro from its base type when the subtype's tp_setattr and tp_setattro are both NULL.

void* PyTypeObject.tp_reserved
Reserved slot, formerly known as tp_compare.

reprfunc PyTypeObject.tp_repr
An optional pointer to a function that implements the built-in function repr().

The signature is the same as for PyObject_Repr(); it must return a string or a Unicode object. Ideally, this function should return a string that, when passed to eval(), given a suitable environment, returns an object with the same value. If this is not feasible, it should return a string starting with '<' and ending with '>' from which both the type and the value of the object can be deduced.

When this field is not set, a string of the form <%s object at %p> is returned, where %s is replaced by the type name, and %p by the object's memory address.

This field is inherited by subtypes.

PyNumberMethods* tp_as_number
Pointer to an additional structure that contains fields relevant only to objects which implement the number protocol. These fields are
documented in *Number Object Structures*.

The `tp_as_number` field is not inherited, but the contained fields are inherited individually.

**PySequenceMethods**\* `tp_as_sequence`  
Pointer to an additional structure that contains fields relevant only to objects which implement the sequence protocol. These fields are documented in *Sequence Object Structures*.

The `tp_as_sequence` field is not inherited, but the contained fields are inherited individually.

**PyMappingMethods**\* `tp_as_mapping`  
Pointer to an additional structure that contains fields relevant only to objects which implement the mapping protocol. These fields are documented in *Mapping Object Structures*.

The `tp_as_mapping` field is not inherited, but the contained fields are inherited individually.

**hashfunc** `PyTypeObject.tp_hash`  
An optional pointer to a function that implements the built-in function `hash()`. The signature is the same as for `PyObject_HASH()`; it must return a value of the type `Py_hash_t`. The value `-1` should not be returned as a normal return value; when an error occurs during the computation of the hash value, the function should set an exception and return `-1`.

This field can be set explicitly to `PyObject_HASH_NotImplemented()` to block inheritance of the
hash method from a parent type. This is interpreted as the equivalent of `__hash__ = None` at the Python level, causing `isinstance(o, collections.Hashable)` to correctly return False. Note that the converse is also true - setting `__hash__ = None` on a class at the Python level will result in the `tp_hash` slot being set to `PyObject_HashNotImplemented()`.

When this field is not set, an attempt to take the hash of the object raises `TypeError`.

This field is inherited by subtypes together with `tp_richcompare`: a subtype inherits both of `tp_richcompare` and `tp_hash`, when the subtype’s `tp_richcompare` and `tp_hash` are both `NULL`.

ternaryfunc **PyTypeObject.tp_call**

An optional pointer to a function that implements calling the object. This should be `NULL` if the object is not callable. The signature is the same as for `PyObject_Call()`.

This field is inherited by subtypes.

reprfunc **PyTypeObject.tp_str**

An optional pointer to a function that implements the built-in operation `str()`. (Note that `str` is a type now, and `str()` calls the constructor for that type. This constructor calls `PyObject_Str()` to do the actual work, and `PyObject_Str()` will call this handler.)

The signature is the same as for `PyObject_Str()`; it must return a string or a Unicode object. This function should return a “friendly” string representation of the object, as this is the representation that will be used, among other things, by the `print()` function.
When this field is not set, \texttt{PyObject\_Repr()} is called to return a string representation.

This field is inherited by subtypes.

\textbf{getattrofunc} \texttt{PyTypeObject.tp\_getattro}

An optional pointer to the get-attribute function.

The signature is the same as for \texttt{PyObject\_GetAttr()}. It is usually convenient to set this field to \texttt{PyObject\_GenericGetAttr()}, which implements the normal way of looking for object attributes.

This field is inherited by subtypes together with \texttt{tp\_getattr}: a subtype inherits both \texttt{tp\_getattr} and \texttt{tp\_getattro} from its base type when the subtype's \texttt{tp\_getattr} and \texttt{tp\_getattro} are both \texttt{NULL}.

\textbf{setattrofunc} \texttt{PyTypeObject.tp\_setattro}

An optional pointer to the set-attribute function.

The signature is the same as for \texttt{PyObject\_SetAttr()}. It is usually convenient to set this field to \texttt{PyObject\_GenericSetAttr()}, which implements the normal way of setting object attributes.

This field is inherited by subtypes together with \texttt{tp\_setattr}: a subtype inherits both \texttt{tp\_setattr} and \texttt{tp\_setattro} from its base type when the subtype's \texttt{tp\_setattr} and \texttt{tp\_setattro} are both \texttt{NULL}.

\textbf{PyBufferProcs*} \texttt{PyTypeObject.tp\_as\_buffer}

Pointer to an additional structure that contains fields relevant only
to objects which implement the buffer interface. These fields are documented in *Buffer Object Structures*.

The `tp_as_buffer` field is not inherited, but the contained fields are inherited individually.

**long `PyTypeObject.tp_flags`**

This field is a bit mask of various flags. Some flags indicate variant semantics for certain situations; others are used to indicate that certain fields in the type object (or in the extension structures referenced via `tp_as_number`, `tp_as_sequence`, `tp_as_mapping`, and `tp_as_buffer`) that were historically not always present are valid; if such a flag bit is clear, the type fields it guards must not be accessed and must be considered to have a zero or `NULL` value instead.

Inheritance of this field is complicated. Most flag bits are inherited individually, i.e. if the base type has a flag bit set, the subtype inherits this flag bit. The flag bits that pertain to extension structures are strictly inherited if the extension structure is inherited, i.e. the base type’s value of the flag bit is copied into the subtype together with a pointer to the extension structure. The `Py_TPFLAGS_HAVE_GC` flag bit is inherited together with the `tp_traverse` and `tp_clear` fields, i.e. if the `Py_TPFLAGS_HAVE_GC` flag bit is clear in the subtype and the `tp_traverse` and `tp_clear` fields in the subtype exist and have `NULL` values.

The following bit masks are currently defined; these can be ORed together using the `|` operator to form the value of the `tp_flags` field. The macro `PyType_HasFeature()` takes a type and a flags value, `tp` and `f`, and checks whether `tp->tp_flags & f` is non-
zero.

**Py_TPFLAGS_HEAPTYPE**

This bit is set when the type object itself is allocated on the heap. In this case, the ob_type field of its instances is considered a reference to the type, and the type object is INCREF'ed when a new instance is created, and DECREF'ed when an instance is destroyed (this does not apply to instances of subtypes; only the type referenced by the instance's ob_type gets INCREF'ed or DECREF'ed).

**Py_TPFLAGS_BASETYPE**

This bit is set when the type can be used as the base type of another type. If this bit is clear, the type cannot be subtyped (similar to a “final” class in Java).

**Py_TPFLAGS_READY**

This bit is set when the type object has been fully initialized by `PyType_Ready()`.

**Py_TPFLAGS_READYING**

This bit is set while `PyType_Ready()` is in the process of initializing the type object.

**Py_TPFLAGS_HAVE_GC**

This bit is set when the object supports garbage collection. If this bit is set, instances must be created using `PyObject_GC_New()` and destroyed using `PyObject_GC_Del()`. More information in section Supporting Cyclic Garbage Collection. This bit also implies that the GC-related fields `tp_traverse` and `tp_clear` are present in the type object.
\textbf{Py\_TPFLAGS\_DEFAULT}

This is a bitmask of all the bits that pertain to the existence of certain fields in the type object and its extension structures. Currently, it includes the following bits: 
\texttt{Py\_TPFLAGS\_HAVE\_STACKLESS\_EXTENSION}, 
\texttt{Py\_TPFLAGS\_HAVE\_VERSION\_TAG}.

\texttt{char* PyTypeObject\_tp\_doc}

An optional pointer to a NUL-terminated C string giving the docstring for this type object. This is exposed as the \_\_doc\_\_ attribute on the type and instances of the type.

This field is \textit{not} inherited by subtypes.

\texttt{traverseproc PyTypeObject\_tp\_traverse}

An optional pointer to a traversal function for the garbage collector. This is only used if the \texttt{Py\_TPFLAGS\_HAVE\_GC} flag bit is set. More information about Python’s garbage collection scheme can be found in section \textit{Supporting Cyclic Garbage Collection}.

The \texttt{tp\_traverse} pointer is used by the garbage collector to detect reference cycles. A typical implementation of a \texttt{tp\_traverse} function simply calls \texttt{Py\_VISIT()} on each of the instance’s members that are Python objects. For example, this is function \texttt{local\_traverse()} from the \_\_thread\_ extension module:

\begin{verbatim}
static int local_traverse(localobject *self, visitproc visit
{
    Py_VISIT(self->args);
    Py_VISIT(self->kw);
    Py_VISIT(self->dict);
\end{verbatim}
Note that `Py_VISIT()` is called only on those members that can participate in reference cycles. Although there is also a `self- >key` member, it can only be `NULL` or a Python string and therefore cannot be part of a reference cycle.

On the other hand, even if you know a member can never be part of a cycle, as a debugging aid you may want to visit it anyway just so the `gc` module’s `get_referents()` function will include it.

Note that `Py_VISIT()` requires the `visit` and `arg` parameters to `local_traverse()` to have these specific names; don’t name them just anything.

This field is inherited by subtypes together with `tp_clear` and the `Py_TPFLAGS_HAVE_GC` flag bit: the flag bit, `tp_traverse`, and `tp_clear` are all inherited from the base type if they are all zero in the subtype.

**inquiry** `PyTypeObject.tp_clear`

An optional pointer to a clear function for the garbage collector. This is only used if the `Py_TPFLAGS_HAVE_GC` flag bit is set.

The `tp_clear` member function is used to break reference cycles in cyclic garbage detected by the garbage collector. Taken together, all `tp_clear` functions in the system must combine to break all reference cycles. This is subtle, and if in any doubt supply a `tp_clear` function. For example, the tuple type does not implement a `tp_clear` function, because it’s possible to prove that no reference cycle can be composed entirely of tuples.
Therefore the `tp_clear` functions of other types must be sufficient to break any cycle containing a tuple. This isn't immediately obvious, and there's rarely a good reason to avoid implementing `tp_clear`.

Implementations of `tp_clear` should drop the instance's references to those of its members that may be Python objects, and set its pointers to those members to `NULL`, as in the following example:

```c
static int local_clear(localobject *self)
{
    Py_CLEAR(self->key);
    Py_CLEAR(self->args);
    Py_CLEAR(self->kw);
    Py_CLEAR(self->dict);
    return 0;
}
```

The `Py_CLEAR()` macro should be used, because clearing references is delicate: the reference to the contained object must not be decremented until after the pointer to the contained object is set to `NULL`. This is because decrementing the reference count may cause the contained object to become trash, triggering a chain of reclamation activity that may include invoking arbitrary Python code (due to finalizers, or weakref callbacks, associated with the contained object). If it's possible for such code to reference `self` again, it's important that the pointer to the contained object be `NULL` at that time, so that `self` knows the contained object can no longer be used. The `Py_CLEAR()` macro performs the operations in a safe order.
Because the goal of \texttt{tp\_clear} functions is to break reference cycles, it's not necessary to clear contained objects like Python strings or Python integers, which can't participate in reference cycles. On the other hand, it may be convenient to clear all contained Python objects, and write the type's \texttt{tp\_dealloc} function to invoke \texttt{tp\_clear}.

More information about Python's garbage collection scheme can be found in section \textit{Supporting Cyclic Garbage Collection}.

This field is inherited by subtypes together with \texttt{tp\_traverse} and the \texttt{Py\_TPFLAGS\_HAVE\_GC} flag bit: the flag bit, \texttt{tp\_traverse}, and \texttt{tp\_clear} are all inherited from the base type if they are all zero in the subtype.

\textbf{richcmpfunc} \texttt{PyTypeObject.tp\_richcompare}

An optional pointer to the rich comparison function, whose signature is \texttt{PyObject*tp\_richcompare(PyObject*a, \PyObj**b, int op)}.

The function should return the result of the comparison (usually \texttt{Py\_True} or \texttt{Py\_False}). If the comparison is undefined, it must return \texttt{Py\_NotImplemented}, if another error occurred it must return \texttt{NULL} and set an exception condition.

\textbf{Note:} If you want to implement a type for which only a limited set of comparisons makes sense (e.g. \texttt{==} and \texttt{!\=} , but not \texttt{<} and friends), directly raise \texttt{TypeError} in the rich comparison function.

This field is inherited by subtypes together with \texttt{tp\_hash}: a subtype inherits \texttt{tp\_richcompare} and \texttt{tp\_hash} when the
subtype's `tp_richcompare` and `tp_hash` are both `NULL`.

The following constants are defined to be used as the third argument for `tp_richcompare` and for `PyObject_RichCompare()`:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Comparison</th>
</tr>
</thead>
<tbody>
<tr>
<td>Py_LT</td>
<td>&lt;</td>
</tr>
<tr>
<td>Py_LE</td>
<td>&lt;=</td>
</tr>
<tr>
<td>Py_EQ</td>
<td>==</td>
</tr>
<tr>
<td>Py_NE</td>
<td>!=</td>
</tr>
<tr>
<td>Py_GT</td>
<td>&gt;</td>
</tr>
<tr>
<td>Py_GE</td>
<td>&gt;=</td>
</tr>
</tbody>
</table>

`long PyTypeObject.tp_weaklistoffset`

If the instances of this type are weakly referenceable, this field is greater than zero and contains the offset in the instance structure of the weak reference list head (ignoring the GC header, if present); this offset is used by `PyObject_ClearWeakRefs()` and the `PyWeakref_*()` functions. The instance structure needs to include a field of type `PyObject*` which is initialized to `NULL`.

