When the size of the transport buffer reaches the high-water limit (the protocol is paused), block until the size of the buffer is drained down to the low-water limit and the protocol is resumed. When there is nothing to wait for, the yield-from continues immediately.

Yielding from `drain()` gives the opportunity for the loop to schedule the write operation and flush the buffer. It should especially be used when a possibly large amount of data is written to the transport, and the coroutine does not yield-from between calls to `write()`.

This method is a coroutine.

`get_extra_info(name, default=None)`
Return optional transport information: see `BaseTransport.get_extra_info()`.

`write(data)`
Write some `data` bytes to the transport: see `WriteTransport.write()`.

`writelines(data)`
Write a list (or any iterable) of data bytes to the transport: see `WriteTransport.writelines()`.

`write_eof()`
Close the write end of the transport after flushing buffered data: see `WriteTransport.write_eof()`.
18.5.5.4. StreamReaderProtocol

class asyncio.StreamReaderProtocol(stream_reader, client_connected_cb=None, loop=None)

Trivial helper class to adapt between Protocol and StreamReader. Subclass of Protocol.

stream_reader is a StreamReader instance, client_connected_cb is an optional function called with (stream_reader, stream_writer) when a connection is made, loop is the event loop instance to use.

(This is a helper class instead of making StreamReader itself a Protocol subclass, because the StreamReader has other potential uses, and to prevent the user of the StreamReader from accidentally calling inappropriate methods of the protocol.)
18.5.5.5. IncompleteReadError

*exception* asyncio.**IncompleteReadError**

Incomplete read error, subclass of **EOFError**.

**expected**

Total number of expected bytes (**int**).

**partial**

Read bytes string before the end of stream was reached (**bytes**).
18.5.5.6. Stream examples

18.5.5.6.1. TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```python
import asyncio

@asyncio.coroutine
def tcp_echo_client(message, loop):
    reader, writer = yield from asyncio.open_connection()

    print('Send: %r' % message)
    writer.write(message.encode())

    data = yield from reader.read(100)
    print('Received: %r' % data.decode())

    print('Close the socket')
    writer.close()

message = 'Hello World!'
loop = asyncio.get_event_loop()
loop.run_until_complete(tcp_echo_client(message, loop))
loop.close()
```

See also: The TCP echo client protocol example uses the `BaseEventLoop.create_connection()` method.

18.5.5.6.2. TCP echo server using streams

TCP echo server using the `asyncio.start_server()` function:
import asyncio

@asyncio.coroutine
def handle_echo(reader, writer):
    data = yield from reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')
    print("Received %r from %r" % (message, addr))

    print("Send: %r" % message)
    writer.write(data)
    yield from writer.drain()

    print("Close the client socket")
    writer.close()

loop = asyncio.get_event_loop()
coro = asyncio.start_server(handle_echo, '127.0.0.1')
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}' .format(serversockets[0].getsockname()))
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()

See also: The TCP echo server protocol example uses the BaseEventLoop.create_server() method.
18.5.5.6.3. Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```python
import asyncio
import urllib.parse
import sys

@asyncio.coroutine
def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        connect = asyncio.open_connection(url.hostname)
    else:
        connect = asyncio.open_connection(url.hostname)
    reader, writer = yield from connect
    query = ('HEAD {path} HTTP/1.0\r\n'  
             'Host: {hostname}\r\n'  
             '\r\n').format(path=url.path or '/', hostname=url.hostname)
    writer.write(query.encode('latin-1'))
    while True:
        line = yield from reader.readline()
        if not line:
            break
        line = line.decode('latin1').rstrip()
        if line:
            print('HTTP header> %s' % line)

    # Ignore the body, close the socket
    writer.close()

url = sys.argv[1]
loop = asyncio.get_event_loop()
task = asyncio.ensure_future(print_http_headers(url))
loop.run_until_complete(task)
```
18.5.5.6.4. Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the `open_connection()` function:

```python
import asyncio
try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

@asyncio.coroutine
def wait_for_data(loop):
    # Create a pair of connected sockets
    rsock, wsock = socketpair()

    # Register the open socket to wait for data
    reader, writer = yield from asyncio.open_connection()

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())
```
```python
# Wait for data
data = yield from reader.read(100)

# Got data, we are done: close the socket
print("Received:", data.decode())
writer.close()

# Close the second socket
wsock.close()

loop = asyncio.get_event_loop()
loop.run_until_complete(wait_for_data(loop))
loop.close()
```

See also: The register an open socket to wait for data using a protocol example uses a low-level protocol created by the `BaseEventLoop.create_connection()` method.

The watch a file descriptor for read events example uses the low-level `BaseEventLoop.add_reader()` method to register the file descriptor of a socket.
18. Interprocess Communication and Networking

18.5. asyncio – Asynchronous I/O, event loop, coroutines and tasks
18.5.6. Subprocess
18.5.6.1. Windows event loop

On Windows, the default event loop is `SelectorEventLoop` which does not support subprocesses. `ProactorEventLoop` should be used instead. Example to use it on Windows:

```python
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

See also: Available event loops and Platform support.
18.5.6.2. Create a subprocess: high-level API using Process

Coroutine asyncio.create_subprocess_exec(*args, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Create a subprocess.

The limit parameter sets the buffer limit passed to the StreamReader. See BaseEventLoop.subprocess_exec() for other parameters.

Return a Process instance.

This function is a coroutine.

Coroutine asyncio.create_subprocess_shell(cmd, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Run the shell command cmd.

The limit parameter sets the buffer limit passed to the StreamReader. See BaseEventLoop.subprocess_shell() for other parameters.

Return a Process instance.

It is the application’s responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The shlex.quote() function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.
This function is a coroutine.

Use the `BaseEventLoop.connect_read_pipe()` and `BaseEventLoop.connect_write_pipe()` methods to connect pipes.
18.5.6.3. Create a subprocess: low-level API using subprocess.Popen

Run subprocesses asynchronously using the `subprocess` module.

```python
coroutine BaseEventLoop.subprocess_exec(protocol_factory, *args, stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE, **kwargs)
```

Create a subprocess from one or more string arguments (character strings or bytes strings encoded to the filesystem encoding), where the first string specifies the program to execute, and the remaining strings specify the program’s arguments. (Thus, together the string arguments form the `sys.argv` value of the program, assuming it is a Python script.) This is similar to the standard library `subprocess.Popen` class called with `shell=False` and the list of strings passed as the first argument; however, where `Popen` takes a single argument which is list of strings, `subprocess_exec()` takes multiple string arguments.

The `protocol_factory` must instantiate a subclass of the `asyncio.SubprocessProtocol` class.

Other parameters:

- `stdin`: Either a file-like object representing the pipe to be connected to the subprocess’s standard input stream using `connect_write_pipe()`, or the constant `subprocess.PIPE` (the default). By default a new pipe will be created and connected.
- `stdout`: Either a file-like object representing the pipe to be connected to the subprocess’s standard output stream using `connect_read_pipe()`, or the constant...
subprocess.PIPE (the default). By default a new pipe will be created and connected.

- **stderr**: Either a file-like object representing the pipe to be connected to the subprocess's standard error stream using `connect_read_pipe()`, or one of the constants `subprocess.PIPE` (the default) or `subprocess.STDOUT`. By default a new pipe will be created and connected. When `subprocess.STDOUT` is specified, the subprocess's standard error stream will be connected to the same pipe as the standard output stream.

- All other keyword arguments are passed to `subprocess.Popen` without interpretation, except for `bufsize`, `universal_newlines` and `shell`, which should not be specified at all.

Returns a pair of `(transport, protocol)`, where `transport` is an instance of `BaseSubprocessTransport`.

This method is a coroutine.

See the constructor of the `subprocess.Popen` class for parameters.

coroutine

```python
BaseEventLoop.subprocess_shell(protocol_factory, cmd, *, stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE, **kwargs)
```

Create a subprocess from `cmd`, which is a character string or a bytes string encoded to the filesystem encoding, using the platform's "shell" syntax. This is similar to the standard library `subprocess.Popen` class called with `shell=True`.

The `protocol_factory` must instanciate a subclass of the `asyncio.SubprocessProtocol` class.
See `subprocess_exec()` for more details about the remaining arguments.

Returns a pair of `(transport, protocol)`, where `transport` is an instance of `BaseSubprocessTransport`.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This method is a coroutine.

**See also:** The `BaseEventLoop.connect_read_pipe()` and `BaseEventLoop.connect_write_pipe()` methods.
18.5.6.4. Constants

asyncio.subprocess.PIPE
Special value that can be used as the stdin, stdout or stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that a pipe to the standard stream should be opened.

asyncio.subprocess.STDOUT
Special value that can be used as the stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that standard error should go into the same handle as standard output.

asyncio.subprocess.DEVNULL
Special value that can be used as the stdin, stdout or stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that the special file os.devnull will be used.
18.5.6.5. Process

class asyncio.subprocess.Process

A subprocess created by the create_subprocess_exec() or the create_subprocess_shell() function.

The API of the Process class was designed to be close to the API of the subprocess.Popen class, but there are some differences:

- There is no explicit poll() method
- The communicate() and wait() methods don’t take a timeout parameter: use the wait_for() function
- The universal_newlines parameter is not supported (only bytes strings are supported)
- The wait() method of the Process class is asynchronous whereas the wait() method of the Popen class is implemented as a busy loop.

This class is not thread safe. See also the Subprocess and threads section.

coroutine wait()

Wait for child process to terminate. Set and return returncode attribute.

This method is a coroutine.

Note: This will deadlock when using stdout=PIPE or stderr=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use the communicate() method when using pipes to avoid that.
**coroutine** `communicate(input=None)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional `input` argument should be data to be sent to the child process, or None, if no data should be sent to the child. The type of `input` must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`.

If a `BrokenPipeError` or `ConnectionResetError` exception is raised when writing `input` into stdin, the exception is ignored. It occurs when the process exits before all data are written into stdin.

Note that if you want to send data to the process's stdin, you need to create the Process object with `stdin=PIPE`. Similarly, to get anything other than None in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

This method is a **coroutine**.

---

**Note:** The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

*Changed in version 3.4.2:* The method now ignores `BrokenPipeError` and `ConnectionResetError`.

**send_signal**(signal)

Sends the signal `signal` to the child process.

---

**Note:** On Windows, SIGTERM is an alias for `terminate()`.
CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a `creationflags` parameter which includes CREATE_NEW_PROCESS_GROUP.

**terminate()**
Stop the child. On Posix OSs the method sends `signal.SIGTERM` to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

**kill()**
Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

**stdin**
Standard input stream (`StreamWriter`), None if the process was created with `stdin=None`.

**stdout**
Standard output stream (`StreamReader`), None if the process was created with `stdout=None`.

**stderr**
Standard error stream (`StreamReader`), None if the process was created with `stderr=None`.

**Warning:** Use the `communicate()` method rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to streams pausing reading or writing and blocking the child process.

**pid**
The identifier of the process.
Note that for processes created by the `create_subprocess_shell()` function, this attribute is the process identifier of the spawned shell.

**returncode**

Return code of the process when it exited. A None value indicates that the process has not terminated yet.

A negative value -N indicates that the child was terminated by signal N (Unix only).
18.5.6.6. Subprocess and threads

asyncio supports running subprocesses from different threads, but there are limits:

- An event loop must run in the main thread
- The child watcher must be instantiated in the main thread, before executing subprocesses from other threads. Call the `get_child_watcher()` function in the main thread to instantiate the child watcher.

The `asyncio.subprocess.Process` class is not thread safe.

See also: The Concurrency and multithreading in asyncio section.
18.5.6.7. Subprocess examples

18.5.6.7.1. Subprocess using transport and protocol

Example of a subprocess protocol using to get the output of a subprocess and to wait for the subprocess exit. The subprocess is created by the `BaseEventLoop.subprocess_exec()` method:

```python
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

@asyncio.coroutine
def get_date(loop):
    code = 'import datetime; print(datetime.datetime.now())
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by the protocol
    # redirect the standard output into a pipe
    create = loop.subprocess_exec(lambda: DateProtocol(),
                                    sys.executable, '-',
                                    stdin=None, stderr=None)

    transport, protocol = yield from create
```

```
```
18.5.6.7.2. Subprocess using streams

Example using the Process class to control the subprocess and the StreamReader class to read from the standard output. The subprocess is created by the create_subprocess_exec() function:

```python
import asyncio.subprocess
import sys

@asyncio.coroutine
def get_date():
    # Wait for the subprocess exit using the protocol of the protocol
    yield from exit_future

    # Close the stdout pipe
    transport.close()

    # Read the output which was collected by the pipe method of the protocol
    data = bytes(protocol.output)
    return data.decode('ascii').rstrip()

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date(loop))
print("Current date: %s" % date)
loop.close()
```
```python
code = 'import datetime; print(datetime.datetime.now())

# Create the subprocess, redirect the standard output into a pipe
create = asyncio.create_subprocess_exec(sys.executable, stdout=asyncio.subprocess.PIPE)
proc = yield from create

# Read one line of output
data = yield from proc.stdout.readline()
line = data.decode('ascii').rstrip()

# Wait for the subprocess exit
yield from proc.wait()
return line

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date())
print("Current date: \%s" % date)
loop.close()
```
18.5.7. Synchronization primitives

Locks:

- Lock
- Event
- Condition

Semaphores:

- Semaphore
- BoundedSemaphore

asyncio lock API was designed to be close to classes of the `threading` module (Lock, Event, Condition, Semaphore, BoundedSemaphore), but it has no `timeout` parameter. The `asyncio.wait_for()` function can be used to cancel a task after a timeout.
18.5.7.1. Locks

18.5.7.1.1. Lock

class asyncio.Lock(*, loop=None)

    Primitive lock objects.

A primitive lock is a synchronization primitive that is not owned by a particular coroutine when locked. A primitive lock is in one of two states, ‘locked’ or ‘unlocked’.

It is created in the unlocked state. It has two basic methods, acquire() and release(). When the state is unlocked, acquire() changes the state to locked and returns immediately. When the state is locked, acquire() blocks until a call to release() in another coroutine changes it to unlocked, then the acquire() call resets it to locked and returns. The release() method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a RuntimeError will be raised.

When more than one coroutine is blocked in acquire() waiting for the state to turn to unlocked, only one coroutine proceeds when a release() call resets the state to unlocked; first coroutine which is blocked in acquire() is being processed.

acquire() is a coroutine and should be called with yield from.

Locks also support the context management protocol. (yield from lock) should be used as context manager expression.

This class is not thread safe.
Usage:

```python
lock = Lock()
...
yield from lock
try:
    ...
finally:
    lock.release()
```

Context manager usage:

```python
lock = Lock()
...
with (yield from lock):
    ...
```

Lock objects can be tested for locking state:

```python
if not lock.locked():
    yield from lock
else:
    # lock is acquired
    ...
```

`locked()`

Return True if the lock is acquired.

`coroutine acquire()`

Acquire a lock.

This method blocks until the lock is unlocked, then sets it to locked and returns True.

This method is a coroutine.
**release()**
Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.

---

### 18.5.7.1.2. Event

*class asyncio.Event(*, loop=None)*

An Event implementation, asynchronous equivalent to `threading.Event`.

Class implementing event objects. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true. The flag is initially false.

This class is **not thread safe**.

**clear()**
Reset the internal flag to false. Subsequently, coroutines calling `wait()` will block until `set()` is called to set the internal flag to true again.

**is_set()**
Return True if and only if the internal flag is true.
**set()**

Set the internal flag to true. All coroutines waiting for it to become true are awakened. Coroutine that call `wait()` once the flag is true will not block at all.

**coroutine `wait()`**

Block until the internal flag is true.

If the internal flag is true on entry, return True immediately. Otherwise, block until another coroutine calls `set()` to set the flag to true, then return True.

This method is a **coroutine**.

### 18.5.7.1.3. Condition

```python
class asyncio.Condition(lock=None, *, loop=None)
```

A Condition implementation, asynchronous equivalent to `threading.Condition`.

This class implements condition variable objects. A condition variable allows one or more coroutines to wait until they are notified by another coroutine.

If the `lock` argument is given and not None, it must be a `Lock` object, and it is used as the underlying lock. Otherwise, a new `Lock` object is created and used as the underlying lock.

This class is **not thread safe**.

**coroutine `acquire()`**

Acquire the underlying lock.
This method blocks until the lock is unlocked, then sets it to locked and returns True.

This method is a coroutine.

**notify\( (n=1) \)**

By default, wake up one coroutine waiting on this condition, if any. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method wakes up at most \( n \) of the coroutines waiting for the condition variable; it is a no-op if no coroutines are waiting.

**Note:** An awakened coroutine does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

**locked()**

Return True if the underlying lock is acquired.

**notify_all()**

Wake up all coroutines waiting on this condition. This method acts like `notify()`, but wakes up all waiting coroutines instead of one. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

**release()**

Release the underlying lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.
When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.

coroutine `wait()`

Wait until notified.

If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call for the same condition variable in another coroutine. Once awakened, it re-acquires the lock and returns True.

This method is a coroutine.

coroutine `wait_for(predicate)`

Wait until a predicate becomes true.

The predicate should be a callable which result will be interpreted as a boolean value. The final predicate value is the return value.

This method is a coroutine.
18.5.7.2. Semaphores

18.5.7.2.1. Semaphore

class asyncio.Semaphore(value=1, *, loop=None)

A Semaphore implementation.

A semaphore manages an internal counter which is decremented by each acquire() call and incremented by each release() call. The counter can never go below zero; when acquire() finds that it is zero, it blocks, waiting until some other coroutine calls release().

Semaphores also support the context management protocol.

The optional argument gives the initial value for the internal counter; it defaults to 1. If the value given is less than 0, ValueError is raised.

This class is not thread safe.

coroutine acquire()

Acquire a semaphore.

If the internal counter is larger than zero on entry, decrement it by one and return True immediately. If it is zero on entry, block, waiting until some other coroutine has called release() to make it larger than 0, and then return True.

This method is a coroutine.

locked()
Returns True if semaphore can not be acquired immediately.

**release()**

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another coroutine is waiting for it to become larger than zero again, wake up that coroutine.

18.5.7.2.2. BoundedSemaphore

```python
class asyncio.BoundedSemaphore(value=1, *, loop=None)
```

A bounded semaphore implementation. Inherit from `Semaphore`.

This raises `ValueError` in `release()` if it would increase the value above the initial value.
18.5.8. Queues

Queues:

- Queue
- PriorityQueue
- LifoQueue

asyncio queue API was designed to be close to classes of the queue module (Queue, PriorityQueue, LifoQueue), but it has no timeout parameter. The asyncio.wait_for() function can be used to cancel a task after a timeout.
18.5.8.1. Queue

class asyncio.Queue(maxsize=0, *, loop=None)

A queue, useful for coordinating producer and consumer coroutines.

If `maxsize` is less than or equal to zero, the queue size is infinite. If it is an integer greater than 0, then `yield from put()` will block when the queue reaches `maxsize`, until an item is removed by `get()`.

Unlike the standard library `queue`, you can reliably know this Queue's size with `qsize()`, since your single-threaded asyncio application won't be interrupted between calling `qsize()` and doing an operation on the Queue.

This class is **not thread safe**.

*Changed in version 3.4.4:* New `join()` and `task_done()` methods.

`empty()`

Return True if the queue is empty, False otherwise.

`full()`

Return True if there are `maxsize` items in the queue.

**Note:** If the Queue was initialized with `maxsize=0` (the default), then `full()` is never True.

`coroutine get()`
Remove and return an item from the queue. If queue is empty, wait until an item is available.

This method is a coroutine.

**See also:** The `empty()` method.

**get_nowait()**
Remove and return an item from the queue.

Return an item if one is immediately available, else raise `QueueEmpty`.

**coroutine join()**
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

This method is a coroutine.

*New in version 3.4.4.*

**coroutine put(item)**
Put an item into the queue. If the queue is full, wait until a free slot is available before adding item.

This method is a coroutine.
See also: The full() method.

**put_nowait(item)**

Put an item into the queue without blocking.

If no free slot is immediately available, raise QueueFull.

**qsize()**

Number of items in the queue.

**task_done()**

Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each get() used to fetch a task, a subsequent call to task_done() tells the queue that the processing on the task is complete.

If a join() is currently blocking, it will resume when all items have been processed (meaning that a task_done() call was received for every item that had been put() into the queue).

 Raises ValueError if called more times than there were items placed in the queue.

New in version 3.4.4.

**maxsize**

Number of items allowed in the queue.
18.5.8.2. PriorityQueue

```python
class asyncio.PriorityQueue
    A subclass of Queue; retrieves entries in priority order (lowest first).

    Entries are typically tuples of the form: (priority number, data).
```
18.5.8.3. LifoQueue

```python
class asyncio.LifoQueue
```

A subclass of Queue that retrieves most recently added entries first.

18.5.8.3.1. Exceptions

```python
exception asyncio.QueueEmpty

Exception raised when the get_nowait() method is called on a Queue object which is empty.
```

```python
exception asyncio.QueueFull

Exception raised when the put_nowait() method is called on a Queue object which is full.
```
18. Interprocess Communication and Networking » 18.5. asyncio – Asynchronous I/O, event loop, coroutines and tasks »
18.5.9. Develop with asyncio

Asynchronous programming is different than classical “sequential” programming. This page lists common traps and explains how to avoid them.
The implementation of asyncio has been written for performance. In order to ease the development of asynchronous code, you may wish to enable debug mode.

To enable all debug checks for an application:

- Enable the asyncio debug mode globally by setting the environment variable PYTHONASYNCIODEBUG to 1, or by calling BaseEventLoop.set_debug().
- Set the log level of the asyncio logger to logging.DEBUG. For example, call logging.basicConfig(level=logging.DEBUG) at startup.
- Configure the warnings module to display ResourceWarning warnings. For example, use the -Wdefault command line option of Python to display them.

Examples debug checks:

- Log coroutines defined but never “yielded from”
- call_soon() and call_at() methods raise an exception if they are called from the wrong thread.
- Log the execution time of the selector
- Log callbacks taking more than 100 ms to be executed. The BaseEventLoop.slow_callback_duration attribute is the minimum duration in seconds of “slow” callbacks.
- ResourceWarning warnings are emitted when transports and event loops are not closed explicitly.

See also: The BaseEventLoop.set_debug() method and the asyncio logger.
18.5.9.2. Cancellation

Cancellation of tasks is not common in classic programming. In asynchronous programming, not only it is something common, but you have to prepare your code to handle it.

Futures and tasks can be cancelled explicitly with their `Future.cancel()` method. The `wait_for()` function cancels the waited task when the timeout occurs. There are many other cases where a task can be cancelled indirectly.

Don't call `set_result()` or `set_exception()` method of `Future` if the future is cancelled: it would fail with an exception. For example, write:

```python
if not fut.cancelled():
    fut.set_result('done')
```

Don't schedule directly a call to the `set_result()` or the `set_exception()` method of a future with `BaseEventLoop.call_soon()`: the future can be cancelled before its method is called.

If you wait for a future, you should check early if the future was cancelled to avoid useless operations. Example:

```python
@coroutine
def slow_operation(fut):
    if fut.cancelled():
        return
    # ... slow computation ...
    yield from fut
    # ...
```
The `shield()` function can also be used to ignore cancellation.
18.5.9.3. Concurrency and multithreading

An event loop runs in a thread and executes all callbacks and tasks in the same thread. While a task is running in the event loop, no other task is running in the same thread. But when the task uses `yield from`, the task is suspended and the event loop executes the next task.

To schedule a callback from a different thread, the `BaseEventLoop.call_soon_threadsafe()` method should be used. Example:

```python
loop.call_soon_threadsafe(callback, *args)
```

Most asyncio objects are not thread safe. You should only worry if you access objects outside the event loop. For example, to cancel a future, don’t call directly its `Future.cancel()` method, but:

```python
loop.call_soon_threadsafe(fut.cancel)
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

To schedule a coroutine object from a different thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```python
future = asyncio.run_coroutine_threadsafe(coro_func)  
result = future.result(timeout)  # Wait for the result
```

The `BaseEventLoop.run_in_executor()` method can be used
with a thread pool executor to execute a callback in different thread to not block the thread of the event loop.

**See also:** The *Synchronization primitives* section describes ways to synchronize tasks.

The *Subprocess and threads* section lists asyncio limitations to run subprocesses from different threads.
18.5.9.4. Handle blocking functions correctly

Blocking functions should not be called directly. For example, if a function blocks for 1 second, other tasks are delayed by 1 second which can have an important impact on reactivity.

For networking and subprocesses, the asyncio module provides high-level APIs like protocols.

An executor can be used to run a task in a different thread or even in a different process, to not block the thread of the event loop. See the BaseEventLoop.run_in_executor() method.

See also: The Delayed calls section details how the event loop handles time.
18.5.9.5. Logging

The `asyncio` module logs information with the `logging` module in the logger 'asyncio'. 
18.5.9.6. Detect coroutine objects never scheduled

When a coroutine function is called and its result is not passed to ensure_future() or to the BaseEventLoop.create_task() method, the execution of the coroutine object will never be scheduled which is probably a bug. Enable the debug mode of asyncio to log a warning to detect it.

Example with the bug:

```python
import asyncio

@asyncio.coroutine
def test():
    print("never scheduled")

test()
```

Output in debug mode:

```
Coroutine test() at test.py:3 was never yielded from Coroutine object created at (most recent call last):
    File "test.py", line 7, in <module>
    test()
```

The fix is to call the ensure_future() function or the BaseEventLoop.create_task() method with the coroutine object.

See also: Pending task destroyed.
18.5.9.7. Detect exceptions never consumed

Python usually calls `sys.displayhook()` on unhandled exceptions. If `Future.set_exception()` is called, but the exception is never consumed, `sys.displayhook()` is not called. Instead, a log is emitted when the future is deleted by the garbage collector, with the traceback where the exception was raised.

Example of unhandled exception:

```python
import asyncio

@asyncio.coroutine
def bug():
    raise Exception("not consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(bug())
loop.run_forever()
loop.close()
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<coro() done, defined at Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
      result = next(coro)
  File "asyncio/coroutines.py", line 141, in coro
      res = func(*args, **kw)
  File "test.py", line 5, in bug
      raise Exception("not consumed")
Exception: not consumed
```
Enable the debug mode of asyncio to get the traceback where the task was created. Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at source_traceback: Object created at (most recent call last):
  File "test.py", line 8, in <module>
    asyncio.ensure_future(bug())
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 79, in __next_
    return next(self.gen)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```

There are different options to fix this issue. The first option is to chain the coroutine in another coroutine and use classic try/except:

```
@asyncio.coroutine
def handle_exception():
    try:
        yield from bug()
    except Exception:
        print("exception consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(handle_exception())
loop.run_forever()
loop.close()
```
Another option is to use the `BaseEventLoop.run_until_complete()` function:

```python
task = asyncio.ensure_future(bug())
try:
    loop.run_until_complete(task)
except Exception:
    print("exception consumed")
```

See also: The `Future.exception()` method.
18.5.9.8. Chain coroutines correctly

When a coroutine function calls other coroutine functions and tasks, they should be chained explicitly with `yield from`. Otherwise, the execution is not guaranteed to be sequential.

Example with different bugs using `asyncio.sleep()` to simulate slow operations:

```python
import asyncio

@asyncio.coroutine
def create():
    yield from asyncio.sleep(3.0)
    print("(1) create file")

@asyncio.coroutine
def write():
    yield from asyncio.sleep(1.0)
    print("(2) write into file")

@asyncio.coroutine
def close():
    print("(3) close file")

@asyncio.coroutine
def test():
    asyncio.ensure_future(create())
    asyncio.ensure_future(write())
    asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
    loop.stop()

loop = asyncio.get_event_loop()
asyncio.ensure_future(test())
```
```python
loop.run_forever()
print("Pending tasks at exit: %s" % asyncio.Task.all_tasks)
loop.close()
```

Expected output:

```
(1) create file
(2) write into file
(3) close file
Pending tasks at exit: set()
```

Actual output:

```
(3) close file
(2) write into file
Pending tasks at exit: {<Task pending create() at test.py:7 wait_for=<Future pending cb=[Task._wakeup()]>}
Task was destroyed but it is pending!
task: <Task pending create() done at test.py:5 wait_for=<Future pending cb=[Task._wakeup()]>)
```

The loop stopped before the `create()` finished, `close()` has been called before `write()`, whereas coroutine functions were called in this order: `create()`, `write()`, `close()`.

To fix the example, tasks must be marked with `yield from`:

```python
@asyncio.coroutine
def test():
    yield from asyncio.ensure_future(create())
    yield from asyncio.ensure_future(write())
    yield from asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
loop.stop()
```

Or without `asyncio.ensure_future()`:
@asyncio.coroutine
def test():
    yield from create()
    yield from write()
    yield from close()
    yield from asyncio.sleep(2.0)
    loop.stop()
18.5.9.9. Pending task destroyed

If a pending task is destroyed, the execution of its wrapped coroutine did not complete. It is probably a bug and so a warning is logged.

Example of log:

```
Task was destroyed but it is pending!
task: <Task pending coro=<kill_me() done, defined at test.py:5>
wait_for=<Future pending cb=[Task._wakeup()]>>
```

Enable the debug mode of asyncio to get the traceback where the task was created. Example of log in debug mode:

```
Task was destroyed but it is pending!
source_traceback: Object created at (most recent call last):
   File "test.py", line 15, in <module>
     task = asyncio.ensure_future(coro, loop=loop)
task: <Task pending coro=<kill_me() done, defined at test.py:5>
wait_for=<Future pending cb=[Task._wakeup()]> created at test.py:15>
```

See also: Detect coroutine objects never scheduled.
18.5.9.10. Close transports and event loops

When a transport is no more needed, call its close() method to release resources. Event loops must also be closed explicitly.

If a transport or an event loop is not closed explicitly, a ResourceWarning warning will be emitted in its destructor. By default, ResourceWarning warnings are ignored. The Debug mode of asyncio section explains how to display them.
18.6. **asyncore** — Asynchronous socket handler

**Source code:** Lib/asyncore.py

**Note:** This module exists for backwards compatibility only. For new code we recommend using **asyncio**.

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do “more than one thing at a time.” Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It’s really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the “background.” Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The **asyncore** module solves many of the difficult problems for you, making the task of building sophisticated high-performance network
servers and clients a snap. For “conversational” applications and protocols the companion asynchat module is invaluable.

The basic idea behind both modules is to create one or more network channels, instances of class asyncore.dispatcher and asynchat.async_chat. Creating the channels adds them to a global map, used by the loop() function if you do not provide it with your own map.

Once the initial channel(s) is(are) created, calling the loop() function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

asyncore.loop([timeout[, use_poll[, map[, count]]]])

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The count parameter defaults to None, resulting in the loop terminating only when all channels have been closed. The timeout argument sets the timeout parameter for the appropriate select() or poll() call, measured in seconds; the default is 30 seconds. The use_poll parameter, if true, indicates that poll() should be used in preference to select() (the default is False).

The map parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If map is omitted, a global map is used. Channels (instances of asyncore.dispatcher, asynchat.async_chat and subclasses thereof) can freely be mixed in the map.

class asyncore.dispatcher

The dispatcher class is a thin wrapper around a low-level socket
object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle_connect()</td>
<td>Implied by the first read or write event</td>
</tr>
<tr>
<td>handle_close()</td>
<td>Implied by a read event with no data available</td>
</tr>
<tr>
<td>handle_accepted()</td>
<td>Implied by a read event on a listening socket</td>
</tr>
</tbody>
</table>

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

**handle_read()**

 Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

**handle_write()**
Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```python
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[:sent:]
```

handle_expt()
Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

handle_connect()
Called when the active opener’s socket actually makes a connection. Might send a “welcome” banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()
Called when the socket is closed.

handle_error()
Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()
Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint. Deprecated in version 3.2; use `handle_accepted()` instead.

*Deprecated since version 3.2.*
**handle_accepted**(sock, addr)

Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a `connect()` call for the local endpoint. `sock` is a *new* socket object usable to send and receive data on the connection, and `addr` is the address bound to the socket on the other end of the connection.

*New in version 3.2.*

**readable()**

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

**writable()**

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

**create_socket**(family=socket.AF_INET,
   type=socket.SOCK_STREAM)

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the `socket` documentation for information on creating sockets.
Changed in version 3.3: family and type arguments can be omitted.

**connect**(address)
As with the normal socket object, address is a tuple with the first element the host to connect to, and the second the port number.

**send**(data)
Send data to the remote end-point of the socket.

**recv**(buffer_size)
Read at most buffer_size bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.

Note that recv() may raise BlockingIOError, even though select.select() or select.poll() has reported the socket ready for reading.

**listen**(backlog)
Listen for connections made to the socket. The backlog argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

**bind**(address)
Bind the socket to address. The socket must not already be bound. (The format of address depends on the address family — refer to the socket documentation for more information.) To mark the socket as re-usable (setting the SO_REUSEADDR option), call the dispatcher object's set_reuse_addr() method.
accept()
Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either None or a pair (conn, address) where conn is a new socket object usable to send and receive data on the connection, and address is the address bound to the socket on the other end of the connection. When None is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

close()
Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class asyncore.dispatcher_with_send
A dispatcher subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use asyncchat.async_chat.

class asyncore.file_dispatcher
A file_dispatcher takes a file descriptor or file object along with an optional map argument and wraps it for use with the poll() or loop() functions. If provided a file object or anything with a fileno() method, that method will be called and passed to the file_wrapper constructor. Availability: UNIX.

class asyncore.file_wrapper
A file_wrapper takes an integer file descriptor and calls os.dup()
to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the file_dispatcher class. Availability: UNIX.
18.6.1. asyncore Example basic HTTP client

Here is a very basic HTTP client that uses the `dispatcher` class to implement its socket handling:

```python
import asyncore

class HTTPClient(asyncore.dispatcher):
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.connect((host, 80))
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: %s
' % (path, host), 'ascii')

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print(self.recv(8192))

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[:sent]

client = HTTPClient('www.python.org', '/')
```
asyncore.loop()
18.6.2. asyncore Example basic echo server

Here is a basic echo server that uses the `dispatcher` class to accept connections and dispatches the incoming connections to a handler:

```python
import asyncore

class EchoHandler(asyncore.dispatcher_with_send):
    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):
    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.setReuseAddr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, sock, addr):
        print('Incoming connection from %s' % repr(addr))
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```
18.7. **asynchat** — Asynchronous socket command/response handler

**Source code:** Lib/asynchat.py

**Note:** This module exists for backwards compatibility only. For new code we recommend using **asyncio**.

This module builds on the **asyncore** infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. **asynchat** defines the abstract class **async_chat** that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as **asyncore**, and the two types of channel, **asyncore.dispatcher** and **asynchat.async_chat**, can freely be mixed in the channel map. Typically an **asyncore.dispatcher** server channel generates new **asynchat.async_chat** channel objects as it receives incoming connection requests.

**class** `asynchat.**async_chat**`

This class is an abstract subclass of **asyncore.dispatcher**. To make practical use of the code you must subclass **async_chat**, providing meaningful `collect_incoming_data()` and `found_terminator()` methods. The **asyncore.dispatcher** methods can be used, although not all make sense in a message/response context.
Like `asyncore.dispatcher`, `async_chat` defines a set of events that are generated by an analysis of socket conditions after a `select()` call. Once the polling loop has been started the `async_chat` object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

**ac_in_buffer_size**

The asynchronous input buffer size (default 4096).

**ac_out_buffer_size**

The asynchronous output buffer size (default 4096).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a first-in-first-out queue (fifo) of *producers*. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its `more()` method return the empty bytes object. At this point the `async_chat` object removes the producer from the fifo and starts using the next producer, if any. When the producer fifo is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The methods are described below.
async_chat.close_when_done()

Pushes a None on to the producer fifo. When this producer is popped off the fifo it causes the channel to be closed.

async_chat.collect_incoming_data(data)

Called with data holding an arbitrary amount of received data. The default method, which must be overridden, raises a NotImplementedError exception.

async_chat.discard_buffers()

In emergencies this method will discard any data held in the input and/or output buffers and the producer fifo.

async_chat.found_terminator()

Called when the incoming data stream matches the termination condition set by set_terminator(). The default method, which must be overridden, raises a NotImplementedError exception. The buffered input data should be available via an instance attribute.

async_chat.get_terminator()

Returns the current terminator for the channel.

async_chat.push(data)

Pushes data on to the channel's fifo to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

async_chat.push_with_producer(producer)

Takes a producer object and adds it to the producer fifo associated
with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer's data by calling its `more()` method and send the data to the remote endpoint.

async_chat.set_terminator(term)

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

<table>
<thead>
<tr>
<th>term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Will call <code>found_terminator()</code> when the string is found in the input stream</td>
</tr>
<tr>
<td>integer</td>
<td>Will call <code>found_terminator()</code> when the indicated number of characters have been received</td>
</tr>
<tr>
<td>None</td>
<td>The channel continues to collect data forever</td>
</tr>
</tbody>
</table>

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.
18.7.1. asynchat Example

The following partial example shows how HTTP requests can be read with `async_chat`. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the Content-Length: header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to None to ensure that any extraneous data sent by the web client are ignored.