Do not confuse this field with `tp_weaklist`; that is the list head for weak references to the type object itself.

This field is inherited by subtypes, but see the rules listed below. A subtype may override this offset; this means that the subtype uses a different weak reference list head than the base type. Since the list head is always found via `tp_weaklistoffset`, this should not be a problem.
When a type defined by a class statement has no "__slots__" declaration, and none of its base types are weakly referenceable, the type is made weakly referenceable by adding a weak reference list head slot to the instance layout and setting the `tp_weaklistoffset` of that slot's offset.

When a type's "__slots__" declaration contains a slot named "__weakref__", that slot becomes the weak reference list head for instances of the type, and the slot's offset is stored in the type's `tp_weaklistoffset`.

When a type's "__slots__" declaration does not contain a slot named "__weakref__", the type inherits its `tp_weaklistoffset` from its base type.

**getiterfunc** `PyTypeObject.tp_iter`

An optional pointer to a function that returns an iterator for the object. Its presence normally signals that the instances of this type are iterable (although sequences may be iterable without this function).

This function has the same signature as `PyObject_GetIter()`.

This field is inherited by subtypes.

**iternextfunc** `PyTypeObject.tp_iternext`

An optional pointer to a function that returns the next item in an iterator. When the iterator is exhausted, it must return `NULL`; a `StopIteration` exception may or may not be set. When another error occurs, it must return `NULL` too. Its presence signals that the instances of this type are iterators.

Iterator types should also define the `tp_iter` function, and that
function should return the iterator instance itself (not a new iterator instance).

This function has the same signature as `PyIter_Next()`.

This field is inherited by subtypes.

```c
struct PyMethodDef* PyTypeObject.tp_methods
```
An optional pointer to a static `NULL`-terminated array of `PyMethodDef` structures, declaring regular methods of this type.

For each entry in the array, an entry is added to the type's dictionary (see `tp_dict` below) containing a method descriptor.

This field is not inherited by subtypes (methods are inherited through a different mechanism).

```c
struct PyMemberDef* PyTypeObject.tp_members
```
An optional pointer to a static `NULL`-terminated array of `PyMemberDef` structures, declaring regular data members (fields or slots) of instances of this type.

For each entry in the array, an entry is added to the type's dictionary (see `tp_dict` below) containing a member descriptor.

This field is not inherited by subtypes (members are inherited through a different mechanism).

```c
struct PyGetSetDef* PyTypeObject.tp_getset
```
An optional pointer to a static `NULL`-terminated array of `PyGetSetDef` structures, declaring computed attributes of instances of this type.

For each entry in the array, an entry is added to the type's
dictionary (see `tp_dict` below) containing a getset descriptor.

This field is not inherited by subtypes (computed attributes are inherited through a different mechanism).

Docs for PyGetSetDef:

```c
typedef PyObject *(*getter)(PyObject *, void *);
typedef int (*setter)(PyObject *, PyObject *, void *);

typedef struct PyGetSetDef {
    char *name;   /* attribute name */
    getter get;   /* C function to get the attribute */
    setter set;   /* C function to set the attribute */
    char *doc;    /* optional doc string */
    void *closure; /* optional additional data for getter and setter */
} PyGetSetDef;
```

PyTypeObject* `PyTypeObject.tp_base`

An optional pointer to a base type from which type properties are inherited. At this level, only single inheritance is supported; multiple inheritance require dynamically creating a type object by calling the metatype.

This field is not inherited by subtypes (obviously), but it defaults to `&PyBaseObject_Type` (which to Python programmers is known as the type `object`).

PyObject* `PyTypeObject.tp_dict`

The type’s dictionary is stored here by `PyType_Ready()`.

This field should normally be initialized to `NULL` before `PyType_Ready` is called; it may also be initialized to a dictionary containing initial attributes for the type. Once `PyType_Ready()`
has initialized the type, extra attributes for the type may be added to this dictionary only if they don't correspond to overloaded operations (like `__add__( )`).

This field is not inherited by subtypes (though the attributes defined in here are inherited through a different mechanism).

**Warning:** It is not safe to use `PyDict_SetItem()` on or otherwise modify `tp_dict` with the dictionary C-API.

descrgetfunc **PyTypeObject.tp_descr_get**

An optional pointer to a “descriptor get” function.

The function signature is

```c
PyObject * tp_descr_get(PyObject *self, PyObject * obst, PyObject *ann)
```

This field is inherited by subtypes.

descrsetfunc **PyTypeObject.tp_descr_set**

An optional pointer to a “descriptor set” function.

The function signature is

```c
int tp_descr_set(PyObject *self, PyObject *obj, PyObject *ann)
```

This field is inherited by subtypes.

`long PyTypeObject.tp_dictoffset`

If the instances of this type have a dictionary containing instance variables, this field is non-zero and contains the offset in the instances of the type of the instance variable dictionary; this offset
is used by \texttt{PyObject\_GenericGetAttr()}. 

Do not confuse this field with \texttt{tp\_dict}; that is the dictionary for attributes of the type object itself.

If the value of this field is greater than zero, it specifies the offset from the start of the instance structure. If the value is less than zero, it specifies the offset from the \textit{end} of the instance structure. A negative offset is more expensive to use, and should only be used when the instance structure contains a variable-length part. This is used for example to add an instance variable dictionary to subtypes of \texttt{str} or \texttt{tuple}. Note that the \texttt{tp\_basicsize} field should account for the dictionary added to the end in that case, even though the dictionary is not included in the basic object layout. On a system with a pointer size of 4 bytes, \texttt{tp\_dictoffset} should be set to -4 to indicate that the dictionary is at the very end of the structure.

The real dictionary offset in an instance can be computed from a negative \texttt{tp\_dictoffset} as follows:

```
\texttt{dictoffset = \texttt{tp\_basicsize} + abs(\texttt{ob\_size})\*\texttt{tp\_items}}
\texttt{if \texttt{dictoffset} is not aligned on \texttt{sizeof(void*)}:}
\texttt{   round up to \texttt{sizeof(void*)}}
```

where \texttt{tp\_basicsize}, \texttt{tp\_itemsize} and \texttt{tp\_dictoffset} are taken from the type object, and \texttt{ob\_size} is taken from the instance. The absolute value is taken because ints use the sign of \texttt{ob\_size} to store the sign of the number. (There's never a need to do this calculation yourself; it is done for you by \_\texttt{PyObject\_GetDictPtr()}.)
This field is inherited by subtypes, but see the rules listed below. A subtype may override this offset; this means that the subtype instances store the dictionary at a difference offset than the base type. Since the dictionary is always found via \texttt{tp\_dictoffset}, this should not be a problem.

When a type defined by a class statement has no \texttt{__slots__} declaration, and none of its base types has an instance variable dictionary, a dictionary slot is added to the instance layout and the \texttt{tp\_dictoffset} is set to that slot’s offset.

When a type defined by a class statement has a \texttt{__slots__} declaration, the type inherits its \texttt{tp\_dictoffset} from its base type.

(Adding a slot named \texttt{__dict__} to the \texttt{__slots__} declaration does not have the expected effect, it just causes confusion. Maybe this should be added as a feature just like \texttt{__weakref__} though.)

\textbf{initproc} \texttt{PyTypeObject\_tp\_init} \\
An optional pointer to an instance initialization function.

This function corresponds to the \texttt{\_\_init\_()} method of classes. Like \texttt{\_\_init\_()}, it is possible to create an instance without calling \texttt{\_\_init\_()}, and it is possible to reinitialize an instance by calling its \texttt{\_\_init\_()} method again.

The function signature is

\begin{verbatim}
int tp_init(PyObject *self, PyObject *args, PyObject *)
\end{verbatim}

The self argument is the instance to be initialized; the \texttt{args} and
kwds arguments represent positional and keyword arguments of the call to \_\_init\_().

The \texttt{tp\_init} function, if not \texttt{NULL}, is called when an instance is created normally by calling its type, after the type’s \texttt{tp\_new} function has returned an instance of the type. If the \texttt{tp\_new} function returns an instance of some other type that is not a subtype of the original type, no \texttt{tp\_init} function is called; if \texttt{tp\_new} returns an instance of a subtype of the original type, the subtype’s \texttt{tp\_init} is called.

This field is inherited by subtypes.

\textbf{allocfunc} \texttt{PyTypeObject.tp\_alloc}

An optional pointer to an instance allocation function.

The function signature is

\begin{verbatim}
PyObject *tp_alloc(PyTypeObject *self, Py_ssize_t nitems)
\end{verbatim}

The purpose of this function is to separate memory allocation from memory initialization. It should return a pointer to a block of memory of adequate length for the instance, suitably aligned, and initialized to zeros, but with \texttt{ob\_refcnt} set to 1 and \texttt{ob\_type} set to the type argument. If the type's \texttt{tp\_itemsize} is non-zero, the object's \texttt{ob\_size} field should be initialized to \texttt{nitems} and the length of the allocated memory block should be \texttt{tp\_basicsize + nitems*tp\_itemsize}, rounded up to a multiple of \texttt{sizeof(void*)}; otherwise, \texttt{nitems} is not used and the length of the block should be \texttt{tp\_basicsize}.

Do not use this function to do any other instance initialization, not
even to allocate additional memory; that should be done by `tp_new`.

This field is inherited by static subtypes, but not by dynamic subtypes (subtypes created by a class statement); in the latter, this field is always set to `PyType_GenericAlloc()`, to force a standard heap allocation strategy. That is also the recommended value for statically defined types.

### newfunc `PyTypeObject.tp_new`

An optional pointer to an instance creation function.

If this function is `NULL` for a particular type, that type cannot be called to create new instances; presumably there is some other way to create instances, like a factory function.

The function signature is

```c
PyObject *tp_new(PyTypeObject *subtype, PyObject *);  
```

The subtype argument is the type of the object being created; the `args` and `kwds` arguments represent positional and keyword arguments of the call to the type. Note that subtype doesn’t have to equal the type whose `tp_new` function is called; it may be a subtype of that type (but not an unrelated type).

The `tp_new` function should call `subtype->tp_alloc(subtype, nitems)` to allocate space for the object, and then do only as much further initialization as is absolutely necessary. Initialization that can safely be ignored or repeated should be placed in the `tp_init` handler. A good rule of thumb is that for immutable types, all initialization should take place in
While for mutable types, most initialization should be deferred to \texttt{tp_init}.

This field is inherited by subtypes, except it is not inherited by static types whose \texttt{tp_base} is \texttt{NULL} or \&\texttt{PyBaseObject_Type}.

**Destructor** \texttt{PyTypeObject.tp_free}

An optional pointer to an instance deallocation function. Its signature is \texttt{freefunc}:

\begin{verbatim}
void tp_free(void *)
\end{verbatim}

An initializer that is compatible with this signature is \texttt{PyObject_Free()}.

This field is inherited by static subtypes, but not by dynamic subtypes (subtypes created by a class statement); in the latter, this field is set to a deallocator suitable to match \texttt{PyType_GenericAlloc()} and the value of the \texttt{Py_TPFLAGS_HAVE_GC} flag bit.

**Inquiry** \texttt{PyTypeObject.tp_is_gc}

An optional pointer to a function called by the garbage collector.

The garbage collector needs to know whether a particular object is collectible or not. Normally, it is sufficient to look at the object's type's \texttt{tp_flags} field, and check the \texttt{Py_TPFLAGS_HAVE_GC} flag bit. But some types have a mixture of statically and dynamically allocated instances, and the statically allocated instances are not collectible. Such types should define this function; it should return 1 for a collectible instance, and 0 for a non-collectible instance. The signature is
```c
int tp_is_gc(PyObject *self)
```

(The only example of this are types themselves. The metatype, `PyType_Type`, defines this function to distinguish between statically and dynamically allocated types.)

This field is inherited by subtypes.

`PyObject* PyTypeObject.tp_bases`  
Tuple of base types.

This is set for types created by a class statement. It should be `NULL` for statically defined types.

This field is not inherited.

`PyObject* PyTypeObject.tp_mro`  
Tuple containing the expanded set of base types, starting with the type itself and ending with `object`, in Method Resolution Order.

This field is not inherited; it is calculated fresh by `PyType_Ready()`.

`PyObject* PyTypeObject.tp_cache`  
Unused. Not inherited. Internal use only.

`PyObject* PyTypeObject.tp_subclasses`  
List of weak references to subclasses. Not inherited. Internal use only.

`PyObject* PyTypeObject.tp_weaklist`  
Weak reference list head, for weak references to this type object. Not inherited. Internal use only.
The remaining fields are only defined if the feature test macro COUNT_ALLOC is defined, and are for internal use only. They are documented here for completeness. None of these fields are inherited by subtypes.

**Py_size_t PyTypeObject.tp_allocs**
Number of allocations.

**Py_size_t PyTypeObject.tp_frees**
Number of frees.

**Py_size_t PyTypeObject.tp_maxalloc**
Maximum simultaneously allocated objects.

**PyTypeObject* PyTypeObject.tp_next**
Pointer to the next type object with a non-zero tp_allocs field.

Also, note that, in a garbage collected Python, tp_dealloc may be called from any Python thread, not just the thread which created the object (if the object becomes part of a refcount cycle, that cycle might be collected by a garbage collection on any thread). This is not a problem for Python API calls, since the thread on which tp_dealloc is called will own the Global Interpreter Lock (GIL). However, if the object being destroyed in turn destroys objects from some other C or C++ library, care should be taken to ensure that destroying those objects on the thread which called tp_dealloc will not violate any assumptions of the library.
Number Object Structures

PyNumberMethods

This structure holds pointers to the functions which an object uses to implement the number protocol. Each function is used by the function of similar name documented in the Number Protocol section.

Here is the structure definition:

```c
typedef struct {
    binaryfunc nb_add;
    binaryfunc nb_subtract;
    binaryfunc nb_multiply;
    binaryfunc nb_remainder;
    binaryfunc nb_divmod;
    ternaryfunc nb_power;
    unaryfunc nb_negative;
    unaryfunc nb_positive;
    unaryfunc nb_absolute;
    inquiry nb_bool;
    unaryfunc nb_invert;
    binaryfunc nb_lshift;
    binaryfunc nb_rshift;
    binaryfunc nb_and;
    binaryfunc nb_xor;
    binaryfunc nb_or;
    unaryfunc nb_int;
    void *nb_reserved;
    unaryfunc nb_float;
    binaryfunc nb_inplace_add;
    binaryfunc nb_inplace_subtract;
    binaryfunc nb_inplace_multiply;
} PyNumberMethods;
```
Note: Binary and ternary functions must check the type of all their operands, and implement the necessary conversions (at least one of the operands is an instance of the defined type). If the operation is not defined for the given operands, binary and ternary functions must return Py_NotImplemented, if another error occurred they must return NULL and set an exception.

Note: The nb_reserved field should always be NULL. It was previously called nb_long, and was renamed in Python 3.0.1.
Mapping Object Structures

**PyMappingMethods**

This structure holds pointers to the functions which an object uses to implement the mapping protocol. It has three members:

**lenfunc PyMappingMethods.mp_length**

This function is used by `PyMapping_Length()` and `PyObject_Size()`, and has the same signature. This slot may be set to `NULL` if the object has no defined length.

**binaryfunc PyMappingMethods.mp_subscript**

This function is used by `PyObject_GetItem()` and has the same signature. This slot must be filled for the `PyMapping_Check()` function to return 1, it can be `NULL` otherwise.

**objobjargproc PyMappingMethods.mp_ass_subscript**

This function is used by `PyObject_SetItem()` and has the same signature. If this slot is `NULL`, the object does not support item assignment.
Sequence Object Structures

**PySequenceMethods**

This structure holds pointers to the functions which an object uses to implement the sequence protocol.

**lenfunc PySequenceMethods.sq_length**

This function is used by `PySequence_Size()` and `PyObject_Size()`, and has the same signature.

**binaryfunc PySequenceMethods.sq_concat**

This function is used by `PySequence_Concat()` and has the same signature. It is also used by the `+` operator, after trying the numeric addition via the `nb_add` slot.

**ssizeargfunc PySequenceMethods.sq_repeat**

This function is used by `PySequence_Repeat()` and has the same signature. It is also used by the `*` operator, after trying numeric multiplication via the `nb_mul` slot.

**ssizeargfunc PySequenceMethods.sq_item**

This function is used by `PySequence_GetItem()` and has the same signature. This slot must be filled for the `PySequence_Check()` function to return 1, it can be `NULL` otherwise.

Negative indexes are handled as follows: if the `sq_length` slot is filled, it is called and the sequence length is used to compute a positive index which is passed to `sq_item`. If `sq_length` is `NULL`, the index is passed as is to the function.
ssizeobjargproc \textbf{PySequenceMethods.sq\_ass\_item}

This function is used by \texttt{PySequence\_SetItem()} and has the same signature. This slot may be left to \texttt{NULL} if the object does not support item assignment.

objobjproc \textbf{PySequenceMethods.sq\_contains}

This function may be used by \texttt{PySequence\_Contains()} and has the same signature. This slot may be left to \texttt{NULL}, in this case \texttt{PySequence\_Contains()} simply traverses the sequence until it finds a match.

binaryfunc \textbf{PySequenceMethods.sq\_inplace\_concat}

This function is used by \texttt{PySequence\_InPlaceConcat()} and has the same signature. It should modify its first operand, and return it.

ssizeargfunc \textbf{PySequenceMethods.sq\_inplace\_repeat}

This function is used by \texttt{PySequence\_InPlaceRepeat()} and has the same signature. It should modify its first operand, and return it.
Buffer Object Structures

**PyBufferProcs**

This structure holds pointers to the functions required by the *Buffer protocol*. The protocol defines how an exporter object can expose its internal data to consumer objects.

getbufferproc **PyBufferProcs.bf_getbuffer**

The signature of this function is:

```
int (PyObject *exporter, Py_buffer *view, int flags)
```

Handle a request to `exporter` to fill in `view` as specified by `flags`. Except for point (3), an implementation of this function MUST take these steps:

1. Check if the request can be met. If not, raise `PyExc_BufferError`, set `view->obj` to `NULL` and return -1.
2. Fill in the requested fields.
3. Increment an internal counter for the number of exports.
4. Set `view->obj` to `exporter` and increment `view->obj`.
5. Return 0.

If `exporter` is part of a chain or tree of buffer providers, two main schemes can be used:

- Re-export: Each member of the tree acts as the exporting object and sets `view->obj` to a new reference to itself.
- Redirect: The buffer request is redirected to the root object of the tree. Here, `view->obj` will be a new reference to the root object.
The individual fields of view are described in section Buffer structure, the rules how an exporter must react to specific requests are in section Buffer request types.

All memory pointed to in the Py_buffer structure belongs to the exporter and must remain valid until there are no consumers left. format, shape, strides, suboffsets and internal are read-only for the consumer.

PyBuffer_FillInfo() provides an easy way of exposing a simple bytes buffer while dealing correctly with all request types.

PyObject_GetBuffer() is the interface for the consumer that wraps this function.

releasebufferproc PyBufferProcs.bf_releasebuffer

The signature of this function is:

```c
void (PyObject *exporter, Py_buffer *view);
```

Handle a request to release the resources of the buffer. If no resources need to be released, PyBufferProcs.bf_releasebuffer may be NULL. Otherwise, a standard implementation of this function will take these optional steps:

1. Decrement an internal counter for the number of exports.
2. If the counter is 0, free all memory associated with view.

The exporter MUST use the internal field to keep track of buffer-specific resources. This field is guaranteed to remain constant, while a consumer MAY pass a copy of the original buffer as the view argument.
This function MUST NOT decrement view->obj, since that is done automatically in \texttt{PyBuffer\_Release()} (this scheme is useful for breaking reference cycles).

\texttt{PyBuffer\_Release()} is the interface for the consumer that wraps this function.
Supporting Cyclic Garbage Collection

Python’s support for detecting and collecting garbage which involves circular references requires support from object types which are “containers” for other objects which may also be containers. Types which do not store references to other objects, or which only store references to atomic types (such as numbers or strings), do not need to provide any explicit support for garbage collection.

To create a container type, the tp_flags field of the type object must include the Py_TPFLAGS_HAVE_GC and provide an implementation of the tp_traverse handler. If instances of the type are mutable, a tp_clear implementation must also be provided.

**Py_TPFLAGS_HAVE_GC**

Objects with a type with this flag set must conform with the rules documented here. For convenience these objects will be referred to as container objects.

Constructors for container types must conform to two rules:

1. The memory for the object must be allocated using PyObject_GC_New() or PyObject_GC_NewVar().
2. Once all the fields which may contain references to other containers are initialized, it must call PyObject_GC_Track().

TYPE* **PyObject_GC_New**(TYPE, PyTypeObject *type)

Analogous to PyObject_New() but for container objects with the Py_TPFLAGS_HAVE_GC flag set.
TYPE* `PyObject_GC_NewVar`(TYPE, PyTypeObject *type, Py_ssize_t size)

Analogous to `PyObject_NewVar()` but for container objects with the `Py_TPFLAGS_HAVE_GC` flag set.

TYPE* `PyObject_GC_Resize`(TYPE, PyVarObject *op, Py_ssize_t newsize)

Resize an object allocated by `PyObject_NewVar()`. Returns the resized object or `NULL` on failure.

void `PyObject_GC_Track`(PyObject *op)

Adds the object `op` to the set of container objects tracked by the collector. The collector can run at unexpected times so objects must be valid while being tracked. This should be called once all the fields followed by the `tp_traverse` handler become valid, usually near the end of the constructor.

void `_PyObject_GC_TRACK`(PyObject *op)

A macro version of `PyObject_GC_Track()`. It should not be used for extension modules.

Similarly, the deallocator for the object must conform to a similar pair of rules:

1. Before fields which refer to other containers are invalidated, `PyObject_GC_UnTrack()` must be called.
2. The object’s memory must be deallocated using `PyObject_GC_Del()`.

void `PyObject_GC_Del`(void *op)

Releases memory allocated to an object using `PyObject_GC_New()` or `PyObject_GC_NewVar()`.
void **PyObject_GC_UnTrack**(void *op)

Remove the object *op* from the set of container objects tracked by the collector. Note that **PyObject_GC_Track()** can be called again on this object to add it back to the set of tracked objects. The deallocator (**tp_dealloc** handler) should call this for the object before any of the fields used by the **tp_traverse** handler become invalid.

void **_PyObject_GC_UNTRACK**(PyObject *op)

A macro version of **PyObject_GC_UnTrack()**. It should not be used for extension modules.

The **tp_traverse** handler accepts a function parameter of this type:

int (**visitproc**)(PyObject *object, void *arg)

Type of the visitor function passed to the **tp_traverse** handler. The function should be called with an object to traverse as *object* and the third parameter to the **tp_traverse** handler as *arg*. The Python core uses several visitor functions to implement cyclic garbage detection; it's not expected that users will need to write their own visitor functions.

The **tp_traverse** handler must have the following type:

int (**traverseproc**)(PyObject *self, visitproc visit, void *arg)

Traversal function for a container object. Implementations must call the *visit* function for each object directly contained by *self*, with the parameters to *visit* being the contained object and the *arg* value passed to the handler. The *visit* function must not be called with a **NULL** object argument. If *visit* returns a non-zero value that value should be returned immediately.
To simplify writing `tp_traverse` handlers, a `Py_VISIT()` macro is provided. In order to use this macro, the `tp_traverse` implementation must name its arguments exactly `visit` and `arg`:

```c
void Py_VISIT(PyObject *o)
    Call the visit callback, with arguments o and arg. If visit returns a non-zero value, then return it. Using this macro, `tp_traverse` handlers look like:

    static int
    my_traverse(Noddy *self, visitproc visit, void *a
    {
        Py_VISIT(self->foo);
        Py_VISIT(self->bar);
        return 0;
    }
```

The `tp_clear` handler must be of the `inquiry` type, or `NULL` if the object is immutable.

```c
int (*inquiry)(PyObject *self)
    Drop references that may have created reference cycles. Immutable objects do not have to define this method since they can never directly create reference cycles. Note that the object must still be valid after calling this method (don’t just call `PyDECREF()` on a reference). The collector will call this method if it detects that this object is involved in a reference cycle.
```
API and ABI Versioning

PY_VERSION_HEX is the Python version number encoded in a single integer.

For example if the PY_VERSION_HEX is set to 0x030401a2, the underlying version information can be found by treating it as a 32 bit number in the following manner:

<table>
<thead>
<tr>
<th>Bytes</th>
<th>Bits (big endian order)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1-8</td>
<td>PY_MAJOR_VERSION (the 3 in 3.4.1a2)</td>
</tr>
<tr>
<td>2</td>
<td>9-16</td>
<td>PY_MINOR_VERSION (the 4 in 3.4.1a2)</td>
</tr>
<tr>
<td>3</td>
<td>17-24</td>
<td>PY_MICRO_VERSION (the 1 in 3.4.1a2)</td>
</tr>
<tr>
<td>4</td>
<td>25-28</td>
<td>PY_RELEASE_LEVEL (0xA for alpha, 0xB for beta, 0xC for release candidate and 0xF for final), in this case it is alpha.</td>
</tr>
<tr>
<td></td>
<td>29-32</td>
<td>PY_RELEASE_SERIAL (the 2 in 3.4.1a2, zero for final releases)</td>
</tr>
</tbody>
</table>

Thus 3.4.1a2 is hexversion 0x030401a2.

All the given macros are defined in Include/patchlevel.h.
1. An Introduction to Distutils

This document covers using the Distutils to distribute your Python modules, concentrating on the role of developer/distributor: if you're looking for information on installing Python modules, you should refer to the *Installing Python Modules* chapter.
1.1. Concepts & Terminology

Using the Distutils is quite simple, both for module developers and for users/administrators installing third-party modules. As a developer, your responsibilities (apart from writing solid, well-documented and well-tested code, of course!) are:

- write a setup script (`setup.py` by convention)
- (optional) write a setup configuration file
- create a source distribution
- (optional) create one or more built (binary) distributions

Each of these tasks is covered in this document.

Not all module developers have access to a multitude of platforms, so it's not always feasible to expect them to create a multitude of built distributions. It is hoped that a class of intermediaries, called packagers, will arise to address this need. Packagers will take source distributions released by module developers, build them on one or more platforms, and release the resulting built distributions. Thus, users on the most popular platforms will be able to install most popular Python module distributions in the most natural way for their platform, without having to run a single setup script or compile a line of code.
1.2. A Simple Example

The setup script is usually quite simple, although since it's written in Python, there are no arbitrary limits to what you can do with it, though you should be careful about putting arbitrarily expensive operations in your setup script. Unlike, say, Autoconf-style configure scripts, the setup script may be run multiple times in the course of building and installing your module distribution.