```python
import asyncchat

class http_request_handler(asyncchat.async_chat):
    def __init__(self, sock, addr, sessions, log):
        asyncchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b"
        self.set_terminator(b"\n\n\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log
```
```python
def collect_incoming_data(self, data):
    """Buffer the data""
    self.ibuffer.append(data)

def found_terminator(self):
    if self.reading_headers:
        self.reading_headers = False
        self.parse_headers(b"".join(self.ibuffer)
        self.ibuffer = []
    if self.op.upper() == b"POST":
        clen = self.headers.getheader("content-length")
        self.set_terminator(int(clen))
    else:
        self.handling = True
        self.set_terminator(None)
        self.handle_request()
    elif not self.handling:
        self.set_terminator(None)  # browsers sometimes over-send
        self.cgi_data = parse(self.headers, b"
        self.handling = True
        self.ibuffer = []
        self.handle_request()
```
18.8. **signal** — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python.
18.8.1. General rules

The `signal.signal()` function allows to define custom handlers to be executed when a signal is received. A small number of default handlers are installed: SIGPIPE is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and SIGINT is translated into a `KeyboardInterrupt` exception.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for SIGCHLD, which follows the underlying implementation.

There is no way to “block” signals temporarily from critical sections (since this is not supported by all Unix flavors).

18.8.1.1. Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the virtual machine to execute the corresponding Python signal handler at a later point (for example at the next bytecode instruction). This has consequences:

- It makes little sense to catch synchronous errors like SIGFPE or SIGSEGV that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the `faulthandler` module to report on synchronous errors.
- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run
uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when the calculation finishes.

18.8.1.2. Signals and threads

Python signal handlers are always executed in the main Python thread, even if the signal was received in another thread. This means that signals can't be used as a means of inter-thread communication. You can use the synchronization primitives from the `threading` module instead.

Besides, only the main thread is allowed to set a new signal handler.
18.8.2. Module contents

*Changed in version 3.5:* signal (SIG*), handler (SIG_DFL, SIG_IGN) and sigmask (SIG_BLOCK, SIG_UNBLOCK, SIG_SETMASK) related constants listed below were turned into enums. `getsignal()`, `pthread_sigmask()`, `sigpending()` and `sigwait()` functions return human-readable enums.

The variables defined in the `signal` module are:

**signal.SIG_DFL**

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for SIGQUIT is to dump core and exit, while the default action for SIGCHLD is to simply ignore it.

**signal.SIG_IGN**

This is another standard signal handler, which will simply ignore the given signal.

**SIG* **

All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for `signal()` lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

**signal.CTRL_C_EVENT**
The signal corresponding to the Ctrl+C keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 3.2.*

**signal.CTRL_BREAK_EVENT**

The signal corresponding to the Ctrl+Break keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 3.2.*

**signal.NSIG**

One more than the number of the highest signal number.

**signal.ITIMER_REAL**

Decrements interval timer in real time, and delivers SIGALRM upon expiration.

**signal.ITIMER_VIRTUAL**

Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

**signal.ITIMER_PROF**

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

**signal.SIG_BLOCK**
A possible value for the *how* parameter to `pthread_sigmask()` indicating that signals are to be blocked.

*New in version 3.3.*

`signal.SIG_UNBLOCK`

A possible value for the *how* parameter to `pthread_sigmask()` indicating that signals are to be unblocked.

*New in version 3.3.*

`signal.SIG_SETMASK`

A possible value for the *how* parameter to `pthread_sigmask()` indicating that the signal mask is to be replaced.

*New in version 3.3.*

The `signal` module defines one exception:

*exception* `signal.TimerError`

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `OSError`.

*New in version 3.3:* This error used to be a subtype of `IOError`, which is now an alias of `OSError`.

The `signal` module defines the following functions:

`signal.alarm(time)`

If `time` is non-zero, this function requests that a SIGALRM signal be sent to the process in `time` seconds. Any previously scheduled
alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If time is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page *alarm(2)*.) Availability: Unix.

**`signal.getsignal(signalnum)`**

Return the current signal handler for the signal `signalnum`. The returned value may be a callable Python object, or one of the special values `signal.SIG_IGN`, `signal.SIG_DFL` or `None`. Here, `signal.SIG_IGN` means that the signal was previously ignored, `signal.SIG_DFL` means that the default way of handling the signal was previously in use, and `None` means that the previous signal handler was not installed from Python.

**`signal.pause()`**

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page *signal(2)*.)

See also `sigwait()`, `sigwaitinfo()`, `sigtimedwait()` and `sigpending()`.

**`signal.pthread_kill(thread_id, signalnum)`**

Send the signal `signalnum` to the thread `thread_id`, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be *executed by the main thread*. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with `InterruptedError`. 
Use `threading.get_ident()` or the `ident` attribute of `threading.Thread` objects to get a suitable value for `thread_id`.

If `signalnum` is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Availability: Unix (see the man page `pthread_kill(3)` for further information).

See also `os.kill()`.

`New in version 3.3.`

`signal.pthread_sigmask( how, mask )`

Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of `how`, as follows.

- **SIG_BLOCK**: The set of blocked signals is the union of the current set and the `mask` argument.
- **SIG_UNBLOCK**: The signals in `mask` are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- **SIG_SETMASK**: The set of blocked signals is set to the `mask` argument.

`mask` is a set of signal numbers (e.g. `{signal.SIGINT, signal.SIGTERM}`). Use `range(1, signal.NSIG)` for a full mask including all signals.
For example, `signal.pthread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

Availability: Unix. See the man page `sigprocmask(3)` and `pthread_sigmask(3)` for further information.

See also `pause()`, `sigpending()` and `sigwait()`.

*New in version 3.3.*

`signal.setitimer(which, seconds[, interval])`  
Sets given interval timer (one of `signal.ITIMER_REAL`, `signal.ITIMER_VIRTUAL` or `signal.ITIMER_PROF`) specified by `which` to fire after `seconds` (float is accepted, different from `alarm()`) and after that every `interval` seconds. The interval timer specified by `which` can be cleared by setting `seconds` to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; `signal.ITIMER_REAL` will deliver SIGALRM, `signal.ITIMER_VIRTUAL` sends SIGVTALRM, and `signal.ITIMER_PROF` will deliver SIGPROF.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an `ItimerError`. Availability: Unix.

`signal.getitimer(which)`  
Returns current value of a given interval timer specified by `which`. Availability: Unix.
**signal.set_wakeup_fd(fd)**

Set the wakeup file descriptor to *fd*. When a signal is received, the signal number is written as a single byte into the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned. *fd* must be non-blocking. It is up to the library to remove any bytes before calling poll or select again.

Use for example `struct.unpack('%uB' % len(data), data)` to decode the signal numbers list.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

*Changed in version 3.5:* On Windows, the function now also supports socket handles.

**signal.siginterrupt(signalnum, flag)**

Change system call restart behaviour: if *flag* is `False`, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true *flag* value for the given signal.

**signal.signal(signalnum, handler)**

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values `signal.SIG_IGN` or
**signal.SIG_DFL**. The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The **handler** is called with two arguments: the signal number and the current stack frame (None or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the `inspect` module).

On Windows, `signal()` can only be called with SIGABRT, SIGFPE, SIGILL, SIGINT, SIGSEGV, or SIGTERM. A `ValueError` will be raised in any other case.

**signal.sigpending()**

Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix (see the man page `sigpending(2)` for further information).

See also `pause()`, `pthread_sigmask()` and `sigwait()`.

*New in version 3.3.*

**signal.sigwait(sigset)**

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set `sigset`. The function accepts the signal (removes it from the pending list of signals), and returns
the signal number.

Availability: Unix (see the man page `sigwait(3)` for further information).

See also `pause()`, `pthread_sigmask()`, `sigpending()`, `sigwaitinfo()` and `sigtimedwait()`.

*New in version 3.3.*

**signal.** `sigwaitinfo(sigset)`

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set `sigset`. The function accepts the signal and removes it from the pending list of signals. If one of the signals in `sigset` is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an `InterruptedError` if it is interrupted by a signal that is not in `sigset`.

The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_signo`, `si_code`, `si_errno`, `si_pid`, `si_uid`, `si_status`, `si_band`.

Availability: Unix (see the man page `sigwaitinfo(2)` for further information).

See also `pause()`, `sigwait()` and `sigtimedwait()`.

*New in version 3.3.*

*Changed in version 3.5:* The function is now retried if interrupted by a signal not in `sigset` and the signal handler does not raise an exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475) for the rationale).
signal.\texttt{sigtimedwait}(\textit{sigset, timeout})

Like \texttt{sigwaitinfo()}, but takes an additional \textit{timeout} argument specifying a timeout. If \textit{timeout} is specified as 0, a poll is performed. Returns \texttt{None} if a timeout occurs.

Availability: Unix (see the man page \texttt{sigtimedwait(2)} for further information).

See also \texttt{pause()}, \texttt{sigwait()} and \texttt{sigwaitinfo()}.

\textit{New in version 3.3.}

\textit{Changed in version 3.5:} The function is now retried with the recomputed \textit{timeout} if interrupted by a signal not in \textit{sigset} and the signal handler does not raise an exception (see \texttt{PEP 475} for the rationale).
18.8.3. Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```python
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)  # Disable the alarm
```

18.9. mmap — Memory-mapped file support

Memory-mapped file objects behave like both bytearray and like file objects. You can use mmap objects in most places where bytearray are expected; for example, you can use the re module to search through a memory-mapped file. You can also change a single byte by doing obj[index] = 97, or change a subsequence by assigning to a slice: obj[i1:i2] = b'...'. You can also read and write data starting at the current file position, and seek() through the file to different positions.

A memory-mapped file is created by the mmap constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its fileno() method to obtain the correct value for the fileno parameter. Otherwise, you can open the file using the os.open() function, which returns a file descriptor directly (the file still needs to be closed when done).

**Note:** If you want to create a memory-mapping for a writable, buffered file, you should flush() the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, access may be specified as an optional keyword parameter. access accepts one of three values: ACCESS_READ, ACCESS_WRITE, or ACCESS_COPY to specify read-only, write-through or copy-on-write
memory respectively. access can be used on both Unix and Windows. If access is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an ACCESS_READ memory map raises a TypeError exception. Assignment to an ACCESS_WRITE memory map affects both memory and the underlying file. Assignment to an ACCESS_COPY memory map affects memory but does not update the underlying file.

To map anonymous memory, -1 should be passed as the fileno along with the length.

```python
class mmap.mmap(fileno, length, tagname=None, access=ACCESS_DEFAULT[, offset])
```

(Windows version) Maps length bytes from the file specified by the file handle fileno, and creates a mmap object. If length is larger than the current size of the file, the file is extended to contain length bytes. If length is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the
file. offset defaults to 0. offset must be a multiple of the ALLOCATIONGRANULARITY.

class mmap

mmap(fileno, length, flags=MAP_SHARED,
prot=PROT_WRITE|PROT_READ, access=ACCESS_DEFAULT[, offset])

(UNIX version) Maps length bytes from the file specified by the file descriptor fileno, and returns a mmap object. If length is 0, the maximum length of the map will be the current size of the file when mmap is called.

flags specifies the nature of the mapping. MAP_PRIVATE creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and MAP_SHARED creates a mapping that’s shared with all other processes mapping the same areas of the file. The default value is MAP_SHARED.

prot, if specified, gives the desired memory protection; the two most useful values are PROT_READ and PROT_WRITE, to specify that the pages may be read or written. prot defaults to PROT_READ | PROT_WRITE.

access may be specified in lieu of flags and prot as an optional keyword parameter. It is an error to specify both flags, prot and access. See the description of access above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. offset defaults to 0. offset must be a multiple of the PAGESIZE or ALLOCATIONGRANULARITY.
To ensure validity of the created memory mapping the file specified by the descriptor `fileno` is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap`:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!
"
)

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python"
    # read content via slice notation
    print(mm[:5])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!"
    # ... and read again using standard file methods
    mm.seek(0)
    print(mm.readline())  # prints b"Hello world"
    # close the map
    mm.close()
```

`mmap` can also be used as a context manager in a `with` statement:

```
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write("Hello world!")
```
New in version 3.2: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```python
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!"

pid = os.fork()

if pid == 0:  # In a child process
    mm.seek(0)
    print(mm.readline())
    mm.close()
```

Memory-mapped file objects support the following methods:

**close()**

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

**closed**

True if the file is closed.

New in version 3.2.

**find(sub[, start[, end]])**

Returns the lowest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range `start`,
Optional arguments \textit{start} and \textit{end} are interpreted as in slice notation. Returns -1 on failure.

\textbf{flush([offset[, size]])}

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If \textit{offset} and \textit{size} are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

\textbf{(Windows version)} A nonzero value returned indicates success; zero indicates failure.

\textbf{(Unix version)} A zero value is returned to indicate success. An exception is raised when the call failed.

\textbf{move(dest, src, count)}

Copy the \textit{count} bytes starting at offset \textit{src} to the destination index \textit{dest}. If the mmap was created with \texttt{ACCESS\_READ}, then calls to \texttt{move} will raise a \texttt{TypeError} exception.

\textbf{read([n])}

Return a \texttt{bytes} containing up to \textit{n} bytes starting from the current file position. If the argument is omitted, \texttt{None} or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.

\textit{Changed in version 3.3:} Argument can be omitted or \texttt{None}.

\textbf{read\_byte()}

Returns a byte at the current file position as an integer, and advances the file position by 1.

**readline()**
Returns a single line, starting at the current file position and up to the next newline.

**resize(newsize)**
Resizes the map and the underlying file, if any. If the mmap was created with ACCESS_READ or ACCESS_COPY, resizing the map will raise a `TypeError` exception.

**rfind(sub[start:end])**
Returns the highest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns -1 on failure.

**seek(pos[whence])**
Set the file's current position. `whence` argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).

**size()**
Return the length of the file, which can be larger than the size of the memory-mapped area.

**tell()**
Returns the current position of the file pointer.
**write**(*bytes*)

Write the bytes in *bytes* into memory at the current position of the file pointer; the file position is updated to point after the bytes that were written. If the mmap was created with ACCESS_READ, then writing to it will raise a **TypeError** exception.

**write_byte**(*byte*)

Write the integer *byte* into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with ACCESS_READ, then writing to it will raise a **TypeError** exception.
19. Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the Internet.

- 19.1. email — An email and MIME handling package
  - 19.1.1. email.message: Representing an email message
  - 19.1.2. email.parser: Parsing email messages
    - 19.1.2.1. FeedParser API
    - 19.1.2.2. Parser class API
    - 19.1.2.3. Additional notes
  - 19.1.3. email.generator: Generating MIME documents
  - 19.1.4. email.policy: Policy Objects
  - 19.1.5. email.headerregistry: Custom Header Objects
  - 19.1.6. email.contentmanager: Managing MIME Content
    - 19.1.6.1. Content Manager Instances
  - 19.1.7. email.mime: Creating email and MIME objects from scratch
  - 19.1.8. email.header: Internationalized headers
  - 19.1.9. email.charset: Representing character sets
  - 19.1.10. email.encoders: Encoders
  - 19.1.11. email.errors: Exception and Defect classes
  - 19.1.12. email.utils: Miscellaneous utilities
  - 19.1.13. email.iterators: Iterators
  - 19.1.14. email: Examples
    - 19.1.14.1. Examples using the Provisional API
  - 19.1.15. Package History
  - 19.1.16. Differences from mimelib

- 19.2. json — JSON encoder and decoder
  - 19.2.1. Basic Usage
  - 19.2.2. Encoders and Decoders
- 19.2.3. Exceptions
- 19.2.4. Standard Compliance and Interoperability
  - 19.2.4.1. Character Encodings
  - 19.2.4.2. Infinite and NaN Number Values
  - 19.2.4.3. Repeated Names Within an Object
  - 19.2.4.4. Top-level Non-Object, Non-Array Values
  - 19.2.4.5. Implementation Limitations
- 19.2.5. Command Line Interface
  - 19.2.5.1. Command line options
- 19.3. mailcap — Mailcap file handling
- 19.4. mailbox — Manipulate mailboxes in various formats
  - 19.4.1. Mailbox objects
    - 19.4.1.1. Maildir
    - 19.4.1.2. mbox
    - 19.4.1.3. MH
    - 19.4.1.4. Babyl
    - 19.4.1.5. MMDF
  - 19.4.2. Message objects
    - 19.4.2.1. MaildirMessage
    - 19.4.2.2. mboxMessage
    - 19.4.2.3. MHMessage
    - 19.4.2.4. BabylMessage
    - 19.4.2.5. MMDFMessage
  - 19.4.3. Exceptions
  - 19.4.4. Examples
- 19.5. mimetypes — Map filenames to MIME types
  - 19.5.1. MimeTypes Objects
- 19.6. base64 — Base16, Base32, Base64, Base85 Data Encodings
- 19.7. binhex — Encode and decode binhex4 files
  - 19.7.1. Notes
- 19.8. binascii — Convert between binary and ASCII
- 19.9. quopri — Encode and decode MIME quoted-printable data
19.10. uu — Encode and decode uuencode files

19.1. **email** — An email and MIME handling package

The **email** package is a library for managing email messages, including MIME and other [RFC 2822]-based message documents. It is specifically *not* designed to do any sending of email messages to SMTP ([RFC 2821]), NNTP, or other servers; those are functions of modules such as **smtplib** and **nntplib**. The **email** package attempts to be as RFC-compliant as possible, supporting in addition to [RFC 2822], such MIME-related RFCs as [RFC 2045], [RFC 2046], [RFC 2047], and [RFC 2231].

The primary distinguishing feature of the **email** package is that it splits the parsing and generating of email messages from the internal **object model** representation of email. Applications using the **email** package deal primarily with objects; you can add sub-objects to messages, remove sub-objects from messages, completely re-arrange the contents, etc. There is a separate parser and a separate generator which handles the transformation from flat text to the object model, and then back to flat text again. There are also handy subclasses for some common MIME object types, and a few miscellaneous utilities that help with such common tasks as extracting and parsing message field values, creating RFC-compliant dates, etc.

The following sections describe the functionality of the **email** package. The ordering follows a progression that should be common in applications: an email message is read as flat text from a file or other source, the text is parsed to produce the object structure of the email message, this structure is manipulated, and finally, the object tree is rendered back into flat text.
It is perfectly feasible to create the object structure out of whole cloth — i.e. completely from scratch. From there, a similar progression can be taken as above.

Also included are detailed specifications of all the classes and modules that the email package provides, the exception classes you might encounter while using the email package, some auxiliary utilities, and a few examples. For users of the older mimelib package, or previous versions of the email package, a section on differences and porting is provided.

Contents of the email package documentation:

- 19.1.1. email.message: Representing an email message
- 19.1.2. email.parser: Parsing email messages
  - 19.1.2.1. FeedParser API
  - 19.1.2.2. Parser class API
  - 19.1.2.3. Additional notes
- 19.1.3. email.generator: Generating MIME documents
- 19.1.4. email.policy: Policy Objects
- 19.1.5. email.headerregistry: Custom Header Objects
- 19.1.6. email.contentmanager: Managing MIME Content
  - 19.1.6.1. Content Manager Instances
- 19.1.7. email.mime: Creating email and MIME objects from scratch

19.1.15. Package History

This table describes the release history of the email package, corresponding to the version of Python that the package was released with. For purposes of this document, when you see a note about change or added versions, these refer to the Python version the change was made in, not the email package version. This table also describes the Python compatibility of each version of the package.

<table>
<thead>

After Version 5.1 (Python 3.2), the email package no longer has a version that is separate from the Python version. (See the What’s New in Python documents for the respective Python versions for details on changes.)

Here are the major differences between email version 5.1 and version 5.0:

- It is once again possible to parse messages containing non-ASCII bytes, and to reproduce such messages if the data containing the non-ASCII bytes is not modified.
• New functions `message_from_bytes()` and `message_from_binary_file()`, and new classes `BytesFeedParser` and `BytesParser` allow binary message data to be parsed into model objects.

• Given bytes input to the model, `get_payload()` will by default decode a message body that has a `Content-Transfer-Encoding` of 8bit using the charset specified in the MIME headers and return the resulting string.

• Given bytes input to the model, `Generator` will convert message bodies that have a `Content-Transfer-Encoding` of 8bit to instead have a 7bit `Content-Transfer-Encoding`.

• New class `BytesGenerator` produces bytes as output, preserving any unchanged non-ASCII data that was present in the input used to build the model, including message bodies with a `Content-Transfer-Encoding` of 8bit.

Here are the major differences between `email` version 5.0 and version 4:

• All operations are on unicode strings. Text inputs must be strings, text outputs are strings. Outputs are limited to the ASCII character set and so can be encoded to ASCII for transmission. Inputs are also limited to ASCII; this is an acknowledged limitation of email 5.0 and means it can only be used to parse email that is 7bit clean.

Here are the major differences between `email` version 4 and version 3:

• All modules have been renamed according to PEP 8 standards. For example, the version 3 module `email.Message` was renamed to `email.message` in version 4.

• A new subpackage `email.mime` was added and all the version 3
email.MIME* modules were renamed and situated into the *email.mime* subpackage. For example, the version 3 module *email.MIMEText* was renamed to *email.mime.text*.

Note that the version 3 names will continue to work until Python 2.6.

- The *email.mime.application* module was added, which contains the MIMEApplication class.

- Methods that were deprecated in version 3 have been removed. These include Generator.__call__(), Message.get_type(), Message.get_main_type(), Message.get_subtype().

- Fixes have been added for RFC 2231 support which can change some of the return types for Message.get_param and friends. Under some circumstances, values which used to return a 3-tuple now return simple strings (specifically, if all extended parameter segments were unencoded, there is no language and charset designation expected, so the return type is now a simple string). Also, %-decoding used to be done for both encoded and unencoded segments; this decoding is now done only for encoded segments.

Here are the major differences between email version 3 and version 2:

- The FeedParser class was introduced, and the Parser class was implemented in terms of the FeedParser. All parsing therefore is non-strict, and parsing will make a best effort never to raise an exception. Problems found while parsing messages are stored in the message’s defect attribute.
All aspects of the API which raised DeprecationWarnings in version 2 have been removed. These include the `_encoder` argument to the MIMEText constructor, the Message.add_payload() method, the Utils.dump_address_pair() function, and the functions Utils.decode() and Utils.encode().

New DeprecationWarnings have been added to: Generator.__call__(), Message.get_type(), Message.get_main_type(), Message.get_subtype(), and the `strict` argument to the Parser class. These are expected to be removed in future versions.

Support for Pythons earlier than 2.3 has been removed.

Here are the differences between email version 2 and version 1:

- The email.Header and email.Charset modules have been added.

- The pickle format for Message instances has changed. Since this was never (and still isn't) formally defined, this isn't considered a backward incompatibility. However if your application pickles and unpickles Message instances, be aware that in email version 2, Message instances now have private variables `_charset` and `_default_type`.

- Several methods in the Message class have been deprecated, or their signatures changed. Also, many new methods have been added. See the documentation for the Message class for details. The changes should be completely backward compatible.

- The object structure has changed in the face of message/rfc822 content types. In email version 1, such a type would be represented by a scalar payload, i.e. the container message's
is_multipart() returned false, get_payload() was not a list object, but a single Message instance.

This structure was inconsistent with the rest of the package, so the object representation for message/rfc822 content types was changed. In email version 2, the container does return True from is_multipart(), and get_payload() returns a list containing a single Message item.

Note that this is one place that backward compatibility could not be completely maintained. However, if you’re already testing the return type of get_payload(), you should be fine. You just need to make sure your code doesn’t do a set_payload() with a Message instance on a container with a content type of message/rfc822.

- The Parser constructor’s strict argument was added, and its parse() and parsestr() methods grew a headersonly argument. The strict flag was also added to functions email.message_from_file() and email.message_from_string().

- Generator.__call__() is deprecated; use Generator.flatten instead. The Generator class has also grown the clone() method.

- The DecodedGenerator class in the email.generator module was added.

- The intermediate base classes MIMENonMultipart and MIMEMultipart have been added, and interposed in the class hierarchy for most of the other MIME-related derived classes.
- The `_encoder` argument to the `MIMEText` constructor has been deprecated. Encoding now happens implicitly based on the `_charset` argument.

- The following functions in the `email.Utils` module have been deprecated: `dump_address_pairs()`, `decode()`, and `encode()`. The following functions have been added to the module: `make_msgid()`, `decode_rfc2231()`, `encode_rfc2231()`, and `decode_params()`.

- The non-public function `email.Iterators._structure()` was added.
19.1.16. Differences from mimelib

The email package was originally prototyped as a separate library called mimelib. Changes have been made so that method names are more consistent, and some methods or modules have either been added or removed. The semantics of some of the methods have also changed. For the most part, any functionality available in mimelib is still available in the email package, albeit often in a different way. Backward compatibility between the mimelib package and the email package was not a priority.

Here is a brief description of the differences between the mimelib and the email packages, along with hints on how to port your applications.

Of course, the most visible difference between the two packages is that the package name has been changed to email. In addition, the top-level package has the following differences:

- messageFromString() has been renamed to message_from_string().
- messageFromFile() has been renamed to message_from_file().

The Message class has the following differences:

- The method asString() was renamed to as_string().
- The method ismultipart() was renamed to is_multipart().
- The get_payload() method has grown a decode optional argument.
- The method getall() was renamed to get_all().
The method `addheader()` was renamed to `add_header()`.
- The method `gettype()` was renamed to `get_type()`.
- The method `getmaintype()` was renamed to `get_main_type()`.
- The method `getsubtype()` was renamed to `get_subtype()`.
- The method `getparams()` was renamed to `get_params()`. Also, whereas `getparams()` returned a list of strings, `get_params()` returns a list of 2-tuples, effectively the key/value pairs of the parameters, split on the '=' sign.
- The method `getparam()` was renamed to `get_param()`.
- The method `getcharsets()` was renamed to `get_charsets()`.
- The method `getfilename()` was renamed to `get_filename()`.
- The method `getboundary()` was renamed to `get_boundary()`.
- The method `setboundary()` was renamed to `set_boundary()`.
- The method `getdecodedpayload()` was removed. To get similar functionality, pass the value 1 to the `decode` flag of the `get_payload()` method.
- The method `getpayloadastext()` was removed. Similar functionality is supported by the `DecodedGenerator` class in the `email.generator` module.
- The method `getbodyastext()` was removed. You can get similar functionality by creating an iterator with `typed_subpart_iterator()` in the `email.iterators` module.

The `Parser` class has no differences in its public interface. It does have some additional smarts to recognize `message/delivery-status` type messages, which it represents as a `Message` instance containing
separate Message subparts for each header block in the delivery status notification [1].

The Generator class has no differences in its public interface. There is a new class in the email generator module though, called DecodedGenerator which provides most of the functionality previously available in the Message.getpayloadastext() method.

The following modules and classes have been changed:

- The MIMEBase class constructor arguments _major and _minor have changed to _maintype and _subtype respectively.

- The Image class/module has been renamed to MIMEImage. The _minor argument has been renamed to _subtype.

- The Text class/module has been renamed to MIMEText. The _minor argument has been renamed to _subtype.

- The MessageRFC822 class/module has been renamed to MIMEMessage. Note that an earlier version of mimelib called this class/module RFC822, but that clashed with the Python standard library module rfc822 on some case-insensitive file systems.

   Also, the MIMEMessage class now represents any kind of MIME message with main type message. It takes an optional argument _subtype which is used to set the MIME subtype. _subtype defaults to rfc822.

mimelib provided some utility functions in its address and date modules. All of these functions have been moved to the email.utils module.
The MsgReader class/module has been removed. Its functionality is most closely supported in the `body_line_iterator()` function in the `email.iterators` module.

Footnotes

[1] Delivery Status Notifications (DSN) are defined in RFC 1894.
19.1.1. **email.message**: Representing an email message

The central class in the `email` package is the `Message` class, imported from the `email.message` module. It is the base class for the `email` object model. `Message` provides the core functionality for setting and querying header fields, and for accessing message bodies.

Conceptually, a `Message` object consists of *headers* and *payloads*. Headers are **RFC 2822** style field names and values where the field name and value are separated by a colon. The colon is not part of either the field name or the field value.

Headers are stored and returned in case-preserving form but are matched case-insensitively. There may also be a single envelope header, also known as the `Unix-From` header or the `From_` header. The payload is either a string in the case of simple message objects or a list of `Message` objects for MIME container documents (e.g. `multipart/*` and `message/rfc822').

`Message` objects provide a mapping style interface for accessing the message headers, and an explicit interface for accessing both the headers and the payload. It provides convenience methods for generating a flat text representation of the message object tree, for accessing commonly used header parameters, and for recursively walking over the object tree.

Here are the methods of the `Message` class:

```python
class email.message.Message(policy=compat32)
```
If *policy* is specified (it must be an instance of a *policy* class) use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the *policy* documentation.

*Changed in version 3.3:* The *policy* keyword argument was added.

**as_string**(*unixfrom=False, maxheaderlen=0, policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to False. For backward compatibility reasons, *maxheaderlen* defaults to 0, so if you want a different value you must override it explicitly (the value specified for *max_line_length* in the policy will be ignored by this method).

The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the Generator.

Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with From that is required by the unix mbox format. For more flexibility, instantiate a *Generator* instance and use its *flatten()* method directly. For example:
```python
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=True, maxheaderlen)
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode “unknown character” code points. (See also `as_bytes()` and `BytesGenerator`.)

*Changed in version 3.4:* the `policy` keyword argument was added.

```python
__str__()
```
Equivalent to `as_string()`. Allows `str(msg)` to produce a string containing the formatted message.

```python
as_bytes(unixfrom=False, policy=None)
```
Return the entire message flattened as a bytes object. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to False. The `policy` argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified `policy` will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the `Message` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).
Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with From that is required by the unix mbox format. For more flexibility, instantiate a **BytesGenerator** instance and use its **flatten()** method directly. For example:

```python
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxheaderlen)
g.flatten(msg)
text = fp.getvalue()
```

*New in version 3.4.*

**__bytes__()**

Equivalent to **as_bytes()**. Allows `bytes(msg)` to produce a `bytes` object containing the formatted message.

*New in version 3.4.*

**is_multipart()**

Return True if the message's payload is a list of sub-**Message** objects, otherwise return False. When **is_multipart()** returns False, the payload should be a string object. (Note that **is_multipart()** returning True does not necessarily mean that “msg.get_content_maintype() == 'multipart'” will return the True. For example, **is_multipart** will return True when the **Message** is of type `message/rfc822`.)

**set_unixfrom(unixfrom)**
Set the message’s envelope header to `unixfrom`, which should be a string.

**get_unixfrom()**
Return the message’s envelope header. Defaults to None if the envelope header was never set.

**attach(payload)**
Add the given `payload` to the current payload, which must be None or a list of `Message` objects before the call. After the call, the payload will always be a list of `Message` objects. If you want to set the payload to a scalar object (e.g. a string), use `set_payload()` instead.

**get_payload(i=None, decode=False)**
Return the current payload, which will be a list of `Message` objects when `is_multipart()` is True, or a string when `is_multipart()` is False. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument `i`, `get_payload()` will return the `i`-th element of the payload, counting from zero, if `is_multipart()` is True. An `IndexError` will be raised if `i` is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. `is_multipart()` is False) and `i` is given, a `TypeError` is raised.

Optional `decode` is a flag indicating whether the payload should be decoded or not, according to the `Content-Transfer-Encoding` header. When True and the message is not a multipart, the payload will be decoded if this header’s value is quoted-
printable or base64. If some other encoding is used, or `Content-Transfer-Encoding` header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the `decode` flag is True, then None is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added to the message’s defect property (InvalidBase64PaddingDefect or InvalidBase64CharactersDefect, respectively).

When `decode` is False (the default) the body is returned as a string without decoding the `Content-Transfer-Encoding`. However, for a `Content-Transfer-Encoding` of 8bit, an attempt is made to decode the original bytes using the charset specified by the `Content-Type` header, using the replace error handler. If no charset is specified, or if the charset given is not recognized by the email package, the body is decoded using the default ASCII charset.

**set_payload**(*payload*, *charset=None*)

Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see `set_charset()` for details.

**set_charset**(*charset*)

Set the character set of the payload to *charset*, which can either be a Charset instance (see `email.charset`), a string naming a character set, or None. If it is a string, it will be converted to a Charset instance. If *charset* is None, the
charset parameter will be removed from the Content-Type header (the message will not be otherwise modified). Anything else will generate a TypeError.

If there is no existing MIME-Version header one will be added. If there is no existing Content-Type header, one will be added with a value of text/plain. Whether the Content-Type header already exists or not, its charset parameter will be set to charset.output_charset. If charset.input_charset and charset.output_charset differ, the payload will be re-encoded to the output_charset. If there is no existing Content-Transfer-Encoding header, then the payload will be transfer-encoded, if needed, using the specified Charset, and a header with the appropriate value will be added. If a Content-Transfer-Encoding header already exists, the payload is assumed to already be correctly encoded using that Content-Transfer-Encoding and is not modified.

get_charset()

Return the Charset instance associated with the message's payload.

The following methods implement a mapping-like interface for accessing the message’s RFC 2822 headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by keys(), but in a Message object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the
header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as Header objects with a charset of unknown-8bit.

__len__()  
Return the total number of headers, including duplicates.

__contains__(name)  
Return true if the message object has a field named name. Matching is done case-insensitively and name should not include the trailing colon. Used for the in operator, e.g.:

```python
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

__getitem__(name)  
Return the value of the named header field. name should not include the colon field separator. If the header is missing, None is returned; a KeyError is never raised.

Note that if the named field appears more than once in the message’s headers, exactly which of those field values will be returned is undefined. Use the get_all() method to get the
values of all the extant named headers.

__setitem__(name, val)
Add a header to the message with field name name and value val. The field is appended to the end of the message’s existing fields.

Note that this does not overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name name, delete the field first, e.g.:

```python
del msg['subject']
msg['subject'] = 'Python roolz!'
```

__delitem__(name)
Delete all occurrences of the field with name name from the message’s headers. No exception is raised if the named field isn’t present in the headers.

keys()
Return a list of all the message’s header field names.

values()
Return a list of all the message’s field values.

items()
Return a list of 2-tuples containing all the message’s field headers and values.

get(name, failobj=None)
Return the value of the named header field. This is identical to __getitem__() except that optional failobj is returned if the
named header is missing (defaults to None).

Here are some additional useful methods:

**get_all(name, failobj=None)**

Return a list of all the values for the field named name. If there are no such named headers in the message, failobj is returned (defaults to None).

**add_header(_name, _value, **_params)**

Extended header setting. This method is similar to __setitem__() except that additional header parameters can be provided as keyword arguments. _name is the header field to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the key will be added. If the value contains non-ASCII characters, it can be specified as a three tuple in the format (CHARSET, LANGUAGE, VALUE), where CHARSET is a string naming the charset to be used to encode the value, LANGUAGE can usually be set to None or the empty string (see RFC 2231 for other possibilities), and VALUE is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in RFC 2231 format using a CHARSET of utf-8 and a LANGUAGE of None.

Here's an example:
This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.
```

An example with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
filename=('iso-8859-1', '', 'Fuß
```

Which produces

```
Content-Disposition: attachment; filename*="iso-
```

**replace_header**(_name, _value)

Replace a header. Replace the first header found in the message that matches _name, retaining header order and field name case. If no matching header was found, a **KeyError** is raised.

**get_content_type**()

Return the message’s content type. The returned string is coerced to lower case of the form `maintype/subtype`. If there was no `Content-Type` header in the message the default type as given by `get_default_type()` will be returned. Since according to **RFC 2045**, messages always have a default type, `get_content_type()` will always return a value.

**RFC 2045** defines a message’s default type to be `text/plain`
unless it appears inside a multipart/digest container, in which case it would be message/rfc822. If the Content-Type header has an invalid type specification, RFC 2045 mandates that the default type be text/plain.

get_content_maintype()
Return the message’s main content type. This is the maintype part of the string returned by get_content_type().

get_content_subtype()
Return the message’s sub-content type. This is the subtype part of the string returned by get_content_type().

get_default_type()
Return the default content type. Most messages have a default content type of text/plain, except for messages that are subparts of multipart/digest containers. Such subparts have a default content type of message/rfc822.

set_default_type(ctype)
Set the default content type. ctype should either be text/plain or message/rfc822, although this is not enforced. The default content type is not stored in the Content-Type header.

get_params(failobj=None, header='content-type', unquote=True)
Return the message’s Content-Type parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the ‘=’ sign. The left hand side of the ‘=’ is the key, while the right hand side is the value. If there is no ‘=’ sign in the parameter the value is the empty string, otherwise the value is as described in get_param() and is unquoted if optional
unquote is True (the default).

Optional failobj is the object to return if there is no Content-Type header. Optional header is the header to search instead of Content-Type.

get_param(param, failobj=None, header='content-type', unquote=True)

Return the value of the Content-Type header's parameter param as a string. If the message has no Content-Type header or if there is no such parameter, then failobj is returned (defaults to None).

Optional header if given, specifies the message header to use instead of Content-Type.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was RFC 2231 encoded. When it's a 3-tuple, the elements of the value are of the form (CHARSET, LANGUAGE, VALUE). Note that both CHARSET and LANGUAGE can be None, in which case you should consider VALUE to be encoded in the us-ascii charset. You can usually ignore LANGUAGE.

If your application doesn’t care whether the parameter was encoded as in RFC 2231, you can collapse the parameter value by calling email.utils.collapse_rfc2231_value(), passing in the return value from get_param(). This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn’t. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```
In any case, the parameter value (either the returned string, or the VALUE item in the 3-tuple) is always unquoted, unless unquote is set to False.

```python
set_param(param, value, header='Content-Type', requote=True, charset=None, language='', replace=False)
```

Set a parameter in the `Content-Type` header. If the parameter already exists in the header, its value will be replaced with `value`. If the `Content-Type` header as not yet been defined for this message, it will be set to `text/plain` and the new parameter value will be appended as per RFC 2045.

Optional `header` specifies an alternative header to `Content-Type`, and all parameters will be quoted as necessary unless optional `requote` is False (the default is True).

If optional `charset` is specified, the parameter will be encoded according to RFC 2231. Optional `language` specifies the RFC 2231 language, defaulting to the empty string. Both `charset` and `language` should be strings.

If `replace` is False (the default) the header is moved to the end of the list of headers. If `replace` is True, the header will be updated in place.

*Changed in version 3.4:* replace keyword was added.

```python
del_param(param, header='content-type', requote=True)
```

Remove the given parameter completely from the `Content-Type` header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary.
unless `requote` is False (the default is True). Optional `header` specifies an alternative to `Content-Type`.

**set_type**(type, header='Content-Type', requote=True)

Set the main type and subtype for the `Content-Type` header. `type` must be a string in the form `maintype/subtype`, otherwise a `ValueError` is raised.

This method replaces the `Content-Type` header, keeping all the parameters in place. If `requote` is False, this leaves the existing header’s quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the `header` argument. When the `Content-Type` header is set a `MIME-Version` header is also added.

**get_filename**(failobj=None)

Return the value of the filename parameter of the `Content-Disposition` header of the message. If the header does not have a filename parameter, this method falls back to looking for the name parameter on the `Content-Type` header. If neither is found, or the header is missing, then `failobj` is returned. The returned string will always be unquoted as per `email.utils.unquote()`.

**get_boundary**(failobj=None)

Return the value of the boundary parameter of the `Content-Type` header of the message, or `failobj` if either the header is missing, or has no boundary parameter. The returned string will always be unquoted as per `email.utils.unquote()`.
**set_boundary**(boundary)

Set the boundary parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

**get_content_charset**(failobj=None)

Return the charset parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no charset parameter, *failobj* is returned.

Note that this method differs from *get_charset()* which returns the *Charset* instance for the default encoding of the message body.

**get_charsets**(failobj=None)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the charset parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-
Type header, no charset parameter, or is not of the text main MIME type, then that item in the returned list will be failobj.

**get_content_disposition()**
Return the lowercased value (without parameters) of the message’s Content-Disposition header if it has one, or None. The possible values for this method are inline, attachment or None if the message follows RFC 2183.

*New in version 3.5.*

**walk()**
The walk() method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use walk() as the iterator in a for loop; each iteration returns the next subpart.

Here’s an example that prints the MIME type of every part of a multipart message structure:

```python
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plaint
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

walk iterates over the subparts of any part where is_multipart() returns True, even though
msg.get_content_maintype() == 'multipart' may return False. We can see this in our example by making use of the _structure debug helper function:

```python
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart')
...     part.is_multipart()
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
  text/plain
message/delivery-status
  text/plain
  text/plain
message/rfc822
  text/plain
```

Here the message parts are not multipartes, but they do contain subparts. is_multipart() returns True and walk descends into the subparts.

**Message** objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart
boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See `email.parser` and `email.generator` for details.

Note that if the message object has no preamble, the *preamble* attribute will be None.

**epilogue**

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the *Generator* to print a newline at the end of the file.

**defects**

The *defects* attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.
19.1.2. **email.parser**: Parsing email messages

Message object structures can be created in one of two ways: they can be created from whole cloth by instantiating `Message` objects and stringing them together via `attach()` and `set_payload()` calls, or they can be created by parsing a flat text representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a string or a file object, and the parser will return to you the root `Message` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the `get_payload()` and `walk()` methods.

There are actually two parser interfaces available for use, the classic `Parser` API and the incremental `FeedParser` API. The classic `Parser` API is fine if you have the entire text of the message in memory as a string, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate for when you're reading the message from a stream which might block waiting for more input (e.g. reading an email message from a socket). The `FeedParser` can consume and parse the message incrementally, and only returns the root object when you close the parser [1].

Note that the parser can be extended in limited ways, and of course
you can implement your own parser completely from scratch. There is no magical connection between the `email` package's bundled parser and the `Message` class, so your custom parser can create message object trees any way it finds necessary.
19.1.2.1. FeedParser API

The **FeedParser**, imported from the `email.feedparser` module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (e.g. a socket). The **FeedParser** can of course be used to parse an email message fully contained in a string or a file, but the classic **Parser** API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The **FeedParser**'s API is simple; you create an instance, feed it a bunch of text until there's no more to feed it, then close the parser to retrieve the root message object. The **FeedParser** is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's `defects` attribute with a list of any problems it found in a message. See the `email.errors` module for the list of defects that it can find.

Here is the API for the **FeedParser**:

```python
class email.parser.FeedParser(_factory=email.message.Message, *, policy=policy.compat32)

Create a **FeedParser** instance. Optional `_factory` is a no-argument callable that will be called whenever a new message object is needed. It defaults to the `email.message.Message` class.
If `policy` is specified (it must be an instance of a `policy` class) use the rules it specifies to update the representation of the message. If `policy` is not set, use the `compat32` policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the `policy` documentation.

`Changed in version 3.3: Added the policy keyword.`

`feed(data)`

Feed the `FeedParser` some more data. `data` should be a string containing one or more lines. The lines can be partial and the `FeedParser` will stitch such partial lines together properly. The lines in the string can have any of the common three line endings, carriage return, newline, or carriage return and newline (they can even be mixed).

`close()`

Closing a `FeedParser` completes the parsing of all previously fed data, and returns the root message object. It is undefined what happens if you feed more data to a closed `FeedParser`.

`class` email.parser.BytesFeedParser(_factory=email.message.Message

Works exactly like `FeedParser` except that the input to the `feed()` method must be bytes and not string.

`New in version 3.2.`
19.1.2.2. Parser class API

The `Parser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a string or file. The `email.parser` module also provides header-only parsers, called `HeaderParser` and `BytesHeaderParser`, which can be used if you're only interested in the headers of the message. `HeaderParser` and `BytesHeaderParser` can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body as a string. They have the same API as the `Parser` and `BytesParser` classes.

*New in version 3.3:* The `BytesHeaderParser` class.

```python
class email.parser.Parser(_class=email.message.Message, *, policy=policy.compat32)
```

The constructor for the `Parser` class takes an optional argument `_class`. This must be a callable factory (such as a function or a class), and it is used whenever a sub-message object needs to be created. It defaults to `Message` (see `email.message`). The factory will be called without arguments.

If `policy` is specified (it must be an instance of a `policy` class) use the rules it specifies to update the representation of the message. If `policy` is not set, use the `compat32` policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the `policy` documentation.

*Changed in version 3.3:* Removed the `strict` argument that was deprecated in 2.4. Added the `policy` keyword.
The other public `Parser` methods are:

**parse**(fp, headersonly=False)

Read all the data from the file-like object `fp`, parse the resulting text, and return the root message object. `fp` must support both the `readline()` and the `read()` methods on file-like objects.

The text contained in `fp` must be formatted as a block of RFC 2822 style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts).

Optional `headersonly` is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

**parsestr**(text, headersonly=False)

Similar to the `parse()` method, except it takes a string object instead of a file-like object. Calling this method on a string is exactly equivalent to wrapping `text` in a `StringIO` instance first and calling `parse()`.

Optional `headersonly` is as with the `parse()` method.

```python
class email.parser.BytesParser(_class=email.message.Message, *, policy=policy.compat32)
```

This class is exactly parallel to `Parser`, but handles bytes input. The `_class` and `strict` arguments are interpreted in the same way as for the `Parser` constructor.
If *policy* is specified (it must be an instance of a *policy* class) use the rules it specifies to update the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the *policy* documentation.

*Changed in version 3.3:* Removed the *strict* argument. Added the *policy* keyword.

**parse**(*fp, headersonly=False*)

Read all the data from the binary file-like object *fp*, parse the resulting bytes, and return the message object. *fp* must support both the *readline()* and the *read()* methods on file-like objects.

The bytes contained in *fp* must be formatted as a block of **RFC 2822** style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a *Content-Transfer-Encoding* of 8bit.

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is *False*, meaning it parses the entire contents of the file.

**parsebytes**(*bytes, headersonly=False*)

Similar to the *parse()* method, except it takes a byte string object instead of a file-like object. Calling this method on a byte string is exactly equivalent to wrapping *text* in a **BytesIO** instance first and calling *parse()*.
Optional *headersonly* is as with the *parse()* method.

*New in version 3.2.*

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level *email* package namespace.

**email.message_from_string(s,  
_class=email.message.Message, *, policy=policy.compat32)**

Return a message object structure from a string. This is exactly equivalent to *Parser().parsestr(s)*. *_class* and *policy* are interpreted as with the *Parser* class constructor.

*Changed in version 3.3:* Removed the *strict* argument. Added the *policy* keyword.