If all you want to do is distribute a module called foo, contained in a file foo.py, then your setup script can be as simple as this:

```python
from distutils.core import setup
setup(
    name='foo',
    version='1.0',
    py_modules=['foo'],
)
```

Some observations:

- most information that you supply to the Distutils is supplied as keyword arguments to the `setup()` function
- those keyword arguments fall into two categories: package metadata (name, version number) and information about what's in the package (a list of pure Python modules, in this case)
- modules are specified by module name, not filename (the same will hold true for packages and extensions)
- it's recommended that you supply a little more metadata, in particular your name, email address and a URL for the project (see section Writing the Setup Script for an example)

To create a source distribution for this module, you would create a setup script, `setup.py`, containing the above code, and run this
command from a terminal:

```
python setup.py sdist
```

For Windows, open a command prompt window (Start ▸ Accessories) and change the command to:

```
setup.py sdist
```

`sdist` will create an archive file (e.g., tarball on Unix, ZIP file on Windows) containing your setup script `setup.py`, and your module `foo.py`. The archive file will be named `foo-1.0.tar.gz` (or `.zip`), and will unpack into a directory `foo-1.0`.

If an end-user wishes to install your `foo` module, all she has to do is download `foo-1.0.tar.gz` (or `.zip`), unpack it, and—from the `foo-1.0` directory—run

```
python setup.py install
```

which will ultimately copy `foo.py` to the appropriate directory for third-party modules in their Python installation.

This simple example demonstrates some fundamental concepts of the Distutils. First, both developers and installers have the same basic user interface, i.e. the setup script. The difference is which Distutils commands they use: the `sdist` command is almost exclusively for module developers, while `install` is more often for installers (although most developers will want to install their own code occasionally).

If you want to make things really easy for your users, you can create one or more built distributions for them. For instance, if you are running on a Windows machine, and want to make things easy for
other Windows users, you can create an executable installer (the most appropriate type of built distribution for this platform) with the `bdist_wininst` command. For example:

```
python setup.py bdist_wininst
```

will create an executable installer, `foo-1.0.win32.exe`, in the current directory.

Other useful built distribution formats are RPM, implemented by the `bdist_rpm` command, Solaris `pkgtool` (`bdist_pkgtool`), and HP-UX `swinstall` (`bdist_sdux`). For example, the following command will create an RPM file called `foo-1.0.noarch.rpm`:

```
python setup.py bdist_rpm
```

(The `bdist_rpm` command uses the `rpm` executable, therefore this has to be run on an RPM-based system such as Red Hat Linux, SuSE Linux, or Mandrake Linux.)

You can find out what distribution formats are available at any time by running

```
python setup.py bdist --help-formats
```
1.3. General Python terminology

If you’re reading this document, you probably have a good idea of what modules, extensions, and so forth are. Nevertheless, just to be sure that everyone is operating from a common starting point, we offer the following glossary of common Python terms:

module
   the basic unit of code reusability in Python: a block of code imported by some other code. Three types of modules concern us here: pure Python modules, extension modules, and packages.

pure Python module
   a module written in Python and contained in a single .py file (and possibly associated .pyc and/or .pyo files). Sometimes referred to as a “pure module.”

extension module
   a module written in the low-level language of the Python implementation: C/C++ for Python, Java for Jython. Typically contained in a single dynamically loadable pre-compiled file, e.g. a shared object (.so) file for Python extensions on Unix, a DLL (given the .pyd extension) for Python extensions on Windows, or a Java class file for Jython extensions. (Note that currently, the Distutils only handles C/C++ extensions for Python.)

package
   a module that contains other modules; typically contained in a directory in the filesystem and distinguished from other directories by the presence of a file __init__.py.

root package
   the root of the hierarchy of packages. (This isn’t really a package, since it doesn’t have an __init__.py file. But we have to call it something.) The vast majority of the standard library is in the root
package, as are many small, standalone third-party modules that don't belong to a larger module collection. Unlike regular packages, modules in the root package can be found in many directories: in fact, every directory listed in `sys.path` contributes modules to the root package.
1.4. Distutils-specific terminology

The following terms apply more specifically to the domain of distributing Python modules using the Distutils:

module distribution
   a collection of Python modules distributed together as a single downloadable resource and meant to be installed *en masse*. Examples of some well-known module distributions are NumPy, SciPy, PIL (the Python Imaging Library), or mxBase. (This would be called a package, except that term is already taken in the Python context: a single module distribution may contain zero, one, or many Python packages.)

pure module distribution
   a module distribution that contains only pure Python modules and packages. Sometimes referred to as a “pure distribution.”

non-pure module distribution
   a module distribution that contains at least one extension module. Sometimes referred to as a “non-pure distribution.”

distribution root
   the top-level directory of your source tree (or source distribution); the directory where setup.py exists. Generally setup.py will be run from this directory.
2. Writing the Setup Script

The setup script is the centre of all activity in building, distributing, and installing modules using the Distutils. The main purpose of the setup script is to describe your module distribution to the Distutils, so that the various commands that operate on your modules do the right thing. As we saw in section *A Simple Example* above, the setup script consists mainly of a call to `setup()`, and most information supplied to the Distutils by the module developer is supplied as keyword arguments to `setup()`.

Here’s a slightly more involved example, which we’ll follow for the next couple of sections: the Distutils’ own setup script. (Keep in mind that although the Distutils are included with Python 1.6 and later, they also have an independent existence so that Python 1.5.2 users can use them to install other module distributions. The Distutils’ own setup script, shown here, is used to install the package into Python 1.5.2.)

```python
#!/usr/bin/env python
from distutils.core import setup
setup(name='Distutils',
      version='1.0',
      description='Python Distribution Utilities',
      author='Greg Ward',
      author_email='gward@python.net',
      url='http://www.python.org/sigs/distutils-sig/',
      packages=['distutils','distutils.command'],
)
```

There are only two differences between this and the trivial one-file
distribution presented in section *A Simple Example*: more metadata, and the specification of pure Python modules by package, rather than by module. This is important since the Distutils consist of a couple of dozen modules split into (so far) two packages; an explicit list of every module would be tedious to generate and difficult to maintain. For more information on the additional meta-data, see section *Additional meta-data*.

Note that any pathnames (files or directories) supplied in the setup script should be written using the Unix convention, i.e. slash-separated. The Distutils will take care of converting this platform-neutral representation into whatever is appropriate on your current platform before actually using the pathname. This makes your setup script portable across operating systems, which of course is one of the major goals of the Distutils. In this spirit, all pathnames in this document are slash-separated.

This, of course, only applies to pathnames given to Distutils functions. If you, for example, use standard Python functions such as `glob.glob()` or `os.listdir()` to specify files, you should be careful to write portable code instead of hardcoding path separators:

```python
glob.glob(os.path.join('mydir', 'subdir', '*\.html'))
os.listdir(os.path.join('mydir', 'subdir'))
```
2.1. Listing whole packages

The *packages* option tells the Distutils to process (build, distribute, install, etc.) all pure Python modules found in each package mentioned in the *packages* list. In order to do this, of course, there has to be a correspondence between package names and directories in the filesystem. The default correspondence is the most obvious one, i.e. package *distutils* is found in the directory *distutils* relative to the distribution root. Thus, when you say `packages = ['foo']` in your setup script, you are promising that the Distutils will find a file `foo/__init__.py` (which might be spelled differently on your system, but you get the idea) relative to the directory where your setup script lives. If you break this promise, the Distutils will issue a warning but still process the broken package anyway.

If you use a different convention to lay out your source directory, that’s no problem: you just have to supply the *package_dir* option to tell the Distutils about your convention. For example, say you keep all Python source under *lib*, so that modules in the “root package” (i.e., not in any package at all) are in *lib*, modules in the *foo* package are in *lib/foo*, and so forth. Then you would put

```python
package_dir = {'': 'lib'}
```

in your setup script. The keys to this dictionary are package names, and an empty package name stands for the root package. The values are directory names relative to your distribution root. In this case, when you say `packages = ['foo']`, you are promising that the file `lib/foo/__init__.py` exists.

Another possible convention is to put the foo package right in *lib*,
the foo.bar package in lib/bar, etc. This would be written in the setup script as

```python
target = {'foo': 'lib'}
```

A package: dir entry in the package_dir dictionary implicitly applies to all packages below package, so the foo.bar case is automatically handled here. In this example, having packages = ['foo', 'foo.bar'] tells the Distutils to look for lib/__init__.py and lib/bar/__init__.py. (Keep in mind that although package_dir applies recursively, you must explicitly list all packages in packages: the Distutils will not recursively scan your source tree looking for any directory with an __init__.py file.)
2.2. Listing individual modules

For a small module distribution, you might prefer to list all modules rather than listing packages—especially the case of a single module that goes in the “root package” (i.e., no package at all). This simplest case was shown in section A Simple Example; here is a slightly more involved example:

```python
py_modules = ['mod1', 'pkg.mod2']
```

This describes two modules, one of them in the “root” package, the other in the pkg package. Again, the default package/directory layout implies that these two modules can be found in `mod1.py` and `pkg/mod2.py`, and that `pkg/__init__.py` exists as well. And again, you can override the package/directory correspondence using the `package_dir` option.
2.3. Describing extension modules

Just as writing Python extension modules is a bit more complicated than writing pure Python modules, describing them to the Distutils is a bit more complicated. Unlike pure modules, it's not enough just to list modules or packages and expect the Distutils to go out and find the right files; you have to specify the extension name, source file(s), and any compile/link requirements (include directories, libraries to link with, etc.).

All of this is done through another keyword argument to setup(), the ext_modules option. ext_modules is just a list of Extension instances, each of which describes a single extension module. Suppose your distribution includes a single extension, called foo and implemented by foo.c. If no additional instructions to the compiler/linker are needed, describing this extension is quite simple:

```
Extension('foo', ['foo.c'])
```

The Extension class can be imported from distutils.core along with setup(). Thus, the setup script for a module distribution that contains only this one extension and nothing else might be:

```
from distutils.core import setup, Extension
setup(name='foo',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

The Extension class (actually, the underlying extension-building machinery implemented by the build_ext command) supports a great deal of flexibility in describing Python extensions, which is explained in
the following sections.

2.3.1. Extension names and packages

The first argument to the `Extension` constructor is always the name of the extension, including any package names. For example,

```python
Extension('foo', ['src/foo1.c', 'src/foo2.c'])
```

describes an extension that lives in the root package, while

```python
Extension('pkg.foo', ['src/foo1.c', 'src/foo2.c'])
```

describes the same extension in the `pkg` package. The source files and resulting object code are identical in both cases; the only difference is where in the filesystem (and therefore where in Python’s namespace hierarchy) the resulting extension lives.

If you have a number of extensions all in the same package (or all under the same base package), use the `ext_package` keyword argument to `setup()`. For example,

```python
setup(...,
    ext_package='pkg',
    ext_modules=[Extension('foo', ['foo.c']),
                 Extension('subpkg.bar', ['bar.c']])
)
```

will compile `foo.c` to the extension `pkg.foo`, and `bar.c` to `pkg.subpkg.bar`.

2.3.2. Extension source files
The second argument to the `Extension` constructor is a list of source files. Since the Distutils currently only support C, C++, and Objective-C extensions, these are normally C/C++/Objective-C source files. (Be sure to use appropriate extensions to distinguish C++ source files: `.cc` and `.cpp` seem to be recognized by both Unix and Windows compilers.)

However, you can also include SWIG interface (.i) files in the list; the `build_ext` command knows how to deal with SWIG extensions: it will run SWIG on the interface file and compile the resulting C/C++ file into your extension.

This warning notwithstanding, options to SWIG can be currently passed like this:

```python
def setup(...,  
    ext_modules=[Extension('_foo', ['foo.i'],  
                        swig_opts=['-modern', ''],  
                        py_modules=['foo'],  
                        )  
```

Or on the command line like this:

```
> python setup.py build_ext --swig-opts="-modern -I../include"
```

On some platforms, you can include non-source files that are processed by the compiler and included in your extension. Currently, this just means Windows message text (.mc) files and resource definition (.rc) files for Visual C+++. These will be compiled to binary resource (.res) files and linked into the executable.

### 2.3.3. Preprocessor options
Three optional arguments to `Extension` will help if you need to specify include directories to search or preprocessor macros to define/undefine: `include_dirs`, `define_macros`, and `undef_macros`.

For example, if your extension requires header files in the `include` directory under your distribution root, use the `include_dirs` option:

```
Extension('foo', ['foo.c'], include_dirs=['include'])
```

You can specify absolute directories there; if you know that your extension will only be built on Unix systems with X11R6 installed to `/usr`, you can get away with

```
Extension('foo', ['foo.c'], include_dirs=['/usr/include'])
```

You should avoid this sort of non-portable usage if you plan to distribute your code: it's probably better to write C code like

```
#include <X11/Xlib.h>
```

If you need to include header files from some other Python extension, you can take advantage of the fact that header files are installed in a consistent way by the Distutils `install_headers` command. For example, the Numerical Python header files are installed (on a standard Unix installation) to `/usr/local/include/python1.5/Numerical`. (The exact location will differ according to your platform and Python installation.) Since the Python include directory — `/usr/local/include/python1.5` in this case—is always
included in the search path when building Python extensions, the best approach is to write C code like