**email.message_from_bytes(s,  
_class=email.message.Message, *, policy=policy.compat32)**

Return a message object structure from a byte string. This is exactly equivalent to *BytesParser().parsebytes(s)*. Optional *_class* and *strict* are interpreted as with the *Parser* class constructor.

*New in version 3.2.*

*Changed in version 3.3:* Removed the *strict* argument. Added the *policy* keyword.

**email.message_from_file(fp,  
_class=email.message.Message, *, policy=policy.compat32)**

Return a message object structure tree from an open *file object*. This is exactly equivalent to *Parser().parse(fp)*. *_class* and
policy are interpreted as with the Parser class constructor.

Changed in version Removed: the strict argument. Added the policy keyword.

email.message_from_binary_file(fp, _class=email.message.Message, *, policy=policy.compat32)

Return a message object structure tree from an open binary file object. This is exactly equivalent to BytesParser().parse(fp). _class and policy are interpreted as with the Parser class constructor.

New in version 3.2.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

Here’s an example of how you might use this at an interactive Python prompt:

```python
>>> import email
>>> msg = email.message_from_string(myString)
```
19.1.2.3. Additional notes

Here are some notes on the parsing semantics:

- Most non-
  multipart type messages are parsed as a single message object with a string payload. These objects will return False for is_multipart(). Their get_payload() method will return a string object.
- All multipart type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return True for is_multipart() and their get_payload() method will return the list of Message subparts.
- Most messages with a content type of message/* (e.g. message/delivery-status and message/rfc822) will also be parsed as container object containing a list payload of length 1. Their is_multipart() method will return True. The single element in the list payload will be a sub-message object.
- Some non-standards compliant messages may not be internally consistent about their multipart-edness. Such messages may have a Content-Type header of type multipart, but their is_multipart() method may return False. If such messages were parsed with the FeedParser, they will have an instance of the MultipartInvariantViolationDefect class in their defects attribute list. See email.errors for details.

Footnotes

[1] As of email package version 3.0, introduced in Python 2.4, the classic Parser was re-implemented in terms of the FeedParser, so the semantics and results are identical between the two parsers.
19.1. email — An email and MIME handling package
19.1.3. email.generator: Generating MIME documents

One of the most common tasks is to generate the flat text of the email message represented by a message object structure. You will need to do this if you want to send your message via the `smtplib` module or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a flat text document is the job of the `Generator` class.

Again, as with the `email.parser` module, you aren't limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the transformation from flat text, to a message structure via the `Parser` class, and back to flat text, is idempotent (the input is identical to the output) [1]. On the other hand, using the Generator on a `Message` constructed by program may result in changes to the `Message` object as defaults are filled in.

`bytes` output can be generated using the `BytesGenerator` class. If the message object structure contains non-ASCII bytes, this generator’s `flatten()` method will emit the original bytes. Parsing a binary message and then flattening it with `BytesGenerator` should be idempotent for standards compliant messages.

Here are the public methods of the `Generator` class, imported from the `email.generator` module:
class email.generator.Generator(outfp, mangle_from_=True, maxheaderlen=78, *, policy=None)

The constructor for the Generator class takes a file-like object called outfp for an argument. outfp must support the write() method and be usable as the output file for the print() function.

Optional mangle_from_ is a flag that, when True, puts a > character in front of any line in the body that starts exactly as From, i.e. From followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such lines be mistaken for a Unix mailbox format envelope header separator (see WHY THE CONTENT-LENGTH FORMAT IS BAD for details). mangle_from_ defaults to True, but you might want to set this to False if you are not writing Unix mailbox format files.

Optional maxheaderlen specifies the longest length for a non-continued header. When a header line is longer than maxheaderlen (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the Header class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by RFC 2822.

The policy keyword specifies a policy object that controls a number of aspects of the generator’s operation. If no policy is specified, then the policy attached to the message object passed to flatten is used.

Changed in version 3.3: Added the policy keyword.

The other public Generator methods are:

flatten(msg, unixfrom=False, linesep=None)
Print the textual representation of the message object structure rooted at \textit{msg} to the output file specified when the \texttt{Generator} instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded.

Optional \textit{unixfrom} is a flag that forces the printing of the envelope header delimiter before the first \texttt{RFC 2822} header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to \texttt{False} to inhibit the printing of the envelope delimiter.

Note that for subparts, no envelope header is ever printed.

Optional \textit{linesep} specifies the line separator character used to terminate lines in the output. If specified it overrides the value specified by the \textit{msg}'s or \texttt{Generator}'s policy.

Because strings cannot represent non-ASCII bytes, if the policy that applies when flatten is run has \texttt{cte_type} set to 8bit, \texttt{Generator} will operate as if it were set to 7bit. This means that messages parsed with a Bytes parser that have a \texttt{Content-Transfer-Encoding} of 8bit will be converted to a use a 7bit Content-Transfer-Encoding. Non-ASCII bytes in the headers will be \texttt{RFC 2047} encoded with a charset of unknown-8bit.

\textit{Changed in version 3.2: Added support for re-encoding 8bit message bodies, and the \textit{linesep} argument.}

\textit{clone}(\textit{fp})

Return an independent clone of this \texttt{Generator} instance with the exact same options.

\textit{write}(\textit{s})
Write the string \textit{s} to the underlying file object, i.e. \texttt{outfp} passed to \texttt{Generator}'s constructor. This provides just enough file-like API for \texttt{Generator} instances to be used in the \texttt{print()} function.

As a convenience, see the \texttt{Message} methods \texttt{as\_string()} and \texttt{str(aMessage)}, a.k.a. \texttt{\_\_str\_()}, which simplify the generation of a formatted string representation of a message object. For more detail, see \texttt{email.message}.

\texttt{class email\.generator\.BytesGenerator(outfp, mangle\_from\_=True, maxheaderlen=78, \*, policy=None)}

The constructor for the \texttt{BytesGenerator} class takes a binary file-like object called \texttt{outfp} for an argument. \texttt{outfp} must support a \texttt{write()} method that accepts binary data.

Optional \texttt{mangle\_from\_} is a flag that, when True, puts a > character in front of any line in the body that starts exactly as From, i.e. From followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such lines be mistaken for a Unix mailbox format envelope header separator (see \texttt{WHY THE CONTENT-LENGTH FORMAT IS BAD} for details). \texttt{mangle\_from\_} defaults to True, but you might want to set this to False if you are not writing Unix mailbox format files.

Optional \texttt{maxheaderlen} specifies the longest length for a non-continued header. When a header line is longer than \texttt{maxheaderlen} (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the \texttt{Header} class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by \texttt{RFC 2822}. 

The `policy` keyword specifies a `policy` object that controls a number of aspects of the generator’s operation. If no `policy` is specified, then the `policy` attached to the message object passed to `flatten` is used.

*Changed in version 3.3:* Added the `policy` keyword.

The other public `BytesGenerator` methods are:

```python
flatten(msg, unixfrom=False, linesep=None)
```

Print the textual representation of the message object structure rooted at `msg` to the output file specified when the `BytesGenerator` instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded. If the `policy` option `cte_type` is 8bit (the default), then any bytes with the high bit set in the original parsed message that have not been modified will be copied faithfully to the output. If `cte_type` is 7bit, the bytes will be converted as needed using an ASCII-compatible Content-Transfer-Encoding. In particular, RFC-invalid non-ASCII bytes in headers will be encoded using the MIME unknown-8bit character set, thus rendering them RFC-compliant.

Messages parsed with a Bytes parser that have a `Content-Transfer-Encoding` of 8bit will be reconstructed as 8bit if they have not been modified.

Optional `unixfrom` is a flag that forces the printing of the envelope header delimiter before the first RFC 2822 header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to `False` to inhibit the printing of the envelope delimiter.
Note that for subparts, no envelope header is ever printed.

Optional \textit{linesep} specifies the line separator character used to terminate lines in the output. If specified it overrides the value specified by the Generator or \texttt{msg}'s policy.

\textbf{clone}(\texttt{fp})

Return an independent clone of this \texttt{BytesGenerator} instance with the exact same options.

\textbf{write}(\texttt{s})

Write the string \texttt{s} to the underlying file object. \texttt{s} is encoded using the ASCII codec and written to the \texttt{write} method of the \texttt{outfp} passed to the \texttt{BytesGenerator}'s constructor. This provides just enough file-like API for \texttt{BytesGenerator} instances to be used in the \texttt{print()} function.

\textit{New in version 3.2.}

The \texttt{email.generator} module also provides a derived class, called \texttt{DecodedGenerator} which is like the \texttt{Generator} base class, except that non-text parts are substituted with a format string representing the part.

\texttt{class email.generator.\textbf{DecodedGenerator}(outfp, mangle_from_=True, maxheaderlen=78, fmt=None)}

This class, derived from \texttt{Generator} walks through all the subparts of a message. If the subpart is of main type \texttt{text}, then it prints the decoded payload of the subpart. Optional \texttt{mangle_from_} and \texttt{maxheaderlen} are as with the \texttt{Generator} base class.

If the subpart is not of main type \texttt{text}, optional \texttt{fmt} is a format string that is used instead of the message payload. \texttt{fmt} is expanded with
the following keywords, \%(keyword)s format:

- **type** – Full MIME type of the non-text part
- **maintype** – Main MIME type of the non-text part
- **subtype** – Sub-MIME type of the non-text part
- **filename** – Filename of the non-text part
- **description** – Description associated with the non-text part
- **encoding** – Content transfer encoding of the non-text part

The default value for *fmt* is None, meaning

```
[Non-text (%(type)s) part of message omitted, file
```

**Footnotes**

This statement assumes that you use the appropriate setting for the `unixfrom` argument, and that you set `maxheaderlen=0` (which will preserve whatever the input line lengths were). It is also not strictly true, since in many cases runs of whitespace in headers are collapsed into single blanks. The latter is a bug that will eventually be fixed.

[1]
19. Internet Data Handling

19.1. `email` — An email and MIME handling package
19.1.4. `email.policy`: Policy Objects

*New in version 3.3.*

The `email` package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary ‘body’), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main RFCs, some do not. And even when working with email, there are times when it is desirable to break strict compliance with the RFCs.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A `Policy` object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. `Policy` instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. This policy is named `Compat32`, with a corresponding pre-defined instance named `compat32`. It provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

The first part of this documentation covers the features of `Policy`, an
abstract base class that defines the features that are common to all policy objects, including compat32. This includes certain hook methods that are called internally by the email package, which a custom policy could override to obtain different behavior.

When a Message object is created, it acquires a policy. By default this will be compat32, but a different policy can be specified. If the Message is created by a parser, a policy passed to the parser will be the policy used by the Message it creates. If the Message is created by the program, then the policy can be specified when it is created. When a Message is passed to a generator, the generator uses the policy from the Message by default, but you can also pass a specific policy to the generator that will override the one stored on the Message object.

Policy instances are immutable, but they can be cloned, accepting the same keyword arguments as the class constructor and returning a new Policy instance that is a copy of the original but with the specified attributes values changed.

As an example, the following code could be used to read an email message from a file on disk and pass it to the system sendmail program on a Unix system:

```python
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE
>>> with open('mymsg.txt', 'rb') as f:
...     msg = message_from_binary_file(f, policy=policy)
>>> p = Popen(['sendmail', msg['To'][0].addresses[0]],
>>> g = BytesGenerator(p.stdin, policy=msg.policy.clone)
>>> g.flatten(msg)
```
Here we are telling `BytesGenerator` to use the RFC correct line separator characters when creating the binary string to feed into sendmail's stdin, where the default policy would use \n line separators.

Some email package methods accept a `policy` keyword argument, allowing the policy to be overridden for that method. For example, the following code uses the `as_bytes()` method of the `msg` object from the previous example and writes the message to a file using the native line separators for the platform on which it is running:

```python
>>> import os
>>> with open('converted.txt', 'wb') as f:
...     f.write(msg.as_bytes(policy=msg.policy.clone)
```

Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```python
>>> compat_SMTP = policy.compat32.clone(linesep='\r\n')
>>> compat_strict = policy.compat32.clone(raise_on_defect=True)
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```python
>>> policy100 = policy.compat32.clone(max_line_length=100)
>>> policy80 = policy.compat32.clone(max_line_length=80)
```
class email.policy.Policy(**kw)

This is the abstract base class for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the clone() method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

**max_line_length**

The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per RFC 5322. A value of 0 or None indicates that no line wrapping should be done at all.

**linesep**

The string to be used to terminate lines in serialized output. The default is \n because that's the internal end-of-line discipline used by Python, though \r\n is required by the RFCs.
**cte_type**

Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

<table>
<thead>
<tr>
<th>7bit</th>
<th>all data must be “7 bit clean” (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.</th>
</tr>
</thead>
<tbody>
<tr>
<td>8bit</td>
<td>data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see ‘binary_fold’ below for an exception), but body parts may use the 8bit CTE.</td>
</tr>
</tbody>
</table>

A cte_type value of 8bit only works with BytesGenerator, not Generator, because strings cannot contain binary data. If a Generator is operating under a policy that specifies cte_type=8bit, it will act as if cte_type is 7bit.

**raise_on_defect**

If True, any defects encountered will be raised as errors. If False (the default), defects will be passed to the register_defect() method.

**mangle_from_**

If True, lines starting with “From “ in the body are escaped by putting a > in front of them. This parameter is used when the message is being serialized by a generator. Default: False.

*New in version 3.5: The mangle_from_ parameter.*

The following Policy method is intended to be called by code using the email library to create policy instances with custom settings:
clone(**kw)

Return a new Policy instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining Policy methods are called by the email package code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

handle_defect(obj, defect)

Handle a defect found on obj. When the email package calls this method, defect will always be a subclass of Defect.

The default implementation checks the raise_on_defect flag. If it is True, defect is raised as an exception. If it is False (the default), obj and defect are passed to register_defect().

register_defect(obj, defect)

Register a defect on obj. In the email package, defect will always be a subclass of Defect.

The default implementation calls the append method of the defects attribute of obj. When the email package calls handle_defect, obj will normally have a defects attribute that has an append method. Custom object types used with the email package (for example, custom Message objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

header_max_count(name)
Return the maximum allowed number of headers named *name*.

Called when a header is added to a *Message* object. If the returned value is not 0 or *None*, and there are already a number of headers with the name *name* equal to the value returned, a *ValueError* is raised.

Because the default behavior of *Message.*`__setitem__` is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a *Message* programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns None for all header names.

**header_source_parse**(*sourcelines*)

The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the (*name*, *value*) tuple that is to be stored in the *Message* to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, *name* should be the case preserved name (all characters up to the ‘:‘ separator), while *value* should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.
sourcelines may contain surrogateescaped binary data.

There is no default implementation

**header_store_parse**(name, value)

The email package calls this method with the name and value provided by the application program when the application program is modifying a Message programmatically (as opposed to a Message created by a parser). The method should return the (name, value) tuple that is to be stored in the Message to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the name and value should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

**header_fetch_parse**(name, value)

The email package calls this method with the name and value currently stored in the Message when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the Message; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.
There is no default implementation

**fold(name, value)**

The email package calls this method with the *name* and *value* currently stored in the Message for a given header. The method should return a string that represents that header “folded” correctly (according to the policy settings) by composing the *name* with the *value* and inserting *linesep* characters at the appropriate places. See RFC 5322 for a discussion of the rules for folding email headers.

*value* may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

**fold_binary(name, value)**

The same as **fold()**, except that the returned value should be a bytes object rather than a string.

*value* may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

**class email.policy.Compat32(**kw**)**

This concrete *Policy* is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The *policy* module also defines an instance of this class, *compat32*, that is used as the default policy. Thus the default behavior of the email package is to maintain compatibility with Python 3.2.

The following attributes have values that are different from the *Policy* default:

**mangle_from_**
The default is True.

The class provides the following concrete implementations of the abstract methods of Policy:

**header_source_parse**(*sourcelines*)

The name is parsed as everything up to the `':` and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

**header_store_parse**(*name, value*)

The name and value are returned unmodified.

**header_fetch_parse**(*name, value*)

If the value contains binary data, it is converted into a Header object using the unknown-8bit charset. Otherwise it is returned unmodified.

**fold**(*name, value*)

Headers are folded using the Header folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the max_line_length. Non-ASCII binary data are CTE encoded using the unknown-8bit charset.

**fold_binary**(*name, value*)

Headers are folded using the Header folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the max_line_length. If cte_type is 7bit, non-ascii binary data is CTE encoded using the unknown-8bit charset. Otherwise the original source header is used,
with its existing line breaks and any (RFC invalid) binary data it may contain.

An instance of `Compat32` is provided as a module constant:

```python
email.policy.compat32
```

An instance of `Compat32`, providing backward compatibility with the behavior of the email package in Python 3.2.

---

**Note:** The documentation below describes new policies that are included in the standard library on a **provisional basis**. Backwards incompatible changes (up to and including removal of the feature) may occur if deemed necessary by the core developers.

```python
class email.policy.EmailPolicy(**kw)
```

This concrete `Policy` provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) `RFC 5322`, `RFC 2047`, and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are `str` subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement `RFC 2047` and `RFC 5322`.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:

```python
utf8
```

If `False`, follow `RFC 5322`, supporting non-ASCII characters in headers by encoding them as “encoded words”. If `True`, follow `RFC 6532` and use `utf-8` encoding for headers. Messages formatted in this way may be passed to SMTP servers that
support the SMTPUTF8 extension (RFC 6531).

refold_source
If the value for a header in the Message object originated from a parser (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into stream form. The possible values are:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>all source values use original folding</td>
</tr>
<tr>
<td>long</td>
<td>source values that have any line that is longer than max_line_length will be refolded</td>
</tr>
<tr>
<td>all</td>
<td>all values are refolded.</td>
</tr>
</tbody>
</table>

The default is long.

header_factory
A callable that takes two arguments, name and value, where name is a header field name and value is an unfolded header field value, and returns a string subclass that represents that header. A default header_factory (see headerregistry) is provided that understands some of the RFC 5322 header field types. (Currently address fields and date fields have special treatment, while all other fields are treated as unstructured. This list will be completed before the extension is marked stable.)

content_manager
An object with at least two methods: get_content and set_content. When the get_content() or set_content() method of a Message object is called, it calls the corresponding method of this object, passing it the message object as its first
argument, and any arguments or keywords that were passed to it as additional arguments. By default content_manager is set to raw_data_manager.

*New in version 3.4.*

The class provides the following concrete implementations of the abstract methods of `Policy`:

**header_max_count**(*name*)

Returns the value of the `max_count` attribute of the specialized class used to represent the header with the given name.

**header_source_parse**(*sourcelines*)

The implementation of this method is the same as that for the `Compat32` policy.

**header_store_parse**(*name, value*)

The name is returned unchanged. If the input value has a name attribute and it matches `name` ignoring case, the value is returned unchanged. Otherwise the `name` and `value` are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.

**header_fetch_parse**(*name, value*)

If the value has a name attribute, it is returned to unmodified. Otherwise the `name`, and the `value` with any CR or LF characters removed, are passed to the `header_factory`, and the resulting header object is returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.
**fold**(*name*, *value*)

Header folding is controlled by the `refold_source` policy setting. A value is considered to be a 'source value' if and only if it does not have a name attribute (having a name attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the `name` and the `value` with any CR and LF characters removed to the header_factory. Folding of a header object is done by calling its `fold` method with the current policy.

Source values are split into lines using `splitlines()`. If the value is not to be refolded, the lines are rejoined using the `linesep` from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the `refold_source` setting, which causes the binary data to be CTE encoded using the unknown-8bit charset.

**fold_binary**(*name*, *value*)

The same as `fold()` if `cte_type` is 7bit, except that the returned value is bytes.

If `cte_type` is 8bit, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded, regardless of the `refold_header` setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of `EmailPolicy` provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the HTTP instance) may be adjusted to
conform even more closely to the RFCs relevant to their domains.

**email.policy.default**

An instance of EmailPolicy with all defaults unchanged. This policy uses the standard Python \n line endings rather than the RFC-correct \r\n.

**email.policy.SMTP**

Suitable for serializing messages in conformance with the email RFCs. Like default, but with linesep set to \r\n, which is RFC compliant.

**email.policy.SMTPUTF8**

The same as SMTP except that utf8 is True. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the smtplib.SMTP.send_message() method handles this automatically).

**email.policy.HTTP**

Suitable for serializing headers with for use in HTTP traffic. Like SMTP except that max_line_length is set to None (unlimited).

**email.policy.strict**

Convenience instance. The same as default except that raise_on_defect is set to True. This allows any policy to be made strict by writing:

```python
somepolicy + policy.strict
```

With all of these *EmailPolicies*, the effective API of the email
package is changed from the Python 3.2 API in the following ways:

- Setting a header on a `Message` results in that header being parsed and a header object created.
- Fetching a header value from a `Message` results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the `Message` is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in `headerregistry`. 
19.1.5. **email.headerregistry**: Custom Header Objects

**Note**: The headerregistry module has been included in the standard library on a **provisional basis**. Backwards incompatible changes (up to and including removal of the module) may occur if deemed necessary by the core developers.

*New in version 3.3*: as a **provisional module**.

Headers are represented by customized subclasses of `str`. The particular class used to represent a given header is determined by the `header_factory` of the `policy` in effect when the headers are created. This section documents the particular `header_factory` implemented by the email package for handling **RFC 5322** compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from `EmailPolicy`, all headers are produced by `HeaderRegistry` and have `BaseHeader` as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class `UnstructuredHeader` as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the `HeaderRegistry`. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.
The sections below first document the header base classes and their attributes, followed by the API for modifying the behavior of `HeaderRegistry`, and finally the support classes used to represent the data parsed from structured headers.

```python
class email.headerregistry.BaseHeader(name, value)
```

`name` and `value` are passed to `BaseHeader` from the `header_factory` call. The string value of any header object is the `value` fully decoded to unicode.

This base class defines the following read-only properties:

**name**

The name of the header (the portion of the field before the `:`). This is exactly the value passed in the `header_factory` call for `name`; that is, case is preserved.

**defects**

A tuple of `HeaderDefect` instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the `errors` module for a discussion of the types of defects that may be reported.

**max_count**

The maximum number of headers of this type that can have the same name. A value of None means unlimited. The `BaseHeader` value for this attribute is None; it is expected that specialized header classes will override this value as needed.

`BaseHeader` also provides the following method, which is called by the email library code and should not in general be called by
application programs:

**fold(\*, policy)**

Return a string containing linesep characters as required to correctly fold the header according to policy. A cte_type of 8bit will be treated as if it were 7bit, since strings may not contain binary data.

BaseHeader by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, BaseHeader requires that the specialized class provide a classmethod() named parse. This method is called as follows:

```python
parse(string, kwds)
```

kwds is a dictionary containing one pre-initialized key, defects. defects is an empty list. The parse method should append any detected defects to this list. On return, the kwds dictionary *must* contain values for at least the keys decoded and defects. decoded should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that string may contain transport encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.

BaseHeader's __new__ then creates the header instance, and calls its init method. The specialized class only needs to provide an init method if it wishes to set additional attributes beyond those provided by BaseHeader itself. Such an init method should look like this:
```python
def init(self, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the kwds dictionary should be removed and handled, and the remaining contents of kw (and args) passed to the BaseHeader init method.

class email.headerregistry.UnstructuredHeader

An “unstructured” header is the default type of header in RFC 5322. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header is the Subject header.

In RFC 5322, an unstructured header is a run of arbitrary text in the ASCII character set. RFC 2047, however, has an RFC 5322 compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a value containing encoded words is passed to the constructor, the UnstructuredHeader parser converts such encoded words back in to the original unicode, following the RFC 2047 rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

class email.headerregistry.DateHeader

RFC 5322 specifies a very specific format for dates within email headers. The DateHeader parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes
found “in the wild”.

This header type provides the following additional attributes:

**datetime**

If the header value can be recognized as a valid date of one form or another, this attribute will contain a `datetime` instance representing that date. If the timezone of the input date is specified as `-0000` (indicating it is in UTC but contains no information about the source timezone), then `datetime` will be a naive `datetime`. If a specific timezone offset is found (including `+0000`), then `datetime` will contain an aware `datetime` that uses `datetime.timezone` to record the timezone offset.

The decoded value of the header is determined by formatting the `datetime` according to the **RFC 5322** rules; that is, it is set to:

```python
email.utils.format_datetime(self.datetime)
```

When creating a DateHeader, `value` may be `datetime` instance. This means, for example, that the following code is valid and does what one would expect:

```python
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of `-0000`. Much more useful is to use the `localtime()` function from the `utils` module:

```python
msg['Date'] = utils.localtime()
```
This example sets the date header to the current time and date using the current timezone offset.

class email.headerregistry.AddressHeader

Address headers are one of the most complex structured header types. The AddressHeader class provides a generic interface to any address header.

This header type provides the following additional attributes:

**groups**

A tuple of `Group` objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address Groups whose `display_name` is None.

**addresses**

A tuple of `Address` objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the point where the group occurs in the value (that is, the list of addresses is “flattened” into a one dimensional list).

The decoded value of the header will have all encoded words decoded to unicode. `idna` encoded domain names are also decoded to unicode. The decoded value is set by joining the `str` value of the elements of the groups attribute with ',', '.

A list of `Address` and `Group` objects in any combination may be used to set the value of an address header. Group objects whose `display_name` is None will be interpreted as single addresses,
which allows an address list to be copied with groups intact by using the list obtained groups attribute of the source header.

```py
class email.headerregistry.SingleAddressHeader
    A subclass of AddressHeader that adds one additional attribute:
    
    **address**
    The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default policy), accessing this attribute will result in a ValueError.
```

Many of the above classes also have a Unique variant (for example, UniqueUnstructuredHeader). The only difference is that in the Unique variant, `max_count` is set to 1.

```py
class email.headerregistry.MIMEVersionHeader
    There is really only one valid value for the MIME-Version header, and that is 1.0. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per RFC 2045, then the header object will have non-None values for the following attributes:
    
    **version**
    The version number as a string, with any whitespace and/or comments removed.
    
    **major**
    The major version number as an integer
    
    **minor**
    The minor version number as an integer
```
class email.headerregistry.ParameterizedMIMEHeader

MOME headers all start with the prefix ‘Content-‘. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

**params**

A dictionary mapping parameter names to parameter values.

class email.headerregistry.ContentTypeHeader

A ParameterizedMIMEHeader class that handles the Content-Type header.

**content_type**

The content type string, in the form maintype/subtype.

**maintype**

**subtype**

class email.headerregistry.ContentDispositionHeader

A ParameterizedMIMEHeader class that handles the Content-Disposition header.

**content-disposition**

inline and attachment are the only valid values in common use.

class email.headerregistry.ContentTransferEncoding

Handles the Content-Transfer-Encoding header.

**cte**
Valid values are 7bit, 8bit, base64, and quoted-printable. See **RFC 2045** for more information.

class
e-mail.headerregistry.HeaderRegistry(base_class=BaseHeader,
default_class=UnstructuredHeader, use_default_map=True)

This is the factory used by **EmailPolicy** by default. HeaderRegistry builds the class used to create a header instance dynamically, using *base_class* and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by *default_class* is used as the specialized class. When *use_default_map* is True (the default), the standard mapping of header names to classes is copied into the registry during initialization. *base_class* is always the last class in the generated class’s __bases__ list.

The default mappings are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>UniqueUnstructuredHeader</td>
</tr>
<tr>
<td>date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>resent-date</td>
<td>DateHeader</td>
</tr>
<tr>
<td>orig-date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>sender</td>
<td>UniqueSingleAddressHeader</td>
</tr>
<tr>
<td>resent-sender</td>
<td>SingleAddressHeader</td>
</tr>
<tr>
<td>to</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-to</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>cc</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-cc</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>from</td>
<td>UniqueAddressHeader</td>
</tr>
</tbody>
</table>
HeaderRegistry has the following methods:

```python
def map_to_type(self, name, cls):
    name is the name of the header to be mapped. It will be
    converted to lower case in the registry. cls is the specialized
    class to be used, along with base_class, to create the class
    used to instantiate headers that match name.
```

```python
def __getitem__(name):
    Construct and return a class to handle creating a name header.
```

```python
def __call__(name, value):
    Retrieves the specialized header associated with name from
    the registry (using default_class if name does not appear in the
    registry) and composes it with base_class to produce a class,
    calls the constructed class's constructor, passing it the same
    argument list, and finally returns the class instance created
    thereby.
```

The following classes are the classes used to represent data parsed
from structured headers and can, in general, be used by an application
program to construct structured values to assign to specific headers.

```python
class email.headerregistry.Address(display_name='',
    username='',
    domain='',
    addr_spec=None)
```

The class used to represent an email address. The general form of
an address is:

```
[display_name] <username@domain>
```
or:

```python
username@domain
```

where each part must conform to specific syntax rules spelled out in **RFC 5322**.

As a convenience `addr_spec` can be specified instead of `username` and `domain`, in which case `username` and `domain` will be parsed from the `addr_spec`. An `addr_spec` must be a properly RFC quoted string; if it is not Address will raise an error. Unicode characters are allowed and will be properly encoded when serialized. However, per the RFCs, unicode is *not* allowed in the username portion of the address.

**display_name**

The display name portion of the address, if any, with all quoting removed. If the address does not have a display name, this attribute will be an empty string.

**username**

The username portion of the address, with all quoting removed.

**domain**

The domain portion of the address.

**addr_spec**

The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

```python
__str__()
```
The str value of the object is the address quoted according to RFC 5322 rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (RFC 5321), Address handles one special case: if username and domain are both the empty string (or None), then the string value of the Address is <>.

```python
class email.headerregistry.Group(display_name=None, addresses=None)
```

The class used to represent an address group. The general form of an address group is:

```
display_name: [address-list];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a Group may also be used to represent single addresses that are not part of a group by setting display_name to None and providing a list of the single address as addresses.

**display_name**

The display_name of the group. If it is None and there is exactly one Address in addresses, then the Group represents a single address that is not in a group.

**addresses**

A possibly empty tuple of Address objects representing the addresses in the group.

```python
__str__()
```

The str value of a Group is formatted according to RFC 5322,
but with no Content Transfer Encoding of any non-ASCII characters. If display_name is none and there is a single Address in the addresses list, the str value will be the same as the str of that single Address.
19.1.6. `email.contentmanager`: Managing MIME Content

**Note:** The contentmanager module has been included in the standard library on a provisional basis. Backwards incompatible changes (up to and including removal of the module) may occur if deemed necessary by the core developers.

New in version 3.4: as a provisional module.

The `message` module provides a class that can represent an arbitrary email message. That basic message model has a useful and flexible API, but it provides only a lower-level API for interacting with the generic parts of a message (the headers, generic header parameters, and the payload, which may be a list of sub-parts). This module provides classes and tools that provide an enhanced and extensible API for dealing with various specific types of content, including the ability to retrieve the content of the message as a specialized object type rather than as a simple bytes object. The module automatically takes care of the RFC-specified MIME details (required headers and parameters, etc.) for the certain common content types content properties, and support for additional types can be added by an application using the extension mechanisms.

This module defines the eponymous “Content Manager” classes. The base `ContentManager` class defines an API for registering content management functions which extract data from `Message` objects or insert data and headers into `Message` objects, thus providing a way of converting between `Message` objects containing data and other representations of that data (Python data types, specialized Python
objects, external files, etc). The module also defines one concrete content manager: `raw_data_manager` converts between MIME content types and str or bytes data. It also provides a convenient API for managing the MIME parameters when inserting content into Messages. It also handles inserting and extracting Message objects when dealing with the message/rfc822 content type.

Another part of the enhanced interface is subclasses of `Message` that provide new convenience API functions, including convenience methods for calling the Content Managers derived from this module.

**Note:** Although `EmailMessage` and `MIMEPart` are currently documented in this module because of the provisional nature of the code, the implementation lives in the `email.message` module.

class email.message.**EmailMessage**(policy=default)

If `policy` is specified (it must be an instance of a `policy` class) use the rules it specifies to udpate and serialize the representation of the message. If `policy` is not set, use the `default` policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated \r\n, it uses the Python standard \n line endings). For more information see the `policy` documentation.

This class is a subclass of `Message`. It adds the following methods:

**is_attachment()**

Return True if there is a `Content-Disposition` header and its (case insensitive) value is attachment, False otherwise.

*Changed in version 3.4.2:* `is_attachment` is now a method instead of a property, for consistency with `is_multipart()`.
get_body(preferencelist=('related', 'html', 'plain'))

Return the MIME part that is the best candidate to be the “body” of the message.

preferencelist must be a sequence of strings from the set related, html, and plain, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the get_body method is called.

If related is not included in preferencelist, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a multipart/related, check the start parameter and if a part with a matching Content-ID is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the multipart/related.

If a part has a Content-Disposition header, only consider the part a candidate match if the value of the header is inline.

If none of the candidates matches any of the preferences in preferencelist, return None.

Notes: (1) For most applications the only preferencelist combinations that really make sense are ('plain',), ('html', 'plain'), and the default, ('related', 'html', 'plain'). (2) Because matching starts with the object on which get_body is called, calling get_body on a multipart/related will return the object itself unless
preferences has a non-default value. (3) Messages (or message parts) that do not specify a Content-Type or whose Content-Type header is invalid will be treated as if they are of type text/plain, which may occasionally cause get_body to return unexpected results.

iter_attachments()
Return an iterator over all of the parts of the message that are not candidate “body” parts. That is, skip the first occurrence of each of text/plain, text/html, multipart/related, or multipart/alternative (unless they are explicitly marked as attachments via Content-Disposition: attachment), and return all remaining parts. When applied directly to a multipart/related, return an iterator over the all the related parts except the root part (ie: the part pointed to by the start parameter, or the first part if there is no start parameter or the start parameter doesn’t match the Content-ID of any of the parts). When applied directly to a multipart/alternative or a non-multipart, return an empty iterator.

iter_parts()
Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-multipart. (See also walk().)

get_content(*args, content_manager=None, **kw)
Call the get_content method of the content_manager, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If content_manager is not specified, use the content_manager specified by the current policy.
set_content(*args, content_manager=None, **kw)

Call the set_content method of the content_manager, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If content_manager is not specified, use the content_manager specified by the current policy.

make_related(boundary=None)

Convert a non-multipart message into a multipart/related message, moving any existing Content-headers and payload into a (new) first part of the multipart. If boundary is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_alternative(boundary=None)

Convert a non-multipart or a multipart/related into a multipart/alternative, moving any existing Content-headers and payload into a (new) first part of the multipart. If boundary is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_mixed(boundary=None)

Convert a non-multipart, a multipart/related, or a multipart-alternative into a multipart/mixed, moving any existing Content-headers and payload into a (new) first part of the multipart. If boundary is specified, use it as the boundary string in the multipart, otherwise leave the
boundary to be automatically created when it is needed (for example, when the message is serialized).

add_related(*args, content_manager=None, **kw)
If the message is a multipart/related, create a new message object, pass all of the arguments to its set_content() method, and attach() it to the multipart. If the message is a non-multipart, call make_related() and then proceed as above. If the message is any other type of multipart, raise a TypeError. If content_manager is not specified, use the content_manager specified by the current policy. If the added part has no Content-Disposition header, add one with the value inline.

add_alternative(*args, content_manager=None, **kw)
If the message is a multipart/alternative, create a new message object, pass all of the arguments to its set_content() method, and attach() it to the multipart. If the message is a non-multipart or multipart/related, call make_alternative() and then proceed as above. If the message is any other type of multipart, raise a TypeError. If content_manager is not specified, use the content_manager specified by the current policy.

add_attachment(*args, content_manager=None, **kw)
If the message is a multipart/mixed, create a new message object, pass all of the arguments to its set_content() method, and attach() it to the multipart. If the message is a non-multipart, multipart/related, or multipart/alternative, call make_mixed() and then proceed as above. If content_manager is not specified, use the
content_manager specified by the current policy. If the added part has no Content-Disposition header, add one with the value attachment. This method can be used both for explicit attachments (Content-Disposition: attachment) and inline attachments (Content-Disposition: inline), by passing appropriate options to the content_manager.

**clear()**
Remove the payload and all of the headers.

**clear_content()**
Remove the payload and all of the Content- headers, leaving all other headers intact and in their original order.

*class email.message.MIMEPart*(policy=default)*
This class represents a subpart of a MIME message. It is identical to EmailMessage, except that no MIME-Version headers are added when set_content() is called, since sub-parts do not need their own MIME-Version headers.

*class email.contentmanager.ContentManager*
Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the get_content and set_content dispatch methods.

**get_content**(msg, *args, **kw)
Look up a handler function based on the mimetype of msg (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from msg and return an object that encodes information about the extracted data.
To find the handler, look for the following keys in the registry, stopping with the first one found:

- the string representing the full MIME type (maintype/subtype)
- the string representing the maintype
- the empty string

If none of these keys produce a handler, raise a `KeyError` for the full MIME type.

**set_content**( `msg`, `obj`, *`args`, **`kw` *)

If the maintype is multipart, raise a `TypeError`; otherwise look up a handler function based on the type of `obj` (see next paragraph), call `clear_content()` on the `msg`, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store `obj` into `msg`, possibly making other changes to `msg` as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of `obj` (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's qualname (`typ.__qualname__`)
- the type's name (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the **MRO** (`typ.__mro__`). Finally, if no
other key yields a handler, check for a handler for the key None. If there is no handler for None, raise a `KeyError` for the fully qualified name of the type.

Also add a `MIME-Version` header if one is not present (see also `MIMEPart`).

```python
add_get_handler(key, handler)
```

Record the function `handler` as the handler for `key`. For the possible values of `key`, see `get_content()`.

```python
add_set_handler(typekey, handler)
```

Record `handler` as the function to call when an object of a type matching `typekey` is passed to `set_content()`. For the possible values of `typekey`, see `set_content()`.
19.1.6.1. Content Manager Instances

Currently the email package provides only one concrete content manager, `raw_data_manager`, although more may be added in the future. `raw_data_manager` is the `content_manager` provided by `EmailPolicy` and its derivatives.

`email.contentmanager.raw_data_manager`

This content manager provides only a minimum interface beyond that provided by `Message` itself: it deals only with text, raw byte strings, and `Message` objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

`email.contentmanager.get_content(msg, errors='replace')`

Return the payload of the part as either a string (for text parts), a `EmailMessage` object (for message/rfc822 parts), or a bytes object (for all other non-multipart types). Raise a `KeyError` if called on a multipart. If the part is a text part and `errors` is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

`email.contentmanager.set_content(msg, subtype="plain", charset='utf-8' cte=None, disposition=None,`
Add the headers and payload to `msg`:

Add a **Content-Type** header with a `maintype/subtype` value.

- For `str`, set the MIME `maintype` to `text`, and set the `subtype` to `subtype` if it is specified, or `plain` if it is not.
- For `bytes`, use the specified `maintype` and `subtype`, or raise a `TypeError` if they are not specified.
- For `Message` objects, set the `maintype` to `message`, and set the `subtype` to `subtype` if it is specified or `rfc822` if it is not. If `subtype` is partial, raise an error (bytes objects must be used to construct message/partial parts).
- For `<list>`, which should be a list of `Message` objects, set the `maintype` to `multipart`, and the `subtype` to `subtype` if it is specified, and `mixed` if it is not. If the message parts in the `<list>` have `MIME-Version` headers, remove them.

If `charset` is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified `charset` is a known alias for a standard
MIME charset name, use the standard charset instead.

If \texttt{cte} is set, encode the payload using the specified content transfer encoding, and set the \texttt{Content-Transfer-Encoding} header to that value. For \texttt{str} objects, if it is not set use heuristics to determine the most compact encoding. Possible values for \texttt{cte} are \texttt{quoted-printable}, \texttt{base64}, \texttt{7bit}, \texttt{8bit}, and \texttt{binary}. If the input cannot be encoded in the specified encoding (eg: \texttt{7bit}), raise a \texttt{ValueError}. For \texttt{Message}, per \texttt{RFC 2046}, raise an error if a \texttt{cte} of \texttt{quoted-printable} or \texttt{base64} is requested for \texttt{subtype rfc822}, and for any \texttt{cte} other than \texttt{7bit} for \texttt{subtype external-body}. For \texttt{message/rfc822}, use \texttt{8bit} if \texttt{cte} is not specified. For all other values of \texttt{subtype}, use \texttt{7bit}.

\textbf{Note:} A \texttt{cte} of \texttt{binary} does not actually work correctly yet. The \texttt{Message} object as modified by \texttt{set_content} is correct, but \texttt{BytesGenerator} does not serialize it correctly.

If \texttt{disposition} is set, use it as the value of the \texttt{Content-Disposition} header. If not specified, and \texttt{filename} is specified, add the header with the value attachment. If it is not specified and \texttt{filename} is also not specified, do not add the header. The only valid values for \texttt{disposition} are attachment and inline.

If \texttt{filename} is specified, use it as the value of the \texttt{filename} parameter of the \texttt{Content-Disposition} header. There is no default.

If \texttt{cid} is specified, add a \texttt{Content-ID} header with \texttt{cid} as its value.

If \texttt{params} is specified, iterate its \texttt{items} method and use the
resulting (key, value) pairs to set additional parameters on the *Content-Type* header.

If *headers* is specified and is a list of strings of the form headernamename: headervalue or a list of header objects (distinguished from strings by having a name attribute), add the headers to *msg*.
19.1.7. **email.mime**: Creating email and MIME objects from scratch

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual `Message` objects by hand. In fact, you can also take an existing structure and add new `Message` objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating `Message` instances, adding attachments and all the appropriate headers manually. For MIME messages though, the `email` package provides some convenient subclasses to make things easier.

Here are the classes:

```python
class email.mime.base.MIMEBase(_maintype, _subtype, **_params)
```

Module: `email.mime.base`

This is the base class for all the MIME-specific subclasses of `Message`. Ordinarily you won’t create instances specifically of `MIMEBase`, although you could. `MIMEBase` is provided primarily as a convenient base class for more specific MIME-aware subclasses.

 `_maintype` is the `Content-Type` major type (e.g. `text` or `image`), and `_subtype` is the `Content-Type` minor type (e.g. `plain` or `gif`).
_params is a parameter key/value dictionary and is passed directly to Message.add_header.

The MIMEBase class always adds a Content-Type header (based on _maintype, _subtype, and _params), and a MIME-Version header (always set to 1.0).

class email.mime.nonmultipart.MIMENonMultipart
Module: email.mime.nonmultipart

A subclass of MIMEBase, this is an intermediate base class for MIME messages that are not multipart. The primary purpose of this class is to prevent the use of the attach() method, which only makes sense for multipart messages. If attach() is called, a MultipartConversionError exception is raised.

class email.mime.multipart.MIMEMultipart(_subtype='mixed', boundary=None, _subparts=None, **_params)
Module: email.mime.multipart

A subclass of MIMEBase, this is an intermediate base class for MIME messages that are multipart. Optional _subtype defaults to mixed, but can be used to specify the subtype of the message. A Content-Type header of multipart/_subtype will be added to the message object. A MIME-Version header will also be added.

Optional boundary is the multipart boundary string. When None (the default), the boundary is calculated when needed (for example, when the message is serialized).

_subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always
attach new subparts to the message by using the `Message.attach` method.

Additional parameters for the `Content-Type` header are taken from the keyword arguments, or passed into the `_params` argument, which is a keyword dictionary.

```python
class email.mime.application.MIMEApplication(_data, _subtype='octet-stream', _encoder=email.encoders.encode_base64, **_params)
Module: email.mime.application
```

A subclass of `MIMENonMultipart`, the `MIMEApplication` class is used to represent MIME message objects of major type `application`. `_data` is a string containing the raw byte data. Optional `_subtype` specifies the MIME subtype and defaults to `octet-stream`.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the `MIMEApplication` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

`_params` are passed straight through to the base class constructor.

```python
class email.mime.audio.MIMEAudio(_audiodata, _subtype=None, _encoder=email.encoders.encode_base64, **_params)
Module: email.mime.audio
```
A subclass of MIMENonMultipart, the MIMEAudio class is used to create MIME message objects of major type audio. _audiodata is a string containing the raw audio data. If this data can be decoded by the standard Python module sndhdr, then the subtype will be automatically included in the Content-Type header. Otherwise you can explicitly specify the audio subtype via the _subtype argument. If the minor type could not be guessed and _subtype was not given, then TypeError is raised.

Optional _encoder is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the MIMEAudio instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

_params are passed straight through to the base class constructor.

class email.mime.image.MIMEImage(_imagedata,
_subtype=None,_encoder=email.encoders.encode_base64,
**_params)
Module: email.mime.image

A subclass of MIMENonMultipart, the MIMEImage class is used to create MIME message objects of major type image. _imagedata is a string containing the raw image data. If this data can be decoded by the standard Python module imghdr, then the subtype will be automatically included in the Content-Type header. Otherwise you can explicitly specify the image subtype via the _subtype argument. If the minor type could not be guessed and
Optional _encoder is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the MIMEImage instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

__params__ are passed straight through to the MIMEBase constructor.

class email.mime.message.MIMEMessage(_msg,
   _subtype='rfc822')
   Module: email.mime.message

A subclass of MIMENonMultipart, the MIMEMessage class is used to create MIME objects of main type message. _msg is used as the payload, and must be an instance of class Message (or a subclass thereof), otherwise a TypeError is raised.

Optional _subtype sets the subtype of the message; it defaults to rfc822.

class email.mime.text.MIMEText(_text, _subtype='plain',
   _charset=None)
   Module: email.mime.text

A subclass of MIMENonMultipart, the MIMEText class is used to create MIME objects of major type text. _text is the string for the payload. _subtype is the minor type and defaults to plain. _charset is the character set of the text and is passed as an argument to the
MIMENonMultipart constructor; it defaults to us-ascii if the string contains only ascii code points, and utf-8 otherwise. The _charset parameter accepts either a string or a Charset instance.

Unless the _charset argument is explicitly set to None, the MIMEText object created will have both a Content-Type header with a charset parameter, and a Content-Transfer-Encoding header. This means that a subsequent set_payload call will not result in an encoded payload, even if a charset is passed in the set_payload command. You can “reset” this behavior by deleting the Content-Transfer-Encoding header, after which a set_payload call will automatically encode the new payload (and add a new Content-Transfer-Encoding header).

*Changed in version 3.5:* _charset also accepts Charset instances.*
19.1. `email` — An email and MIME handling package
19.1.8. `email.header`: Internationalized headers

`RFC 2822` is the base standard that describes the format of email messages. It derives from the older `RFC 822` standard which came into widespread use at a time when most email was composed of ASCII characters only. `RFC 2822` is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into `RFC 2822`-compliant format. These RFCs include `RFC 2045`, `RFC 2046`, `RFC 2047`, and `RFC 2231`. The `email` package supports these standards in its `email.header` and `email.charset` modules.

If you want to include non-ASCII characters in your email headers, say in the `Subject` or `To` fields, you should use the `Header` class and assign the field in the `Message` object to an instance of `Header` instead of using a string for the header value. Import the `Header` class from the `email.header` module. For example:

```python
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
```
Notice here how we wanted the Subject field to contain a non-ASCII character? We did this by creating a Header instance and passing in the character set that the byte string was encoded in. When the subsequent Message instance was flattened, the Subject field was properly RFC 2047 encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the Header class description:

```
class email.header.Header(s=None, charset=None, maxlinelen=None, header_name=None, continuation_ws=' ', errors='strict')
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional s is the initial header value. If None (the default), the initial header value is not set. You can later append to the header with append() method calls. s may be an instance of bytes or str, but see the append() documentation for semantics.

Optional charset serves two purposes: it has the same meaning as the charset argument to the append() method. It also sets the default character set for all subsequent append() calls that omit the charset argument. If charset is not provided in the constructor (the default), the us-ascii character set is used both as s's initial charset and as the default for subsequent append() calls.

The maximum line length can be specified explicitly via maxlinelen. For splitting the first line to a shorter value (to account for the field header which isn't included in s, e.g. Subject) pass in the name of the field in header_name. The default maxlinelen is 76, and the
default value for header_name is None, meaning it is not taken into account for the first line of a long, split header.

Optional continuation_ws must be RFC 2822-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. continuation_ws defaults to a single space space character.

Optional errors is passed straight through to the append() method.

append(s, charset=None, errors='strict')

Append the string s to the MIME header.

Optional charset, if given, should be a Charset instance (see email.charset) or the name of a character set, which will be converted to a Charset instance. A value of None (the default) means that the charset given in the constructor is used.

s may be an instance of bytes or str. If it is an instance of bytes, then charset is the encoding of that byte string, and a UnicodeError will be raised if the string cannot be decoded with that character set.

If s is an instance of str, then charset is a hint specifying the character set of the characters in the string.

In either case, when producing an RFC 2822-compliant header using RFC 2047 rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional errors is passed as the errors argument to the decode
call if s is a byte string.

**encode**(splitchars='; ', \t', maxlinelen=None, linesep='\n')

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional `splitchars` is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of RFC 2822's 'higher level syntactic breaks': split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect RFC 2047 encoded lines.

`maxlinelen`, if given, overrides the instance's value for the maximum line length.

`linesep` specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (\n), but \r\n can be specified in order to produce headers with RFC-compliant line separators.

*Changed in version 3.2: Added the `linesep` argument.*

The **Header** class also provides a number of methods to support standard operators and built-in functions.

**__str__**()

Returns an approximation of the **Header** as a string, using an
unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of 'unknown-8bit' are decoded as ASCII using the 'replace' error handler.

*Changed in version 3.2:* Added handling for the 'unknown-8bit' charset.

```python
__eq__(other)
```
This method allows you to compare two `Header` instances for equality.

```python
__ne__(other)
```
This method allows you to compare two `Header` instances for inequality.

The `email.header` module also provides the following convenient functions.

```python
e-mail.header.decode_header(header)
```
Decode a message header value without converting the character set. The header value is in `header`.

This function returns a list of `(decoded_string, charset)` pairs containing each of the decoded parts of the header. `charset` is None for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here’s an example:

```python
>>> from email.header import decode_header
```
email.header._make_header(decoded_seq, maxlinelen=None, header_name=None, continuation_ws=' ')

Create a Header instance from a sequence of pairs as returned by decode_header().

decode_header() takes a header value string and returns a sequence of pairs of the format (decoded_string, charset) where charset is the name of the character set.

This function takes one of those sequence of pairs and returns a Header instance. Optional maxlinelen, header_name, and continuation_ws are as in the Header constructor.
19.1.9. **email.charset:** Representing character sets

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

```python
class email.charset.Charset(input_charset=DEFAULT_CHARSET)
    Map character sets to their email properties.
```

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional `input_charset` is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if `input_charset` is `iso-8859-
1, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If input_charset is euc-jp, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the euc-jp character set to the iso-2022-jp character set.

Charset instances have the following data attributes:

**input_charset**
The initial character set specified. Common aliases are converted to their official email names (e.g. latin_1 is converted to iso-8859-1). Defaults to 7-bit us-ascii.

**header_encoding**
If the character set must be encoded before it can be used in an email header, this attribute will be set to Charset.QP (for quoted-printable), Charset.BASE64 (for base64 encoding), or Charset.SHORTEST for the shortest of QP or BASE64 encoding. Otherwise, it will be None.

**body_encoding**
Same as header_encoding, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. Charset.SHORTEST is not allowed for body_encoding.

**output_charset**
Some character sets must be converted before they can be used in email headers or bodies. If the input_charset is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be None.
**input_codec**

The name of the Python codec used to convert the `input_charset` to Unicode. If no conversion codec is necessary, this attribute will be None.

**output_codec**

The name of the Python codec used to convert Unicode to the `output_charset`. If no conversion codec is necessary, this attribute will have the same value as the `input_codec`.

*Charset* instances also have the following methods:

**get_body_encoding()**

Return the content transfer encoding used for body encoding.

This is either the string quoted-printable or base64 depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the `Content-Transfer-Encoding` header itself to whatever is appropriate.

Returns the string quoted-printable if `body_encoding` is QP, returns the string base64 if `body_encoding` is BASE64, and returns the string 7bit otherwise.

**get_output_charset()**

Return the output character set.

This is the `output_charset` attribute if that is not None, otherwise it is `input_charset`.

**header_encode(string)**
Header-encode the string `string`.

The type of encoding (base64 or quoted-printable) will be based on the `header_encoding` attribute.

**header_encode_lines**(*string, maxlengths*)

Header-encode a `string` by converting it first to bytes.

This is similar to `header_encode()` except that the string is fit into maximum line lengths as given by the argument `maxlengths`, which must be an iterator: each element returned from this iterator will provide the next maximum line length.

**body_encode**(*string*)

Body-encode the string `string`.

The type of encoding (base64 or quoted-printable) will be based on the `body_encoding` attribute.

The `Charset` class also provides a number of methods to support standard operations and built-in functions.

**__str__**()

Returns `input_charset` as a string coerced to lower case. **__repr__**() is an alias for **__str__**.

**__eq__**(other)

This method allows you to compare two `Charset` instances for equality.

**__ne__**(other)

This method allows you to compare two `Charset` instances for inequality.
The `email.charset` module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

`email.charset.add_charset(charset, header_enc=None, body_enc=None, output_charset=None)`

Add character properties to the global registry.

`charset` is the input character set, and must be the canonical name of a character set.

Optional `header_enc` and `body_enc` is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for `header_enc`. The default is `None` for no encoding.

Optional `output_charset` is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `Charset.convert()` is called. The default is to output in the same character set as the input.

Both `input_charset` and `output_charset` must have Unicode codec entries in the module’s character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the `codecs` module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

`email.charset.add_alias(alias, canonical)`

Add a character set alias. `alias` is the alias name, e.g. `latin-1`. 
canonical is the character set's canonical name, e.g. iso-8859-1.

The global charset alias registry is kept in the module global dictionary ALIASES.

email.charset.add_codec(charset, codecname)
Add a codec that map characters in the given character set to and from Unicode.

charset is the canonical name of a character set. codecname is the name of a Python codec, as appropriate for the second argument to the str's encode() method.
19.1. **email** — An email and MIME handling package
19.1.10. **email.encoders:** Encoders

When creating `Message` objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for `image/*` and `text/*` type messages containing binary data.

The `email` package provides some convenient encodings in its `encoders` module. These encoders are actually used by the `MIMEAudio` and `MIMEImage` class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the `Content-Transfer-Encoding` header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a `TypeError` if passed a message whose type is multipart.

Here are the encoding functions provided:

```python
email.encoders.encode_quopri(msg)
```

Encodes the payload into quoted-printable form and sets the `Content-Transfer-Encoding` header to quoted-printable [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

```python
email.encoders.encode_base64(msg)
```

Encodes the payload into base64 form and sets the `Content-Transfer-Encoding` header to base64 [1].
Transfer-Encoding header to base64. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

```
email.encoders.encode_7or8bit(msg)
```

This doesn’t actually modify the message’s payload, but it does set the Content-Transfer-Encoding header to either 7bit or 8bit as appropriate, based on the payload data.

```
email.encoders.encode_noop(msg)
```

This does nothing; it doesn’t even set the Content-Transfer-Encoding header.

**Footnotes**

[1] Note that encoding with `encode_quopri()` also encodes all tabs and space characters in the data.
19.1.11. `email.errors`: Exception and Defect classes

The following exception classes are defined in the `email.errors` module:

* `exception email.errors.MessageError`
  This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

* `exception email.errors.MessageParseError`
  This is the base class for exceptions raised by the `Parser` class. It is derived from `MessageError`.

* `exception email.errors.HeaderParseError`
  Raised under some error conditions when parsing the RFC 2822 headers of a message, this class is derived from `MessageParseError`. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

  Situations where it can be raised include finding an envelope header after the first RFC 2822 header of the message, finding a continuation line before the first RFC 2822 header is found, or finding a line in the headers which is neither a header or a continuation line.

* `exception email.errors.BoundaryError`
  Raised under some error conditions when parsing the RFC 2822 headers of a message, this class is derived from
**MessageParseError**. It can be raised from the `Parser.parse` or `Parser.parsestr` methods.

Situations where it can be raised include not being able to find the starting or terminating boundary in a `multipart/*` message when strict parsing is used.

**exception** `email.errors.MultipartConversionError`  
Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message’s `Content-Type` main type is not either `multipart` or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here’s the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a `multipart/alternative` had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`, but this class is not an exception!

- **NoBoundaryInMultipartDefect** – A message claimed to be a multipart, but had no `boundary` parameter.
- **StartBoundaryNotFoundDefect** – The start boundary
claimed in the *Content-Type* header was never found.

- **CloseBoundaryNotFoundDefect** – A start boundary was found, but no corresponding close boundary was ever found.

  *New in version 3.3.*

- **FirstHeaderLineIsContinuationDefect** – The message had a continuation line as its first header line.

- **MisplacedEnvelopeHeaderDefect** - A “Unix From” header was found in the middle of a header block.

- **MissingHeaderBodySeparatorDefect** - A line was found while parsing headers that had no leading white space but contained no ‘:’. Parsing continues assuming that the line represents the first line of the body.

  *New in version 3.3.*

- **MalformedHeaderDefect** – A header was found that was missing a colon, or was otherwise malformed.

  *Deprecated since version 3.3:* This defect has not been used for several Python versions.

- **MultipartInvariantViolationDefect** – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its *is_multipart()* method may return false even though its content type claims to be *multipart*.

- **InvalidBase64PaddingDefect** – When decoding a block of base64 encoded bytes, the padding was not correct. Enough
padding is added to perform the decode, but the resulting decoded bytes may be invalid.

- **InvalidBase64CharactersDefect** – When decoding a block of base64 encoded bytes, characters outside the base64 alphabet were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.
19.1. `email` — An email and MIME handling package
19.1.12. **email.utils:**
Miscellaneous utilities

There are several useful utilities provided in the `email.utils` module:

**email.utils.quote(str)**
Return a new string with backslashes in `str` replaced by two backslashes, and double quotes replaced by backslash-double quote.

**email.utils.unquote(str)**
Return a new string which is an *unquoted* version of `str`. If `str` ends and begins with double quotes, they are stripped off. Likewise if `str` ends and begins with angle brackets, they are stripped off.

**email.utils.parseaddr(address)**
Parse address – which should be the value of some address-containing field such as `To` or `Cc` – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of (’, ’) is returned.

**email.utils.formataddr(pair, charset='utf-8')**
The inverse of `parseaddr()`, this takes a 2-tuple of the form (realname, email_address) and returns the string value suitable for a `To` or `Cc` header. If the first element of `pair` is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the RFC 2047 encoding of the realname if the realname contains non-
ASCII characters. Can be an instance of `str` or a `Charset`. Defaults to utf-8.

*Changed in version 3.3:* Added the `charset` option.

`email.utils.getaddresses(fieldvalues)`

This method returns a list of 2-tuples of the form returned by `parseaddr()`. `fieldvalues` is a sequence of header field values as might be returned by `Message.get_all`. Here's a simple example that gets all the recipients of a message:

```python
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

`email.utils.parsedate(date)`

Attempts to parse a date according to the rules in RFC 2822. However, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. `date` is a string containing an RFC 2822 date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()``; otherwise None will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

`email.utils.parsedate_tz(date)`

Performs the same function as `parsedate()`, but returns either None or a 10-tuple; the first 9 elements make up a tuple that can
be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time) [1]. If the input string has no timezone, the last element of the tuple returned is None. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.**parsedate_to_datetime**(date)

The inverse of `format_datetime()`. Performs the same function as `parsedate()`, but on success returns a `datetime`. If the input date has a timezone of -0000, the datetime will be a naive datetime, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the datetime will be an aware datetime with the corresponding a `timezone tzinfo`.

*New in version 3.3.*

email.utils.**mktime_tz**(tuple)

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is None, assume local time.

email.utils.**formatdate**(timeval=None, localtime=False, usegmt=False)

Returns a date string as per RFC 2822, e.g.:

```plaintext
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional `timeval` if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.
Optional `localtime` is a flag that when True, interprets `timeval`, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is False meaning UTC is used.

Optional `usegmt` is a flag that when True, outputs a date string with the timezone as an ascii string GMT, rather than a numeric -0000. This is needed for some protocols (such as HTTP). This only applies when `localtime` is False. The default is False.

```python
email.utils.format_datetime(dt, usegmt=False)
```

Like `formatdate`, but the input is a `datetime` instance. If it is a naive datetime, it is assumed to be “UTC with no information about the source timezone”, and the conventional -0000 is used for the timezone. If it is an aware datetime, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then `usegmt` may be set to True, in which case the string GMT is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

*New in version 3.3.*

```python
email.utils.localtime(dt=None)
```

Return local time as an aware datetime object. If called without arguments, return current time. Otherwise `dt` argument should be a `datetime` instance, and it is converted to the local time zone according to the system time zone database. If `dt` is naive (that is, `dt.tzinfo` is None), it is assumed to be in local time. In this case, a positive or zero value for `isdst` causes `localtime` to presume initially that summer time (for example, Daylight Saving Time) is or is not (respectively) in effect for the specified time. A negative value for `isdst` causes the `localtime` to attempt to divine whether...
summer time is in effect for the specified time.

New in version 3.3.

e-mail.utils.make_msgid(idstring=None, domain=None)

Returns a string suitable for an RFC 2822-compliant Message-ID header. Optional idstring if given, is a string used to strengthen the uniqueness of the message id. Optional domain if given provides the portion of the msgid after the '@'. The default is the local hostname. It is not normally necessary to override this default, but may be useful in certain cases, such as constructing distributed system that uses a consistent domain name across multiple hosts.

Changed in version 3.2: Added the domain keyword.

e-mail.utils.decode_rfc2231(s)

Decode the string s according to RFC 2231.

e-mail.utils.encode_rfc2231(s, charset=None, language=None)

Encode the string s according to RFC 2231. Optional charset and language, if given is the character set name and language name to use. If neither is given, s is returned as-is. If charset is given but language is not, the string is encoded using the empty string for language.

e-mail.utils-collapse_rfc2231_value(value, errors='replace', fallback_charset='us-ascii')

When a header parameter is encoded in RFC 2231 format, Message.get_param may return a 3-tuple containing the character set, language, and value. collapse_rfc2231_value() turns this into a unicode string. Optional errors is passed to the errors argument of str's
**encode()** method; it defaults to 'replace'. Optional *fallback_charset* specifies the character set to use if the one in the **RFC 2231** header is not known by Python; it defaults to 'us-ascii'.

For convenience, if the *value* passed to **collapse_rfc2231_value()** is not a tuple, it should be a string and it is returned unquoted.

**email.utils.decode_params(params)**

Decode parameters list according to **RFC 2231**. *params* is a sequence of 2-tuples containing elements of the form *(content-type, string-value)*.

**Footnotes**

[1] Note that the sign of the timezone offset is the opposite of the sign of the *time.timezone* variable for the same timezone; the latter variable follows the POSIX standard while this module follows **RFC 2822**.
19.1. **email** — An email and MIME handling package
19.1.13. **email.iterators**: Iterators

Iterating over a message object tree is fairly easy with the `Message.walk` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

`email.iterators.body_line_iterator(msg, decode=False)`

This iterates over all the payloads in all the subparts of `msg`, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn’t a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.

Optional `decode` is passed through to `Message.get_payload`.

`email.iterators.typed_subpart_iterator(msg, maintype='text', subtype=None)`

This iterates over all the subparts of `msg`, returning only those subparts that match the MIME type specified by `maintype` and `subtype`.

Note that `subtype` is optional; if omitted, then subpart MIME type matching is done only with the main type. `maintype` is optional too; it defaults to `text`.

Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`. 
The following function has been added as a useful debugging tool. It should not be considered part of the supported public interface for the package.

```
email.iterators._structure(msg, fp=None, level=0, include_default=False)
```

Prints an indented representation of the content types of the message object structure. For example:

```
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
  text/plain
  text/plain
  multipart/digest
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
    message/rfc822
      text/plain
  text/plain
```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python's `print()` function. `level` is used internally. `include_default`, if true, prints the default type as well.
19.1.14. **email**: Examples

Here are a few examples of how to use the `email` package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message:

```python
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.mime.text import MIMEText

# Open a plain text file for reading.  For this example,
# the text file contains only ASCII characters.
with open(textfile) as fp:
    # Create a text/plain message
    msg = MIMEText(fp.read())

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()
```

And parsing RFC822 headers can easily be done by the `parse(filename)` or `parsestr(message_as_string)` methods of the
Parser() class:

```python
# Import the email modules we'll need
from email.parser import Parser

# If the e-mail headers are in a file, uncomment these two lines:
# with open(messagefile) as fp:
#     headers = Parser().parse(fp)

# Or for parsing headers in a string, use:
headers = Parser().parsestr('From: <user@example.com>
    To: <someone_else@example.com>
    Subject: Test message
    
    Body would go here

# Now the header items can be accessed as a dictionary:
print('To: %s' % headers['to'])
print('From: %s' % headers['from'])
print('Subject: %s' % headers['subject'])
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```python
# Import smtplib for the actual sending function
import smtplib

# Here are the email package modules we'll need
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
COMMASPACE = ',', '

# Create the container (outer) email message.
msg = MIMEMultipart()
msg['Subject'] = 'Our family reunion'
```
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = COMMASPACE.join(family)
msg.preamble = 'Our family reunion

# Assume we know that the image files are all in PNG format
for file in pngfiles:
    # Open the files in binary mode. Let the MIMEImage class automatically
    # guess the specific image type.
    with open(file, 'rb') as fp:
        img = MIMEImage(fp.read())
    msg.attach(img)

# Send the email via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()

Here's an example of how to send the entire contents of a directory as an email message: [1]

#!/usr/bin/env python3

"""Send the contents of a directory as a MIME message"

import os
import sys
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from argparse import ArgumentParser

from email import encoders
from email.message import Message
from email.mime.audio import MIMEAudio
from email.mime.base import MIMEBase
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

COMMASPACE = ',

def main():
    parser = ArgumentParser(description="Send the contents of a directory as a MIME message. Unless the -o option is given, the email is sent by SMTP server, which then does the normal delivery process. Your local machine must be running an SMTP server.
"
    parser.add_argument('-d', '--directory',
        help="Mail the contents of the specified directory, otherwise use the current directory. Only the regular files in the directory are sent, and we don't recurse to subdirectories.
"
    parser.add_argument('-o', '--output',
        metavar='FILE',
        help="Print the composed message to FILE instead of sending the message to the SMTP server.
"
    parser.add_argument('-s', '--sender', required=True,
        help='The value of the From: header (required)
"
    parser.add_argument('-r', '--recipient', required=True,
        action='append', metavar='RECIPIENT',
        default=[], dest='recipients',
        help='A To: header value (at least one required)
"
    args = parser.parse_args()
directory = args.directory
    if not directory:
        directory = '.
    # Create the enclosing (outer) message
    outer = MIMEMultipart()
outer['Subject'] = 'Contents of directory %s' %
outer['To'] = COMMASPACE.join(args.recipients)
outer['From'] = args.sender
outer.preamble = 'You will not see this in a MIME-aware mail reader.'

for filename in os.listdir(directory):
    path = os.path.join(directory, filename)
    if not os.path.isfile(path):
        continue
    # Guess the content type based on the file's extension.
    # This will be ignored, although we should check for simple things like
    # gzip'd or compressed files.
    ctype, encoding = mimetypes.guess_type(path)
    if ctype is None or encoding is not None:
        # No guess could be made, or the file is encoded (compressed).
        ctype = 'application/octet-stream'
    maintype, subtype = ctype.split('/', 1)
    if maintype == 'text':
        with open(path) as fp:
            # Note: we should handle calculating the charset
            msg = MIMEText(fp.read(), _subtype=subtype)
    elif maintype == 'image':
        with open(path, 'rb') as fp:
            msg = MIMEImage(fp.read(), _subtype=subtype)
    elif maintype == 'audio':
        with open(path, 'rb') as fp:
            msg = MIMEAudio(fp.read(), _subtype=subtype)
    else:
        with open(path, 'rb') as fp:
            msg = MIMEBase(maintype, subtype)
            msg.set_payload(fp.read())
            # Encode the payload using Base64
            encoders.encode_base64(msg)
            # Set the filename parameter
            msg.add_header('Content-Disposition', 'attachment', filename=filename)
    outer.attach(msg)
# Now send or store the message
composed = outer.as_string()
if args.output:
with open(args.output, 'w') as fp:
fp.write(composed)
else:
with smtplib.SMTP('localhost') as s:
s.sendmail(args.sender, args.recipients,

if __name__ == '__main__':
main()

Here’s an example of how to unpack a MIME message like the one
above, into a directory of files:
#!/usr/bin/env python3
"""Unpack a MIME message into a directory of files."""
import
import
import
import
import

os
sys
email
errno
mimetypes

from argparse import ArgumentParser

def main():
parser = ArgumentParser(description="""\
Unpack a MIME message into a directory of files.
""")
parser.add_argument('-d', '--directory', required
help="""Unpack the MIME message into
directory, which will be created if i


```python
import email
import os
import sys
import mimetypes

parser = ArgumentParser('msgfile')
args = parser.parse_args()

with open(args.msgfile) as fp:
    msg = email.message_from_file(fp)

try:
    os.mkdir(args.directory)
except FileExistsError:
    pass

counter = 1
for part in msg.walk():
    if part.get_content_maintype() == 'multipart'
        continue

    filename = part.get_filename()
    if not filename:
        ext = mimetypes.guess_extension(part.get_content_type())
        if not ext:
            ext = '.bin'
        filename = 'part-%03d%s' % (counter, ext)
        counter += 1
        with open(os.path.join(args.directory, filename)) as fp:
            fp.write(part.get_payload(decode=True))
```

Here’s an example of how to create an HTML message with an alternative plain text version: [2]
#!/usr/bin/env python3

import smtplib

from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

# me == my email address
# you == recipient's email address
me = "my@email.com"
you = "your@email.com"

# Create message container - the correct MIME type is multipart/alternative.
msg = MIMEMultipart('alternative')
msg['Subject'] = "Link"
msg['From'] = me
msg['To'] = you

# Create the body of the message (a plain-text and an HTML version).
text = "Hi!\nHow are you?\nHere is the link you wanted:\n"
<html>
  <head></head>
  <body>
    <p>Hi!<br>How are you?<br>Here is the <a href="https://www.python.org">link</a> you wanted.
  </p>
  </body>
</html>

# Record the MIME types of both parts - text/plain and text/html.
part1 = MIMEText(text, 'plain')
part2 = MIMEText(html, 'html')

# Attach parts into message container.
msg.attach(part1)
msg.attach(part2)
According to RFC 2046, the last part of a multipart message, in this case the HTML message, is best and preferred.

msg.attach(part1)
msg.attach(part2)

Send the message via local SMTP server.
s = smtplib.SMTP('localhost')
sendmail function takes 3 arguments: sender's address, recipient's address and message to send - here it is sent as one string.
s.sendmail(me, you, msg.as_string())
s.quit()
19.1.14.1. Examples using the Provisional API

Here is a reworking of the last example using the provisional API. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

This example also shows how easy it is to include non-ASCII, and simplifies the sending of the message using the send_message() method of the smtplib module.

```python
#!/usr/bin/env python3

import smtplib
from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Ayons asperges pour le déjeuner"
msg['From'] = Address("Pepé Le Pew", "pepe@example.com")
msg['To'] = (Address("Penelope Pussycat", "penelope@example.com")
            Address("Fabrette Pussycat", "fabrette@example.com")
msg.set_content(""
Salut!
--Pepé
```
# Add the html version. This converts the message into a container, with the original text message as the first part and the new html message as the second part.

```python
asparagus_cid = make_msgid()
msg.add_alternative("""
<html>
<head></head>
<body>
    <p>Salut!</p>
    <p>Cela ressemble à un excellent recipie</p>
    </a> déjeuner.
</p>
    <img src="cid:{asparagus_cid}" />
</body>
</html>""",
```

```python
.format(asparagus_cid=asparagus_cid[1:-1]), subtype=
```

# note that we needed to peel the <> off the msgid for use in the html.

# Now add the related image to the html part.
```

```python
with open("roasted-asparagus.jpg", 'rb') as img:
    msg.get_payload()[1].add_related(img.read(), 'image',
```

```python
cid=asparagus_cid
```

# Make a local copy of what we are going to send.
```

```python
with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))
```

# Send the message via local SMTP server.
```

```python
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

If we were instead sent the message from the last example, here is
one way we could process it:

```python
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

# An imaginary module that would make this work and be safe.
from imaginary import magic_html_parser

# In a real program you'd get the filename from the
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary,
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content,
# the least formatted payload is and print the first
# if the message has no plain text part printing the
# is probably useless, but this is just a conceptual
simplest = msg.get_body(preferencelist=('plain', 'html'))
print()
print('').join(simplest.get_content().splitlines(keepends=True))

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()
```
# We can extract the richest alternative in order to display it:

```python
r = msg.get_body()
partfiles = {}
if 'text' in r['content-type'].maintype:
    if 'plain' in r['content-type'].subtype:
        for line in r.get_content().splitlines:
            print(line)
            sys.exit()
    elif 'html' in r['content-type'].subtype:
        body = r
else:
    print("Don't know how to display {}".format(r))
    sys.exit()
elif 'multipart' in r['content-type'].content_type:
    body = r
    for part in r.iter_attachments():
        fn = part.get_filename()
        if fn:
            extension = os.path.splitext(part.get_filename())
        else:
            extension = mimetypes.guess_extension(part)
    with tempfile.NamedTemporaryFile(suffix=extension) as f:
        f.write(part.get_content())
        # again strip the <> to go from email form
        # to the filenames in partfiles. It also
        # of the html. It could be written using html.parser.
        f.write(magic_html_parser(body.get_content(), partfiles))
        webbrowser.open(f.name)
        os.remove(f.name)
for fn in partfiles.values():
    os.remove(fn)
```

Of course, there are lots of email messages that could break this simple-minded program, but it will handle the most common ones.

Up to the prompt, the output from the above is:

To: Penelope Pussycat <"penelope@example.com">, Fabrette Pussycat <"fabrette@example.com">
From: Pepé Le Pew <pepe@example.com>
Subject: Ayons asperges pour le déjeuner

Salut!

Footnotes

[1] Thanks to Matthew Dixon Cowles for the original inspiration and examples.

19.2. json — JSON encoder and decoder

JSON (JavaScript Object Notation), specified by RFC 7159 (which obsoletes RFC 4627) and by ECMA-404, is a lightweight data interchange format inspired by JavaScript object literal syntax (although it is not a strict subset of JavaScript [1]).

json exposes an API familiar to users of the standard library marshal and pickle modules.

Encoding basic Python object hierarchies:

```python
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}, {
"foo": {
"bar": [
"baz", null, 1.0,
2]
}]
>>> print(json.dumps("\"foo\bar\"
"\"foo\bar"
>>> print(json.dumps('\u1234'))
"\u1234"
>>> print(json.dumps('\\'))
"\"
>>> print(json.dumps({"c": 0, "b": 0, "a": 0}, sort_ {"a": 0, "b": 0, "c": 0}
>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'\"["streaming API"]\"
```

Compact encoding:
>>> import json
>>> json.dumps([1,2,3,{'4': 5, '6': 7}], separators=
'[1,2,3,{"4":5,"6":7}]'

Pretty printing:
>>> import json
>>> print(json.dumps({'4': 5, '6': 7}, sort_keys=True
{
"4": 5,
"6": 7
}

Decoding JSON:
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]'
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']

Specializing JSON object decoding:

>>> import json
>>> def as_complex(dct):
...
if '__complex__' in dct:
...
return complex(dct['real'], dct['imag'])
...
return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}'


Extending JSONEncoder:

```python
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise
...         return json.JSONEncoder.default(self, obj)

>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[2.0', ', ', '1.0', ', ']
```

Using json.tool from the shell to validate and pretty-print:

```bash
$ echo '{"json":"obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes:
```

See Command Line Interface for detailed documentation.
Note: JSON is a subset of YAML 1.2. The JSON produced by this module’s default settings (in particular, the default separators value) is also a subset of YAML 1.0 and 1.1. This module can thus also be used as a YAML serializer.
19.2.1. Basic Usage

```python
json.dump(obj, fp, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)
```

Serialize `obj` as a JSON formatted stream to `fp` (a `.write()`-supporting file-like object) using this conversion table.

If `skipkeys` is True (default: False), then dict keys that are not of a basic type (`str`, `int`, `float`, `bool`, `None`) will be skipped instead of raising a `TypeError`.

The `json` module always produces `str` objects, not `bytes` objects. Therefore, `fp.write()` must support `str` input.

If `ensure_ascii` is True (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is False, these characters will be output as-is.

If `check_circular` is False (default: True), then the circular reference check for container types will be skipped and a circular reference will result in an `OverflowError` (or worse).

If `allow_nan` is False (default: True), then it will be a `ValueError` to serialize out of range `float` values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification, instead of using the JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`).

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or "" will only insert newlines.
None (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If `indent` is a string (such as "\t"), that string is used to indent each level.

*Changed in version 3.2:* Allow strings for `indent` in addition to integers.

If specified, `separators` should be an `(item_separator, key_separator)` tuple. The default is (`', ', ':'`) if `indent` is `None` and (`', ', ':'`) otherwise. To get the most compact JSON representation, you should specify (`', ', ':'`) to eliminate whitespace.

*Changed in version 3.4:* Use (`', ', ':'`) as default if `indent` is not `None`.

`default(obj)` is a function that should return a serializable version of `obj` or raise `TypeError`. The default simply raises `TypeError`.

If `sort_keys` is `True` (default: `False`), then the output of dictionaries will be sorted by key.

To use a custom `JSONEncoder` subclass (e.g. one that overrides the default() method to serialize additional types), specify it with the `cls` kwarg; otherwise `JSONEncoder` is used.

```python
json.dumps(obj, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)
```

Serialize `obj` to a JSON formatted `str` using this conversion table. The arguments have the same meaning as in `dump()`.
Note: Unlike `pickle` and `marshal`, JSON is not a framed protocol, so trying to serialize multiple objects with repeated calls to `dump()` using the same `fp` will result in an invalid JSON file.

Note: Keys in key/value pairs of JSON are always of the type `str`. When a dictionary is converted into JSON, all the keys of the dictionary are coerced to strings. As a result of this, if a dictionary is converted into JSON and then back into a dictionary, the dictionary may not equal the original one. That is, `loads(dumps(x)) != x` if `x` has non-string keys.

`json.load(fp, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)`

Deserialize `fp` (a `.read()`-supporting file-like object containing a JSON document) to a Python object using this conversion table.

`object_hook` is an optional function that will be called with the result of any object literal decoded (a `dict`). The return value of `object_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders (e.g. JSON-RPC class hinting).

`object_pairs_hook` is an optional function that will be called with the result of any object literal decoded with an ordered list of pairs. The return value of `object_pairs_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, `collections.OrderedDict()` will remember the order of insertion). If `object_hook` is also defined, the `object_pairs_hook` takes priority.
Changed in version 3.1: Added support for `object_pairs_hook`.

`parse_float`, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

`parse_int`, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

`parse_constant`, if specified, will be called with one of the following strings: '-Infinity', 'Infinity', 'NaN'. This can be used to raise an exception if invalid JSON numbers are encountered.

Changed in version 3.1: `parse_constant` doesn’t get called on ‘null’, ‘true’, ‘false’ anymore.

To use a custom `JSONDecoder` subclass, specify it with the `cls` kwarg; otherwise `JSONDecoder` is used. Additional keyword arguments will be passed to the constructor of the class.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

```python
json.loads(s, encoding=None, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)
```

Deserialize `s` (a `str` instance containing a JSON document) to a Python object using this conversion table.

The other arguments have the same meaning as in `load()`,
except `encoding` which is ignored and deprecated.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.
19.2.2. Encoders and Decoders

class json.JSONDecoder(object_hook=None, parse_float=None, parse_int=None, parse_constant=None, strict=True, object_pairs_hook=None)

    Simple JSON decoder.

    Performs the following translations in decoding by default:

<table>
<thead>
<tr>
<th>JSON</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>dict</td>
</tr>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>string</td>
<td>str</td>
</tr>
<tr>
<td>number (int)</td>
<td>int</td>
</tr>
<tr>
<td>number (real)</td>
<td>float</td>
</tr>
<tr>
<td>true</td>
<td>True</td>
</tr>
<tr>
<td>false</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

It also understands NaN, Infinity, and -Infinity as their corresponding float values, which is outside the JSON spec.

*object_hook*, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given *dict*. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).

*object_pairs_hook*, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the *dict*. This feature
can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, collections.OrderedDict() will remember the order of insertion). If object_hook is also defined, the object_pairs_hook takes priority.

*Changed in version 3.1:* Added support for object_pairs_hook.

*parse_float*, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to float(num_str). This can be used to use another datatype or parser for JSON floats (e.g. decimal.Decimal).

*parse_int*, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to int(num_str). This can be used to use another datatype or parser for JSON integers (e.g. float).

*parse_constant*, if specified, will be called with one of the following strings: '-Infinity', 'Infinity', 'NaN', 'null', 'true', 'false'. This can be used to raise an exception if invalid JSON numbers are encountered.

If strict is False (True is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0-31 range, including '\t' (tab), '\n', '\r' and '\0'.

If the data being deserialized is not a valid JSON document, a JSONDecodeError will be raised.

**decode(s)**

Return the Python representation of s (a str instance
containing a JSON document).

`JSONDecodeError` will be raised if the given JSON document is not valid.

**raw_decode(s)**

Decode a JSON document from `s` (a `str` beginning with a JSON document) and return a 2-tuple of the Python representation and the index in `s` where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

```python
class json.JSONEncoder(skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None)
```

Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

<table>
<thead>
<tr>
<th>Python</th>
<th>JSON</th>
</tr>
</thead>
<tbody>
<tr>
<td>dict</td>
<td>object</td>
</tr>
<tr>
<td>list, tuple</td>
<td>array</td>
</tr>
<tr>
<td>str</td>
<td>string</td>
</tr>
<tr>
<td>int, float, int- &amp; float-derived Enums</td>
<td>number</td>
</tr>
<tr>
<td>True</td>
<td>true</td>
</tr>
<tr>
<td>False</td>
<td>false</td>
</tr>
<tr>
<td>None</td>
<td>null</td>
</tr>
</tbody>
</table>

*Changed in version 3.4:* Added support for int- and float-derived Enum classes.
To extend this to recognize other objects, subclass and implement a `default()` method with another method that returns a serializable object for `o` if possible, otherwise it should call the superclass implementation (to raise `TypeError`).

If `skipkeys` is False (the default), then it is a `TypeError` to attempt encoding of keys that are not str, int, float or None. If `skipkeys` is True, such items are simply skipped.

If `ensure_ascii` is True (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is False, these characters will be output as-is.

If `check_circular` is True (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an `OverflowError`). Otherwise, no such check takes place.

If `allow_nan` is True (the default), then NaN, Infinity, and -Infinity will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a `ValueError` to encode such floats.

If `sort_keys` is True (default False), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or "" will only insert newlines. None (the default) selects the most compact representation. Using
a positive integer indent indents that many spaces per level. If \textit{indent} is a string (such as "\t"), that string is used to indent each level.

\textit{Changed in version 3.2:} Allow strings for \textit{indent} in addition to integers.

If specified, \textit{separators} should be an \texttt{(item\_separator, key\_separator)} tuple. The default is \texttt{(', ', ': ')} if \textit{indent} is None and \texttt{(', ', ': ')} otherwise. To get the most compact JSON representation, you should specify \texttt{(', ', ': ')} to eliminate whitespace.

\textit{Changed in version 3.4:} Use \texttt{(', ', ': ')} as default if \textit{indent} is not None.

If specified, \textit{default} is a function that gets called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a \texttt{TypeError}.

\texttt{default(o)}

Implement this method in a subclass such that it returns a serializable object for \texttt{o}, or calls the base implementation (to raise a \texttt{TypeError}).

For example, to support arbitrary iterators, you could implement \texttt{default} like this:

\begin{verbatim}
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        \end{verbatim}
return list(iterable)
# Let the base class default method raise the
return json.JSONEncoder.default(self, o)

**encode(o)**

Return a JSON string representation of a Python data structure, o. For example:

```python
>>> json.JSONEncoder().encode({"foo": ["bar", "baz"]})
"{"foo": ["bar", "baz"]}
```

**iterencode(o)**

Encode the given object, o, and yield each string representation as available. For example:

```python
for chunk in json.JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```
19.2.3. Exceptions

`exception json.JSONDecodeError(msg, doc, pos, end=None)`

Subclass of `ValueError` with the following additional attributes:

**msg**
- The unformatted error message.

**doc**
- The JSON document being parsed.

**pos**
- The start index of `doc` where parsing failed.

**lineno**
- The line corresponding to `pos`.

**colno**
- The column corresponding to `pos`.

*New in version 3.5.*
19.2.4. Standard Compliance and Interoperability

The JSON format is specified by RFC 7159 and by ECMA-404. This section details this module’s level of compliance with the RFC. For simplicity, JSONEncoder and JSONDecoder subclasses, and parameters other than those explicitly mentioned, are not considered.