```c
#include <Numerical/arrayobject.h>
```

If you must put the `Numerical` include directory right into your header search path, though, you can find that directory using the Distutils `distutils.sysconfig` module:

```python
from distutils.sysconfig import get_python_inc
incdir = os.path.join(get_python_inc(plat_specific=1),
setup(...,
    Extension(..., include_dirs=[incdir]),
)
```

Even though this is quite portable—it will work on any Python installation, regardless of platform—it’s probably easier to just write your C code in the sensible way.

You can define and undefine pre-processor macros with the `define_macros` and `undef_macros` options. `define_macros` takes a list of `(name, value)` tuples, where `name` is the name of the macro to define (a string) and `value` is its value: either a string or None. (Defining a macro `FOO` to None is the equivalent of a bare `#define FOO` in your C source: with most compilers, this sets `FOO` to the string `1`.) `undef_macros` is just a list of macros to undefine.

For example:

```python
Extension(...,
    define_macros=[('NDEBUG', '1'),
                   ('HAVE_STRFTIME', None)],
    undef_macros=['HAVE_FOO', 'HAVE_BAR'])
```
is the equivalent of having this at the top of every C source file:

```c
#define NDEBUG 1
#define HAVE_STRFTIME
#undef HAVE_FOO
#undef HAVE_BAR
```

### 2.3.4. Library options

You can also specify the libraries to link against when building your extension, and the directories to search for those libraries. The `libraries` option is a list of libraries to link against, `library_dirs` is a list of directories to search for libraries at link-time, and `runtime_library_dirs` is a list of directories to search for shared (dynamically loaded) libraries at run-time.

For example, if you need to link against libraries known to be in the standard library search path on target systems

```python
Extension(...,
    libraries=['gdbm', 'readline'])
```

If you need to link with libraries in a non-standard location, you'll have to include the location in `library_dirs`:

```python
Extension(...,
    library_dirs=['/usr/X11R6/lib'],
    libraries=['X11', 'Xt'])
```

(Again, this sort of non-portable construct should be avoided if you intend to distribute your code.)

### 2.3.5. Other options
There are still some other options which can be used to handle special cases.

The *optional* option is a boolean; if it is true, a build failure in the extension will not abort the build process, but instead simply not install the failing extension.

The *extra_objects* option is a list of object files to be passed to the linker. These files must not have extensions, as the default extension for the compiler is used.

*extra_compile_args* and *extra_link_args* can be used to specify additional command line options for the respective compiler and linker command lines.

*export_symbols* is only useful on Windows. It can contain a list of symbols (functions or variables) to be exported. This option is not needed when building compiled extensions: Distutils will automatically add *initmodule* to the list of exported symbols.

The *depends* option is a list of files that the extension depends on (for example header files). The build command will call the compiler on the sources to rebuild extension if any on this files has been modified since the previous build.
2.4. Relationships between Distributions and Packages

A distribution may relate to packages in three specific ways:

1. It can require packages or modules.
2. It can provide packages or modules.
3. It can obsolete packages or modules.

These relationships can be specified using keyword arguments to the `distutils.core.setup()` function.

Dependencies on other Python modules and packages can be specified by supplying the `requires` keyword argument to `setup()`. The value must be a list of strings. Each string specifies a package that is required, and optionally what versions are sufficient.

To specify that any version of a module or package is required, the string should consist entirely of the module or package name. Examples include 'mymodule' and 'xml.parsers.expat'.

If specific versions are required, a sequence of qualifiers can be supplied in parentheses. Each qualifier may consist of a comparison operator and a version number. The accepted comparison operators are:

```
<  >  ==
<=  >=  !=
```

These can be combined by using multiple qualifiers separated by commas (and optional whitespace). In this case, all of the qualifiers must be matched; a logical AND is used to combine the evaluations.
Let's look at a bunch of examples:

<table>
<thead>
<tr>
<th>Requires Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>==1.0</td>
<td>Only version 1.0 is compatible</td>
</tr>
<tr>
<td>&gt;1.0, !=1.5.1, &lt;2.0</td>
<td>Any version after 1.0 and before 2.0 is compatible, except 1.5.1</td>
</tr>
</tbody>
</table>

Now that we can specify dependencies, we also need to be able to specify what we provide that other distributions can require. This is done using the `provides` keyword argument to `setup()`. The value for this keyword is a list of strings, each of which names a Python module or package, and optionally identifies the version. If the version is not specified, it is assumed to match that of the distribution.

Some examples:

<table>
<thead>
<tr>
<th>Provides Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>mypkg</td>
<td>Provide mypkg, using the distribution version</td>
</tr>
<tr>
<td>mypkg (1.1)</td>
<td>Provide mypkg version 1.1, regardless of the distribution version</td>
</tr>
</tbody>
</table>

A package can declare that it obsoletes other packages using the `obsoletes` keyword argument. The value for this is similar to that of the `requires` keyword: a list of strings giving module or package specifiers. Each specifier consists of a module or package name optionally followed by one or more version qualifiers. Version qualifiers are given in parentheses after the module or package name.

The versions identified by the qualifiers are those that are obsoleted by the distribution being described. If no qualifiers are given, all
versions of the named module or package are understood to be obsoleted.
2.5. Installing Scripts

So far we have been dealing with pure and non-pure Python modules, which are usually not run by themselves but imported by scripts.

Scripts are files containing Python source code, intended to be started from the command line. Scripts don’t require Distutils to do anything very complicated. The only clever feature is that if the first line of the script starts with `#!` and contains the word “python”, the Distutils will adjust the first line to refer to the current interpreter location. By default, it is replaced with the current interpreter location. The `--executable` (or `-e`) option will allow the interpreter path to be explicitly overridden.

The `scripts` option simply is a list of files to be handled in this way. From the PyXML setup script:

```python
setup(...,
    scripts=['scripts/xmlproc_parse', 'scripts/xmlproc_val'],
)
```

*Changed in version 3.1:* All the scripts will also be added to the MANIFEST file if no template is provided. See *Specifying the files to distribute*. 
2.6. Installing Package Data

Often, additional files need to be installed into a package. These files are often data that's closely related to the package’s implementation, or text files containing documentation that might be of interest to programmers using the package. These files are called package data.

Package data can be added to packages using the `package_data` keyword argument to the `setup()` function. The value must be a mapping from package name to a list of relative path names that should be copied into the package. The paths are interpreted as relative to the directory containing the package (information from the `package_dir` mapping is used if appropriate); that is, the files are expected to be part of the package in the source directories. They may contain glob patterns as well.

The path names may contain directory portions; any necessary directories will be created in the installation.

For example, if a package should contain a subdirectory with several data files, the files can be arranged like this in the source tree:

```
src/
    mypkg/
       __init__.py
       module.py
       data/
          tables.dat
          spoons.dat
          forks.dat
```

The corresponding call to `setup()` might be:
setup(...,
    packages=['mypkg'],
    package_dir={'mypkg': 'src/mypkg'},
    package_data={'mypkg': ['data/*.dat']},
)

*Changed in version 3.1:* All the files that match `package_data` will be added to the `MANIFEST` file if no template is provided. See *Specifying the files to distribute.*
2.7. Installing Additional Files

The `data_files` option can be used to specify additional files needed by the module distribution: configuration files, message catalogs, data files, anything which doesn’t fit in the previous categories.

`data_files` specifies a sequence of `(directory, files)` pairs in the following way:

```python
setup(...,
    data_files=[('bitmaps', ['bm/b1.gif', 'bm/b2.gif']),
                ('config', ['cfg/data.cfg']),
                ('/etc/init.d', ['init-script'])])
```

Note that you can specify the directory names where the data files will be installed, but you cannot rename the data files themselves.

Each `(directory, files)` pair in the sequence specifies the installation directory and the files to install there. If `directory` is a relative path, it is interpreted relative to the installation prefix (Python’s `sys.prefix` for pure-Python packages, `sys.exec_prefix` for packages that contain extension modules). Each file name in `files` is interpreted relative to the `setup.py` script at the top of the package source distribution. No directory information from `files` is used to determine the final location of the installed file; only the name of the file is used.

You can specify the `data_files` options as a simple sequence of files without specifying a target directory, but this is not recommended, and the `install` command will print a warning in this case. To install data files directly in the target directory, an empty string should be given as the directory.
Changed in version 3.1: All the files that match data_files will be added to the MANIFEST file if no template is provided. See *Specifying the files to distribute.*
2.8. Additional meta-data

The setup script may include additional meta-data beyond the name and version. This information includes:

<table>
<thead>
<tr>
<th>Meta-Data</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name of the package</td>
<td>short string</td>
<td>(1)</td>
</tr>
<tr>
<td>version</td>
<td>version of this release</td>
<td>short string</td>
<td>(1)(2)</td>
</tr>
<tr>
<td>author</td>
<td>package author's name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>author_email</td>
<td>email address of the package author</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer</td>
<td>package maintainer’s name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer_email</td>
<td>email address of the package maintainer</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>url</td>
<td>home page for the package</td>
<td>URL</td>
<td>(1)</td>
</tr>
<tr>
<td>description</td>
<td>short, summary description of the package</td>
<td>short string</td>
<td></td>
</tr>
<tr>
<td>long_description</td>
<td>longer description of the package</td>
<td>long string</td>
<td>(5)</td>
</tr>
<tr>
<td>download_url</td>
<td>location where the package may be downloaded</td>
<td>URL</td>
<td>(4)</td>
</tr>
<tr>
<td>classifiers</td>
<td>a list of classifiers</td>
<td>list of strings</td>
<td>(4)</td>
</tr>
<tr>
<td>platforms</td>
<td>a list of platforms</td>
<td>list of strings</td>
<td></td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------</td>
<td>----------------</td>
<td></td>
</tr>
<tr>
<td>license</td>
<td>license for the package</td>
<td>short string</td>
<td>(6)</td>
</tr>
</tbody>
</table>

Notes:

1. These fields are required.
2. It is recommended that versions take the form `major.minor[.patch[.sub]]`.
3. Either the author or the maintainer must be identified. If maintainer is provided, distutils lists it as the author in PKG-INFO.
4. These fields should not be used if your package is to be compatible with Python versions prior to 2.2.3 or 2.3. The list is available from the PyPI website.
5. The `long_description` field is used by PyPI when you are registering a package, to build its home page.
6. The `license` field is a text indicating the license covering the package where the license is not a selection from the “License” Trove classifiers. See the Classifier field. Notice that there's a licence distribution option which is deprecated but still acts as an alias for `license`.

‘short string’
   A single line of text, not more than 200 characters.

‘long string’
   Multiple lines of plain text in reStructuredText format (see http://docutils.sf.net/).

‘list of strings’
   See below.

Encoding the version information is an art in itself. Python packages generally adhere to the version format `major.minor[.patch][sub]`. The
major number is 0 for initial, experimental releases of software. It is incremented for releases that represent major milestones in a package. The minor number is incremented when important new features are added to the package. The patch number increments when bug-fix releases are made. Additional trailing version information is sometimes used to indicate sub-releases. These are “a1,a2,...,aN” (for alpha releases, where functionality and API may change), “b1,b2,...,bN” (for beta releases, which only fix bugs) and “pr1,pr2,...,prN” (for final pre-release release testing). Some examples:

0.1.0
  the first, experimental release of a package
1.0.1a2
  the second alpha release of the first patch version of 1.0

classifiers are specified in a Python list:

```python
setup(...,
    classifiers=[
        'Development Status :: 4 - Beta',
        'Environment :: Console',
        'Environment :: Web Environment',
        'Intended Audience :: End Users/Desktop',
        'Intended Audience :: Developers',
        'Intended Audience :: System Administrators',
        'License :: OSI Approved :: Python Software Foundation License',
        'Operating System :: MacOS :: MacOS X',
        'Operating System :: Microsoft :: Windows',
        'Operating System :: POSIX',
        'Programming Language :: Python',
        'Topic :: Communications :: Email',
        'Topic :: Office/Business',
        'Topic :: Software Development :: Bug Tracking',
    ],
)```
If you wish to include classifiers in your `setup.py` file and also wish to remain backwards-compatible with Python releases prior to 2.2.3, then you can include the following code fragment in your `setup.py` before the `setup()` call.

```python
# patch distutils if it can't cope with the "classifiers" or "download_url" keywords
from sys import version
if version < '2.2.3':
    from distutils.dist import DistributionMetadata
    DistributionMetadata.classifiers = None
    DistributionMetadata.download_url = None
```
2.9. Debugging the setup script

Sometimes things go wrong, and the setup script doesn’t do what the developer wants.

Distutils catches any exceptions when running the setup script, and print a simple error message before the script is terminated. The motivation for this behaviour is to not confuse administrators who don’t know much about Python and are trying to install a package. If they get a big long traceback from deep inside the guts of Distutils, they may think the package or the Python installation is broken because they don’t read all the way down to the bottom and see that it’s a permission problem.

On the other hand, this doesn't help the developer to find the cause of the failure. For this purpose, the DISTUTILS_DEBUG environment variable can be set to anything except an empty string, and distutils will now print detailed information what it is doing, and prints the full traceback in case an exception occurs.
3. Writing the Setup Configuration File

Often, it’s not possible to write down everything needed to build a distribution \textit{a priori}: you may need to get some information from the user, or from the user’s system, in order to proceed. As long as that information is fairly simple—a list of directories to search for C header files or libraries, for example—then providing a configuration file, setup.cfg, for users to edit is a cheap and easy way to solicit it. Configuration files also let you provide default values for any command option, which the installer can then override either on the command-line or by editing the config file.