This module does not comply with the RFC in a strict fashion, implementing some extensions that are valid JavaScript but not valid JSON. In particular:

- Infinite and NaN number values are accepted and output;
- Repeated names within an object are accepted, and only the value of the last name-value pair is used.

Since the RFC permits RFC-compliant parsers to accept input texts that are not RFC-compliant, this module’s deserializer is technically RFC-compliant under default settings.

19.2.4.1. Character Encodings

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability.

As permitted, though not required, by the RFC, this module’s serializer sets ensure_ascii=True by default, thus escaping the output so that the resulting strings only contain ASCII characters.

Other than the ensure_ascii parameter, this module is defined strictly in terms of conversion between Python objects and Unicode
strings, and thus does not otherwise directly address the issue of character encodings.

The RFC prohibits adding a byte order mark (BOM) to the start of a JSON text, and this module’s serializer does not add a BOM to its output. The RFC permits, but does not require, JSON deserializers to ignore an initial BOM in their input. This module’s deserializer raises a ValueError when an initial BOM is present.

The RFC does not explicitly forbid JSON strings which contain byte sequences that don’t correspond to valid Unicode characters (e.g. unpaired UTF-16 surrogates), but it does note that they may cause interoperability problems. By default, this module accepts and outputs (when present in the original str) code points for such sequences.

19.2.4.2. Infinite and NaN Number Values

The RFC does not permit the representation of infinite or NaN number values. Despite that, by default, this module accepts and outputs Infinity, -Infinity, and NaN as if they were valid JSON number literal values:

```python
>>> # Neither of these calls raises an exception, but
>>> json.dumps(float('-inf'))
'Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```
In the serializer, the `allow_nan` parameter can be used to alter this behavior. In the deserializer, the `parse_constant` parameter can be used to alter this behavior.

### 19.2.4.3. Repeated Names Within an Object

The RFC specifies that the names within a JSON object should be unique, but does not mandate how repeated names in JSON objects should be handled. By default, this module does not raise an exception; instead, it ignores all but the last name-value pair for a given name:

```python
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

The `object_pairs_hook` parameter can be used to alter this behavior.

### 19.2.4.4. Top-level Non-Object, Non-Array Values

The old version of JSON specified by the obsolete RFC 4627 required that the top-level value of a JSON text must be either a JSON object or array (Python `dict` or `list`), and could not be a JSON null, boolean, number, or string value. RFC 7159 removed that restriction, and this module does not and has never implemented that restriction in either its serializer or its deserializer.

Regardless, for maximum interoperability, you may wish to voluntarily adhere to the restriction yourself.

### 19.2.4.5. Implementation Limitations
Some JSON deserializer implementations may set limits on:

- the size of accepted JSON texts
- the maximum level of nesting of JSON objects and arrays
- the range and precision of JSON numbers
- the content and maximum length of JSON strings

This module does not impose any such limits beyond those of the relevant Python datatypes themselves or the Python interpreter itself.

When serializing to JSON, beware any such limitations in applications that may consume your JSON. In particular, it is common for JSON numbers to be deserialized into IEEE 754 double precision numbers and thus subject to that representation’s range and precision limitations. This is especially relevant when serializing Python int values of extremely large magnitude, or when serializing instances of “exotic” numerical types such as `decimal.Decimal`.
19.2.5. Command Line Interface

The json.tool module provides a simple command line interface to validate and pretty-print JSON objects.

If the optional infile and outfile arguments are not specified, sys.stdin and sys.stdout will be used respectively:

```
$ echo '{"json": "obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: }
```

*Changed in version 3.5:* The output is now in the same order as the input. Use the `-sort-keys` option to sort the output of dictionaries alphabetically by key.

19.2.5.1. Command line options

**infile**

The JSON file to be validated or pretty-printed:

```
$ python -m json.tool mp_films.json
[
    {
        "title": "And Now for Something Completely Different",
        "year": 1971
    },
    {
        "title": "Monty Python and the Holy Grail"
    }
]```
If `infile` is not specified, read from `sys.stdin`.

`outfile`

Write the output of the `infile` to the given `outfile`. Otherwise, write it to `sys.stdout`.

`--sort-keys`

Sort the output of dictionaries alphabetically by key.

*New in version 3.5.*

`-h, --help`

Show the help message.

**Footnotes**

As noted in the errata for RFC 7159, JSON permits literal U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) characters in strings, whereas JavaScript (as of ECMAScript Edition 5.1) does not.

[1]
Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the `xmpeg` program can be automatically started to view the file.

The mailcap format is documented in RFC 1524, “A User Agent Configuration Mechanism For Multimedia Mail Format Information,” but is not an Internet standard. However, mailcap files are supported on most Unix systems.

```
mailcap.findmatch(caps, MIMEtype, key='view', filename='/dev/null', plist=[])  
```

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, (None, None) is returned.

`key` is the name of the field desired, which represents the type of activity to be performed; the default value is `‘view’, since in the
most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See RFC 1524 for a complete list of these fields.

filename is the filename to be substituted for %s in the command line; the default value is '/dev/null' which is almost certainly not what you want, so usually you'll override it by specifying a filename.

plist can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter's value. Mailcap entries can contain named parameters like %{foo}, which will be replaced by the value of the parameter named 'foo'. For example, if the command line showpartial % {id} %{number} %{total} was in a mailcap file, and plist was set to ['id=1', 'number=2', 'total=3'], the resulting command line would be 'showpartial 1 2 3'.

In a mailcap file, the “test” field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. findmatch() will automatically check such conditions and skip the entry if the check fails.

mailcap.getcaps()

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the findmatch() function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.
The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file $HOME/.mailcap will override settings in the system mailcap files /etc/mailcap, /usr/etc/mailcap, and /usr/local/etc/mailcap.

An example usage:

```python
>>> import mailcap
>>> d=mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223')
('xmpeg tmp1223', {'view': 'xmpeg %s'})
```
19. Internet Data Handling
19.4. `mailbox` — Manipulate mailboxes in various formats

This module defines two classes, `Mailbox` and `Message`, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the `email.message` module's `Message` class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

See also:

Module `email`

Represent and manipulate messages.
19.4.1. **Mailbox objects**

```python
class mailbox.Mailbox

A mailbox, which may be inspected and modified.
```

The `Mailbox` class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from `Mailbox` and your code should instantiate a particular subclass.

The `Mailbox` interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the `Mailbox` instance with which they will be used and are only meaningful to that `Mailbox` instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a `Mailbox` instance using the set-like method `add()` and removed using a `del` statement or the set-like methods `remove()` and `discard()`.

`Mailbox` interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a `Message` instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a `Mailbox` instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the `Mailbox` instance.

The default `Mailbox` iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and
well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you're modifying a mailbox, you must lock it by calling the `lock()` and `unlock()` methods before reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

`Mailbox` instances have the following methods:

**add**(*message*)

Add *message* to the mailbox and return the key that has been assigned to it.

Parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

*Changed in version 3.2:* Support for binary input was added.
**remove(key)**
**__delitem__(key)**
**discard(key)**

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a **KeyError** exception is raised if the method was called as **remove()** or **__delitem__()** but no exception is raised if the method was called as **discard()**. The behavior of **discard()** may be preferred if the underlying mailbox format supports concurrent modification by other processes.

**__setitem__(key, message)**

Replace the message corresponding to *key* with *message*. Raise a **KeyError** exception if no message already corresponds to *key*.

As with **add()**, parameter *message* may be a **Message** instance, an **email.message.Message** instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific **Message** subclass (e.g., if it's an **mboxMessage** instance and this is an **mbox** instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

**iterkeys()**
**keys()**

Return an iterator over all keys if called as **iterkeys()** or return a list of keys if called as **keys()**.
itervalues()
__iter__()
values()

Return an iterator over representations of all messages if called as itervalues() or __iter__() or return a list of such representations if called as values(). The messages are represented as instances of the appropriate format-specific Message subclass unless a custom message factory was specified when the Mailbox instance was initialized.

**Note:** The behavior of __iter__() is unlike that of dictionaries, which iterate over keys.

iteritems()
items()

Return an iterator over (key, message) pairs, where key is a key and message is a message representation, if called as iteritems() or return a list of such pairs if called as items(). The messages are represented as instances of the appropriate format-specific Message subclass unless a custom message factory was specified when the Mailbox instance was initialized.

get(key, default=None)
__getitem__(key)

Return a representation of the message corresponding to key. If no such message exists, default is returned if the method was called as get() and a KeyError exception is raised if the method was called as __getitem__(). The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was
specified when the Mailbox instance was initialized.

**get_message(key)**

Return a representation of the message corresponding to *key* as an instance of the appropriate format-specific Message subclass, or raise a **KeyError** exception if no such message exists.

**get_bytes(key)**

Return a byte representation of the message corresponding to *key*, or raise a **KeyError** exception if no such message exists.

*New in version 3.2.*

**get_string(key)**

Return a string representation of the message corresponding to *key*, or raise a **KeyError** exception if no such message exists. The message is processed through `email.message.Message` to convert it to a 7bit clean representation.

**get_file(key)**

Return a file-like representation of the message corresponding to *key*, or raise a **KeyError** exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

*Changed in version 3.2:* The file object really is a binary file; previously it was incorrectly returned in text mode. Also, the file-like object now supports the context management protocol: you can use a `with` statement to automatically close it.
Note: Unlike other representations of messages, file-like representations are not necessarily independent of the Mailbox instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

__contains__(key)
Return True if key corresponds to a message, False otherwise.

__len__()
Return a count of messages in the mailbox.

clear()
Delete all messages from the mailbox.

pop(key, default=None)
Return a representation of the message corresponding to key and delete the message. If no such message exists, return default. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the Mailbox instance was initialized.

popitem()
Return an arbitrary (key, message) pair, where key is a key and message is a message representation, and delete the corresponding message. If the mailbox is empty, raise a KeyError exception. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the
Mailbox instance was initialized.

**update**(*arg*)
Parameter *arg* should be a *key-to-message* mapping or an iterable of *(key, message)* pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using **__setitem__**( ). As with **__setitem__**( ), each *key* must already correspond to a message in the mailbox or else a **KeyError** exception will be raised, so in general it is incorrect for *arg* to be a Mailbox instance.

**Note:** Unlike with dictionaries, keyword arguments are not supported.

**flush()**
Write any pending changes to the filesystem. For some Mailbox subclasses, changes are always written immediately and **flush()** does nothing, but you should still make a habit of calling this method.

**lock()**
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An **ExternalClashError** is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should always lock the mailbox before making any modifications to its contents.

**unlock()**
Release the lock on the mailbox, if any.
close()
Flush the mailbox, unlock it if necessary, and close any open files. For some Mailbox subclasses, this method does nothing.

19.4.1.1. Maildir

class mailbox.Maildir(dirname, factory=None, create=True)
A subclass of Mailbox for mailboxes in Maildir format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MaildirMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

It is for historical reasons that dirname is named as such rather than path.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: tmp, new, and cur. Messages are created momentarily in the tmp subdirectory and then moved to the new subdirectory to finalize delivery. A mail user agent may subsequently move the message to the cur subdirectory and store information about the state of the message in a special “info” section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent
are also supported. Any subdirectory of the main mailbox is considered a folder if "." is the first character in its name. Folder names are represented by `Maildir` without the leading ".". Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using "." to delimit levels, e.g., “Archived.2005.07”.

**Note:** The Maildir specification requires the use of a colon (':') in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point ("!'") is a popular choice. For example:

```
import mailbox
mailbox.Maildir.colon = '!'  
```

The colon attribute may also be set on a per-instance basis.

`Maildir` instances have all of the methods of `Mailbox` in addition to the following:

**list_folders()**

Return a list of the names of all folders.

**get_folder(folder)**

Return a `Maildir` instance representing the folder whose name is `folder`. A `NoSuchMailboxError` exception is raised if the folder does not exist.

**add_folder(folder)**

Create a folder whose name is `folder` and return a `Maildir` instance representing it.
**remove_folder**(*folder*)
Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

**clean()**
Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some Mailbox methods implemented by Maildir deserve special remarks:

**add**(message)
**__setitem__**(key, message)
**update**(arg)

**Warning:** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

**flush()**
All changes to Maildir mailboxes are immediately applied, so this method does nothing.

**lock()**
**unlock()**
Maildir mailboxes do not support (or require) locking, so these methods do nothing.
close()

Maildir instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

get_file(key)

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

The original specification of the format.

Using maildir format
Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on “info” semantics.

maildir man page from Courier
Another specification of the format. Describes a common extension for supporting folders.

19.4.1.2. mbox

class mailbox.mbox(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in mbox format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, mboxMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.
The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From ”.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, mbox implements the original format, which is sometimes referred to as mboxo. This means that the Content-Length header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “>From ” when storing the message, although occurrences of “>From ” are not transformed to “From ” when reading the message.

Some Mailbox methods implemented by mbox deserve special remarks:

**get_file**(key)

Using the file after calling flush() or close() on the mbox instance may yield unpredictable results or raise an exception.

**lock**

**unlock**

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

See also:

**mbox man page from qmail**

A specification of the format and its variations.

**mbox man page from tin**

Another specification of the format, with details on locking.
Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad

An argument for using the original mbox format rather than a variation.

“mbox” is a family of several mutually incompatible mailbox formats

A history of mbox variations.

19.4.1.3. MH

class mailbox.MH(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in MH format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MHMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called folders) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support sequences, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called .mh_sequences in each folder.

The MH class manipulates MH mailboxes, but it does not attempt to emulate all of mh's behaviors. In particular, it does not modify and is not affected by the context or .mh_profile files that are used by mh to store its state and configuration.
MH instances have all of the methods of Mailbox in addition to the following:

**list_folders()**
Return a list of the names of all folders.

**get_folder(folder)**
Return an MH instance representing the folder whose name is `folder`. A NoSuchMailboxError exception is raised if the folder does not exist.

**add_folder(folder)**
Create a folder whose name is `folder` and return an MH instance representing it.

**remove_folder(folder)**
Delete the folder whose name is `folder`. If the folder contains any messages, a NotEmptyError exception will be raised and the folder will not be deleted.

**get_sequences()**
Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

**set_sequences(sequences)**
Re-define the sequences that exist in the mailbox based upon `sequences`, a dictionary of names mapped to key lists, like returned by get_sequences().

**pack()**
Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated
correspondingly.

**Note:** Already-issued keys are invalidated by this operation and should not be subsequently used.

Some **Mailbox** methods implemented by **MH** deserve special remarks:

```python
code
remove(key)
__delitem__(key)
discard(key)
```

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

```
lock()
unlock()
```

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

```
get_file(key)
```

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

```
flush()
```

All changes to MH mailboxes are immediately applied, so this method does nothing.
close()

MH instances do not keep any open files, so this method is equivalent to unlock().

nmh - Message Handling System
Home page of nmh, an updated version of the original mh.

MH & nmh: Email for Users & Programmers
A GPL-licensed book on mh and nmh, with some information on the mailbox format.

19.4.1.4. Babylon

class mailbox.Babylon(path, factory=None, create=True)
A subclass of Mailbox for mailboxes in Babylon format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, BabylonMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

Babylon is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore ('\037') and Control-L ('\014'). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore ('\037') character.

Messages in a Babylon mailbox have two sets of headers, original
headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of labels, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

Babyl instances have all of the methods of Mailbox in addition to the following:

get_labels()

Return a list of the names of all user-defined labels used in the mailbox.

Note: The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some Mailbox methods implemented by Babyl deserve special remarks:

get_file(key)

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an io.BytesIO instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

lock()
unlock()

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

See also:

Format of Version 5 Babyl Files
A specification of the Babyl format.

Reading Mail with Rmail
The Rmail manual, with some information on Babyl semantics.

19.4.1.5. MMDF

class mailbox.MMDF(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in MMDF format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MMDFMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A ('\001') characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are “From ”, but additional occurrences of “From ” are not transformed to “>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.
Some Mailbox methods implemented by MMDF deserve special remarks:

**get_file**(key)

Using the file after calling `flush()` or `close()` on the MMDF instance may yield unpredictable results or raise an exception.

**lock()**

**unlock()**

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

---

**See also:**

**mmdf man page from tin**

A specification of MMDF format from the documentation of tin, a newsreader.

**MMDF**

A Wikipedia article describing the Multichannel Memorandum Distribution Facility.
19.4.2. Message objects

class mailbox.Message(message=None)

If message is omitted, the new instance is created in a default, empty state. If message is an email.message.Message instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if message is a Message instance. If message is a string, a byte string, or a file, it should contain an RFC 2822-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that Message instances be used to represent messages retrieved using Mailbox instances. In some situations, the time and memory required to generate Message representations might not be acceptable. For such situations, Mailbox instances also offer string and file-like representations,
and a custom message factory may be specified when a Mailbox instance is initialized.

19.4.2.1. MaildirMessage

class mailbox.MaildirMessage(message=None)
A message with Maildir-specific behaviors. Parameter message has the same meaning as with the Message constructor.

Typically, a mail user agent application moves all of the messages in the new subdirectory to the cur subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they’ve actually been read. Each message in cur has an “info” section added to its file name to store information about its state. (Some mail readers may also add an “info” section to messages in new.) The “info” section may take one of two forms: it may contain “2,” followed by a list of standardized flags (e.g., “2,FR”) or it may contain “1,” followed by so-called experimental information. Standard flags for Maildir messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Draft</td>
<td>Under composition</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>P</td>
<td>Passed</td>
<td>Forwarded, resent, or bounced</td>
</tr>
<tr>
<td>R</td>
<td>Replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>S</td>
<td>Seen</td>
<td>Read</td>
</tr>
<tr>
<td>T</td>
<td>Trashed</td>
<td>Marked for subsequent deletion</td>
</tr>
</tbody>
</table>

MaildirMessage instances offer the following methods:
get_subdir()
Return either “new” (if the message should be stored in the new subdirectory) or “cur” (if the message should be stored in the cur subdirectory).

Note: A message is typically moved from new to cur after its mailbox has been accessed, whether or not the message is has been read. A message msg has been read if "S" in msg.get_flags() is True.

set_subdir(subdir)
Set the subdirectory the message should be stored in. Parameter subdir must be either “new” or “cur”.

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The empty string is returned if no flags are set or if “info” contains experimental semantics.

set_flags(flags)
Set the flags specified by flags and unset all others.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character. The current “info” is overwritten whether or not it contains experimental information rather than flags.

remove_flag(flag)
Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If “info” contains experimental information rather than flags, the current “info” is not modified.

**get_date()**

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

**set_date(date)**

Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

**get_info()**

Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

**set_info(info)**

Set “info” to *info*, which should be a string.

When a MaildirMessage instance is created based upon an mboxMessage or MMDFMessage instance, the Status and X-Status headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>O flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>R flag</td>
<td>A flag</td>
</tr>
<tr>
<td>S flag</td>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
<td>D flag</td>
</tr>
</tbody>
</table>
When a `MaildirMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>R flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When a `MaildirMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>P flag</td>
<td>“forwarded” or “resent” label</td>
</tr>
<tr>
<td>R flag</td>
<td>“answered” label</td>
</tr>
<tr>
<td>T flag</td>
<td>“deleted” label</td>
</tr>
</tbody>
</table>

19.4.2.2. `mboxMessage`

`class mailbox.mboxMessage(message=None)`

A message with mbox-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Messages in an mbox mailbox are stored together in a single file. The sender’s envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable
variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in `Status` and `X-Status` headers.

Conventional flags for mbox messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the `Status` header, and the “D”, “F”, and “A” flags are stored in the `X-Status` header. The flags and headers typically appear in the order mentioned.

`mboxMessage` instances offer the following methods:

**get_from()**

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_, time_=None)**

Set the “From ” line to `from_`, which should be specified without a leading “From ” or trailing newline. For convenience, `time_` may be specified and will be formatted appropriately and appended to `from_`. If `time_` is specified, it should be a `time.struct_time` instance, a tuple suitable for passing to
time.strftime(), or True (to use time.gmtime()).

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

set_flags(flags)
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an mboxMessage instance is created based upon a MaildirMessage instance, a “From ” line is generated based upon the MaildirMessage instance's delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>--------</td>
<td>-------</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When a `Message` instance is created based upon an `MMDFMessage` instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
</tbody>
</table>
19.4.2.3. **MHMessage**

```python
class mailbox.MHMessage(message=None)
```

A message with MH-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard `mh` and `nmh`) use sequences in much the same way flags are used with other formats, as follows:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>flagged</td>
<td>Marked as important</td>
</tr>
</tbody>
</table>

`MHMessage` instances offer the following methods:

```python
def get_sequences()
    Return a list of the names of sequences that include this message.

def set_sequences(sequences)
    Set the list of sequences that include this message.

def add_sequence(sequence)
```
Add *sequence* to the list of sequences that include this message.

**remove_sequence**(*sequence*)

Remove *sequence* from the list of sequences that include this message.

When an **MHMessage** instance is created based upon a **MaildirMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no S flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>R flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an **MHMessage** instance is created based upon an **mboxMessage** or **MMDFMessage** instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no R flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>A flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an **MHMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>“unseen” label</td>
</tr>
</tbody>
</table>
19.4.2.4. **BabylMessage**

```python
class mailbox.BabylMessage(message=None)
```

A message with Babyl-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>filed</td>
<td>Copied to another file or mailbox</td>
</tr>
<tr>
<td>answered</td>
<td>Replied to</td>
</tr>
<tr>
<td>forwarded</td>
<td>Forwarded</td>
</tr>
<tr>
<td>edited</td>
<td>Modified by the user</td>
</tr>
<tr>
<td>resent</td>
<td>Resent</td>
</tr>
</tbody>
</table>

By default, Rmail displays only visible headers. The `BabylMessage` class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

`BabylMessage` instances offer the following methods:

- **get_labels()**
  Return a list of labels on the message.

- **set_labels(labels)**
Set the list of labels on the message to `labels`.

`add_label(label)`
Add `label` to the list of labels on the message.

`remove_label(label)`
Remove `label` from the list of labels on the message.

`get_visible()`
Return an `Message` instance whose headers are the message’s visible headers and whose body is empty.

`set_visible(visible)`
Set the message’s visible headers to be the same as the headers in `message`. Parameter `visible` should be a `Message` instance, an `email.message.Message` instance, a string, or a file-like object (which should be open in text mode).

`update_visible()`
When a `BabylMessage` instance’s original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of `Date`, `From`, `Reply-To`, `To`, `CC`, and `Subject` that are present in the original headers but not the visible headers are added to the visible headers.

When a `BabylMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:
<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no S flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>T flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>R flag</td>
</tr>
<tr>
<td>“forwarded” label</td>
<td>P flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the `Status` and `X-Status` headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no R flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>D flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>A flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“answered” label</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

19.4.2.5. **MMDFMessage**

```python
class mailbox.MMDFMessage(message=None)
```

A message with MMDF-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

As with message in an mbox mailbox, MMDF messages are stored
with the sender’s address and the delivery date in an initial line beginning with “From ”. Likewise, flags that indicate the state of the message are typically stored in Status and X-Status headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

**MMDFMessage** instances offer the following methods, which are identical to those offered by **mboxMessage**:

**get_from()**

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from**(from_, time_=None)

Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a
time.struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

set_flags(flags)
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an MMDFMessage instance is created based upon a MaildirMessage instance, a “From” line is generated based upon the MaildirMessage instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an *MMDFMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an *MMDFMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When an *MMDFMessage* instance is created based upon an *mboxMessage* instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>
19.4.3. Exceptions

The following exception classes are defined in the `mailbox` module:

**exception mailbox.Error**

The based class for all other module-specific exceptions.

**exception mailbox.NoSuchMailboxError**

Raised when a mailbox is expected but is not found, such as when instantiating a `Mailbox` subclass with a path that does not exist (and with the `create` parameter set to `False`), or when opening a folder that does not exist.

**exception mailbox.NotEmptyError**

Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

**exception mailbox.ExternalClashError**

Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

**exception mailbox.FormatError**

Raised when the data in a file cannot be parsed, such as when an `MH` instance attempts to read a corrupted `.mh_sequences` file.
19.4.4. Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```python
global import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']  # Could possibly be None.
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babylon mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```python
global import mailbox
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-bugs')
```
boxes = {name: mailbox.mbox('~/email/%s' % name) for name in list_names}

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue  # The message is malformed.

    for name in list_names:
        list_id = message['list-id']
        if list_id and name in list_id:
            # Get mailbox to use
            box = boxes[name]

            # Write copy to disk before removing original.
            # If there's a crash, you might duplicate that, but
            # that's better than losing a message completely.
            box.lock()
            box.add(message)
            box.flush()
            box.unlock()

            # Remove original message
            inbox.lock()
            inbox.discard(key)
            inbox.flush()
            inbox.unlock()
            break  # Found destination,

for box in boxes.itervalues():
    box.close()
19.5. **mimetypes** — Map filenames to MIME types

**Source code:** Lib/mimetypes.py

The `mimetypes` module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

```python
mimetypes.guess_type(url, strict=True)
```

Guess the type of a file based on its filename or URL, given by `url`. The return value is a tuple `(type, encoding)` where `type` is None if the type can't be guessed (missing or unknown suffix) or a string of the form 'type/subtype', usable for a MIME `content-type` header.

`encoding` is None for no encoding or the name of the program used to encode (e.g. `compress` or `gzip`). The encoding is suitable for use as a `Content-Encoding` header, not as a `Content-Transfer-Encoding` header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case
sensitively, then case insensitively.

The optional strict argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA. When strict is True (the default), only the IANA types are supported; when strict is False, some additional non-standard but commonly used MIME types are also recognized.

`mimetypes.guess_all_extensions(type, strict=True)`

Guess the extensions for a file based on its MIME type, given by type. The return value is a list of strings giving all possible filename extensions, including the leading dot ('.'). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by `guess_type()`.

The optional strict argument has the same meaning as with the `guess_type()` function.

`mimetypes.guess_extension(type, strict=True)`

Guess the extension for a file based on its MIME type, given by type. The return value is a string giving a filename extension, including the leading dot ('.'). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by `guess_type()` If no extension can be guessed for type, None is returned.

The optional strict argument has the same meaning as with the `guess_type()` function.

Some additional functions and data items are available for controlling the behavior of the module.
mimetypes.init(files=None)

Initialize the internal data structures. If given, files must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from knownfiles; on Windows, the current registry settings are loaded. Each file named in files or knownfiles takes precedence over those named before it. Calling init() repeatedly is allowed.

Specifying an empty list for files will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

Changed in version 3.2: Previously, Windows registry settings were ignored.

mimetypes.read_mime_types(filename)

Load the type map given in the file filename, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file filename does not exist or cannot be read, None is returned.

mimetypes.add_type(type, ext, strict=True)

Add a mapping from the MIME type type to the extension ext. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When strict is True (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

mimetypes.inited
Flag indicating whether or not the global data structures have been initialized. This is set to True by `init()`.

`mimetypes.knownfiles`
List of type map file names commonly installed. These files are typically named `mime.types` and are installed in different locations by different packages.

`mimetypes.suffix_map`
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

`mimetypes.encodings_map`
Dictionary mapping filename extensions to encoding types.

`mimetypes.types_map`
Dictionary mapping filename extensions to MIME types.

`mimetypes.common_types`
Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

An example usage of the module:

```python
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
```
'gzip'

```python
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```
19.5.1. MimeTypes Objects

The MimeTypes class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the mimetypes module.

```python
class mimetypes.MimeTypes(filenames=(), strict=True)
```

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional mime.types-style files into the database using the `read()` or `readfp()` methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional `filenames` parameter can be used to cause additional files to be loaded “on top” of the default database.

**MimeTypes.suffix_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global `suffix_map` defined in the module.

**MimeTypes.encodings_map**

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global `encodings_map` defined in the module.
MimeTypes.types_map

Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by common_types and types_map.

MimeTypes.types_map_inv

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by common_types and types_map.

MimeTypes.guess_extension(type, strict=True)

Similar to the guess_extension() function, using the tables stored as part of the object.

MimeTypes.guess_type(url, strict=True)

Similar to the guess_type() function, using the tables stored as part of the object.

MimeTypes.guess_all_extensions(type, strict=True)

Similar to the guess_all_extensions() function, using the tables stored as part of the object.

MimeTypes.read(filename, strict=True)

Load MIME information from a file named filename. This uses readfp() to parse the file.

If strict is True, information will be added to list of standard types, else to the list of non-standard types.

MimeTypes.readfp(fp, strict=True)
Load MIME type information from an open file `fp`. The file must have the format of the standard `mime.types` files.

If `strict` is True, information will be added to the list of standard types, else to the list of non-standard types.

MimeTypes.\texttt{read\_windows\_registry}(\texttt{strict=True})

Load MIME type information from the Windows registry. Availability: Windows.

If `strict` is True, information will be added to the list of standard types, else to the list of non-standard types.

\textit{New in version 3.2.}
19.6. **base64** — Base16, Base32, Base64, Base85 Data Encodings

This module provides functions for encoding binary data to printable ASCII characters and decoding such encodings back to binary data. It provides encoding and decoding functions for the encodings specified in **RFC 3548**, which defines the Base16, Base32, and Base64 algorithms, and for the de-facto standard Ascii85 and Base85 encodings.

The **RFC 3548** encodings are suitable for encoding binary data so that it can safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the **uuencode** program.

There are two **RFC 3548** interfaces provided by this module. The modern interface supports encoding and decoding ASCII byte string objects using all three **RFC 3548** defined alphabets (normal, URL-safe, and filesystem-safe). Additionally, the decoding functions of the modern interface also accept Unicode strings containing only ASCII characters. The legacy interface provides for encoding and decoding to and from file-like objects as well as byte strings, but only using the Base64 standard alphabet.

*Changed in version 3.3:* ASCII-only Unicode strings are now accepted by the decoding functions of the modern interface.

*Changed in version 3.4:* Any **bytes-like objects** are now accepted by all encoding and decoding functions in this module. Ascii85/Base85 support added.
The modern interface provides:

\texttt{base64.b64encode}(s, \texttt{altchars=None})

Encode a byte string using Base64.

\textit{s} is the string to encode. Optional \texttt{altchars} must be a string of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the + and / characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is None, for which the standard Base64 alphabet is used.

The encoded byte string is returned.

\texttt{base64.b64decode}(s, \texttt{altchars=None, validate=False})

Decode a Base64 encoded byte string.

\textit{s} is the byte string to decode. Optional \texttt{altchars} must be a string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the + and / characters.

The decoded string is returned. A \texttt{binascii.Error} exception is raised if \textit{s} is incorrectly padded.

If \texttt{validate} is False (the default), non-base64-alphabet characters are discarded prior to the padding check. If \texttt{validate} is True, non-base64-alphabet characters in the input result in a \texttt{binascii.Error}.

\texttt{base64.standard_b64encode}(s)

Encode byte string \textit{s} using the standard Base64 alphabet.

\texttt{base64.standard_b64decode}(s)
Decode byte string s using the standard Base64 alphabet.

`base64.urlsafe_b64encode(s)`

Encode byte string s using a URL-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet. The result can still contain =.

`base64.urlsafe_b64decode(s)`

Decode byte string s using a URL-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet.

`base64.b32encode(s)`

Encode a byte string using Base32. s is the string to encode. The encoded string is returned.

`base64.b32decode(s, casefold=False, map01=None)`

Decode a Base32 encoded byte string.

s is the byte string to decode. Optional casefold is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is False.

RFC 3548 allows for optional mapping of the digit 0 (zero) to the letter O (oh), and for optional mapping of the digit 1 (one) to either the letter l (eye) or letter L (el). The optional argument map01 when not None, specifies which letter the digit 1 should be mapped to (when map01 is not None, the digit 0 is always mapped to the letter O). For security purposes the default is None, so that 0 and 1 are not allowed in the input.

The decoded byte string is returned. A `binascii.Error` is raised if s is incorrectly padded or if there are non-alphabet characters present in the string.
base64.\texttt{b16encode}(s)

Encode a byte string using Base16.

\texttt{s} is the string to encode. The encoded byte string is returned.

base64.\texttt{b16decode}(s, \texttt{casefold}=False)

Decode a Base16 encoded byte string.

\texttt{s} is the string to decode. Optional \texttt{casefold} is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is False.

The decoded byte string is returned. A \texttt{TypeError} is raised if \texttt{s} were incorrectly padded or if there are non-alphabet characters present in the string.

base64.\texttt{a85encode}(s, *, \texttt{foldspaces}=False, \texttt{wrapcol}=0, \texttt{pad}=False, \texttt{adobe}=False)

Encode a byte string using Ascii85.

\texttt{s} is the string to encode. The encoded byte string is returned.

\texttt{foldspaces} is an optional flag that uses the special short sequence ‘y’ instead of 4 consecutive spaces (ASCII 0x20) as supported by ‘btoa’. This feature is not supported by the “standard” Ascii85 encoding.

\texttt{wrapcol} controls whether the output should have newline (‘n’) characters added to it. If this is non-zero, each output line will be at most this many characters long.

\texttt{pad} controls whether the input string is padded to a multiple of 4 before encoding. Note that the \texttt{btoa} implementation always pads.
adobe controls whether the encoded byte sequence is framed with <~ and ~>, which is used by the Adobe implementation.

New in version 3.4.

`.a85decode(s, *, foldspaces=False, adobe=False, ignorechars=b'tnr')`

Decode an Ascii85 encoded byte string.

s is the byte string to decode.

foldspaces is a flag that specifies whether the ‘y’ short sequence should be accepted as shorthand for 4 consecutive spaces (ASCII 0x20). This feature is not supported by the “standard” Ascii85 encoding.

adobe controls whether the input sequence is in Adobe Ascii85 format (i.e. is framed with <~ and ~>).

ignorechars should be a byte string containing characters to ignore from the input. This should only contain whitespace characters, and by default contains all whitespace characters in ASCII.

New in version 3.4.

`.b85encode(s, pad=False)`

Encode a byte string using base85, as used in e.g. git-style binary diffs.

If pad is true, the input is padded with “\0” so its length is a multiple of 4 characters before encoding.

New in version 3.4.
Decode base85-encoded byte string. Padding is implicitly removed, if necessary.

*New in version 3.4.*

**Note:** Both Base85 and Ascii85 have an expansion factor of 5 to 4 (5 Base85 or Ascii85 characters can encode 4 binary bytes), while the better-known Base64 has an expansion factor of 6 to 4. They are therefore more efficient when space expensive. They differ by details such as the character map used for encoding.

The legacy interface:

**base64.decode(input, output)**

Decode the contents of the binary `input` file and write the resulting binary data to the `output` file. `input` and `output` must be *file objects*. `input` will be read until `input.read()` returns an empty bytes object.

**base64.decodebytes(s)**

**base64.decodestring(s)**

Decode the byte string `s`, which must contain one or more lines of base64 encoded data, and return a byte string containing the resulting binary data. `decodestring` is a deprecated alias.

*New in version 3.1.*

**base64.encode(input, output)**

Encode the contents of the binary `input` file and write the resulting base64 encoded data to the `output` file. `input` and `output` must be *file objects*. `input` will be read until `input.read()` returns an
empty bytes object. \texttt{encode()} returns the encoded data plus a trailing newline character (b'\n').

\texttt{base64.encodebytes(s)}
\texttt{base64.encodestring(s)}

Encode the byte string \textit{s}, which can contain arbitrary binary data, and return a byte string containing one or more lines of base64-encoded data. \texttt{encodebytes()} returns a string containing one or more lines of base64-encoded data always including an extra trailing newline (b'\n'). \texttt{encodestring} is a deprecated alias.

An example usage of the module:

\begin{verbatim}
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded')
>>> encoded
b'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
b'data to be encoded'
\end{verbatim}

\textbf{Module \texttt{binascii}}

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

\textbf{RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies}

Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.
19.7. `binhex` — Encode and decode binhex4 files

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. Only the data fork is handled.

The `binhex` module defines the following functions:

`binhex.binhex(input, output)`

Convert a binary file with filename `input` to binhex file `output`. The `output` parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

`binhex.hexbin(input, output)`

Decode a binhex file `input`. `input` may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named `output`, unless the argument is `None` in which case the output filename is read from the binhex file.

The following exception is also defined:

`exception binhex.Error`

Exception raised when something can’t be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.

See also:

Module `binascii`

Support module containing ASCII-to-binary and binary-to-ASCII
conversions.
19.7.1. Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).

As of this writing, \texttt{hexbin()} appears to not work in all cases.
19.8. **binascii** — Convert between binary and ASCII

The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu`, `base64`, or `binhex` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

**Note:** `a2b_*` functions accept Unicode strings containing only ASCII characters. Other functions only accept bytes-like objects (such as `bytes`, `bytearray` and other objects that support the buffer protocol).

*Changed in version 3.3:* ASCII-only unicode strings are now accepted by the `a2b_*` functions.

The `binascii` module defines the following functions:

- `binascii.a2b_uu(string)`
  
  Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

- `binascii.b2a_uu(data)`
  
  Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of `data` should be at most 45.
binascii.\texttt{a2b\_base64(string)}

Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

binascii.\texttt{b2a\_base64(data)}

Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char. The length of data should be at most 57 to adhere to the base64 standard.

binascii.\texttt{a2b\_qp(data, header=False)}

Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument header is present and true, underscores will be decoded as spaces.

binascii.\texttt{b2a\_qp(data, quotetabs=False, istext=True, header=False)}

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument quotetabs is present and true, all tabs and spaces will be encoded. If the optional argument istext is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument header is present and true, spaces will be encoded as underscores per RFC1522. If the optional argument header is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

binascii.\texttt{a2b\_hqx(string)}

Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number
of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

\texttt{binascii.rledecode_hqx(data)}

Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses \texttt{0x90} after a byte as a repeat indicator, followed by a count. A count of \texttt{0} specifies a byte value of \texttt{0x90}. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the \texttt{Incomplete} exception is raised.

*Changed in version 3.2:* Accept only bytestring or bytearray objects as input.

\texttt{binascii.rlecode_hqx(data)}

Perform binhex4 style RLE-compression on \texttt{data} and return the result.

\texttt{binascii.b2a_hqx(data)}

Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

\texttt{binascii.crc_hqx(data, crc)}

Compute the binhex4 crc value of \texttt{data}, starting with an initial \texttt{crc} and returning the result.

\texttt{binascii.crc32(data[, crc])}

Compute CRC-32, the 32-bit checksum of data, starting with an initial \texttt{crc}. This is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc) & 0xffffffff
print('crc32 = {:#010x}'.format(crc))

**Note:** To generate the same numeric value across all Python versions and platforms use crc32(data) & 0xffffffff. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

**binascii.b2a_hex(data)**
**binascii.hexlify(data)**

Return the hexadecimal representation of the binary data. Every byte of data is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of data.

**binascii.a2b_hex(hexstr)**
**binascii.unhexlify(hexstr)**

Return the binary data represented by the hexadecimal string hexstr. This function is the inverse of b2a_hex(). hexstr must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise a TypeError is raised.

**exception binascii.Error**

Exception raised on errors. These are usually programming errors.

**exception binascii.Incomplete**

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more
data and trying again.

See also:

**Module base64**
Support for base64 encoding used in MIME email messages.

**Module binhex**
Support for the binhex format used on the Macintosh.

**Module uu**
Support for UU encoding used on Unix.

**Module quopri**
Support for quoted-printable encoding used in MIME email messages.
19.9. **quopri** — Encode and decode MIME quoted-printable data

**Source code:** Lib/quopri.py

This module performs quoted-printable transport encoding and decoding, as defined in [RFC 1521](https://tools.ietf.org/html/rfc1521): “MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies”. The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the `base64` module is more compact if there are many such characters, as when sending a graphics file.

**quopri.decode**(*input*, *output*, *header=False*)

Decode the contents of the *input* file and write the resulting decoded binary data to the *output* file. *input* and *output* must be binary file objects. If the optional argument *header* is present and true, underscore will be decoded as space. This is used to decode “Q”-encoded headers as described in [RFC 1522](https://tools.ietf.org/html/rfc1522): “MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text”.

**quopri.encode**(*input*, *output*, *quotetabs*, *header=False*)

Encode the contents of the *input* file and write the resulting quoted-printable data to the *output* file. *input* and *output* must be binary file objects. *quotetabs*, a flag which controls whether to encode embedded spaces and tabs must be provided and when true it
encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per RFC 1521. header is a flag which controls if spaces are encoded as underscores as per RFC 1522.

quopri.decodestring(s, header=False)
   Like decode(), except that it accepts a source bytes and returns the corresponding decoded bytes.

quopri.encodestring(s, quotetabs=False, header=False)
   Like encode(), except that it accepts a source bytes and returns the corresponding encoded bytes. By default, it sends a False value to quotetabs parameter of the encode() function.

Module base64
   Encode and decode MIME base64 data
19.10. uu — Encode and decode uuencode files

Source code: Lib/uu.py

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname '-' is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is 'rb' or 'wb' on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The uu module defines the following functions:

uu.encode(in_file, out_file, name=None, mode=None)

Uuencode file in_file into file out_file. The uuencoded file will have the header specifying name and mode as the defaults for the results of decoding the file. The default defaults are taken from in_file, or '-' and 0o666 respectively.

uu.decode(in_file, out_file=None, mode=None, quiet=False)

This call decodes uuencoded file in_file placing the result on file out_file. If out_file is a pathname, mode is used to set the permission bits if the file must be created. Defaults for out_file and
mode are taken from the uuencode header. However, if the file specified in the header already exists, a uu.Error is raised.

decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting quiet to a true value silences this warning.

exception uu.Error
Subclass of Exception, this can be raised by uu.decode() under various situations, such as described above, but also including a badly formatted header, or truncated input file.

Module binascii
Support module containing ASCII-to-binary and binary-to-ASCII conversions.
20. Structured Markup Processing Tools

Python supports a variety of modules to work with various forms of structured data markup. This includes modules to work with the Standard Generalized Markup Language (SGML) and the Hypertext Markup Language (HTML), and several interfaces for working with the Extensible Markup Language (XML).

- 20.1. html — HyperText Markup Language support
- 20.2. html.parser — Simple HTML and XHTML parser
  - 20.2.1. Example HTML Parser Application
  - 20.2.2. HTMLParser Methods
  - 20.2.3. Examples
- 20.3. html.entities — Definitions of HTML general entities
- 20.4. XML Processing Modules
  - 20.4.1. XML vulnerabilities
  - 20.4.2. The defusedxml and defusedexpat Packages
- 20.5. xml.etree.ElementTree — The ElementTree XML API
  - 20.5.1. Tutorial
    - 20.5.1.1. XML tree and elements
    - 20.5.1.2. Parsing XML
    - 20.5.1.3. Pull API for non-blocking parsing
    - 20.5.1.4. Finding interesting elements
    - 20.5.1.5. Modifying an XML File
    - 20.5.1.6. Building XML documents
    - 20.5.1.7. Parsing XML with Namespaces
    - 20.5.1.8. Additional resources
  - 20.5.2. XPath support
    - 20.5.2.1. Example
    - 20.5.2.2. Supported XPath syntax
20.5.3. Reference
  - 20.5.3.1. Functions
  - 20.5.3.2. Element Objects
  - 20.5.3.3. ElementTree Objects
  - 20.5.3.4. QName Objects
  - 20.5.3.5. TreeBuilder Objects
  - 20.5.3.6. XMLParser Objects
  - 20.5.3.7. XMLPullParser Objects
  - 20.5.3.8. Exceptions

20.6. xml.dom — The Document Object Model API
  - 20.6.1. Module Contents
  - 20.6.2. Objects in the DOM
    - 20.6.2.1. DOMImplementation Objects
    - 20.6.2.2. Node Objects
    - 20.6.2.3. NodeList Objects
    - 20.6.2.4. DocumentType Objects
    - 20.6.2.5. Document Objects
    - 20.6.2.6. Element Objects
    - 20.6.2.7. Attr Objects
    - 20.6.2.8. NamedNodeMap Objects
    - 20.6.2.9. Comment Objects
    - 20.6.2.10. Text and CDATASection Objects
    - 20.6.2.11. ProcessingInstruction Objects
    - 20.6.2.12. Exceptions
  - 20.6.3. Conformance
    - 20.6.3.1. Type Mapping
    - 20.6.3.2. Accessor Methods

20.7. xml.dom.minidom — Minimal DOM implementation
  - 20.7.1. DOM Objects
  - 20.7.2. DOM Example
  - 20.7.3. minidom and the DOM standard

20.8. xml.dom.pulldom — Support for building partial DOM trees
  - 20.8.1. DOMEventStream Objects
- 20.9. xml.sax — Support for SAX2 parsers
  - 20.9.1. SAXException Objects
- 20.10. xml.sax.handler — Base classes for SAX handlers
  - 20.10.1. ContentHandler Objects
  - 20.10.2. DTDHandler Objects
  - 20.10.3. EntityResolver Objects
  - 20.10.4. ErrorHandler Objects
- 20.11. xml.sax.saxutils — SAX Utilities
- 20.12. xml.sax.xmlreader — Interface for XML parsers
  - 20.12.1. XMLReader Objects
  - 20.12.2. IncrementalParser Objects
  - 20.12.3. Locator Objects
  - 20.12.4. InputSource Objects
  - 20.12.5. The Attributes Interface
  - 20.12.6. The AttributesNS Interface
- 20.13. xml.parsers.expat — Fast XML parsing using Expat
  - 20.13.1. XMLParser Objects
  - 20.13.2. ExpatError Exceptions
  - 20.13.3. Example
  - 20.13.4. Content Model Descriptions
  - 20.13.5. Expat error constants
20.1. **html** — HyperText Markup Language support

**Source code:** `Lib/html/__init__.py`

This module defines utilities to manipulate HTML.

**html.escape(s, quote=True)**

Convert the characters `&`, `<` and `>` in string `s` to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag `quote` is true, the characters `"` and `'` are also translated; this helps for inclusion in an HTML attribute value delimited by quotes, as in `<a href="...">`.

*New in version 3.2.*

**html.unescape(s)**

Convert all named and numeric character references (e.g. `&gt;`, `&#62;`, `&x3e;`) in the string `s` to the corresponding unicode characters. This function uses the rules defined by the HTML 5 standard for both valid and invalid character references, and the list of HTML 5 named character references.

*New in version 3.4.*

Submodules in the `html` package are:

- **html.parser** – HTML/XHTML parser with lenient parsing mode
• **html.entities** – HTML entity definitions
20.2. `html.parser` — Simple HTML and XHTML parser

Source code: `Lib/html/parser.py`

This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML.

```python
class html.parser.HTMLParser(*, convert_charrefs=True)
```

Create a parser instance to parse invalid markup.

If `convert_charrefs` is True (the default), all character references (except the ones in `script`/`style` elements) are automatically converted to the corresponding Unicode characters.

An `HTMLParser` instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass `HTMLParser` and override its methods to implement the desired behavior.

This parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

*Changed in version 3.4:* `convert_charrefs` keyword argument added.

*Changed in version 3.5:* The default value for argument
convert_charrefs is now True.
20.2.1. Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the `HTMLParser` class to print out start tags, end tags, and data as they are encountered:

```python
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)
    def handle_endtag(self, tag):
        print("Encountered an end tag:", tag)
    def handle_data(self, data):
        print("Encountered some data:", data)

parser = MyHTMLParser()
parsed.feed('<html><head><title>Test</title></head>''<body><h1>Parse me!</h1></body></html>
```

The output will then be:

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data: Test
Encountered an end tag: title
Encountered an end tag: head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data: Parse me!
Encountered an end tag: h1
Encountered an end tag: body
Encountered an end tag: html
```
20.2.2. **HTMLParser** Methods

**HTMLParser** instances have the following methods:

**HTMLParser**.\(\text{feed}(data)\)

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or close() is called. \(data\) must be \text{str}.

**HTMLParser**.\(\text{close}()\)

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method close().

**HTMLParser**.\(\text{reset}()\)

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser**.\(\text{getpos}()\)

Return current line number and offset.

**HTMLParser**.\(\text{get_starttag_text}()\)

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are
encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for `handle_startendtag()`):

**HTMLParser**. `handle_starttag(tag, attrs)`

This method is called to handle the start of a tag (e.g. `<div id="main">`).

The `tag` argument is the name of the tag converted to lower case. The `attrs` argument is a list of (name, value) pairs containing the attributes found inside the tag's <> brackets. The name will be translated to lower case, and quotes in the value have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="http://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [('href', 'http://www.cwi.nl/')]).`

All entity references from `html.entities` are replaced in the attribute values.

**HTMLParser**. `handle_endtag(tag)`

This method is called to handle the end tag of an element (e.g. `</div>`).

The `tag` argument is the name of the tag converted to lower case.

**HTMLParser**. `handle_startendtag(tag, attrs)`

Similar to `handle_starttag()`, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply
calls `handle_starttag()` and `handle_endtag()`.

**HTMLParser**. `handle_data(data)`

This method is called to process arbitrary data (e.g. text nodes and the content of `<script>`...`</script>` and `<style>`...`</style>`).

**HTMLParser**. `handle_entityref(name)`

This method is called to process a named character reference of the form `&name;` (e.g. `&gt;`), where `name` is a general entity reference (e.g. 'gt'). This method is never called if `convert_charrefs` is True.

**HTMLParser**. `handle_charref(name)`

This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `&gt;` is `&#62;`, whereas the hexadecimal is `&#x3E;`; in this case the method will receive '62' or 'x3E'. This method is never called if `convert_charrefs` is True.

**HTMLParser**. `handle_comment(data)`

This method is called when a comment is encountered (e.g. `<!-- comment -->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument ' comment '.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<![if IE 9]>IE9-specific content<![endif]-->`, this method will receive '[[if IE 9]>IE9-specific content<![endif]'.

**HTMLParser**. `handle_decl(decl)`

This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The `decl` parameter will be the entire contents of the declaration inside the `<!...>` markup (e.g. 'DOCTYPE html').

**HTMLParser**. `handle_pi(data)`

Method called when a processing instruction is encountered. The `data` parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'"">`. It is intended to be overridden by a derived class; the base class implementation does nothing.

**Note:** The `HTMLParser` class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing '?' will cause the '?' to be included in `data`.

**HTMLParser**. `unknown_decl(data)`

This method is called when an unrecognized declaration is read by the parser.

The `data` parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class. The base class implementation does nothing.
20.2.3. Examples

The following class implements a parser that will be used to illustrate more examples:

```python
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("attr:", attr)
    def handle_endtag(self, tag):
        print("End tag:", tag)
    def handle_data(self, data):
        print(\"Data:", data)
    def handle_comment(self, data):
        print(\"Comment:", data)
    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)
    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
        else:
            c = chr(int(name))
        print("Num ent:", c)
    def handle_decl(self, data):
        print("Decl:", data)

parser = MyHTMLParser()
```

Parsing a doctype:
Decl : DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN"
  "http://www.w3.org/TR/html4/strict.dtd"

Parsing an element with a few attributes and a title:

```python
>>> parser.feed('<img src="python-logo.png" alt="The Python logo">')
Start tag: img
  attr: ('src', 'python-logo.png')
  attr: ('alt', 'The Python logo')
```

```python
>>> parser.feed('<h1>Python</h1>')
Start tag: h1
Data : Python
End tag : h1
```

The content of script and style elements is returned as is, without further parsing:

```python
>>> parser.feed('<style type="text/css">#python { color: green }</style>')
Start tag: style
  attr: ('type', 'text/css')
Data : #python { color: green }
End tag : style
```

```python
>>> parser.feed('<script type="text/javascript">alert("<strong>hello!</strong>"};</script>')
Start tag: script
  attr: ('type', 'text/javascript')
Data : alert("<strong>hello!</strong>"};
End tag : script
```

Parsing comments:
Parsing named and numeric character references and converting them to the correct char (note: these 3 references are all equivalent to '>):

```python
>>> parser.feed('&gt;&amp;#62;&amp;#x3E;')
Named ent: >
Num ent : >
```

Feeding incomplete chunks to `feed()` works, but `handle_data()` might be called more than once (unless `convert_charrefs` is set to `True`):

```python
>>> for chunk in ['<sp', 'an>buff', 'ered ', 'text</s', ...
    parser.feed(chunk)
...
Start tag: span
Data : buff
Data : ered
Data : text
End tag : span
```

Parsing invalid HTML (e.g. unquoted attributes) also works:

```python
>>> parser.feed('<p><a class=link href=#main>tag soup
Start tag: p
Start tag: a
    attr: ('class', 'link')
    attr: ('href', '#main')
Data : tag soup
```
20.3. html.entities — Definitions of HTML general entities

Source code: Lib/html/entities.py

This module defines four dictionaries, html5, name2codepoint, codepoint2name, and entitydefs.

html.entities.html5
A dictionary that maps HTML5 named character references [1] to
the equivalent Unicode character(s), e.g. html5['gt;'] == '>'. Note that the trailing semicolon is included in the name (e.g. 'gt;'), however some of the names are accepted by the standard even without the semicolon: in this case the name is present with
and without the ';'. See also html.unescape().

New in version 3.3.

html.entities.entitydefs
A dictionary mapping XHTML 1.0 entity definitions to their
replacement text in ISO Latin-1.

html.entities.name2codepoint
A dictionary that maps HTML entity names to the Unicode code
points.

html.entities.codepoint2name
A dictionary that maps Unicode code points to HTML entity names.
Footnotes

20.4. XML Processing Modules

Python’s interfaces for processing XML are grouped in the xml package.

**Warning:** The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see the XML vulnerabilities and The defusedxml and defusedexpat Packages sections.

It is important to note that modules in the xml package require that there be at least one SAX-compliant XML parser available. The Expat parser is included with Python, so the xml.parsers.expat module will always be available.

The documentation for the xml.dom and xml.sax packages are the definition of the Python bindings for the DOM and SAX interfaces.

The XML handling submodules are:

- `xml.etree.ElementTree`: the ElementTree API, a simple and lightweight XML processor
- `xml.dom`: the DOM API definition
- `xml.dom.minidom`: a minimal DOM implementation
- `xml.dom.pulldom`: support for building partial DOM trees
- `xml.sax`: SAX2 base classes and convenience functions
- `xml.parsers.expat`: the Expat parser binding
20.4.1. XML vulnerabilities

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse XML features to carry out denial of service attacks, access local files, generate network connections to other machines, or circumvent firewalls.

The following table gives an overview of the known attacks and whether the various modules are vulnerable to them.

<table>
<thead>
<tr>
<th>kind</th>
<th>sax</th>
<th>etree</th>
<th>minidom</th>
<th>pulldom</th>
<th>xmlrpc</th>
</tr>
</thead>
<tbody>
<tr>
<td>billion laughs</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>quadratic blowup</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>external entity expansion</td>
<td>Yes</td>
<td>No (1)</td>
<td>No (2)</td>
<td>Yes</td>
<td>No (3)</td>
</tr>
<tr>
<td>DTD retrieval</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>decompression bomb</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. `xml.etree.ElementTree` doesn't expand external entities and raises a `ParserError` when an entity occurs.
2. `xml.dom.minidom` doesn't expand external entities and simply returns the unexpanded entity verbatim.
3. `xmlrpc` doesn't expand external entities and omits them.

billion laughs / exponential entity expansion

The Billion Laughs attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, and the final entity definition contains a small string. The exponential expansion results in several gigabytes of text and consumes lots of memory and CPU
quadratic blowup entity expansion

A quadratic blowup attack is similar to a Billion Laughs attack; it abuses entity expansion, too. Instead of nested entities it repeats one large entity with a couple of thousand chars over and over again. The attack isn’t as efficient as the exponential case but it avoids triggering parser countermeasures that forbid deeply-nested entities.

decompression bomb

Decompression bombs (aka ZIP bomb) apply to all XML libraries that can parse compressed XML streams such as gzipped HTTP streams or LZMA-compressed files. For an attacker it can reduce the amount of transmitted data by three magnitudes or more.

The documentation for defusedxml on PyPI has further information about all known attack vectors with examples and references.
20.4.2. The defusedxml and defusedexpat Packages

defusedxml is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. Use of this package is recommended for any server code that parses untrusted XML data. The package also ships with example exploits and extended documentation on more XML exploits such as XPath injection.

defusedexpat provides a modified libexpat and a patched pyexpat module that have countermeasures against entity expansion DoS attacks. The defusedexpat module still allows a sane and configurable amount of entity expansions. The modifications may be included in some future release of Python, but will not be included in any bugfix releases of Python because they break backward compatibility.
20.5. `xml.etree.ElementTree` — The ElementTree XML API

The `xml.etree.ElementTree` module implements a simple and efficient API for parsing and creating XML data.

*Changed in version 3.3:* This module will use a fast implementation whenever available. The `xml.etree.cElementTree` module is deprecated.

**Warning:** The `xml.etree.ElementTree` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.
20.5.1. Tutorial

This is a short tutorial for using `xml.etree.ElementTree` (ET in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

20.5.1.1. XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. ET has two classes for this purpose - `ElementTree` represents the whole XML document as a tree, and `Element` represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the `ElementTree` level. Interactions with a single XML element and its sub-elements are done on the `Element` level.

20.5.1.2. Parsing XML

We'll be using the following XML document as the sample data for this section:

```xml
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank>1</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank>4</rank>
  </country>
</data>
```
We can import this data by reading from a file:

```python
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```python
root = ET.fromstring(country_data_as_string)
```

`fromstring()` parses XML from a string directly into an `Element`, which is the root element of the parsed tree. Other parsing functions may create an `ElementTree`. Check the documentation to be sure.

As an `Element`, `root` has a tag and a dictionary of attributes:

```python
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:
Children are nested, and we can access specific child nodes by index:

```python
>>> root[0][1].text
'2008'
```

**Note:** Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom `TreeBuilder` instance to the `XMLParser` constructor.

### 20.5.1.3. Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an `XMLParser` and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed `Element` objects.
The most powerful tool for doing this is **XMLPullParser**. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with **XMLPullParser.feed()** calls. To get the parsed XML elements, call **XMLPullParser.read_events()**. Here is an example:

```python
>>> parser = ET.XMLPullParser(['start', 'end'])
>>> parser.feed('<mytag>sometext')</n
>>> list(parser.read_events())
[('start', <Element 'mytag' at 0x7fa66db2be58>)]

>>> parser.feed(' more text</mytag>')

>>> for event, elem in parser.read_events():
...     print(event)
...     print(elem.tag, 'text=' , elem.text)
...     end
```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, **XMLPullParser** can be inconvenient to use for simpler use-cases. If you don’t mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at **iterparse()**. It can be useful when you're reading a large XML document and don’t want to hold it wholly in memory.

### 20.5.1.4. Finding interesting elements

**Element** has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For
example, `Element.iter()`:

```python
>>> for neighbor in root.iter('neighbor):
...   print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

`Element.findall()` finds only elements with a tag which are direct children of the current element. `Element.find()` finds the first child with a particular tag, and `Element.text` accesses the element's text content. `Element.get()` accesses the element's attributes:

```python
>>> for country in root.findall('country'):
...   rank = country.find('rank').text
...   name = country.get('name')
...   print(name, rank)
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using XPath.

20.5.1.5. Modifying an XML File

`ElementTree` provides a simple way to build XML documents and write them to files. The `ElementTree.write()` method serves this purpose.
Once created, an `Element` object may be manipulated by directly changing its fields (such as `Element.text`), adding and modifying attributes (`Element.set()` method), as well as adding new children (for example with `Element.append()`).

Let's say we want to add one to each country's rank, and add an updated attribute to the rank element:

```python
>>> for rank in root.iter('rank):
...    new_rank = int(rank.text) + 1
...    rank.text = str(new_rank)
...    rank.set('updated', 'yes')
...
>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank updated="yes">2</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank updated="yes">5</rank>
    <year>2011</year>
    <gdppc>59900</gdppc>
    <neighbor name="Malaysia" direction="N"/>
  </country>
  <country name="Panama">
    <rank updated="yes">69</rank>
    <year>2011</year>
  </country>
</data>
```
We can remove elements using `Element.remove()`. Let’s say we want to remove all countries with a rank higher than 50:

```python
gdpcc = 13600
<neighbor name="Costa Rica" direction="W"/>
<neighbor name="Colombia" direction="E"/>
</country>
</data>
```  

```python
for country in root.findall('country'):
    rank = int(country.find('rank').text)
    if rank > 50:
        root.remove(country)
```  

```python
>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
</data>
```
20.5.1.6. Building XML documents

The SubElement() function also provides a convenient way to create new sub-elements for a given element:

```python
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /></c><d /></a>
```

20.5.1.7. Parsing XML with Namespaces

If the XML input has namespaces, tags and attributes with prefixes in the form prefix:sometag get expanded to {uri}sometag where the prefix is replaced by the full URI. Also, if there is a default namespace, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix “fictional” and the other serving as the default namespace:

```xml
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
       xmlns="http://people.example.com">
  <actor>
    <name>John Cleese</name>
    <fictional:character>Lancelot</fictional:character>
    <fictional:character>Archie Leach</fictional:character>
  </actor>
  <actor>
    <name>Eric Idle</name>
    <fictional:character>Sir Robin</fictional:character>
  </actor>
</actors>
```
One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a find() or findall():

```python
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name').text
    print(name)
    for char in actor.findall('{http://characters.example.com}character'):
        print('  |-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```python
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns).text
    print(name)
    for char in actor.findall('role:character', ns):
        print('  |-->', char.text)
```

These two approaches both output:

```
John Cleese
  |--> Lancelot
```
20.5.1.8. Additional resources

See http://effbot.org/zone/element-index.htm for tutorials and links to other docs.
20.5.2. XPath support

This module provides limited support for XPath expressions for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

20.5.2.1. Example

Here's an example that demonstrates some of the XPath capabilities of the module. We'll be using the countrydata XML document from the Parsing XML section:

```python
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall("./year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall("./*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of
root.findall("./neighbor[2]")
```
20.5.2.2. Supported XPath syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tag</code></td>
<td>Selects all child elements with the given tag. For example, spam selects all child elements named spam, and spam/egg selects all grandchildren named egg in all children named spam.</td>
</tr>
<tr>
<td><code>*</code></td>
<td>Selects all child elements. For example, */egg selects all grandchildren named egg.</td>
</tr>
<tr>
<td><code>.</code></td>
<td>Selects the current node. This is mostly useful at the beginning of the path, to indicate that it’s a relative path.</td>
</tr>
<tr>
<td><code>//</code></td>
<td>Selects all subelements, on all levels beneath the current element. For example, .//egg selects all egg elements in the entire tree.</td>
</tr>
<tr>
<td><code>..</code></td>
<td>Selects the parent element. Returns None if the path attempts to reach the ancestors of the start element (the element <code>find</code> was called on).</td>
</tr>
<tr>
<td><code>[@attrib]</code></td>
<td>Selects all elements that have the given attribute.</td>
</tr>
<tr>
<td><code>[@attrib='value']</code></td>
<td>Selects all elements for which the given attribute has the given value. The value cannot contain quotes.</td>
</tr>
<tr>
<td><code>[tag]</code></td>
<td>Selects all elements that have a child named tag. Only immediate children are supported.</td>
</tr>
<tr>
<td><code>[tag='text']</code></td>
<td>Selects all elements that have a child named tag whose complete text content,</td>
</tr>
</tbody>
</table>
including descendants, equals the given text.

| position | Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression last() (for the last position), or a position relative to the last position (e.g. last()-1). |

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another predicate. position predicates must be preceded by a tag name.
20.5.3. Reference

20.5.3.1. Functions

```python
xml.etree.ElementTree.Comment(text=None)
```

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. `text` is a string containing the comment string. Returns an element instance representing a comment.

Note that `XMLParser` skips over comments in the input instead of creating comment objects for them. An `ElementTree` will only contain comment nodes if they have been inserted into the tree using one of the `Element` methods.

```python
xml.etree.ElementTree.dump(elem)
```

Writes an element tree or element structure to `sys.stdout`. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it’s written as an ordinary XML file.

`elem` is an element tree or an individual element.

```python
xml.etree.ElementTree.fromstring(text)
```

Parses an XML section from a string constant. Same as `XML()`. `text` is a string containing XML data. Returns an `Element` instance.

```python
xml.etree.ElementTree.fromstringlist(sequence, parser=None)
```

Parses an XML document from a sequence of string fragments.
**sequence** is a list or other sequence containing XML data fragments. **parser** is an optional parser instance. If not given, the standard **XMLParser** parser is used. Returns an **Element** instance.

*New in version 3.2.*

**xml.etree.ElementTree.iselement(element)**

Checks if an object appears to be a valid element object. **element** is an element instance. Returns a true value if this is an element object.

**xml.etree.ElementTree.iterparse(source, events=None, parser=None)**

Parses an XML section into an element tree incrementally, and reports what’s going on to the user. **source** is a filename or file object containing XML data. **events** is a sequence of events to report back. The supported events are the strings "start", "end", "start-ns" and "end-ns" (the “ns” events are used to get detailed namespace information). If **events** is omitted, only "end" events are reported. **parser** is an optional parser instance. If not given, the standard **XMLParser** parser is used. **parser** must be a subclass of **XMLParser** and can only use the default **TreeBuilder** as a target. Returns an iterator providing (event, elem) pairs.

Note that while **iterparse()** builds the tree incrementally, it issues blocking reads on **source** (or the file it names). As such, it's unsuitable for applications where blocking reads can’t be made. For fully non-blocking parsing, see **XMLPullParser**.

**Note:** **iterparse()** only guarantees that it has seen the “>”
character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.
If you need a fully populated element, look for “end” events instead.

*Deprecated since version 3.4:* The `parser` argument.

```python
xml.etree.ElementTree.parse(source, parser=None)
```

Parses an XML section into an element tree. `source` is a filename or file object containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns an `ElementTree` instance.

```python
xml.etree.ElementTree.ProcessingInstruction(target, text=None)
```

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. `target` is a string containing the PI target. `text` is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that `XMLParser` skips over processing instructions in the input instead of creating comment objects for them. An `ElementTree` will only contain processing instruction nodes if they have been inserted into the tree using one of the `Element` methods.

```python
xml.etree.ElementTree.register_namespace(prefix, uri)
```

Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI
will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

*New in version 3.2.*

```python
xml.etree.ElementTree.SubElement(parent, tag, attrib={}, **extra)
```

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

```python
xml.etree.ElementTree.tostring(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```

Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding* [1] is the output encoding (default is US-ASCII). Use encoding="unicode" to generate a Unicode string (otherwise, a bytestring is generated). *method* is either "xml", "html" or "text" (default is "xml"). *short_empty_elements* has the same meaning as in `ElementTree.write()`. Returns an (optionally) encoded string containing the XML data.

*New in version 3.4: The short_empty_elements parameter.*

```python
xml.etree.ElementTree.tostringlist(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```

Generates a string representation of an XML element, including all
subelements. *element* is an *Element* instance. *encoding [1]* is the output encoding (default is US-ASCII). Use encoding="unicode" to generate a Unicode string (otherwise, a bytestring is generated). *method* is either "xml", "html" or "text" (default is "xml"). *short_empty_elements* has the same meaning as in ElementTree.write(). Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that \[ b"".join(tostringlist(element)) \] == tostring(element).

*New in version 3.2.*

*New in version 3.4:* The *short_empty_elements* parameter.

```python
xml.etree.ElementTree.XML(text, parser=None)
```

Parses an XML section from a string constant. This function can be used to embed “XML literals” in Python code. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

```python
xml.etree.ElementTree.XMLID(text, parser=None)
```

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns a tuple containing an *Element* instance and a dictionary.

### 20.5.3.2. Element Objects

```python
class xml.etree.ElementTree.Element(tag, attrib={}, **extra)
```
Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. `tag` is the element name. `attrib` is an optional dictionary, containing element attributes. `extra` contains additional attributes, given as keyword arguments.

**tag**

A string identifying what kind of data this element represents (the element type, in other words).

**text**

**tail**

These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the `text` attribute holds either the text between the element’s start tag and its first child or end tag, or None, and the `tail` attribute holds either the text between the element’s end tag and the next tag, or None. For the XML data

```xml
<a><b>1</c>2<d/></b>3</c></b>4</a>
```

the `a` element has None for both `text` and `tail` attributes, the `b` element has text "1" and tail "4", the `c` element has text "2" and tail None, and the `d` element has text None and tail "3".

To collect the inner text of an element, see `itertext()`, for example "".join(element.itertext()).

Applications may store arbitrary objects in these attributes.
**attrib**

A dictionary containing the element’s attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

**clear()**

Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to None.

**get(key, default=None)**

Gets the element attribute named *key*.

Returns the attribute value, or *default* if the attribute was not found.

**items()**

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

**keys()**

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

**set(key, value)**

Set the attribute *key* on the element to *value*. 
The following methods work on the element’s children (subelements).

**append**(subelement)
Adds the element `subelement` to the end of this element’s internal list of subelements. Raises `TypeError` if `subelement` is not an `Element`.

**extend**(subelements)
Appends `subelements` from a sequence object with zero or more elements. Raises `TypeError` if a subelement is not an `Element`.

*New in version 3.2.*

**find**(match, namespaces=None)
Finds the first subelement matching `match`. `match` may be a tag name or a path. Returns an element instance or None. `namespaces` is an optional mapping from namespace prefix to full name.

**findall**(match, namespaces=None)
Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order. `namespaces` is an optional mapping from namespace prefix to full name.

**findtext**(match, default=None, namespaces=None)
Finds text for the first subelement matching `match`. `match` may be a tag name or a path. Returns the text content of the first matching element, or `default` if no element was found. Note that if the matching element has no text content an empty string is
returned. *namespaces* is an optional mapping from namespace prefix to full name.

**getchildren()**

*Deprecated since version 3.2: Use list(elem) or iteration.*

**getiterator**(tag=None)

*Deprecated since version 3.2: Use method `Element.iter()` instead.*

**insert**(index, subelement)

Inserts *subelement* at the given position in this element. Raises *TypeError* if *subelement* is not an *Element*.

**iter**(tag=None)

Creates a tree *iterator* with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not None or '*' , only elements whose tag equals *tag* are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

*New in version 3.2.*

**iterfind**(match, namespaces=None)

Finds all matching subelements, by tag name or *path*. Returns an iterable yielding all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name.

*New in version 3.2.*

**itertext()**
Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

*New in version 3.2.*

**makeelement**(tag, attrib)

Creates a new element object of the same type as this element. Do not call this method, use the `SubElement()` factory function instead.

**remove**(subelement)

Removes `subelement` from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

Element objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`. Caution: Elements with no subelements will test as False. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```python
element = root.find('foo')

if not element: # careful!
    print("element not found, or element has no subelements")

if element is None:
    print("element not found")
```

20.5.3.3. ElementTree Objects
class xml.etree.ElementTree.ElementTree(element=None, file=None)

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

_element_ is the root element. The tree is initialized with the contents of the XML _file_ if given.

_setroot(element)_

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. _element_ is an element instance.

_find(match, namespaces=None)_

Same as Element.find(), starting at the root of the tree.

_findall(match, namespaces=None)_

Same as Element.findall(), starting at the root of the tree.

_findtext(match, default=None, namespaces=None)_

Same as Element.findtext(), starting at the root of the tree.

_getiterator(tag=None)_

Deprecated since version 3.2: Use method ElementTree.iter() instead.

_getroot()_

Returns the root element for this tree.

_iter(tag=None)_

Creates and returns a tree iterator for the root element. The
iterator loops over all elements in this tree, in section order. tag is the tag to look for (default is to return all elements).

**iterfind**(match, namespaces=None)

Same as `Element.iterfind()`, starting at the root of the tree.

*New in version 3.2.*

**parse**(source, parser=None)

Loads an external XML section into this element tree. source is a file name or file object. parser is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns the section root element.

**write**(file, encoding="us-ascii", xml_declaration=None, default_namespace=None, method="xml", *, short_empty_elements=True)

Writes the element tree to a file, as XML. file is a file name, or a file object opened for writing. encoding [1] is the output encoding (default is US-ASCII). xml_declaration controls if an XML declaration should be added to the file. Use False for never, True for always, None for only if not US-ASCII or UTF-8 or Unicode (default is None). default_namespace sets the default XML namespace (for “xmlns”). method is either "xml", "html" or "text" (default is "xml"). The keyword-only short_empty_elements parameter controls the formatting of elements that contain no content. If True (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (str) or binary (bytes). This is
controlled by the *encoding* argument. If *encoding* is "unicode", the output is a string; otherwise, it's binary. Note that this may conflict with the type of *file* if it's an open *file object*; make sure you do not try to write a string to a binary stream and vice versa.

*New in version 3.4:* The *short_empty_elements* parameter.

This is the XML file that is going to be manipulated:

```xml
<html>
<head>
    <title>Example page</title>
</head>
<body>
    <p>Moved to <a href="http://example.org/">example</a> or <a href="http://example.com/">example.com</a></p>
</body>
</html>
```

Example of changing the attribute “target” of every link in first paragraph:

```python
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")  # Finds first occurrence
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))  # Returns list of all
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ed70>]
>>> for i in links:  # Iterates through all
...    i.attrib["target"] = "blank"
```
20.5.3.4. QName Objects

class xml.etree.ElementTree.QName(text_or_uri, tag=None)
    QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. text_or_uri is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If tag is given, the first argument is interpreted as an URI, and this argument is interpreted as a local name. QName instances are opaque.

20.5.3.5. TreeBuilder Objects

class xml.etree.ElementTree.TreeBuilder(element_factory=None)
    Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format. element_factory, when given, must be a callable accepting two positional arguments: a tag and a dict of attributes. It is expected to return a new element instance.

    close()
        Flushes the builder buffers, and returns the toplevel document element. Returns an Element instance.

    data(data)
        Adds text to the current element. data is a string. This should be
either a bytestring, or a Unicode string.

**end**(*tag*)

Closes the current element. *tag* is the element name. Returns the closed element.

**start**(*tag, attrs*)

Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

In addition, a custom `TreeBuilder` object can provide the following method:

**doctype**(*name, pubid, system*)

Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default `TreeBuilder` class.

*New in version 3.2.*

### 20.5.3.6. XMLParser Objects

```python
class xml.etree.ElementTree.XMLParser(*html=0, target=None, encoding=None*)
```

This class is the low-level building block of the module. It uses `xml.parsers.expat` for efficient, event-based parsing of XML. It can be fed XML data incrementall with the `feed()` method, and parsing events are translated to a push API - by invoking callbacks on the `target` object. If `target` is omitted, the standard `TreeBuilder` is used. The `html` argument was historically used for backwards compatibility and is now deprecated. If `encoding` [1]
is given, the value overrides the encoding specified in the XML file.

*Deprecated since version 3.4:* The `html` argument. The remaining arguments should be passed via keyword to prepare for the removal of the `html` argument.

**close()**

Finishes feeding data to the parser. Returns the result of calling the `close()` method of the `target` passed during construction; by default, this is the toplevel document element.

**doctype**(name, `pubid`, `system`)

*Deprecated since version 3.2:* Define the `TreeBuilder.doctype()` method on a custom `TreeBuilder` target.

**feed**(data)

Feeds data to the parser. `data` is encoded data.

`XMLParser.feed()` calls `target`'s `start(tag, attrs_dict)` method for each opening tag, its `end(tag)` method for each closing tag, and data is processed by method `data(data)`. `XMLParser.close()` calls `target`'s method `close()`. `XMLParser` can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```python
>>> from xml.etree.ElementTree import XMLParser

```
20.5.3.7. XMLPullParser Objects

class
xml.etree.ElementTree.XMLPullParser(events=None)

A pull parser suitable for non-blocking applications. Its input-side
API is similar to that of XMLParser, but instead of pushing calls to
a callback target, XMLPullParser collects an internal list of
parsing events and lets the user read from it. events is a sequence
of events to report back. The supported events are the strings
"start", "end", "start-ns" and "end-ns" (the "ns" events are used to get detailed namespace information). If events is omitted, only "end" events are reported.

**feed**(*data*)

Feed the given bytes data to the parser.

**close**()

Signal the parser that the data stream is terminated. Unlike `XMLParser.close()`, this method always returns `None`. Any events not yet retrieved when the parser is closed can still be read with `read_events()`.

**read_events**()

Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields (event, elem) pairs, where event is a string representing the type of event (e.g. "end") and elem is the encountered `Element` object.

Events provided in a previous call to `read_events()` will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel over iterators obtained from `read_events()` will have unpredictable results.

**Note:** `XMLPullParser` only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present. If you need a fully populated element, look for “end” events
New in version 3.4.

20.5.3.8. Exceptions

class xml.etree.ElementTree.ParseError
XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

**code**
A numeric error code from the expat parser. See the documentation of `xml.parsers.expat` for the list of error codes and their meanings.

**position**
A tuple of `line, column` numbers, specifying where the error occurred.

Footnotes

[1] The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See [http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [http://www.iana.org/assignments/character-sets/character-sets.xhtml](http://www.iana.org/assignments/character-sets/character-sets.xhtml).
20.6. `xml.dom` — The Document Object Model API

The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a
DOMImplementation object class which provides access to Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing Document object. In Python, each DOM implementation will provide a function `getDOMImplementation()`. DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

See also:

**Document Object Model (DOM) Level 2 Specification**
  The W3C recommendation upon which the Python DOM API is based.

**Document Object Model (DOM) Level 1 Specification**
  The W3C recommendation for the DOM supported by `xml.dom.minidom`.

**Python Language Mapping Specification**
This specifies the mapping from OMG IDL to Python.
The `xml.dom` contains the following functions:

`xml.dom.registerDOMImplementation(name, factory)`

Register the `factory` function with the name `name`. The factory function should return an object which implements the DOMImplementation interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

`xml.dom.getDOMImplementation(name=None, features=())`  
Return a suitable DOM implementation. The `name` is either well-known, the module name of a DOM implementation, or None. If it is not None, imports the corresponding module and returns a DOMImplementation object if the import succeeds. If no name is given, and if the environment variable PYTHON_DOM is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an `ImportError`. The features list must be a sequence of (feature, version) pairs which are passed to the hasFeature() method on available DOMImplementation objects.

Some convenience constants are also provided:

`xml.dom.EMPTY_NAMESPACE`

The value used to indicate that no namespace is associated with a
node in the DOM. This is typically found as the namespaceURI of a node, or used as the `namespaceURI` parameter to a namespaces-specific method.

```python
xml.dom.XML_NAMESPACE
```

The namespace URI associated with the reserved prefix `xml`, as defined by *Namespaces in XML* (section 4).

```python
xml.dom.XMLNS_NAMESPACE
```

The namespace URI for namespace declarations, as defined by *Document Object Model (DOM) Level 2 Core Specification* (section 1.1.8).