The setup configuration file is a useful middle-ground between the setup script—which, ideally, would be opaque to installers [1]—and the command-line to the setup script, which is outside of your control and entirely up to the installer. In fact, setup.cfg (and any other Distutils configuration files present on the target system) are processed after the contents of the setup script, but before the command-line. This has several useful consequences:

- installers can override some of what you put in setup.py by editing setup.cfg
- you can provide non-standard defaults for options that are not easily set in setup.py
- installers can override anything in setup.cfg using the command-line options to setup.py

The basic syntax of the configuration file is simple:

```
[command]
```
where command is one of the Distutils commands (e.g. build_py, install), and option is one of the options that command supports. Any number of options can be supplied for each command, and any number of command sections can be included in the file. Blank lines are ignored, as are comments, which run from a '#' character until the end of the line. Long option values can be split across multiple lines simply by indenting the continuation lines.

You can find out the list of options supported by a particular command with the universal --help option, e.g.

```bash
> python setup.py --help build_ext

Options for 'build_ext' command:
  --build-lib (-b) directory for compiled extension
  --build-temp (-t) directory for temporary files
  --inplace (-i) ignore build-lib and put compiled source directory alongside your
  --include-dirs (-I) list of directories to search
  --define (-D) C preprocessor macros to define
  --undef (-U) C preprocessor macros to undef
  --swig-opts list of SWIG command line options
```

Note that an option spelled --foo-bar on the command-line is spelled foo_bar in configuration files.

For example, say you want your extensions to be built “in-place”—that is, you have an extension pkg.ext, and you want the compiled extension file (ext.so on Unix, say) to be put in the same source directory as your pure Python modules pkg.mod1 and pkg.mod2.
You can always use the `--inplace` option on the command-line to ensure this:

```
python setup.py build_ext --inplace
```

But this requires that you always specify the `build_ext` command explicitly, and remember to provide `--inplace`. An easier way is to “set and forget” this option, by encoding it in `setup.cfg`, the configuration file for this distribution:

```
[build_ext]
inplace=1
```

This will affect all builds of this module distribution, whether or not you explicitly specify `build_ext`. If you include `setup.cfg` in your source distribution, it will also affect end-user builds—which is probably a bad idea for this option, since always building extensions in-place would break installation of the module distribution. In certain peculiar cases, though, modules are built right in their installation directory, so this is conceivably a useful ability. (Distributing extensions that expect to be built in their installation directory is almost always a bad idea, though.)

Another example: certain commands take a lot of options that don’t change from run to run; for example, `bdist_rpm` needs to know everything required to generate a “spec” file for creating an RPM distribution. Some of this information comes from the setup script, and some is automatically generated by the Distutils (such as the list of files installed). But some of it has to be supplied as options to `bdist_rpm`, which would be very tedious to do on the command-line for every run. Hence, here is a snippet from the Distutils’ own `setup.cfg`:

```
[bdist_rpm]
```
release = 1
packager = Greg Ward <gward@python.net>
doc_files = CHANGES.txt
          README.txt
          USAGE.txt
doc/
examples/

Note that the doc_files option is simply a whitespace-separated string
split across multiple lines for readability.

See also:

Syntax of config files in “Installing Python Modules”
More information on the configuration files is available in the
manual for system administrators.

Footnotes

[1] This ideal probably won’t be achieved until auto-configuration is
    fully supported by the Distutils.
4. Creating a Source Distribution

As shown in section A Simple Example, you use the sdist command to create a source distribution. In the simplest case,

```
python setup.py sdist
```

(assuming you haven’t specified any sdist options in the setup script or config file), sdist creates the archive of the default format for the current platform. The default format is a gzip’ed tar file (.tar.gz) on Unix, and ZIP file on Windows.

You can specify as many formats as you like using the --formats option, for example:

```
python setup.py sdist --formats=gztar,zip
```

to create a gzipped tarball and a zip file. The available formats are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>gztar</td>
<td>gzip’ed tar file (.tar.gz)</td>
<td>(2),(4)</td>
</tr>
<tr>
<td>bztar</td>
<td>bzip2’ed tar file (.tar.bz2)</td>
<td>(4)</td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.Z)</td>
<td>(4)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td>(4)</td>
</tr>
</tbody>
</table>

Notes:

1. default on Windows
2. default on Unix
3. requires either external **zip** utility or **zipfile** module (part of the standard Python library since Python 1.6)
4. requires external utilities: **tar** and possibly one of **gzip**, **bzip2**, or **compress**
4.1. Specifying the files to distribute

If you don’t supply an explicit list of files (or instructions on how to generate one), the `sdist` command puts a minimal default set into the source distribution:

- all Python source files implied by the `py_modules` and `packages` options
- all C source files mentioned in the `ext_modules` or `libraries` options
- scripts identified by the `scripts` option See *Installing Scripts*.
- anything that looks like a test script: `test/test*\.py` (currently, the Distutils don’t do anything with test scripts except include them in source distributions, but in the future there will be a standard for testing Python module distributions)
- `README.txt` (or `README`), `setup.py` (or whatever you called your setup script), and `setup.cfg`
- all files that matches the `package_data` metadata. See *Installing Package Data*.
- all files that matches the `data_files` metadata. See *Installing Additional Files*.

Sometimes this is enough, but usually you will want to specify additional files to distribute. The typical way to do this is to write a manifest template, called `MANIFEST.in` by default. The manifest template is just a list of instructions for how to generate your manifest file, `MANIFEST`, which is the exact list of files to include in your source distribution. The `sdist` command processes this template and generates a manifest based on its instructions and what it finds in the filesystem.

If you prefer to roll your own manifest file, the format is simple: one
filename per line, regular files (or symlinks to them) only. If you do supply your own `MANIFEST`, you must specify everything: the default set of files described above does not apply in this case.

*Changed in version 3.1:* An existing generated `MANIFEST` will be regenerated without `sdist` comparing its modification time to the one of `MANIFEST.in` or `setup.py`.

*Changed in version 3.1.3:* `MANIFEST` files start with a comment indicating they are generated. Files without this comment are not overwritten or removed.

*Changed in version 3.2.2:* `sdist` will read a `MANIFEST` file if no `MANIFEST.in` exists, like it used to do.

The manifest template has one command per line, where each command specifies a set of files to include or exclude from the source distribution. For an example, again we turn to the Distutils' own manifest template:

```
include *.txt
recursive-include examples *.txt *.py
prune examples/sample?/build
```

The meanings should be fairly clear: include all files in the distribution root matching `*.txt`, all files anywhere under the `examples` directory matching `*.txt` or `*.py`, and exclude all directories matching `examples/sample?/build`. All of this is done after the standard include set, so you can exclude files from the standard set with explicit instructions in the manifest template. (Or, you can use the `--no-defaults` option to disable the standard set entirely.) There are several other commands available in the manifest template mini-language; see section *Creating a source distribution: the sdist
command.

The order of commands in the manifest template matters: initially, we have the list of default files as described above, and each command in the template adds to or removes from that list of files. Once we have fully processed the manifest template, we remove files that should not be included in the source distribution:

- all files in the Distutils “build” tree (default build/)
- all files in directories named RCS, CVS, .svn, .hg, .git, .bzx or _darcs

Now we have our complete list of files, which is written to the manifest for future reference, and then used to build the source distribution archive(s).

You can disable the default set of included files with the --no-defaults option, and you can disable the standard exclude set with --no-prune.

Following the Distutils' own manifest template, let's trace how the sdist command builds the list of files to include in the Distutils source distribution:

1. include all Python source files in the distutils and distutils/command subdirectories (because packages corresponding to those two directories were mentioned in the packages option in the setup script—see section Writing the Setup Script)
2. include README.txt, setup.py, and setup.cfg (standard files)
3. include test/test*.py (standard files)
4. include *.txt in the distribution root (this will find README.txt a second time, but such redundancies are weeded out later)
5. include anything matching *.txt or *.py in the sub-tree under
6. exclude all files in the sub-trees starting at directories matching \texttt{examples/sample?/build}—this may exclude files included by the previous two steps, so it's important that the \texttt{prune} command in the manifest template comes after the \texttt{recursive-include} command.

7. exclude the entire \texttt{build} tree, and any \texttt{RCS}, \texttt{CVS}, \texttt{.svn}, \texttt{.hg}, \texttt{.git}, \texttt{.bzr} and \texttt{_darcs} directories

Just like in the setup script, file and directory names in the manifest template should always be slash-separated; the \texttt{Distutils} will take care of converting them to the standard representation on your platform. That way, the manifest template is portable across operating systems.
4.2. Manifest-related options

The normal course of operations for the `sdist` command is as follows:

- if the manifest file (`MANIFEST` by default) exists and the first line does not have a comment indicating it is generated from `MANIFEST.in`, then it is used as is, unaltered
- if the manifest file doesn't exist or has been previously automatically generated, read `MANIFEST.in` and create the manifest
- if neither `MANIFEST` nor `MANIFEST.in` exist, create a manifest with just the default file set
- use the list of files now in `MANIFEST` (either just generated or read in) to create the source distribution archive(s)

There are a couple of options that modify this behaviour. First, use the `--no-defaults` and `--no-prune` to disable the standard “include” and “exclude” sets.

Second, you might just want to (re)generate the manifest, but not create a source distribution:

```
python setup.py sdist --manifest-only
```

-`o` is a shortcut for `--manifest-only`. 
5. Creating Built Distributions

A “built distribution” is what you’re probably used to thinking of either as a “binary package” or an “installer” (depending on your background). It’s not necessarily binary, though, because it might contain only Python source code and/or byte-code; and we don’t call it a package, because that word is already spoken for in Python. (And “installer” is a term specific to the world of mainstream desktop systems.)

A built distribution is how you make life as easy as possible for installers of your module distribution: for users of RPM-based Linux systems, it’s a binary RPM; for Windows users, it’s an executable installer; for Debian-based Linux users, it’s a Debian package; and so forth. Obviously, no one person will be able to create built distributions for every platform under the sun, so the Distutils are designed to enable module developers to concentrate on their specialty—writing code and creating source distributions—while an intermediary species called packagers springs up to turn source distributions into built distributions for as many platforms as there are packagers.

Of course, the module developer could be his own packager; or the packager could be a volunteer “out there” somewhere who has access to a platform which the original developer does not; or it could be software periodically grabbing new source distributions and turning them into built distributions for as many platforms as the software has access to. Regardless of who they are, a packager uses the setup script and the bdist command family to generate built distributions.

As a simple example, if I run the following command in the Distutils source tree:
then the Distutils builds my module distribution (the Distutils itself in this case), does a “fake” installation (also in the build directory), and creates the default type of built distribution for my platform. The default format for built distributions is a “dumb” tar file on Unix, and a simple executable installer on Windows. (That tar file is considered “dumb” because it has to be unpacked in a specific location to work.)

Thus, the above command on a Unix system creates Distutils-1.0.plat.tar.gz; unpacking this tarball from the right place installs the Distutils just as though you had downloaded the source distribution and run python setup.py install. (The “right place” is either the root of the filesystem or Python's prefix directory, depending on the options given to the bdist_dumb command; the default is to make dumb distributions relative to prefix.)

Obviously, for pure Python distributions, this isn't any simpler than just running python setup.py install—but for non-pure distributions, which include extensions that would need to be compiled, it can mean the difference between someone being able to use your extensions or not. And creating “smart” built distributions, such as an RPM package or an executable installer for Windows, is far more convenient for users even if your distribution doesn't include any extensions.

The bdist command has a --format option, similar to the sdist command, which you can use to select the types of built distribution to generate: for example,

```
python setup.py bdist --format=zip
```
would, when run on a Unix system, create Distutils-1.0.plat.zip—again, this archive would be unpacked from the root directory to install the Distutils.

The available formats for built distributions are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>gztar</td>
<td>gzipped tar file (.tar.gz)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.Z)</td>
<td>(3)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td>(3)</td>
</tr>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(2),(4)</td>
</tr>
<tr>
<td>rpm</td>
<td>RPM</td>
<td>(5)</td>
</tr>
<tr>
<td>pkgtool</td>
<td>Solaris pkgtool</td>
<td></td>
</tr>
<tr>
<td>sdux</td>
<td>HP-UX swinstall</td>
<td></td>
</tr>
<tr>
<td>wininst</td>
<td>self-extracting ZIP file for Windows</td>
<td>(4)</td>
</tr>
<tr>
<td>msi</td>
<td>Microsoft Installer.</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. default on Unix
2. default on Windows
3. requires external utilities: tar and possibly one of gzip, bzip2, or compress
4. requires either external zip utility or zipfile module (part of the standard Python library since Python 1.6)
5. requires external rpm utility, version 3.0.4 or better (use rpm --version to find out which version you have)

You don’t have to use the bdist command with the --formats option; you can also use the command that directly implements the format
Some of these *bdist* “sub-commands” actually generate several similar formats; for instance, the *bdist_dumb* command generates all the “dumb” archive formats (*tar*, *ztar*, *gztar*, and *zip*), and *bdist_rpm* generates both binary and source RPMs. The *bdist* sub-commands, and the formats generated by each, are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>bdist_dumb</em></td>
<td><em>tar</em>, <em>ztar</em>, <em>gztar</em>, <em>zip</em></td>
</tr>
<tr>
<td><em>bdist_rpm</em></td>
<td><em>rpm</em>, <em>srpm</em></td>
</tr>
<tr>
<td><em>bdist_wininst</em></td>
<td><em>wininst</em></td>
</tr>
<tr>
<td><em>bdist_msi</em></td>
<td><em>msi</em></td>
</tr>
</tbody>
</table>

The following sections give details on the individual *bdist_* commands.
5.1. Creating RPM packages

The RPM format is used by many popular Linux distributions, including Red Hat, SuSE, and Mandrake. If one of these (or any of the other RPM-based Linux distributions) is your usual environment, creating RPM packages for other users of that same distribution is trivial. Depending on the complexity of your module distribution and differences between Linux distributions, you may also be able to create RPMs that work on different RPM-based distributions.