```python
xml.dom.XHTML_NAMESPACE
```

The URI of the XHTML namespace as defined by *XHTML 1.0: The Extensible HyperText Markup Language* (section 3.1.1).

In addition, `xml.dom` contains a base Node class and the DOM exception classes. The Node class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The Node class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete Node objects; they are located within the class rather than at the module level to conform with the DOM specifications.
20.6.2. Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

An additional section describes the exceptions defined for working with the DOM in Python.

### 20.6.2.1. DOMImplementation Objects

The DOMImplementation interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new Document and DocumentType objects using the DOMImplementation as well.

**DOMImplementation**. `hasFeature(feature, version)`

Return true if the feature identified by the pair of strings `feature` and `version` is implemented.

**DOMImplementation**. `createDocument(namespaceUri, qualifiedName, doctype)`
Return a new Document object (the root of the DOM), with a child Element object having the given namespaceUri and qualifiedName. The doctype must be a DocumentType object created by createDocumentType(), or None. In the Python DOM API, the first two arguments can also be None in order to indicate that no Element child is to be created.

DOMImplementation.createDocumentType(qualifiedName, publicId, systemId)

Return a new DocumentType object that encapsulates the given qualifiedName, publicId, and systemId strings, representing the information contained in an XML document type declaration.

20.6.2.2. Node Objects

All of the components of an XML document are subclasses of Node.

Node.nodeType

An integer representing the node type. Symbolic constants for the types are on the Node object: ELEMENT_NODE, ATTRIBUTE_NODE, TEXT_NODE, CDATA_SECTION_NODE, ENTITY_NODE, PROCESSING_INSTRUCTION_NODE, COMMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, NOTATION_NODE. This is a read-only attribute.

Node.parentNode

The parent of the current node, or None for the document node. The value is always a Node object or None. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always None. This is a read-only attribute.
Node. **attributes**
A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide None for this attribute. This is a read-only attribute.

Node. **previousSibling**
The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the self element’s start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be None. This is a read-only attribute.

Node. **nextSibling**
The node that immediately follows this one with the same parent. See also previousSibling. If this is the last child of the parent, this attribute will be None. This is a read-only attribute.

Node. **childNodes**
A list of nodes contained within this node. This is a read-only attribute.

Node. **firstChild**
The first child of the node, if there are any, or None. This is a read-only attribute.

Node. **lastChild**
The last child of the node, if there are any, or None. This is a read-only attribute.

Node. **localName**
The part of the tagName following the colon if there is one, else the
entire tagName. The value is a string.

Node.

**prefix**
The part of the tagName preceding the colon if there is one, else the empty string. The value is a string, or None.

Node.

**namespaceURI**
The namespace associated with the element name. This will be a string or None. This is a read-only attribute.

Node.

**nodeName**
This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the tagName property for elements or the name property for attributes. For all node types, the value of this attribute will be either a string or None. This is a read-only attribute.

Node.

**nodeValue**
This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with nodeName. The value is a string or None.

Node.

**hasAttributes()**
Returns true if the node has any attributes.

Node.

**hasChildNodes()**
Returns true if the node has any child nodes.

Node.

**isSameNode**(other)
Returns true if other refers to the same node as this node. This is especially useful for DOM implementations which use any sort of
proxy architecture (because more than one object can refer to the same node).

**Note:** This is based on a proposed DOM Level 3 API which is still in the “working draft” stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node `.appendChild(newChild)`

Add a new child node to this node at the end of the list of children, returning `newChild`. If the node was already in the tree, it is removed first.

Node `.insertBefore(newChild, refChild)`

Insert a new child node before an existing child. It must be the case that `refChild` is a child of this node; if not, `ValueError` is raised. `newChild` is returned. If `refChild` is None, it inserts `newChild` at the end of the children's list.

Node `.removeChild(oldChild)`

Remove a child node. `oldChild` must be a child of this node; if not, `ValueError` is raised. `oldChild` is returned on success. If `oldChild` will not be used further, its `unlink()` method should be called.

Node `.replaceChild(newChild, oldChild)`

Replace an existing node with a new node. It must be the case that `oldChild` is a child of this node; if not, `ValueError` is raised.

Node `.normalize()`

Join adjacent text nodes so that all stretches of text are stored as single Text instances. This simplifies processing text from a DOM
tree for many applications.

Node.`cloneNode`(deep)
Clone this node. Setting `deep` means to clone all child nodes as well. This returns the clone.

20.6.2.3. NodeList Objects

A NodeList represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: the Element objects provides one as its list of child nodes, and the `getElementsByTagName()` and `getElementsByTagNameNS()` methods of Node return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

NodeList.`item(i)`
Return the `i`th item from the sequence, if there is one, or None. The index `i` is not allowed to be less than zero or greater than or equal to the length of the sequence.

NodeList.`length`
The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow NodeList objects to be used as Python sequences. All NodeList implementations must include support for `__len__()` and `__getitem__()`; this allows iteration over the NodeList in `for` statements and proper support for the `len()` built-in function.
If a DOM implementation supports modification of the document, the NodeList implementation must also support the `__setitem__()` and `__delitem__()` methods.

### 20.6.2.4. DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a DocumentType object. The DocumentType for a document is available from the Document object's doctype attribute; if there is no DOCTYPE declaration for the document, the document's doctype attribute will be set to None instead of an instance of this interface.

DocumentType is a specialization of Node, and adds the following attributes:

**DocumentType.publicId**

The public identifier for the external subset of the document type definition. This will be a string or None.

**DocumentType.systemId**

The system identifier for the external subset of the document type definition. This will be a URI as a string, or None.

**DocumentType.internalSubset**

A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be None.

**DocumentType.name**

The name of the root element as given in the DOCTYPE declaration,
if present.

**DocumentType.entities**
This is a NamedNodeMap giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no entities are defined.

**DocumentType.notations**
This is a NamedNodeMap giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no notations are defined.

### 20.6.2.5. Document Objects

A Document represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from Node.

**Document.documentElement**
The one and only root element of the document.

**Document.createElement(tagName)**
Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as insertBefore() or appendChild().

**Document.createElementNS(namespaceURI, tagName)**
Create and return a new element with a namespace. The `tagName` may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

**Document.createTextNode(data)**
Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document.createComment(data)**
Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document.createProcessingInstruction(target, data)**
Create and return a processing instruction node containing the `target` and `data` passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

**Document.createAttribute(name)**
Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.

**Document.createAttributeNS(namespaceURI, qualifiedName)**
Create and return an attribute node with a namespace. The `tagName` may have a prefix. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use
the newly created attribute instance.

Document \texttt{getElementsByTagName}(\texttt{tagName})
Search for all descendants (direct children, children’s children, etc.) with a particular element type name.

Document \texttt{getElementsByTagNameNS}(\texttt{namespaceURI}, \texttt{localName})
Search for all descendants (direct children, children’s children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

**20.6.2.6. Element Objects**

Element is a subclass of Node, so inherits all the attributes of that class.

Element \texttt{.tagName}
The element type name. In a namespace-using document it may have colons in it. The value is a string.

Element \texttt{getElementsByTagName}(\texttt{tagName})
Same as equivalent method in the Document class.

Element \texttt{getElementsByTagNameNS}(\texttt{namespaceURI}, \texttt{localName})
Same as equivalent method in the Document class.

Element \texttt{.hasAttribute}(\texttt{name})
Returns true if the element has an attribute named by \texttt{name}.

Element \texttt{.hasAttributeNS}(\texttt{namespaceURI}, \texttt{localName})
Returns true if the element has an attribute named by \textit{namespaceURI} and \textit{localName}.

**Element.\texttt{getAttribute}(name)**
Return the value of the attribute named by \textit{name} as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

**Element.\texttt{getAttributeNode}(attrname)**
Return the \texttt{Attr} node for the attribute named by \textit{attrname}.

**Element.\texttt{getAttributeNS}(namespaceURI, localName)**
Return the value of the attribute named by \textit{namespaceURI} and \textit{localName} as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

**Element.\texttt{getAttributeNodeNS}(namespaceURI, localName)**
Return an attribute value as a node, given a \textit{namespaceURI} and \textit{localName}.

**Element.\texttt{removeAttribute}(name)**
Remove an attribute by name. If there is no matching attribute, a \texttt{NotFoundError} is raised.

**Element.\texttt{removeAttributeNode}(oldAttr)**
Remove and return \textit{oldAttr} from the attribute list, if present. If \textit{oldAttr} is not present, \texttt{NotFoundError} is raised.

**Element.\texttt{removeAttributeNS}(namespaceURI, localName)**
Remove an attribute by name. Note that it uses a \textit{localName}, not a qname. No exception is raised if there is no matching attribute.

**Element.\texttt{setAttribute}(name, value)**
Set an attribute value from a string.

**Element**. `setAttributeNode(newAttr)`
Add a new attribute node to the element, replacing an existing attribute if necessary if the name attribute matches. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element**. `setAttributeNodeNS(newAttr)`
Add a new attribute node to the element, replacing an existing attribute if necessary if the namespaceURI and `localName` attributes match. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element**. `setAttributeNS(namespaceURI, qname, value)`
Set an attribute value from a string, given a `namespaceURI` and a `qname`. Note that a qname is the whole attribute name. This is different than above.

### 20.6.2.7. Attr Objects

Attr inherits from Node, so inherits all its attributes.

**Attr**. `name`
The attribute name. In a namespace-using document it may include a colon.

**Attr**. `localName`
The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.
**Attr. prefix**

The part of the name preceding the colon if there is one, else the empty string.

**Attr. value**

The text value of the attribute. This is a synonym for the `nodeValue` attribute.

### 20.6.2.8. NamedNodeMap Objects

NamedNodeMap does *not* inherit from Node.

**NamedNodeMap.length**

The length of the attribute list.

**NamedNodeMap.item(index)**

Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the `Element` objects.

### 20.6.2.9. Comment Objects

Comment represents a comment in the XML document. It is a subclass of Node, but cannot have child nodes.

**Comment.data**

The content of the comment as a string. The attribute contains all
characters between the leading <!-- and trailing -->, but does not include them.

20.6.2.10. Text and CDATASection Objects

The Text interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in CDATASection objects. These two interfaces are identical, but provide different values for the nodeType attribute.

These interfaces extend the Node interface. They cannot have child nodes.

Text.data

The content of the text node as a string.

**Note:** The use of a CDATASection node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent CDATASection nodes represent different CDATA marked sections.

20.6.2.11. ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the Node interface and cannot have child nodes.

ProcessingInstruction.target

The content of the processing instruction up to the first whitespace
character. This is a read-only attribute.

**ProcessingInstruction**. **data**

The content of the processing instruction following the first whitespace character.

### 20.6.2.12. Exceptions

The DOM Level 2 recommendation defines a single exception, **DOMException**, and a number of constants that allow applications to determine what sort of error occurred. **DOMException** instances carry a **code** attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the **code** attribute.

**exception** xml.dom.**DOMException**

Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

**exception** xml.dom.**DomstringSizeErr**

Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

**exception** xml.dom.**HierarchyRequestErr**

Raised when an attempt is made to insert a node where the node type is not allowed.
exception xml.dom.IndexSizeErr
  Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.InuseAttributeErr
  Raised when an attempt is made to insert an Attr node that is already present elsewhere in the document.

exception xml.dom.InvalidAccessErr
  Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.InvalidCharacterErr
  This exception is raised when a string parameter contains a character that is not permitted in the context it’s being used in by the XML 1.0 recommendation. For example, attempting to create an Element node with a space in the element type name will cause this error to be raised.

exception xml.dom.InvalidModificationErr
  Raised when an attempt is made to modify the type of a node.

exception xml.dom.InvalidStateErr
  Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.NamespaceErr
  If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.NotFoundErr
  Exception when a node does not exist in the referenced context.
For example, `NamedNodeMap.removeNamedItem()` will raise this if the node passed in does not exist in the map.

*exception* `xml.dom.NotSupportedErr`  
Raised when the implementation does not support the requested type of object or operation.

*exception* `xml.dom.NoDataAllowedErr`  
This is raised if data is specified for a node which does not support data.

*exception* `xml.dom.NoModificationAllowedErr`  
Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

*exception* `xml.dom.SyntaxErr`  
Raised when an invalid or illegal string is specified.

*exception* `xml.dom.WrongDocumentErr`  
Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMSTRING_SIZE_ERR</td>
<td>DomstringSizeErr</td>
</tr>
<tr>
<td>HIERARCHY_REQUEST_ERR</td>
<td>HierarchyRequestErr</td>
</tr>
<tr>
<td>INDEX_SIZE_ERR</td>
<td>IndexSizeErr</td>
</tr>
<tr>
<td>INUSE_ATTRIBUTE_ERR</td>
<td>InuseAttributeErr</td>
</tr>
<tr>
<td>INVALID_ACCESS_ERR</td>
<td>InvalidAccessErr</td>
</tr>
<tr>
<td>Error Code</td>
<td>Error Message</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>INVALID_CHARACTER_ERR</td>
<td>InvalidCharacterErr</td>

</tbody>
</table>
20.6.3. Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

20.6.3.1. Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

<table>
<thead>
<tr>
<th>IDL Type</th>
<th>Python Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool or int</td>
</tr>
<tr>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>long int</td>
<td>int</td>
</tr>
<tr>
<td>unsigned int</td>
<td>int</td>
</tr>
<tr>
<td>DOMString</td>
<td>str or bytes</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

20.6.3.2. Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL attribute declarations in much the way the Java mapping does. Mapping the IDL declarations

```python
readonly attribute string someValue;
attribute string anotherValue;
```

yields three accessor functions: a “get” method for `someValue`
Callable functions

(_get_someValue()), and “get” and “set” methods for anotherValue (_get_anotherValue()) and _set_anotherValue()). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: object.someValue is not required to work, and may raise an AttributeError.

The Python DOM API, however, does require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared readonly may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for readonly attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of getElementsByTagName(), being “live”. The Python DOM API does not require implementations to enforce such requirements.
20.7. xml.dom.minidom — Minimal DOM implementation

Source code: Lib/xml/dom/minidom.py

xml.dom.minidom is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the xml.etree.ElementTree module for their XML processing instead.

**Warning:** The xml.dom.minidom module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

DOM applications typically start by parsing some XML into a DOM. With xml.dom.minidom, this is done through the parse functions:

```python
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\temp\mydata.xml')  # parse an XML file

datasource = open('c:\temp\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The `parse()` function can take either a filename or an open file.
xml.dom.minidom.parse(filename_or_file, parser=None, bufsize=None)

Return a Document from the given input. filename_or_file may be either a file name, or a file-like object. parser, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the parseString() function instead:

xml.dom.minidom.parseString(string, parser=None)

Return a Document that represents the string. This method creates an io.StringIO object for the string and passes that on to parse().

Both functions return a Document object representing the content of the document.

What the parse() and parseString() functions do is connect an XML parser with a “DOM builder” that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it’s simply that these functions do not provide a parser implementation themselves.

You can also create a Document by calling a method on a “DOM Implementation” object. You can get this object either by calling the
getDOMImplementation() function in the xml.dom package or the xml.dom.minidom module. Once you have a Document, you can add child nodes to it to populate the DOM:

```python
from xml.dom.minidom import getDOMImplementation
impl = getDOMImplementation()
newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the documentElement property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```python
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the unlink() method to encourage early cleanup of the now-unneeded objects. unlink() is a xml.dom.minidom-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python’s garbage collector will eventually take care of the objects in the tree.

See also:

Document Object Model (DOM) Level 1 Specification
The W3C recommendation for the DOM supported by `xml.dom.minidom`. 
20.7.1. DOM Objects

The definition of the DOM API for Python is given as part of the `xml.dom` module documentation. This section lists the differences between the API and `xml.dom.minidom`.

Node `.unlink()`

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the Document object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the `with` statement. The following code will automatically unlink `dom` when the `with` block is exited:

```python
with xml.dom.minidom.parse(datasource) as dom:
    ... # Work with dom.
```

Node `.writexml(writer, indent='', addindent='', newl='')`

Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The `indent` parameter is the indentation of the current node. The `addindent` parameter is the incremental indentation to use for subnodes of the current one. The `newl` parameter specifies the string to use to terminate newlines.

For the Document node, an additional keyword argument `encoding`
can be used to specify the encoding field of the XML header.

Node .\texttt{toxml}(\texttt{encoding=\text{None}})

Return a string or byte string containing the XML represented by the DOM node.

With an explicit \textit{encoding} [1] argument, the result is a byte string in the specified encoding. With no \textit{encoding} argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

Node .\texttt{toprettyxml}(\texttt{indent=\text{"\""}, \texttt{newl=\text{"\n"}, \texttt{encoding=\text{"\"}}})

Return a pretty-printed version of the document. \textit{indent} specifies the indentation string and defaults to a tabulator; \textit{newl} specifies the string emitted at the end of each line and defaults to \texttt{\n}.

The \textit{encoding} argument behaves like the corresponding argument of \texttt{toxml()}.  

20.7.2. DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```python
import xml.dom.minidom

document = """"
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print("<html>")
```

handleSlideshowTitle(slideshow.getElementsByTagName("slide"))
slides = slideshow.getElementsByTagName("slide")
handleToc(slides)
handleSlides(slides)
print("</html>")

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title"))
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print("<title>%s</title>" % getText(title.childNodes))

def handleSlideTitle(title):
    print("<h2>%s</h2>" % getText(title.childNodes))

def handlePoints(points):
    print("<ul>"
for point in points:
    handlePoint(point)
print("</ul>")

def handlePoint(point):
    print("<li>%s</li>" % getText(point.childNodes))

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")
        print("<p>%s</p>" % getText(title.childNodes))
handleSlideshow(dom)
20.7.3. minidom and the DOM standard

The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the Document object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. void operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. readonly attributes must not be changed; this is not enforced at runtime.
- The types `short`, `int`, `unsigned int`, `unsigned long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL null value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`);
they must not be changed.

- DOMException is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as `TypeError` and `AttributeError`.
- NodeList objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more “Pythonic” than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom`:

- DOMTimeStamp
- DocumentType
- DOMImplementation
- CharacterData
- CDATASection
- Notation
- Entity
- EntityReference
- DocumentFragment

Most of these reflect information in the XML document that is not of general utility to most DOM users.

**Footnotes**

The encoding name included in the XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not valid in an XML document’s declaration, even though Python accepts it as an encoding name. See [http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [http://www.iana.org/assignments/character-](http://www.iana.org/assignments/character-
20.8. `xml.dom.pulldom` — Support for building partial DOM trees

Source code: `Lib/xml/dom/pulldom.py`

The `xml.dom.pulldom` module provides a “pull parser” which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling “events” from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

**Warning:** The `xml.dom.pulldom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

Example:
```
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName:
        if int(node.getAttribute('price')) > 50:
            doc.expandNode(node)
        print(node.toxml())
```
event is a constant and can be one of:

- START_ELEMENT
- END_ELEMENT
- COMMENT
- START_DOCUMENT
- END_DOCUMENT
- CHARACTERS
- PROCESSING_INSTRUCTION
- IGNORABLE_WHITESPACE

Node is an object of type xml.dom.minidom.Document, xml.dom.minidom.Element or xml.dom.minidom.Text.

Since the document is treated as a “flat” stream of events, the document “tree” is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the DOMEventStream.expandNode() method and switch to DOM-related processing.

```
class xml.dom.pulldom.PullDom(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.

class xml.dom.pulldom.SAX2DOM(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.
```

```
xml.dom.pulldom.parse(stream_or_string, parser=None, bufsize=None)
```
Return a `DOMEventStream` from the given input. `stream_or_string` may be either a file name, or a file-like object. `parser`, if given, must be a `XMLReader` object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the `parseString()` function instead:

```python
xml.dom.pulldom.parseString(string, parser=None)
```

Return a `DOMEventStream` that represents the (Unicode) `string`.

```python
xml.dom.pulldom.default_bufsize
```

Default value for the `bufsize` parameter to `parse()`.

The value of this variable can be changed before calling `parse()` and the new value will take effect.
20.8.1. DOMEventStream Objects

class xml.dom.pulldom.DOMEventStream(stream, parser, bufsize)

getEvent()
Return a tuple containing event and the current node as xml.dom.minidom.Document if event equals START_DOCUMENT, xml.dom.minidom.Element if event equals START_ELEMENT or END_ELEMENT or xml.dom.minidom.Text if event equals CHARACTERS. The current node does not contain informations about its children, unless expandNode() is called.

expandNode(node)
Expands all children of node into node. Example:

```python
xml = '<html><title>Foo</title> <p>Some text </p><div>and more</div> 
for event, node in doc:
    if event == pulldom.START_ELEMENT and node:
        # Following statement only prints '<p/>
        print(node.toxml())
        doc.expandNode(node)
        # Following statement prints node with children
        print(node.toxml())
```

reset()
20.9. xml.sax — Support for SAX2 parsers

The xml.sax package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

**Warning:** The xml.sax module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

The convenience functions are:

```python
xml.sax.make_parser(parser_list=[])  
Create and return a SAX XMLReader object. The first parser found will be used. If parser_list is provided, it must be a sequence of strings which name modules that have a function named create_parser(). Modules listed in parser_list will be used before modules in the default list of parsers.
```

```python
xml.sax.parse(filename_or_stream, handler,  
error_handler=handler.ErrorHandler())  
Create a SAX parser and use it to parse a document. The document, passed in as filename_or_stream, can be a filename or a file object. The handler parameter needs to be a SAX ContentHandler instance. If error_handler is given, it must be a SAX ErrorHandler instance; if omitted, SAXParseException will be raised on all errors. There is no return value; all work must
be done by the handler passed in.

```python
xml.sax.parseString(string, handler,
error_handler=handler.ErrorHandler())
```

Similar to `parse()`, but parses from a buffer `string` received as a parameter. `string` must be a `str` instance or a `bytes-like object`.

*Changed in version 3.5:* Added support of `str` instances.

A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The `InputSource`, `Locator`, `Attributes`, `AttributesNS`, and `XMLReader` interfaces are defined in the module `xml.sax.xmlreader`. The handler interfaces are defined in `xml.sax.handler`. For convenience, `InputSource` (which is often instantiated directly) and the handler classes are also available from `xml.sax`. These interfaces are described below.
In addition to these classes, `xml.sax` provides the following exception classes.

```
exception xml.sax.SAXException(msg, exception=None)
```

Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the `ErrorHandler` interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.

When instantiated, `msg` should be a human-readable description of the error. The optional `exception` parameter, if given, should be None or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

```
exception xml.sax.SAXParseException(msg, exception, locator)
```

Subclass of `SAXException` raised on parse errors. Instances of this class are passed to the methods of the SAX `ErrorHandler` interface to provide information about the parse error. This class supports the SAX `Locator` interface as well as the `SAXException` interface.

```
exception xml.sax.SAXNotRecognizedException(msg, exception=None)
```

Subclass of `SAXException` raised when a SAX `XMLReader` is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar
exception xml.sax.SAXNotSupportedException(msg, exception=None)

Subclass of SAXException raised when a SAX XMLReader is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

**SAX: The Simple API for XML**
This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

Module xml.sax.handler
Definitions of the interfaces for application-provided objects.

Module xml.sax.saxutils
Convenience functions for use in SAX applications.

Module xml.sax.xmlreader
Definitions of the interfaces for parser-provided objects.
20.9.1. SAXException Objects

The **SAXException** exception class supports the following methods:

**SAXException**. **getMessage()**

Return a human-readable message describing the error condition.

**SAXException**. **getException()**

Return an encapsulated exception object, or None.
20.10. `xml.sax.handler` —
Base classes for SAX handlers

The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

`class xml.sax.handler.ContentHandler`

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

`class xml.sax.handler.DTDHandler`

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

`class xml.sax.handler.EntityResolver`

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

`class xml.sax.handler.ErrorHandler`

Interface used by the parser to present error and warning messages to the application. The methods of this object control
whether errors are immediately converted to exceptions or are handled in some other way.

In addition to these classes, \texttt{xml.sax.handler} provides symbolic constants for the feature and property names.

\texttt{xml.sax.handler.feature_namespaces}

value: "http://xml.org/sax/features/namespaces"
true: Perform Namespace processing.
false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
access: (parsing) read-only; (not parsing) read/write

\texttt{xml.sax.handler.feature_namespace_prefixes}

value: "http://xml.org/sax/features/namespace-prefixes"
true: Report the original prefixed names and attributes used for Namespace declarations.
false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
access: (parsing) read-only; (not parsing) read/write

\texttt{xml.sax.handler.feature_string_interning}

value: "http://xml.org/sax/features/string-interning"
true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
false: Names are not necessarily interned, although they may be (default).
access: (parsing) read-only; (not parsing) read/write
xml.sax.handler.feature_validation

value: "http://xml.org/sax/features/validation"
true: Report all validation errors (implies external-general-entities and external-parameter-entities).
false: Do not report validation errors.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_ges

value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes

value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features

List of all features.

xml.sax.handler.property_lexical_handler

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.**property_declaration_handler**

value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.**property_dom_node**

value: "http://xml.org/sax/properties/dom-node"
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**property_xml_string**

value: "http://xml.org/sax/properties/xml-string"
data type: String
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.**all_properties**
List of all known property names.
20.10.1. ContentHandler Objects

Users are expected to subclass `ContentHandler` to support their application. The following methods are called by the parser on the appropriate events in the input document:

**ContentHandler**.`setDocumentLocator(locator)`

Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application’s business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

**ContentHandler**.`startDocument()`

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).
ContentHandler.endDocument()
Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler.startPrefixMapping(prefix, uri)
Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the feature_namespaces feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the startPrefixMapping() and endPrefixMapping() events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that startPrefixMapping() and endPrefixMapping() events are not guaranteed to be properly nested relative to each other: all startPrefixMapping() events will occur before the corresponding startElement() event, and all endPrefixMapping() events will occur after the corresponding endElement() event, but their order is not guaranteed.

ContentHandler.endPrefixMapping(prefix)
End the scope of a prefix-URI mapping.

See startPrefixMapping() for details. This event will always
occur after the corresponding `endElement()` event, but the order of `endPrefixMapping()` events is not otherwise guaranteed.

`ContentHandler.startElement(name, attrs)`
Signals the start of an element in non-namespace mode.

The `name` parameter contains the raw XML 1.0 name of the element type as a string and the `attrs` parameter holds an object of the `Attributes` interface (see The Attributes Interface) containing the attributes of the element. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.

`ContentHandler.endElement(name)`
Signals the end of an element in non-namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElement()` event.

`ContentHandler.startElementNS(name, qname, attrs)`
Signals the start of an element in namespace mode.

The `name` parameter contains the name of the element type as a `(uri, localname)` tuple, the `qname` parameter contains the raw XML 1.0 name used in the source document, and the `attrs` parameter holds an instance of the `AttributesNS` interface (see The AttributesNS Interface) containing the attributes of the element. If no namespace is associated with the element, the `uri` component of `name` will be None. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the
attributes, use the `copy()` method of the `attrs` object.

Parsers may set the `qname` parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

`ContentHandler.endElementNS(name, qname)`
Signals the end of an element in namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElementNS()` method, likewise the `qname` parameter.

`ContentHandler.characters(content)`
Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

`content` may be a string or bytes instance; the expat reader module always produces strings.

**Note:** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use `content` instead of slicing content with the old `offset` and `length` parameters.

`ContentHandler.ignorableWhitespace(whitespace)`
Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

**ContentHandler.** **processingInstruction**(target, data)

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

**ContentHandler.** **skippedEntity**(name)

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the feature_external_ges and the feature_external_pes properties.
20.10.2. DTDHandler Objects

**DTDHandler** instances provide the following methods:

**DTDHandler**.\texttt{notationDecl}(name, publicId, systemId)
- Handle a notation declaration event.

**DTDHandler**.\texttt{unparsedEntityDecl}(name, publicId, systemId, ndata)
- Handle an unparsed entity declaration event.
20.10.3. EntityResolver Objects

EntityResolver.*resolveEntity*(*publicId*, *systemId*)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns *systemId*. 
20.10.4. ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the `XMLReader`. If you create an object that implements this interface, then register the object with your `XMLReader`, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a `SAXParseException` as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

`ErrorHandler.error(exception)`

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

`ErrorHandler.fatalError(exception)`

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

`ErrorHandler.warning(exception)`

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.
20.11. **xml.sax.saxutils** — SAX Utilities

The module **xml.sax.saxutils** contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

```python
xml.sax.saxutils.escape(data, entities={})
```

Escape '&, '<', and '>' in a string of data.

You can escape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters '&', '<' and '>' are always escaped, even if `entities` is provided.

```python
xml.sax.saxutils.unescape(data, entities={})
```

Unescape '&amp;', '&lt;', and '&gt;' in a string of data.

You can unescape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. '&amp;', '&lt;', and '&gt;' are always unescaped, even if `entities` is provided.

```python
xml.sax.saxutils.quoteattr(data, entities={})
```

Similar to `escape()`, but also prepares `data` to be used as an attribute value. The return value is a quoted version of `data` with any additional required replacements. `quoteattr()` will select a quote character based on the content of `data`, attempting to avoid
encoding any quote characters in the string. If both single- and
double-quote characters are already in data, the double-quote
characters will be encoded and data will be wrapped in double-
quotes. The resulting string can be used directly as an attribute
value:

```python
>>> print("<element attr=%s>" % quoteattr("ab ' cd &quot; ef")

This function is useful when generating attribute values for HTML
or any SGML using the reference concrete syntax.

class xml.sax.saxutils.XMLGenerator(out=None,
encoding='iso-8859-1', short_empty_elements=False)

This class implements the ContentHandler interface by writing
SAX events back into an XML document. In other words, using an
XMLGenerator as the content handler will reproduce the original
document being parsed. out should be a file-like object which will
default to sys.stdout. encoding is the encoding of the output stream
which defaults to 'iso-8859-1'. short_empty_elements controls
the formatting of elements that contain no content: if False (the
default) they are emitted as a pair of start/end tags, if set to True
they are emitted as a single self-closed tag.

New in version 3.2: The short_empty_elements parameter.

class xml.sax.saxutils.XMLFilterBase(base)

This class is designed to sit between an XMLReader and the client
application’s event handlers. By default, it does nothing but pass
requests up to the reader and events on to the handlers
unmodified, but subclasses can override specific methods to
modify the event stream or the configuration requests as they pass
`xml.sax.saxutils.prepare_input_source(source, base='')`  
This function takes an input source and an optional base URL and returns a fully resolved `InputSource` object ready for reading. The input source can be given as a string, a file-like object, or an `InputSource` object; parsers will use this function to implement the polymorphic `source` argument to their `parse()` method.
SAX parsers implement the `XMLReader` interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

```python
class xml.sax.xmlreader.XMLReader
    Base class which can be inherited by SAX parsers.
```

```python
class xml.sax.xmlreader.IncrementalParser
    In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won’t return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

    When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

    Note that these methods must *not* be called during parsing, that is, after `parse` has been called and before it returns.

    By default, the class also implements the parse method of the
XMLReader interface using the feed, close and reset methods of
the IncrementalParser interface as a convenience to SAX 2.0
driver writers.

class xml.sax.xmlreader.Locator
Interface for associating a SAX event with a document location. A
locator object will return valid results only during calls to
DocumentHandler methods; at any other time, the results are
unpredictable. If information is not available, methods may return
None.

class xml.sax.xmlreader.InputSource(system_id=None)
Encapsulation of the information needed by the XMLReader to
read entities.

This class may include information about the public identifier,
system identifier, byte stream (possibly with character encoding
information) and/or the character stream of an entity.

Applications will create objects of this class for use in the
XMLReader.parse() method and for returning from
EntityResolver.resolveEntity.

An InputSource belongs to the application, the XMLReader is
not allowed to modify InputSource objects passed to it from the
application, although it may make copies and modify those.

class xml.sax.xmlreader.AttributesImpl(attrs)
This is an implementation of the Attributes interface (see
section The Attributes Interface). This is a dictionary-like object
which represents the element attributes in a startElement() call. In addition to the most useful dictionary operations, it supports
a number of other methods as described by the interface. Objects
of this class should be instantiated by readers; attrs must be a dictionary-like object containing a mapping from attribute names to attribute values.

```python
class xml.sax.xmlreader.AttributesNSImpl(attrs, qnames)
```

Namespace-aware variant of `AttributesImpl`, which will be passed to `startElementNS()`. It is derived from `AttributesImpl`, but understands attribute names as two-tuples of `namespaceURI` and `localname`. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the AttributesNS interface (see section The AttributesNS Interface).
20.12.1. XMLReader Objects

The `XMLReader` interface supports the following methods:

**`XMLReader.parse(source)`**

Process an input source, producing SAX events. The `source` object can be a system identifier (a string identifying the input source – typically a file name or an URL), a file-like object, or an `InputSource` object. When `parse()` returns, the input is completely processed, and the parser object can be discarded or reset.

*Changed in version 3.5: Added support of character streams.*

**`XMLReader.getEntityResolver()`**

Return the current `EntityResolver`.

**`XMLReader.setContentHandler(handler)`**

Set the current `ContentHandler`. If no `ContentHandler` is set, content events will be discarded.

**`XMLReader.getDTDHandler()`**

Return the current `DTDHandler`.

**`XMLReader.setDTDHandler(handler)`**

Set the current `DTDHandler`. If no `DTDHandler` is set, DTD events will be discarded.

**`XMLReader.getEntityResolver()`**

Return the current `EntityResolver`.

**`XMLReader.setEntityResolver(handler)`**
Set the current `EntityResolver`. If no `EntityResolver` is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

**XMLReader**. `getErrorHandler()`  
Return the current `ErrorHandler`.

**XMLReader**. `setErrorHandler(handler)`  
Set the current error handler. If no `ErrorHandler` is set, errors will be raised as exceptions, and warnings will be printed.

**XMLReader**. `setLocale(locale)`  
Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

**XMLReader**. `getFeature(featurename)`  
Return the current setting for feature `featurename`. If the feature is not recognized, SAXNotRecognizedException is raised. The well-known featurenames are listed in the module `xml.sax.handler`.

**XMLReader**. `setFeature(featurename, value)`  
Set the `featurename` to `value`. If the feature is not recognized, SAXNotRecognizedException is raised. If the feature or its setting is not supported by the parser, SAXNotSupportedException is raised.

**XMLReader**. `getProperty(propertyname)`
Return the current setting for property \textit{propertynane}. If the property is not recognized, a \texttt{SAXNotRecognizedException} is raised. The well-known properties are listed in the module \texttt{xml.sax.handler}.

\texttt{XMLReader.setProperty(propertynane, value)}

Set the \textit{propertynane} to \textit{value}. If the property is not recognized, \texttt{SAXNotRecognizedException} is raised. If the property or its setting is not supported by the parser, \texttt{SAXNotSupportedException} is raised.
20.12.2. IncrementalParser Objects

Instances of IncrementalParser offer the following additional methods:

IncrementalParser.\texttt{feed}(data)

Process a chunk of \texttt{data}.

IncrementalParser.\texttt{close}()

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser.\texttt{reset}()

This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.
Instances of `Locator` provide these methods:

- `Locator.getColumnNumber()`
  Return the column number where the current event ends.

- `Locator.getLineNumber()`
  Return the line number where the current event ends.

- `Locator.getPublicId()`
  Return the public identifier for the current event.

- `Locator.getSystemId()`
  Return the system identifier for the current event.
20.12.4. InputSource Objects

InputSource.setPublicId(id)
Sets the public identifier of this InputSource.

InputSource.getPublicId()
Returns the public identifier of this InputSource.

InputSource.setSystemId(id)
Sets the system identifier of this InputSource.

InputSource.getSystemId()
Returns the system identifier of this InputSource.

InputSource.setEncoding(encoding)
Sets the character encoding of this InputSource.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the InputSource is ignored if the InputSource also contains a character stream.

InputSource.getEncoding()
Get the character encoding of this InputSource.

InputSource.setByteStream(bytefile)
Set the byte stream (a binary file) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.
If the application knows the character encoding of the byte stream, it should set it with the `setEncoding` method.

**InputSource**. `getBytesStream()`  
Get the byte stream for this input source.

The `getEncoding` method will return the character encoding for this byte stream, or None if unknown.

**InputSource**. `setCharacterStream(charfile)`  
Set the character stream (a text file) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

**InputSource**. `getCharacterStream()`  
Get the character stream for this input source.
20.12.5. The Attributes Interface

Attributes objects implement a portion of the mapping protocol, including the methods copy(), get(), __contains__(), items(), keys(), and values(). The following methods are also provided:

Attributes.getLength()
Return the number of attributes.

Attributes.getNames()
Return the names of the attributes.

Attributes.getType(name)
Returns the type of the attribute name, which is normally 'CDATA'.

Attributes.getValue(name)
Return the value of attribute name.
20.12.6. The AttributesNS Interface

This interface is a subtype of the Attributes interface (see section The Attributes Interface). All methods supported by that interface are also available on AttributesNS objects.

The following methods are also available:

AttributesNS.getValueByQName(name)
   Return the value for a qualified name.

AttributesNS.getNameByQName(name)
   Return the (namespace, localname) pair for a qualified name.

AttributesNS.getQNameByName(name)
   Return the qualified name for a (namespace, localname) pair.

AttributesNS.getQNames()
   Return the qualified names of all attributes.
20.13. `xml.parsers.expat` — Fast XML parsing using Expat

**Warning:** The `pyexpat` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

The `xml.parsers.expat` module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the `pyexpat` module to provide access to the Expat parser. Direct use of the `pyexpat` module is deprecated.

This module provides one exception and one type object:

* `exception xml.parsers.expat.ExpatError`  
  The exception raised when Expat reports an error. See section `ExpatError Exceptions` for more information on interpreting Expat errors.

* `exception xml.parsers.expat.error`  
  Alias for `ExpatError`.

* `xml.parsers.expat.XMLParserType`  
  The type of the return values from the `ParserCreate()` function.
The `xml.parsers.expat` module contains two functions:

```python
xml.parsers.expat.ErrorString(errno)
```

Returns an explanatory string for a given error number `errno`.

```python
xml.parsers.expat.ParserCreate(encoding=None, namespace_separator=None)
```

Creates and returns a new `xmlparser` object. `encoding`, if specified, must be a string naming the encoding used by the XML data. Expat doesn't support as many encodings as Python does, and its repertoire of encodings can't be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If `encoding` [1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for `namespace_separator`. The value must be a one-character string; a `ValueError` will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers `StartElementHandler` and `EndElementHandler` will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (`chr(0)`) then the namespace URI and the local part will be concatenated without any separator.

For example, if `namespace_separator` is set to a space character (`' '`) and the following document is parsed:

```xml
<?xml version="1.0"?>
<root xmlns = "http://default-namespace.org/
     xmlns:py = "http://www.python.org/ns/"/>
```
StartElementHandler will receive the following strings for each element:

```
http://default-namespace.org/ root
http://www.python.org/ns/ elem1
elem2
```

Due to limitations in the Expat library used by pyexpat, the xmlparser instance returned can only be used to parse a single XML document. Call ParserCreate for each document to provide unique parser instances.

See also:

**The Expat XML Parser**

Home page of the Expat project.
20.13.1. XMLParser Objects

xmlparser objects have the following methods:

**xmlparser.Parse(data[, isfinal])**

Parses the contents of the string *data*, calling the appropriate handler functions to process the parsed data. *isfinal* must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. *data* can be the empty string at any time.

**xmlparser.ParseFile(file)**

Parse XML data reading from the object *file*. *file* only needs to provide the `read(nbytes)` method, returning the empty string when there's no more data.

**xmlparser.SetBase(base)**

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the *base* argument to the `ExternalEntityRefHandler()`, `NotationDeclHandler()`, and `UnparsedEntityDeclHandler()` functions.

**xmlparser.GetBase()**

Returns a string containing the base set by a previous call to `SetBase()`, or None if `SetBase()` hasn't been called.

**xmlparser.GetInputContext()**

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text.
When called while an event handler is not active, the return value is None.

```
xmlparser.ExternalEntityParserCreate(context[, encoding])
```

Create a “child” parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The `context` parameter should be the string passed to the `ExternalEntityRefHandler()` handler function, described below. The child parser is created with the `ordered_attributes` and `specified_attributes` set to the values of this parser.

```
xmlparser.SetParamEntityParsing(flag)
```

Control parsing of parameter entities (including the external DTD subset). Possible `flag` values are `XML_PARAM_ENTITY_PARSING_NEVER`, `XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE` and `XML_PARAM_ENTITY_PARSING_ALWAYS`. Return true if setting the flag was successful.

```
xmlparser.UseForeignDTD([flag])
```

Calling this with a true value for `flag` (the default) will cause Expat to call the `ExternalEntityRefHandler` with `None` for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the `ExternalEntityRefHandler` will still be called, but the `StartDoctypeDeclHandler` and `EndDoctypeDeclHandler` will not be called.

Passing a false value for `flag` will cancel a previous call that passed a true value, but otherwise has no effect.
This method can only be called before the `Parse()` or `ParseFile()` methods are called; calling it after either of those have been called causes `ExpatError` to be raised with the `code` attribute set to `errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_`

`xmlparser` objects have the following attributes:

**xmlparser.buffer_size**

The size of the buffer used when `buffer_text` is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

**xmlparser.buffer_text**

Setting this to true causes the `xmlparser` object to buffer textual content returned by Expat to avoid multiple calls to the `CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

**xmlparser.buffer_used**

If `buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when `buffer_text` is false.

**xmlparser.ordered_attributes**

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this
format.) By default, this attribute is false; it may be changed at any time.

xmlparser.specified_attributes
If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an xmlparser object, and will only have correct values once a call to Parse() or ParseFile() has raised a xml.parsers.expat.ExpatError exception.

xmlparser.ErrorByteIndex
Byte index at which an error occurred.

xmlparser.ErrorCode
Numeric code specifying the problem. This value can be passed to the ErrorString() function, or compared to one of the constants defined in the errors object.

xmlparser.ErrorColumnNumber
Column number at which an error occurred.

xmlparser.ErrorLineNumber
Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an xmlparser object. During a callback reporting a parse
event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

`xmlparser.CurrentByteIndex`  
Current byte index in the parser input.

`xmlparser.CurrentColumnNumber`  
Current column number in the parser input.

`xmlparser.CurrentLineNumber`  
Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object `o`, use `o.handlername = func`. `handlername` must be taken from the following list, and `func` must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

`xmlparser.XmlDeclHandler(version, encoding, standalone)`  
Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional “standalone” declaration. `version` and `encoding` will be strings, and `standalone` will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

`xmlparser.StartDoctypeDeclHandler(doctypeName, systemId, publicId, has_internal_subset)`  
Called when Expat begins parsing the document type declaration
(<!DOCTYPE ...). The `doctypeName` is provided exactly as presented. The `systemId` and `publicId` parameters give the system and public identifiers if specified, or None if omitted. `has_internal_subset` will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

`xmlparser.EndDoctypeDeclHandler()`
Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

`xmlparser.ElementDeclHandler(name, model)`
Called once for each element type declaration. `name` is the name of the element type, and `model` is a representation of the content model.

`xmlparser.AttlistDeclHandler(elname, attname, type, default, required)`
Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. `elname` is the name of the element to which the declaration applies and `attname` is the name of the attribute declared. The attribute type is a string passed as `type`; the possible values are 'CDATA', 'ID', 'IDREF', ... `default` gives the default value for the attribute used when the attribute is not specified by the document instance, or None if there is no default value (#IMPLIED values). If the attribute is required to be given in the document instance, `required` will be true. This requires Expat version 1.95.0 or newer.

`xmlparser.StartElementHandler(name, attributes)`
Called for the start of every element. `name` is a string containing
the element name, and *attributes* is the element attributes. If *ordered_attributes* is true, this is a list (see *ordered_attributes* for a full description). Otherwise it's a dictionary mapping names to values.

```python
xmlparser.EndElementHandler(name)
```
Called for the end of every element.

```python
xmlparser.ProcessingInstructionHandler(target, data)
```
Called for every processing instruction.

```python
xmlparser.CharacterDataHandler(data)
```
Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the *StartCdataSectionHandler*, *EndCdataSectionHandler*, and *ElementDeclHandler* callbacks to collect the required information.

```python
xmlparser.UnparsedEntityDeclHandler(entityName, base, systemId, publicId, notationName)
```
Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use *EntityDeclHandler* instead. (The underlying function in the Expat library has been declared obsolete.)

```python
xmlparser.EntityDeclHandler(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)
```
Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be None for external entities. The *notationName* parameter will be None for parsed entities, and the name of the
notation for unparsed entities. \texttt{is\_parameter\_entity} will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

\texttt{xmlparser.\texttt{NotationDeclHandler}(notationName, base, systemId, publicId)}

Called for notation declarations. \texttt{notationName}, \texttt{base}, and \texttt{systemId}, and \texttt{publicId} are strings if given. If the public identifier is omitted, \texttt{publicId} will be \texttt{None}.

\texttt{xmlparser.\texttt{StartNamespaceDeclHandler}(prefix, uri)}

Called when an element contains a namespace declaration. Namespace declarations are processed before the \texttt{StartElementHandler} is called for the element on which declarations are placed.

\texttt{xmlparser.\texttt{EndNamespaceDeclHandler}(prefix)}

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the \texttt{StartNamespaceDeclHandler} was called to indicate the start of each namespace declaration’s scope. Calls to this handler are made after the corresponding \texttt{EndElementHandler} for the end of the element.

\texttt{xmlparser.\texttt{CommentHandler}(data)}

Called for comments. \texttt{data} is the text of the comment, excluding the leading '\texttt{<!--} and trailing '\texttt{-->}'.

\texttt{xmlparser.\texttt{StartCdataSectionHandler}()} 

Called at the start of a CDATA section. This and
**EndCdataSectionHandler** are needed to be able to identify the syntactical start and end for CDATA sections.

**xmlparser.** **EndCdataSectionHandler()**
Called at the end of a CDATA section.

**xmlparser.** **DefaultHandler**(data)
Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

**xmlparser.** **DefaultHandlerExpand**(data)
This is the same as the **DefaultHandler()**, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

**xmlparser.** **NotStandaloneHandler()**
Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to yes in an XML declaration. If this handler returns 0, then the parser will raise an XML_ERROR_NOT_STANDALONE error. If this handler is not set, no exception is raised by the parser for this condition.

**xmlparser.** **ExternalEntityRefHandler**(context, base, systemId, publicId)
Called for references to external entities. *base* is the current base, as set by a previous call to **SetBase()**. The public and system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be None. The *context* value is
opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the `DefaultHandler` callback, if provided.
20.13.2. ExpatError Exceptions

*ExpatError* exceptions have a number of interesting attributes:

**ExpatError.**`code`

Expat's internal error number for the specific error. The `errors.messages` dictionary maps these error numbers to Expat's error messages. For example:

```python
from xml.parsers.expat import ParserCreate, ExpatError

p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

The `errors` module also provides error message constants and a dictionary `codes` mapping these messages back to the error codes, see below.

**ExpatError.**`lineno`

Line number on which the error was detected. The first line is numbered 1.

**ExpatError.**`offset`

Character offset into the line where the error occurred. The first column is numbered 0.
20.13.3. Example

The following program defines three handlers that just print out their arguments.

```python
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)

def end_element(name):
    print('End element:', name)

def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()

p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version='1.0'?><parent id='top'><child1 name='paul'>Text goes here</child1><child2 name='fred'>More text</child2></parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
```
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
20.13.4. Content Model Descriptions

Content modules are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content module descriptions.

The values of the first two fields are constants defined in the `xml.parsers.expat.model` module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

- `xml.parsers.expat.model.XML_CTYPE_ANY`
  The element named by the model name was declared to have a content model of ANY.

- `xml.parsers.expat.model.XML_CTYPE_CHOICE`
  The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

- `xml.parsers.expat.model.XML_CTYPE_EMPTY`
  Elements which are declared to be EMPTY have this model type.

- `xml.parsers.expat.model.XML_CTYPE_MIXED`

- `xml.parsers.expat.model.XML_CTYPE_NAME`

- `xml.parsers.expat.model.XML_CTYPE_SEQ`
  Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:
xml.parsers.expat.model.XML_CQUANT_NONE
No modifier is given, so it can appear exactly once, as for A.

xml.parsers.expat.model.XML_CQUANT_OPT
The model is optional: it can appear once or not at all, as for A?.

xml.parsers.expat.model.XML_CQUANT_PLUS
The model must occur one or more times (like A+).

xml.parsers.expat.model.XML_CQUANT_REP
The model must occur zero or more times, as for A*.
20.13.5. Expat error constants

The following constants are provided in the `xml.parsers.expat.errors` module. These constants are useful in interpreting some of the attributes of the ExpatError exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error message and not the numeric error code, you do this by comparing its code attribute with `errors.codes[errors.XML_ERROR_CONSTANT_NAME]`.

The `errors` module has the following attributes:

- `xml.parsers.expat.errors.codes`  
  A dictionary mapping numeric error codes to their string descriptions.  
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.messages`  
  A dictionary mapping string descriptions to their error codes.  
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.XML_ERROR_ASYNC_ENTITY`
- `xml.parsers.expat.errors.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`  
  An entity reference in an attribute value referred to an external entity instead of an internal entity.

- `xml.parsers.expat.errors.XML_ERROR_BAD_CHAR_REF`  
  A character reference referred to a character which is illegal in XML (for example, character θ, or `&#0;`).
xml.parsers.expat.errors.XML_ERROR_BINARY_ENTITY
An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

xml.parsers.expat.errors.XML_ERROR_DUPLICATE_ATTRIBUTE
An attribute was used more than once in a start tag.

xml.parsers.expat.errors.XML_ERROR_INCORRECT_ENCODING
xml.parsers.expat.errors.XML_ERROR_INVALID_TOKEN
Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value 0) in a UTF-8 input stream.

xml.parsers.expat.errors.XML_ERROR_JUNK_AFTER_DOC
Something other than whitespace occurred after the document element.

xml.parsers.expat.errors.XML_ERROR_MISPLACED_XML_PI
An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.errors.XML_ERROR_NO_ELEMENTS
The document contains no elements (XML requires all documents to contain exactly one top-level element).

xml.parsers.expat.errors.XML_ERROR_NO_MEMORY
Expat was not able to allocate memory internally.

xml.parsers.expat.errors.XML_ERROR_PARAM_ENTITY_REF
A parameter entity reference was found where it was not allowed.

xml.parsers.expat.errors.XML_ERROR_PARTIAL_CHAR
An incomplete character was found in the input.
xml.parsers.expat.errors.XML_ERROR_RECURSIVE_ENTITY
An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.XML_ERROR_SYNTAX
Some unspecified syntax error was encountered.

xml.parsers.expat.errors.XML_ERROR_TAG_MISMATCH
An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_TOKEN
Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.XML_ERROR_UNDEFINED_ENTITY
A reference was made to an entity which was not defined.

xml.parsers.expat.errors.XML_ERROR_UNKNOWN_ENCODING
The document encoding is not supported by Expat.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_CDATA
A CDATA marked section was not closed.

xml.parsers.expat.errors.XML_ERROR_EXTERNAL_ENTITY_HANDLING
xml.parsers.expat.errors.XML_ERROR_NOT_STANDALONE
The parser determined that the document was not “standalone” though it declared itself to be in the XML declaration, and the NotStandaloneHandler was set and returned 0.

xml.parsers.expat.errors.XML_ERROR_UNEXPECTED_STATE
xml.parsers.expat.errors.XML_ERROR_ENTITY_DECLARED_IN_PIE
An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the xml.parsers.expat module.

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by UseForeignDTD().

An undeclared prefix was found when namespace processing was enabled.

The document attempted to remove the namespace declaration associated with a prefix.

A parameter entity contained incomplete markup.

The document contained no document element at all.

There was an error parsing a text declaration in an external entity.

Characters were found in the public id that are not allowed.

The requested operation was made on a suspended parser, but
isn’t allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_NOT_SUSPENDED
An attempt to resume the parser was made when the parser had not been suspended.

xml.parsers.expat.errors.XML_ERROR_ABORTED
This should not be reported to Python applications.

xml.parsers.expat.errors.XML_ERROR_FINISHED
The requested operation was made on a parser which was finished parsing input, but isn’t allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_SUSPEND_PE

Footnotes

[1] The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and http://www.iana.org/assignments/character-sets/character-sets.xhtml.
21. Internet Protocols and Support

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module `socket`, which is currently supported on most popular platforms. Here is an overview:

- **21.1. webbrowser** — Convenient Web-browser controller
  - 21.1.1. Browser Controller Objects
- **21.2. cgi** — Common Gateway Interface support
  - 21.2.1. Introduction
  - 21.2.2. Using the cgi module
  - 21.2.3. Higher Level Interface
  - 21.2.4. Functions
  - 21.2.5. Caring about security
  - 21.2.6. Installing your CGI script on a Unix system
  - 21.2.7. Testing your CGI script
  - 21.2.8. Debugging CGI scripts
  - 21.2.9. Common problems and solutions
- **21.3. cgitb** — Traceback manager for CGI scripts
- **21.4. wsgiref** — WSGI Utilities and Reference Implementation
  - 21.4.1. wsgiref.util — WSGI environment utilities
  - 21.4.2. wsgiref.headers — WSGI response header tools
  - 21.4.3. wsgiref.simple_server — a simple WSGI HTTP server
  - 21.4.4. wsgiref.validate — WSGI conformance checker
  - 21.4.5. wsgiref.handlers — server/gateway base classes
  - 21.4.6. Examples
- **21.5. urllib** — URL handling modules
- **21.6. urllib.request** — Extensible library for opening URLs
  - 21.6.1. Request Objects
21.6.2. OpenerDirector Objects
21.6.3. BaseHandler Objects
21.6.4. HTTPRedirectHandler Objects
21.6.5. HTTPCookieProcessor Objects
21.6.6. ProxyHandler Objects
21.6.7. HTTPPasswordMgr Objects
21.6.8. HTTPPasswordMgrWithPriorAuth Objects
21.6.9. AbstractBasicAuthHandler Objects
21.6.10. HTTPBasicAuthHandler Objects
21.6.11. ProxyBasicAuthHandler Objects
21.6.12. AbstractDigestAuthHandler Objects
21.6.13. HTTPDigestAuthHandler Objects
21.6.15. HTTPHandler Objects
21.6.16. HTTPSHandler Objects
21.6.17. FileHandler Objects
21.6.18. DataHandler Objects
21.6.19. FTPHandler Objects
21.6.20. CacheFTPHandler Objects
21.6.21. UnknownHandler Objects
21.6.22. HTTPErrorProcessor Objects
21.6.23. Examples
21.6.24. Legacy interface
21.6.25. urllib.request Restrictions

- 21.7. urllib.response — Response classes used by urllib
- 21.8. urllib.parse — Parse URLs into components
  - 21.8.1. URL Parsing
  - 21.8.2. Parsing ASCII Encoded Bytes
  - 21.8.3. Structured Parse Results
  - 21.8.4. URL Quoting
- 21.9. urllib.error — Exception classes raised by urllib.request
- 21.10. urllib.robotparser — Parser for robots.txt
- 21.11. http — HTTP modules
• 21.11.1. HTTP status codes

• 21.12. `http.client` — HTTP protocol client
  • 21.12.1. `HTTPConnection` Objects
  • 21.12.2. `HTTPResponse` Objects
  • 21.12.3. Examples
  • 21.12.4. `HTTPMessage` Objects

• 21.13. `ftplib` — FTP protocol client
  • 21.13.1. `FTP` Objects
  • 21.13.2. `FTP_TLS` Objects

• 21.14. `poplib` — POP3 protocol client
  • 21.14.1. `POP3` Objects
  • 21.14.2. `POP3` Example

• 21.15. `imaplib` — IMAP4 protocol client
  • 21.15.1. `IMAP4` Objects
  • 21.15.2. `IMAP4` Example

• 21.16. `nntplib` — NNTP protocol client
  • 21.16.1. `NNTP` Objects
    • 21.16.1.1. Attributes
    • 21.16.1.2. Methods
  • 21.16.2. Utility functions

• 21.17. `smtplib` — SMTP protocol client
  • 21.17.1. `SMTP` Objects
  • 21.17.2. `SMTP` Example

• 21.18. `smtpd` — SMTP Server
  • 21.18.1. `SMTPServer` Objects
  • 21.18.2. `DebuggingServer` Objects
  • 21.18.3. `PureProxy` Objects
  • 21.18.4. `MailmanProxy` Objects
  • 21.18.5. `SMTPChannel` Objects

• 21.19. `telnetlib` — Telnet client
  • 21.19.1. `Telnet` Objects
  • 21.19.2. `Telnet` Example

• 21.20. `uuid` — UUID objects according to RFC 4122
- 21.20.1. Example
- **21.21. socketserver — A framework for network servers**
  - 21.21.1. Server Creation Notes
  - 21.21.2. Server Objects
  - 21.21.3. RequestHandler Objects
  - 21.21.4. Examples
    - 21.21.4.1. `socketserver.TCPServer` Example
    - 21.21.4.2. `socketserver.UDPServer` Example
    - 21.21.4.3. Asynchronous Mixins
- **21.22. http.server — HTTP servers**
- **21.23. http.cookies — HTTP state management**
  - 21.23.1. Cookie Objects
  - 21.23.2. Morsel Objects
  - 21.23.3. Example
- **21.24. http.cookiejar — Cookie handling for HTTP clients**
  - 21.24.2. FileCookieJar subclasses and co-operation with web browsers
  - 21.24.3. CookiePolicy Objects
  - 21.24.4. DefaultCookiePolicy Objects
  - 21.24.5. Cookie Objects
  - 21.24.6. Examples
- **21.25. xmlrpc — XMLRPC server and client modules**
- **21.26. xmlrpc.client — XML-RPC client access**
  - 21.26.2. DateTime Objects
  - 21.26.3. Binary Objects

21.1. **webbrowser** — Convenient Web-browser controller

**Source code:** Lib/webbrowser.py

The `webbrowser` module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the `open()` function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn’t available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable `BROWSER` exists, it is interpreted as the `os.pathsep`-separated list of browsers to try ahead of the platform defaults. When the value of a list part contains the string `%s`, then it is interpreted as a literal browser command line to be used with the argument URL substituted for `%s`; if the part does not contain `%s`, it is simply interpreted as the name of the browser to launch. [1]

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script `webbrowser` can be used as a command-line interface for the module. It accepts an URL as the argument. It accepts the
following optional parameters: -n opens the URL in a new browser window, if possible; -t opens the URL in a new browser page ("tab"). The options are, naturally, mutually exclusive. Usage example:

```
python -m webbrowser -t "http://www.python.org"
```

The following exception is defined:

```
exception webbrowser.Error
    Exception raised when a browser control error occurs.
```

The following functions are defined:

```
webbrowser.open(url, new=0, autoraise=True)
    Display url using the default browser. If new is 0, the url is opened in the same browser window if possible. If new is 1, a new browser window is opened if possible. If new is 2, a new browser page ("tab") is opened if possible. If autoraise is True, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

    Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

webbrowser.open_new(url)
    Open url in a new window of the default browser, if possible, otherwise, open url in the only browser window.

webbrowser.open_new_tab(url)
    Open url in a new page ("tab") of the default browser, if possible, otherwise equivalent to open_new().```
webbrowser.get(using=None)

Return a controller object for the browser type using. If using is None, return a controller for a default browser appropriate to the caller's environment.

webbrowser.register(name, constructor, instance=None)

Register the browser type name. Once a browser type is registered, the get() function can return a controller for that browser type. If instance is not provided, or is None, constructor will be called without parameters to create an instance when needed. If instance is provided, constructor will never be called, and may be None.

This entry point is only useful if you plan to either set the BROWSER variable or call get() with a nonempty argument matching the name of a handler you declare.

A number of browser types are predefined. This table gives the type names that may be passed to the get() function and the corresponding instantiations for the controller classes, all defined in this module.

</tbody>
</table>

Notes:

1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the KDEDIR variable is not sufficient. Note also that the name “kfm” is used even when using the konqueror command with KDE 2 — the implementation selects the best strategy for running Konqueror.
2. Only on Windows platforms.
3. Only on Mac OS X platform.

*New in version 3.3:* Support for Chrome/Chromium has been added.

Here are some simple examples:

```python
url = 'http://docs.python.org/'

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url)

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```
21.1.1. Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions:

controller. `open(url, new=0, autoraise=True)`

Display `url` using the browser handled by this controller. If `new` is 1, a new browser window is opened if possible. If `new` is 2, a new browser page ("tab") is opened if possible.

controller. `open_new(url)`

Open `url` in a new window of the browser handled by this controller, if possible, otherwise, open `url` in the only browser window. Alias `open_new()`.

controller. `open_new_tab(url)`

Open `url` in a new page ("tab") of the browser handled by this controller, if possible, otherwise equivalent to `open_new()`.

Footnotes

[1] Executables named here without a full path will be searched in the directories given in the PATH environment variable.
21.2. **cgi** — Common Gateway Interface support

**Source code:** Lib/cgi.py

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.
21.2.1. Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server’s special cgi-bin directory. The HTTP server places all sorts of information about the request (such as the client’s hostname, the requested URL, the query string, and lots of other goodies) in the script’s shell environment, executes the script, and sends the script’s output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the “query string” part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```python
print("Content-Type: text/html")  # HTML is followed by blank line, end of headers
print()
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here’s Python code that prints a simple piece of HTML:

```python
print("<TITLE>CGI script output</TITLE>")
```
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
21.2.2. Using the cgi module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```python
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you’d rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```python
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It’s very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the `FieldStorage` class. If the form contains non-ASCII characters, use the `encoding` keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the `Content-Type` header). This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.
The FieldStorage instance can be indexed like a Python dictionary. It allows membership testing with the `in` operator, and also supports the standard dictionary method `keys()` and the built-in function `len()`. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the FieldStorage instance.

For instance, the following code (which assumes that the `Content-Type` header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```python
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print("<H1>Error</H1>")
    print("Please fill in the name and addr fields.
return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of FieldStorage (or MiniFieldStorage, depending on the form encoding). The value attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a FieldStorage or MiniFieldStorage instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If
you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```python
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the `value` attribute or the `getvalue()` method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the `filename` attribute or the `file` attribute. You can then read the data from the `file` attribute before it is automatically closed as part of the garbage collection of the `FieldStorage` instance (the `read()` and `readline()` methods will return bytes):

```python
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while True:
        line = fileitem.file.readline()
        if not line: break
    linecount = linecount + 1
```

FieldStorage objects also support being used in a `with` statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object
for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive multipart/* encoding). When this occurs, the item will be a dictionary-like FieldStorage item. This can be determined by testing its type attribute, which should be multipart/form-data (or perhaps another MIME type matching multipart/*). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type application/x-www-form-urlencoded), the items will actually be instances of the class MiniFieldStorage. In this case, the list, file, and filename attributes are always None.

A form submitted via POST that also has a query string will contain both FieldStorage and MiniFieldStorage items.

*Changed in version 3.4:* The file attribute is automatically closed upon the garbage collection of the creating FieldStorage instance.

*Changed in version 3.5:* Added support for the context management protocol to the FieldStorage class.
21.2.3. Higher Level Interface

The previous section explains how to read CGI form data using the FieldStorage class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```python
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```html
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:
The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another user=foo pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the `upper()` method on a list is not valid (since lists do not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

**FieldStorage.getfirst(name, default=None)**

This method always returns only one value associated with form field `name`. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. If no such form field or value exists then the method returns the value specified by the optional parameter `default`. This parameter defaults to None if not specified.

**FieldStorage.getlist(name)**

This method always returns a list of values associated with form field `name`. The method returns an empty list if no such form field or value exists for `name`. It returns a list consisting of one item if
only one such value exists.

Using these methods you can write nice compact code:

```python
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()  # This way it's safe.
for item in form.getlist("item"):
    do_something(item)
```
21.2.4. Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

cgi.\texttt{parse}(fp=None, environ=os.environ, keep_blank_values=False, strict_parsing=False)

Parse a query in the environment or from a file (the file defaults to \texttt{sys.stdin}). The \texttt{keep_blank_values} and \texttt{strict_parsing} parameters are passed to \texttt{urllib.parse.parse_qs()} unchanged.

cgi.\texttt{parse_qs}(qs, keep_blank_values=False, strict_parsing=False)

This function is deprecated in this module. Use \texttt{urllib.parse.parse_qs()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse_qsl}(qs, keep_blank_values=False, strict_parsing=False)

This function is deprecated in this module. Use \texttt{urllib.parse.parse_qsl()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse_multipart}(fp, pdict)

Parse input of type \texttt{multipart/form-data} (for file uploads). Arguments are \texttt{fp} for the input file and \texttt{pdict} for a dictionary containing other parameters in the \texttt{Content-Type} header.

Returns a dictionary just like \texttt{urllib.parse.parse_qs()} keys
are the field names, each value is a list of values for that field. This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the FieldStorage class instead which is much more flexible.

Note that this does not parse nested multipart parts — use FieldStorage for that.

cgi.parse_header(string)
Parse a MIME header (such as Content-Type) into a main value and a dictionary of parameters.

cgi.test()
Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.print_environ()
Format the shell environment in HTML.

cgi.print_form(form)
Format a form in HTML.

cgi.print_directory()
Format the current directory in HTML.

cgi.print_environ_usage()
Print a list of useful (used by CGI) environment variables in HTML.

cgi.escape(s, quote=False)
Convert the characters '&', '<' and '>' in string s to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag quote is true, the
quotation mark character (") is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in `<a href="...">. Note that single quotes are never translated.

*Deprecated since version 3.2:* This function is unsafe because `quote` is false by default, and therefore deprecated. Use `html.escape()` instead.
21.2.5. Caring about security

There’s one important rule: if you invoke an external program (via the `os.system()` or `os.popen()` functions, or others with similar functionality), make very sure you don’t pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn’t have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.
21.2.6. Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory cgi-bin in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be 0o755 octal (use chmod 0755 filename). Make sure that the first line of the script contains #! starting in column 1 followed by the pathname of the Python interpreter, for instance:

```bash
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be 0o644 for readable and 0o666 for writable. This is because, for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (PATH) or the Python module search path (PYTHONPATH) to be set to anything interesting.

If you need to load modules from a directory which is not on Python’s default module search path, you can change the path in your script,
before importing other modules. For example:

```python
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).
21.2.7. Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.
21.2.8. Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (cgi.py) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it’s installed in the standard cgi-bin directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home
```

If this gives an error of type 404, the server cannot find the script — perhaps you need to install it in a different directory. If it gives another error, there’s an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the cgi.py script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the `cgi` module’s `test()` function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the `cgi.py` file itself.
When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can’t be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server’s log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute some code, you can easily send tracebacks to the Web browser using the `cgitb` module. If you haven’t done so already, just add the lines:

```python
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the `cgitb` module, you can use an even more robust approach (which only uses built-in modules):

```python
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML
interpretation is going on, the traceback will be readable.
21.2.9. Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server’s log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — PATH is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server’s suexec feature.
- Don’t try to give a CGI script a set-uid mode. This doesn’t work on most systems, and is a security liability as well.

Footnotes

Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

[1]
21.3. **cgitb — Traceback manager for CGI scripts**

The `cgitb` module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```python
import cgitb
cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```python
cgitb.enable(display=1, logdir=None, context=5, format="html")
```

This function causes the `cgitb` module to take over the interpreter’s default handling for exceptions by setting the value of `sys.excepthook`.

The optional argument `display` defaults to 1 and can be set to 0 to suppress sending the traceback to the browser. If the argument
logdir is present, the traceback reports are written to files. The value of logdir should be a directory where these files will be placed. The optional argument context is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument format is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

```
cgitb.handler(info=None)
```

This function handles an exception using the default settings (that is, show a report in the browser, but don’t log to a file). This can be used when you’ve caught an exception and want to report it using cgitb. The optional info argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the info argument is not supplied, the current exception is obtained from `sys.exc_info()`.
21.4. **wsgiref** — WSGI Utilities and Reference Implementation

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don’t need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

**wsgiref** is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (**PEP 3333**).

See [http://www.wsgi.org](http://www.wsgi.org) for more information about WSGI, and links to tutorials and other resources.
21.4.1. **wsgiref.util** – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in **PEP 3333**. All of the functions taking an `environ` parameter expect a WSGI-compliant dictionary to be supplied; please see **PEP 3333** for a detailed specification.

```python
wsgiref.util.guess_scheme(environ)
```

Return a guess for whether `wsgi.url_scheme` should be “http” or “https”, by checking for a HTTPS environment variable in the `environ` dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a HTTPS variable with a value of “1” “yes”, or “on” when a request is received via SSL. So, this function returns “https” if such a value is found, and “http” otherwise.

```python
wsgiref.util.request_uri(environ, include_query=True)
```

Return the full request URI, optionally including the query string, using the algorithm found in the “URL Reconstruction” section of **PEP 3333**. If `include_query` is false, the query string is not included in the resulting URI.

```python
wsgiref.util.application_uri(environ)
```

Similar to `request_uri()`, except that the PATH_INFO and QUERY_STRING variables are ignored. The result is the base URI of the application object addressed by the request.
wsgiref.util.shift_path_info(environ)

Shift a single name from PATH_INFO0 to SCRIPT_NAME and return the name. The environ dictionary is modified in-place; use a copy if you need to keep the original PATH_INFO0 or SCRIPT_NAME intact.

If there are no remaining path segments in PATH_INFO0, None is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at /foo, and the request URI path is /foo/bar/baz, and the WSGI application at /foo calls shift_path_info(), it will receive the string “bar”, and the environment will be updated to be suitable for passing to a WSGI application at /foo/bar. That is, SCRIPT_NAME will change from /foo to /foo/bar, and PATH_INFO0 will change from /bar/baz to /baz.

When PATH_INFO0 is just a “/”, this routine returns an empty string and appends a trailing slash to SCRIPT_NAME, even though empty path segments are normally ignored, and SCRIPT_NAME doesn’t normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in /x from ones ending in /x/ when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(environ)

Update environ with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including
HTTP_HOST, SERVER_NAME, SERVER_PORT, REQUEST_METHOD, SCRIPT_NAME, PATH_INFO, and all of the PEP 3333-defined wsgi.* variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```python
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print out the
# environment dictionary after being updated by setup_testing_defaults

def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charset=utf-8')]

    start_response(status, headers)

    ret = ['%s: %s
' % (key, value).encode('utf-8')
        for key, value in environ.items()]
    return ret

httpd = make_server('', 8000, simple_app)
print("Serving on port 8000...")
httpd.serve_forever()
```

In addition to the environment functions above, the wsgiref.util
module also provides these miscellaneous utilities:

\texttt{wsgiref.util.is\_hop\_by\_hop(header\_name)}

Return true if ‘header\_name’ is an HTTP/1.1 “Hop-by-Hop” header, as defined by \texttt{RFC 2616}.

\texttt{class wsgiref.util.FileWrapper(filelike, blksize=8192)}

A wrapper to convert a file-like object to an \texttt{iterator}. The resulting objects support both \texttt{\_getitem()} and \texttt{\_iter()} iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional \texttt{blksize} parameter will be repeatedly passed to the \texttt{filelike} object’s \texttt{read()} method to obtain bytestrings to yield. When \texttt{read()} returns an empty bytestring, iteration is ended and is not resumable.

If \texttt{filelike} has a \texttt{close()} method, the returned object will also have a \texttt{close()} method, and it will invoke the \texttt{filelike} object’s \texttt{close()} method when called.

Example usage:

\begin{verbatim}
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like
filelike = StringIO("This is an example file-like
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
\end{verbatim}
This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

```python
class wsgiref.headers.Headers([headers])

Create a mapping-like object wrapping `headers`, which must be a list of header name/value tuples as described in PEP 3333. The default value of `headers` is an empty list.

`Headers` objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()` and `__contains__()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers’ existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, `Headers` objects do not raise an error when you try to get or delete a key that isn’t in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

`Headers` objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a `Headers` object is the same as the length of its
items(), which is the same as the length of the wrapped header list. In fact, the items() method just returns a copy of the wrapped header list.

Calling bytes() on a Headers object returns a formatted bytestring suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the bytestring is terminated with a blank line.

In addition to their mapping interface and formatting features, Headers objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

**get_all(name)**

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

**add_header(name, value, **_params)**

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or None. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include
dashes. If the parameter value is a string, it is added to the header value parameters in the form name="value". If it is None, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```python
h.add_header('content-disposition', 'attachment')
```

The above will add a header that looks like this:

```text
Content-Disposition: attachment; filename="bud.
```

*Changed in version 3.5: headers parameter is optional.*
21.4.3. **wsgiref.simple_server** — a simple WSGI HTTP server

This module implements a simple HTTP server (based on `http.server`) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the `shift_path_info()` function from `wsgiref.util`.)

```python
wsgiref.simple_server.make_server(host, port, app,
server_class=WSGIServer, handler_class=WSGIRequestHandler)
```

Create a new WSGI server listening on `host` and `port`, accepting connections for `app`. The return value is an instance of the supplied `server_class`, and will process requests using the specified `handler_class`. `app` must be a WSGI application object, as defined by **PEP 3333**.

Example usage:

```python
from wsgiref.simple_server import make_server, demo_app

httpd = make_server('', 8000, demo_app)
print("Serving HTTP on port 8000...")

# Respond to requests until process is killed
httpd.serve_forever()

# Alternative: serve one request, then exit
httpd.handle_request()
```
wsgiref.simple_server.demo_app(environ, start_response)

This function is a small but complete WSGI application that returns a text page containing the message “Hello world!” and a list of the key/value pairs provided in the `environ` parameter. It's useful for verifying that a WSGI server (such as `wsgiref.simple_server`) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)

Create a `WSGIServer` instance. `server_address` should be a (host, port) tuple, and `RequestHandlerClass` should be the subclass of `http.server.BaseHTTPRequestHandler` that will be used to process requests.

You do not normally need to call this constructor, as the `make_server()` function can handle all the details for you.

`WSGIServer` is a subclass of `http.server.HTTPServer`, so all of its methods (such as `serve_forever()` and `handle_request()`) are available. `WSGIServer` also provides these WSGI-specific methods:

set_app(application)

Sets the callable `application` as the WSGI application that will receive requests.

get_app()

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as `set_app()` is normally called by `make_server()`, and the `get_app()` exists mainly for the benefit of request handler
instances.

class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)

Create an HTTP handler for the given request (i.e. a socket), client_address (a (host, port) tuple), and server (WSGIServer instance).

You do not need to create instances of this class directly; they are automatically created as needed by WSGIServer objects. You can, however, subclass this class and supply it as a handler_class to the make_server() function. Some possibly relevant methods for overriding in subclasses:

get_environ()

Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the WSGIServer object's base_environ dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in PEP 3333.

get_stderr()

Return the object that should be used as the wsgi.errors stream. The default implementation just returns sys.stderr.

handle()

Process the HTTP request. The default implementation creates a handler instance using a wsgiref.handlers class to implement the actual WSGI application interface.
21.4.4. **wsgiref.validate** — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using `wsgiref.validate`. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete PEP 3333 compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking's "Python Paste" library.

**wsgiref.validate.validator(application)**

Wrap `application` and return a new WSGI application object. The returned application will forward all requests to the original `application`, and will check that both the `application` and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an `AssertionError` being raised; note, however, that how these errors are handled is server-dependent. For example, `wsgiref.simple_server` and other servers based on `wsgiref.handlers` (that don't override the error handling methods to do something else) will simply output
a message that an error has occurred, and dump the traceback to sys.stderr or some other error stream.

This wrapper may also generate output using the warnings module to indicate behaviors that are questionable but which may not actually be prohibited by PEP 3333. Unless they are suppressed using Python command-line options or the warnings API, any such warnings will be written to sys.stderr (not wsgi.errors, unless they happen to be the same object).

Example usage:

```python
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not a standard, so the validator is going to break
def simple_app(env, start_response):
    status = '200 OK' # HTTP Status
    headers = [('Content-type', 'text/plain')] # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

httpd = make_server('', 8000, validator_app)
print("Listening on port 8000....")
httpd.serve_forever()
```
21.4.5. **wsgiref.handlers** – server/gateway base classes

This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

**class wsgiref.handlers.CGIHandler**

CGI-based invocation via sys.stdin, sys.stdout, sys.stderr and os.environ. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke CGIHandler().run(app), where app is the WSGI application object you wish to invoke.

This class is a subclass of BaseCGIHandler that sets wsgi.run_once to true, wsgi.multithread to false, and wsgi.multiprocess to true, and always uses sys and os to obtain the necessary CGI streams and environment.

**class wsgiref.handlers.IISCGIHandler**

A specialized alternative to CGIHandler, for use when deploying on Microsoft’s IIS web server, without having set the config allowPathInfo option (IIS>=7) or metabase allowPathInfoForScriptMappings (IIS<7).

By default, IIS gives a PATH_INFO that duplicates the SCRIPT_NAME at the front, causing problems for WSGI applications that wish to implement routing. This handler strips any such duplicated path.
IIS can be configured to pass the correct PATH_INFO, but this causes another bug where PATH_TRANSLATED is wrong. Luckily this variable is rarely used and is not guaranteed by WSGI. On IIS<7, though, the setting can only be made on a vhost level, affecting all other script mappings, many of which break when exposed to the PATH_TRANSLATED bug. For this reason IIS<7 is almost never deployed with the fix. (Even IIS7 rarely uses it because there is still no UI for it.)

There is no way for CGI code to tell whether the option was set, so a separate handler class is provided. It is used in the same way as CGIHandler, i.e., by calling IISCGIHandler().run(app), where app is the WSGI application object you wish to invoke.

*New in version 3.2.*

```python
class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)
```

Similar to CGIHandler, but instead of using the sys and os modules, the CGI environment and I/O streams are specified explicitly. The multithread and multiprocess values are used to set the wsgi.multithread and wsgi.multiprocess flags for any applications run by the handler instance.

This class is a subclass of SimpleHandler intended for use with software other than HTTP "origin servers". If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a Status: header to send an HTTP status, you probably want to subclass this instead of SimpleHandler.

```python
class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)
```
Similar to `BaseCGIHandler`, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of `BaseCGIHandler`.

This class is a subclass of `BaseHandler`. It overrides the `__init__()`, `get_stdin()`, `get_stderr()`, `add_cgi_vars()`, `__write()`, and `__flush()` methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the `stdin`, `stdout`, `stderr`, and `environ` attributes.

```python
class wsgiref.handlers.BaseHandler
This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

BaseHandler instances have only one method intended for external use:

```python
run(app)
```
Run the specified WSGI application, `app`.

All of the other `BaseHandler` methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:

```python
__write(data)
```
Buffer the bytes `data` for transmission to the client. It’s okay if this method actually transmits the data; `BaseHandler` just
separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

_flush()
Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if _write() actually sends the data).

get_stdin()
Return an input stream object suitable for use as the wsgi.input of the request currently being processed.

get_stderr()
Return an output stream object suitable for use as the wsgi.errors of the request currently being processed.

add_cgi_vars()
Insert CGI variables for the current request into the environ attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized BaseHandler subclass.

Attributes and methods for customizing the WSGI environment:

wsgi_multithread
The value to be used for the wsgi.multithread environment variable. It defaults to true in BaseHandler, but may have a different default (or be set by the constructor) in the other subclasses.
**wsgi_multiprocess**

The value to be used for the wsgi.multiprocess environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_run_once**

The value to be used for the wsgi.run_once environment variable. It defaults to false in `BaseHandler`, but `CGIHandler` sets it to true by default.

**os_environ**

The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that `wsgiref.handlers` was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

**server_software**

If the `origin_server` attribute is set, this attribute's value is used to set the default SERVER_SOFTWARE WSGI environment variable, and also to set a default Server: header in HTTP responses. It is ignored for handlers (such as `BaseCGIHandler` and `CGIHandler`) that are not HTTP origin servers.

*Changed in version 3.3:* The term “Python” is replaced with implementation specific term like “CPython”, “Jython” etc.
get_scheme()
Return the URL scheme being used for the current request. The default implementation uses the guess_scheme() function from wsgiref.util to guess whether the scheme should be “http” or “https”, based on the current request's environ variables.

setup_environ()
Set the environ attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the get_stdin(), get_stderr(), and add_cgi_vars() methods and the wsgi_file_wrapper attribute. It also inserts a SERVER_SOFTWARE key if not present, as long as the origin_server attribute is a true value and the server_software attribute is set.

Methods and attributes for customizing exception handling:

log_exception(exc_info)
Log the exc_info tuple in the server log. exc_info is a (type, value, traceback) tuple. The default implementation simply writes the traceback to the request's wsgi.errors stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

traceback_limit
The maximum number of frames to include in tracebacks output by the default log_exception() method. If None, all frames
are included.

**error_output**(*environ, start_response*)

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to `start_response` when calling it (as described in the “Error Handling” section of [PEP 3333](https://www.python.org/dev/peps/pep-0333/)).

The default implementation just uses the `error_status`, `error_headers`, and `error_body` attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it’s not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn’t include any.

**error_status**

The HTTP status used for error responses. This should be a status string as defined in [PEP 3333](https://www.python.org/dev/peps/pep-0333/); it defaults to a 500 code and message.

**error_headers**

The HTTP headers used for error responses. This should be a list of WSGI response headers ([(name, value) tuples], as described in [PEP 3333](https://www.python.org/dev/peps/pep-0333/). The default list just sets the content type to text/plain.
**error_body**

The error response body. This should be an HTTP response body bytestring. It defaults to the plain text, “A server error occurred. Please contact the administrator.”

Methods and attributes for **PEP 3333**'s “Optional Platform-Specific File Handling” feature:

**wsgi_file_wrapper**

A `wsgi.file_wrapper` factory, or None. The default value of this attribute is the `wsgiref.util.FileWrapper` class.

**sendfile()**

Override to implement platform-specific file transmission. This method is called only if the application's return value is an instance of the class specified by the `wsgi_file_wrapper` attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

**origin_server**

This attribute should be set to a true value if the handler's `_write()` and `_flush()` are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute's default value is true in `BaseHandler`, but false in `BaseCGIHandler` and `CGIHandler`.

**http_version**
If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".

`wsgiref.handlers.read_environ()`

Transcode CGI variables from `os.environ` to PEP 3333 “bytes in unicode” strings, returning a new dictionary. This function is used by `CGIHandler` and `IISCGIHandler` in place of directly using `os.environ`, which is not necessarily WSGI-compliant on all platforms and web servers using Python 3 – specifically, ones where the OS's actual environment is Unicode (i.e. Windows), or ones where the environment is bytes, but the system encoding used by Python to decode it is anything other than ISO-8859-1 (e.g. Unix systems using UTF-8).

If you are implementing a CGI-based handler of your own, you probably want to use this routine instead of just copying values out of `os.environ` directly.

*New in version 3.2.*
21.4.6. Examples

This is a working “Hello World” WSGI application:

```python
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object that accepts two arguments. For that purpose use a function (note that you're not limited to a class for example). The first argument passed is a dictionary containing CGI-style environment variables and the second variable is the callable object (see PEP 333).

def hello_world_app(environ, start_response):
    status = '200 OK' # HTTP Status
    headers = [('Content-type', 'text/plain; charset=utf-8')]
    start_response(status, headers)
    # The returned object is going to be printed
    return [b"Hello World"]

httpd = make_server('', 8000, hello_world_app)
print("Serving on port 8000...")

# Serve until process is killed
httpd.serve_forever()
```
21.5. **urllib** — URL handling modules

urllib is a package that collects several modules for working with URLs:

- **urllib.request** for opening and reading URLs
- **urllib.error** containing the exceptions raised by **urllib.request**
- **urllib.parse** for parsing URLs
- **urllib.robotparser** for parsing robots.txt files
21.6. `urllib.request` — Extensible library for opening URLs

The `urllib.request` module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

**See also:** The Requests package is recommended for a higher-level http client interface.

The `urllib.request` module defines the following functions:

```python
urllib.request.urlopen(url, data=None, [timeout, ], *
cafile=None, capath=None, cadefault=False, context=None)
```

Open the URL `url`, which can be either a string or a `Request` object.

`data` must be a bytes object specifying additional data to be sent to the server, or None if no such data is needed. `data` may also be an iterable object and in that case Content-Length value must be specified in the headers. Currently HTTP requests are the only ones that use `data`; the HTTP request will be a POST instead of a GET when the `data` parameter is provided.

`data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.parse.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format. It should be encoded to bytes before being used as the
data parameter. The charset parameter in Content-Type header may be used to specify the encoding. If charset parameter is not sent with the Content-Type header, the server following the HTTP 1.1 recommendation may assume that the data is encoded in ISO-8859-1 encoding. It is advisable to use charset parameter with encoding used in Content-Type header with the Request.

urllib.request module uses HTTP/1.1 and includes Connection:close header in its HTTP requests.

The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If context is specified, it must be a ssl.SSLContext instance describing the various SSL options. See HTTPSConnection for more details.

The optional cafile and capath parameters specify a set of trusted CA certificates for HTTPS requests. cafile should point to a single file containing a bundle of CA certificates, whereas capath should point to a directory of hashed certificate files. More information can be found in ssl.SSLContext.load_verify_locations().

The cadefault parameter is ignored.

For http and https urls, this function returns a http.client.HTTPResponse object which has the following HTTPResponse Objects methods.

For ftp, file, and data urls and requests explicitly handled by legacy URLopener and FancyURLopener classes, this function returns a
urllib.response.addinfourl object which can work as context manager and has methods such as

- `geturl()` — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- `info()` — return the meta-information of the page, such as headers, in the form of an `email.message_from_string()` instance (see Quick Reference to HTTP Headers)
- `getcode()` – return the HTTP status code of the response.

Raises `URLError` on errors.

Note that None may be returned if no handler handles the request (though the default installed global `OpenerDirector` uses `UnknownHandler` to ensure this never happens).

In addition, if proxy settings are detected (for example, when a `*_proxy` environment variable like `http_proxy` is set), `ProxyHandler` is default installed and makes sure the requests are handled through the proxy.

The legacy `urllib.urlopen` function from Python 2.6 and earlier has been discontinued; `urllib.request.urlopen()` corresponds to the old `urllib2.urlopen`. Proxy handling, which was done by passing a dictionary parameter to `urllib.urlopen`, can be obtained by using `ProxyHandler` objects.

*Changed in version 3.2:* `cafile` and `capath` were added.

*Changed in version 3.2:* HTTPS virtual hosts are now supported if possible (that is, if `