The usual way to create an RPM of your module distribution is to run the `bdist_rpm` command:

```python
python setup.py bdist_rpm
```

or the `bdist` command with the `--format` option:

```python
python setup.py bdist --formats=rpm
```

The former allows you to specify RPM-specific options; the latter allows you to easily specify multiple formats in one run. If you need to do both, you can explicitly specify multiple `bdist_*` commands and their options:

```python
python setup.py bdist_rpm --packager="John Doe <jdoe@example.org>
bdist_wininst --target-version="2.0"
```

Creating RPM packages is driven by a `.spec` file, much as using the Distutils is driven by the setup script. To make your life easier, the `bdist_rpm` command normally creates a `.spec` file based on the information you supply in the setup script, on the command line, and in
any Distutils configuration files. Various options and sections in the `.spec` file are derived from options in the setup script as follows:

<table>
<thead>
<tr>
<th>RPM <code>.spec</code> file option or section</th>
<th>Distutils setup script option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>Summary (in preamble)</td>
<td><code>description</code></td>
</tr>
<tr>
<td>Version</td>
<td><code>version</code></td>
</tr>
<tr>
<td>Vendor</td>
<td><code>author and author_email, or — &amp; maintainer and maintainer_email</code></td>
</tr>
<tr>
<td>Copyright</td>
<td><code>license</code></td>
</tr>
<tr>
<td>Url</td>
<td><code>url</code></td>
</tr>
<tr>
<td><code>%description</code> (section)</td>
<td><code>long_description</code></td>
</tr>
</tbody>
</table>

Additionally, there are many options in `.spec` files that don’t have corresponding options in the setup script. Most of these are handled through options to the `bdist_rpm` command as follows:

<table>
<thead>
<tr>
<th>RPM <code>.spec</code> file option or section</th>
<th><code>bdist_rpm</code> option</th>
<th>default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Release</td>
<td><code>release</code></td>
<td>“1”</td>
</tr>
<tr>
<td>Group</td>
<td><code>group</code></td>
<td>“Development/Libraries”</td>
</tr>
<tr>
<td>Vendor</td>
<td><code>vendor</code></td>
<td>(see above)</td>
</tr>
<tr>
<td>Packager</td>
<td><code>packager</code></td>
<td>(none)</td>
</tr>
<tr>
<td>Provides</td>
<td><code>provides</code></td>
<td>(none)</td>
</tr>
<tr>
<td>Requires</td>
<td><code>requires</code></td>
<td>(none)</td>
</tr>
<tr>
<td>Conflicts</td>
<td><code>conflicts</code></td>
<td>(none)</td>
</tr>
<tr>
<td>Obsoletes</td>
<td><code>obsoletes</code></td>
<td>(none)</td>
</tr>
<tr>
<td>Distribution</td>
<td>distribution_name</td>
<td>(none)</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------</td>
<td>--------</td>
</tr>
<tr>
<td>BuildRequires</td>
<td>build_requires</td>
<td>(none)</td>
</tr>
<tr>
<td>Icon</td>
<td>icon</td>
<td>(none)</td>
</tr>
</tbody>
</table>

Obviously, supplying even a few of these options on the command-line would be tedious and error-prone, so it’s usually best to put them in the setup configuration file, `setup.cfg`—see section *Writing the Setup Configuration File*. If you distribute or package many Python module distributions, you might want to put options that apply to all of them in your personal Distutils configuration file (~/.pydistutils.cfg).

There are three steps to building a binary RPM package, all of which are handled automatically by the Distutils:

1. create a `.spec` file, which describes the package (analogous to the Distutils setup script; in fact, much of the information in the setup script winds up in the `.spec` file)
2. create the source RPM
3. create the “binary” RPM (which may or may not contain binary code, depending on whether your module distribution contains Python extensions)

Normally, RPM bundles the last two steps together; when you use the Distutils, all three steps are typically bundled together.

If you wish, you can separate these three steps. You can use the `--spec-only` option to make `bdist_rpm` just create the `.spec` file and exit; in this case, the `.spec` file will be written to the “distribution directory”—normally `dist/`, but customizable with the `--dist-dir` option. (Normally, the `.spec` file winds up deep in the “build tree,” in a temporary directory created by `bdist_rpm`.)
5.2. Creating Windows Installers

Executable installers are the natural format for binary distributions on Windows. They display a nice graphical user interface, display some information about the module distribution to be installed taken from the metadata in the setup script, let the user select a few options, and start or cancel the installation.

Since the metadata is taken from the setup script, creating Windows installers is usually as easy as running:

```
python setup.py bdist_wininst
```

or the `bdist` command with the `--formats` option:

```
python setup.py bdist --formats=wininst
```

If you have a pure module distribution (only containing pure Python modules and packages), the resulting installer will be version independent and have a name like `foo-1.0.win32.exe`. These installers can even be created on Unix platforms or Mac OS X.

If you have a non-pure distribution, the extensions can only be created on a Windows platform, and will be Python version dependent. The installer filename will reflect this and now has the form `foo-1.0.win32-py2.0.exe`. You have to create a separate installer for every Python version you want to support.

The installer will try to compile pure modules into bytecode after installation on the target system in normal and optimizing mode. If you don't want this to happen for some reason, you can run the `bdist_wininst` command with the `--no-target-compile` and/or the `--no-`
target-optimize option.

By default the installer will display the cool “Python Powered” logo when it is run, but you can also supply your own 152x261 bitmap which must be a Windows .bmp file with the --bitmap option.

The installer will also display a large title on the desktop background window when it is run, which is constructed from the name of your distribution and the version number. This can be changed to another text by using the --title option.

The installer file will be written to the “distribution directory” — normally dist/, but customizable with the --dist-dir option.
5.3. Cross-compiling on Windows

Starting with Python 2.6, distutils is capable of cross-compiling between Windows platforms. In practice, this means that with the correct tools installed, you can use a 32bit version of Windows to create 64bit extensions and vice-versa.

To build for an alternate platform, specify the `--plat-name` option to the build command. Valid values are currently ‘win32’, ‘win-amd64’ and ‘win-ia64’. For example, on a 32bit version of Windows, you could execute:

```python
code
python setup.py build --plat-name=win-amd64
code
```

to build a 64bit version of your extension. The Windows Installers also support this option, so the command:

```python
code
python setup.py build --plat-name=win-amd64 bdist_wininst
```

would create a 64bit installation executable on your 32bit version of Windows.

To cross-compile, you must download the Python source code and cross-compile Python itself for the platform you are targetting - it is not possible from a binary installation of Python (as the .lib etc file for other platforms are not included.) In practice, this means the user of a 32 bit operating system will need to use Visual Studio 2008 to open the PCBuild/PCbuild.sln solution in the Python source tree and build the “x64” configuration of the ‘pythoncore’ project before cross-compiling extensions is possible.

Note that by default, Visual Studio 2008 does not install 64bit
compilers or tools. You may need to reexecute the Visual Studio setup process and select these tools (using Control Panel->[Add/Remove] Programs is a convenient way to check or modify your existing install.)

5.3.1. The Postinstallation script

Starting with Python 2.3, a postinstallation script can be specified with the **--install-script** option. The basename of the script must be specified, and the script filename must also be listed in the scripts argument to the setup function.

This script will be run at installation time on the target system after all the files have been copied, with `argv[1]` set to `-install`, and again at uninstallation time before the files are removed with `argv[1]` set to `-remove`.

The installation script runs embedded in the windows installer, every output (`sys.stdout`, `sys.stderr`) is redirected into a buffer and will be displayed in the GUI after the script has finished.

Some functions especially useful in this context are available as additional built-in functions in the installation script.

**directory_created**(path)

**file_created**(path)

These functions should be called when a directory or file is created by the postinstall script at installation time. It will register `path` with the uninstaller, so that it will be removed when the distribution is uninstalled. To be safe, directories are only removed if they are empty.

**get_special_folder_path**(csidl_string)
This function can be used to retrieve special folder locations on Windows like the Start Menu or the Desktop. It returns the full path to the folder. `csidl_string` must be one of the following strings:

```
"CSIDL_APPDATA"
"CSIDL_COMMON_STARTMENU"
"CSIDL_STARTMENU"
"CSIDL_COMMON_DESKTOPDIRECTORY"
"CSIDL_DESKTOPDIRECTORY"
"CSIDL_COMMON_STARTUP"
"CSIDL_STARTUP"
"CSIDL_COMMON_PROGRAMS"
"CSIDL_PROGRAMS"
"CSIDL_FONTS"
```

If the folder cannot be retrieved, `OSError` is raised.

Which folders are available depends on the exact Windows version, and probably also the configuration. For details refer to Microsoft's documentation of the `SHGetSpecialFolderPath()` function.

```
def createShortcut(target, description, filename, arguments, workdir, iconpath, iconindex):
    This function creates a shortcut. `target` is the path to the program to be started by the shortcut. `description` is the description of the shortcut. `filename` is the title of the shortcut that the user will see. `arguments` specifies the command line arguments, if any. `workdir` is the working directory for the program. `iconpath` is the file containing
the icon for the shortcut, and iconindex is the index of the icon in the file iconpath. Again, for details consult the Microsoft documentation for the IShellLink interface.
5.4. Vista User Access Control (UAC)

Starting with Python 2.6, bdist_wininst supports a \textit{--user-access-control} option. The default is ‘none’ (meaning no UAC handling is done), and other valid values are ‘auto’ (meaning prompt for UAC elevation if Python was installed for all users) and ‘force’ (meaning always prompt for elevation).
6. The Python Package Index (PyPI)

The Python Package Index (PyPI) holds *meta-data* describing distributions packaged with distutils, as well as package data like distribution files if the package author wishes.

Distutils exposes two commands for submitting package data to PyPI: the *register* command for submitting meta-data to PyPI and the *upload* command for submitting distribution files. Both commands read configuration data from a special file called the *pypirc file*. PyPI *displays a home page* for each package created from the *long_description* submitted by the *register* command.
6.1. Registering Packages

The distutils command **register** is used to submit your distribution’s meta-data to the index. It is invoked as follows:

```
python setup.py register
```

Distutils will respond with the following prompt:

```
running register
We need to know who you are, so please choose either
  1. use your existing login,
  2. register as a new user,
  3. have the server generate a new password for you
  4. quit
Your selection [default 1]:
```

Note: if your username and password are saved locally, you will not see this menu.

If you have not registered with PyPI, then you will need to do so now. You should choose option 2, and enter your details as required. Soon after submitting your details, you will receive an email which will be used to confirm your registration.

Once you are registered, you may choose option 1 from the menu. You will be prompted for your PyPI username and password, and **register** will then submit your meta-data to the index.

You may submit any number of versions of your distribution to the index. If you alter the meta-data for a particular version, you may submit it again and the index will be updated.
PyPI holds a record for each (name, version) combination submitted. The first user to submit information for a given name is designated the Owner of that name. They may submit changes through the `register` command or through the web interface. They may also designate other users as Owners or Maintainers. Maintainers may edit the package information, but not designate other Owners or Maintainers.

By default PyPI displays only the newest version of a given package. The web interface lets one change this default behavior and manually select which versions to display and hide.
6.2. Uploading Packages

The distutils command `upload` pushes the distribution files to PyPI.

The command is invoked immediately after building one or more distribution files. For example, the command

```
python setup.py sdist bdist_wininst upload
```

will cause the source distribution and the Windows installer to be uploaded to PyPI. Note that these will be uploaded even if they are built using an earlier invocation of `setup.py`, but that only distributions named on the command line for the invocation including the `upload` command are uploaded.

The `upload` command uses the username, password, and repository URL from the `$HOME/.pypirc` file (see section *The .pypirc file* for more on this file). If a `register` command was previously called in the same command, and if the password was entered in the prompt, `upload` will reuse the entered password. This is useful if you do not want to store a clear text password in the `$HOME/.pypirc` file.

You can specify another PyPI server with the `--repository=url` option:

```
python setup.py sdist bdist_wininst upload -r http://.../py/pypi
```

See section *The .pypirc file* for more on defining several servers.

You can use the `--sign` option to tell `upload` to sign each uploaded file using GPG (GNU Privacy Guard). The `gpg` program must be available for execution on the system PATH. You can also specify
which key to use for signing using the `--identity=name` option.

Other **upload** options include `--repository=url` or `--repository=section` where *url* is the url of the server and *section* the name of the section in `$HOME/.pypirc`, and `--show-response` (which displays the full response text from the PyPI server for help in debugging upload problems).
6.3. The .pypirc file

The format of the .pypirc file is as follows:

```
[distutils]
index-servers =
    pypi

[pypi]
repository: <repository-url>
username: <username>
password: <password>
```

The distutils section defines a index-servers variable that lists the name of all sections describing a repository.

Each section describing a repository defines three variables:

- **repository**, that defines the url of the PyPI server. Defaults to `http://www.python.org/pypi`.
- **username**, which is the registered username on the PyPI server.
- **password**, that will be used to authenticate. If omitted the user will be prompt to type it when needed.

If you want to define another server a new section can be created and listed in the index-servers variable:

```
[distutils]
index-servers =
    pypi
    other
```
<table>
<thead>
<tr>
<th>Section</th>
<th>Repository</th>
<th>Username</th>
<th>Password</th>
</tr>
</thead>
<tbody>
<tr>
<td>pypi</td>
<td>&lt;repository-url&gt;</td>
<td>&lt;username&gt;</td>
<td>&lt;password&gt;</td>
</tr>
<tr>
<td>other</td>
<td><a href="http://example.com/pypi">http://example.com/pypi</a></td>
<td>&lt;username&gt;</td>
<td>&lt;password&gt;</td>
</tr>
</tbody>
</table>

`register` can then be called with the `-r` option to point the repository to work with:

```
python setup.py register -r http://example.com/pypi
```

For convenience, the name of the section that describes the repository may also be used:

```
python setup.py register -r other
```
6.4. PyPI package display

The `long_description` field plays a special role at PyPI. It is used by the server to display a home page for the registered package.

If you use the `reStructuredText` syntax for this field, PyPI will parse it and display an HTML output for the package home page.

The `long_description` field can be attached to a text file located in the package:

```python
from distutils.core import setup

with open('README.txt') as file:
    long_description = file.read()

setup(name='Distutils',
      long_description=long_description)
```

In that case, `README.txt` is a regular `reStructuredText` text file located in the root of the package besides `setup.py`.

To prevent registering broken `reStructuredText` content, you can use the `rst2html` program that is provided by the `docutils` package and check the `long_description` from the command line:

```
$ python setup.py --long-description | rst2html.py > output.html
```

docutils will display a warning if there's something wrong with your syntax. Because PyPI applies additional checks (e.g. by passing `--no-raw` to `rst2html.py` in the command above), being able to run the command above without warnings does not guarantee that PyPI
will convert the content successfully.
7. Examples

This chapter provides a number of basic examples to help get started with distutils. Additional information about using distutils can be found in the Distutils Cookbook.

See also:

**Distutils Cookbook**
Collection of recipes showing how to achieve more control over distutils.
7.1. Pure Python distribution (by module)

If you're just distributing a couple of modules, especially if they don't live in a particular package, you can specify them individually using the `py_modules` option in the setup script.

In the simplest case, you'll have two files to worry about: a setup script and the single module you're distributing, `foo.py` in this example:

```
<root>/
    setup.py
    foo.py
```

(In all diagrams in this section, `<root>` will refer to the distribution root directory.) A minimal setup script to describe this situation would be:

```
from distutils.core import setup
setup(name='foo',
      version='1.0',
      py_modules=['foo'],
)
```

Note that the name of the distribution is specified independently with the `name` option, and there's no rule that says it has to be the same as the name of the sole module in the distribution (although that's probably a good convention to follow). However, the distribution name is used to generate filenames, so you should stick to letters, digits, underscores, and hyphens.

Since `py_modules` is a list, you can of course specify multiple modules, eg. if you're distributing modules `foo` and `bar`, your setup might look like this:
<root/>
    setup.py
    foo.py
    bar.py

and the setup script might be

    from distutils.core import setup
    setup(name='foobar',
          version='1.0',
          py_modules=['foo', 'bar'],
    )

You can put module source files into another directory, but if you have enough modules to do that, it's probably easier to specify modules by package rather than listing them individually.
7.2. Pure Python distribution (by package)

If you have more than a couple of modules to distribute, especially if they are in multiple packages, it's probably easier to specify whole packages rather than individual modules. This works even if your modules are not in a package; you can just tell the Distutils to process modules from the root package, and that works the same as any other package (except that you don't have to have an __init__.py file).

The setup script from the last example could also be written as

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=[''],
      )
```

(The empty string stands for the root package.)

If those two files are moved into a subdirectory, but remain in the root package, e.g.:

```
<root>/
    setup.py
    src/   foo.py
          bar.py
```

then you would still specify the root package, but you have to tell the Distutils where source files in the root package live:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'': 'src'},
      )
```
More typically, though, you will want to distribute multiple modules in the same package (or in sub-packages). For example, if the `foo` and `bar` modules belong in package `foobar`, one way to layout your source tree is

```python
<root>/
    setup.py
    foobar/
        __init__.py
        foo.py
        bar.py
```

This is in fact the default layout expected by the Distutils, and the one that requires the least work to describe in your setup script:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=['foobar'],
)```

If you want to put modules in directories not named for their package, then you need to use the `package_dir` option again. For example, if the `src` directory holds modules in the `foobar` package:

```python
<root>/
    setup.py
    src/
        __init__.py
        foo.py
        bar.py```
an appropriate setup script would be

```python
from distutils.core import setup
setup(
    name='foobar',
    version='1.0',
    package_dir={'foobar': 'src'},
    packages=['foobar'],
)
```

Or, you might put modules from your main package right in the distribution root:

```xml
<root>/
    setup.py
    __init__.py
    foo.py
    bar.py
```

in which case your setup script would be

```python
from distutils.core import setup
setup(
    name='foobar',
    version='1.0',
    package_dir={'foobar': ''},
    packages=['foobar'],
)
```

(The empty string also stands for the current directory.)

If you have sub-packages, they must be explicitly listed in `packages`, but any entries in `package_dir` automatically extend to sub-packages. (In other words, the Distutils does not scan your source tree, trying to figure out which directories correspond to Python packages by looking for `__init__.py` files.) Thus, if the default layout grows a sub-package:
then the corresponding setup script would be

```python
from distutils.core import setup
ssetup(name='foobar',
       version='1.0',
       packages=['foobar', 'foobar.subfoo'],
)
```

(Again, the empty string in `package_dir` stands for the current directory.)
7.3. Single extension module

Extension modules are specified using the `ext_modules` option. `package_dir` has no effect on where extension source files are found; it only affects the source for pure Python modules. The simplest case, a single extension module in a single C source file, is:

```python
<root>/
    setup.py
    foo.c
```

If the foo extension belongs in the root package, the setup script for this could be

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

If the extension actually belongs in a package, say foopkg, then

With exactly the same source tree layout, this extension can be put in the foopkg package simply by changing the name of the extension:

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foopkg.foo', ['foo.c'])]
)
```
7.4. Checking a package

The check command allows you to verify if your package meta-data meet the minimum requirements to build a distribution.

To run it, just call it using your setup.py script. If something is missing, check will display a warning.

Let's take an example with a simple script:

```python
from distutils.core import setup
setup(name='foobar')
```

Running the check command will display some warnings:

```
$ python setup.py check
running check
warning: check: missing required meta-data: version,
warning: check: missing meta-data: either (author and author_email) or
          (maintainer and maintainer_email) must be supplied
```

If you use the reStructuredText syntax in the long_description field and docutils is installed you can check if the syntax is fine with the check command, using the restructuredtext option.

For example, if the setup.py script is changed like this:

```python
from distutils.core import setup
desc = """"
My description
"""
```
This is the description of the ``foobar`` package.

```python
setup(name='foobar', version='1', author='tarek',
      author_email='tarek@ziade.org',
      url='http://example.com', long_description=desc)
```

Where the long description is broken, check will be able to detect it by using the docutils parser:

```bash
$ python setup.py check --restructuredtext
running check
warning: check: Title underline too short. (line 2)
warning: check: Could not finish the parsing.
```
8. Extending Distutils

Distutils can be extended in various ways. Most extensions take the form of new commands or replacements for existing commands. New commands may be written to support new types of platform-specific packaging, for example, while replacements for existing commands may be made to modify details of how the command operates on a package.

Most extensions of the distutils are made within setup.py scripts that want to modify existing commands; many simply add a few file extensions that should be copied into packages in addition to .py files as a convenience.

Most distutils command implementations are subclasses of the distutils.cmd.Command class. New commands may directly inherit from Command, while replacements often derive from Command indirectly, directly subclassing the command they are replacing. Commands are required to derive from Command.
8.1. Integrating new commands

There are different ways to integrate new command implementations into distutils. The most difficult is to lobby for the inclusion of the new features in distutils itself, and wait for (and require) a version of Python that provides that support. This is really hard for many reasons.

The most common, and possibly the most reasonable for most needs, is to include the new implementations with your setup.py script, and cause the distutils.core.setup() function use them:

```python
from distutils.command.build_py import build_py as _build_py
from distutils.core import setup

class build_py(_build_py):
    """Specialized Python source builder."""

    # implement whatever needs to be different...

setup(cmdclass={'build_py': build_py}, ...
```

This approach is most valuable if the new implementations must be used to use a particular package, as everyone interested in the package will need to have the new command implementation.

Beginning with Python 2.4, a third option is available, intended to allow new commands to be added which can support existing setup.py scripts without requiring modifications to the Python installation. This is expected to allow third-party extensions to provide support for additional packaging systems, but the commands can be used for anything distutils commands can be used for. A new configuration
option, `command_packages` (command-line option `--command-packages`), can be used to specify additional packages to be searched for modules implementing commands. Like all distutils options, this can be specified on the command line or in a configuration file. This option can only be set in the `[global]` section of a configuration file, or before any commands on the command line. If set in a configuration file, it can be overridden from the command line; setting it to an empty string on the command line causes the default to be used. This should never be set in a configuration file provided with a package.

This new option can be used to add any number of packages to the list of packages searched for command implementations; multiple package names should be separated by commas. When not specified, the search is only performed in the `distutils.command` package. When `setup.py` is run with the option `--command-packages distcmds,buildcmds`, however, the packages `distutils.command`, `distcmds`, and `buildcmds` will be searched in that order. New commands are expected to be implemented in modules of the same name as the command by classes sharing the same name. Given the example command line option above, the command `bdist_openpkg` could be implemented by the class `distcmds.bdist_openpkg.bdist_openpkg` or `buildcmds.bdist_openpkg.bdist_openpkg`. 
8.2. Adding new distribution types

Commands that create distributions (files in the dist/ directory) need to add (command, filename) pairs to self.distribution.dist_files so that upload can upload it to PyPI. The filename in the pair contains no path information, only the name of the file itself. In dry-run mode, pairs should still be added to represent what would have been created.
9. Command Reference
9.1. Installing modules: the **install** command family

The install command ensures that the build commands have been run and then runs the subcommands **install_lib**, **install_data** and **install_scripts**.

9.1.1. **install_data**

This command installs all data files provided with the distribution.

9.1.2. **install_scripts**

This command installs all (Python) scripts in the distribution.
9.2. Creating a source distribution: the \texttt{sdist} command

The manifest template commands are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>include pat1 pat2 ...</code></td>
<td>include all files matching any of the listed patterns</td>
</tr>
<tr>
<td><code>exclude pat1 pat2 ...</code></td>
<td>exclude all files matching any of the listed patterns</td>
</tr>
<tr>
<td><code>recursive-include dir pat1 pat2 ...</code></td>
<td>include all files under \textit{dir} matching any of the listed patterns</td>
</tr>
<tr>
<td><code>recursive-exclude dir pat1 pat2 ...</code></td>
<td>exclude all files under \textit{dir} matching any of the listed patterns</td>
</tr>
<tr>
<td><code>global-include pat1 pat2 ...</code></td>
<td>include all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td><code>global-exclude pat1 pat2 ...</code></td>
<td>exclude all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td><code>prune dir</code></td>
<td>exclude all files under \textit{dir}</td>
</tr>
<tr>
<td><code>graft dir</code></td>
<td>include all files under \textit{dir}</td>
</tr>
</tbody>
</table>

The patterns here are Unix-style “glob” patterns: \ast \ matches any sequence of regular filename characters, \? \ matches any single regular filename character, and \texttt{[range]} \ matches any of the characters in \texttt{range} (e.g., \texttt{a-z}, \texttt{a-zA-Z}, \texttt{a-f0-9_}). The definition of “regular filename character” is platform-specific: on Unix it is anything except slash; on Windows anything except backslash or colon.
10. API Reference
10.1. **distutils.core** — Core Distutils functionality

The **distutils.core** module is the only module that needs to be installed to use the Distutils. It provides the **setup()** (which is called from the setup script). Indirectly provides the distutils.dist.Distribution and distutils.cmd.Command class.

**distutils.core.** **setup**(arguments)

The basic do-everything function that does most everything you could ever ask for from a Distutils method.

The setup function takes a large number of arguments. These are laid out in the following table.

<table>
<thead>
<tr>
<th>argument name</th>
<th>value</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the package</td>
<td>a string</td>
</tr>
<tr>
<td>version</td>
<td>The version number of the package; see distutils.version</td>
<td>a string</td>
</tr>
<tr>
<td>description</td>
<td>A single line describing the package</td>
<td>a string</td>
</tr>
<tr>
<td>long_description</td>
<td>Longer description of the package</td>
<td>a string</td>
</tr>
<tr>
<td>author</td>
<td>The name of the package author</td>
<td>a string</td>
</tr>
<tr>
<td>author_email</td>
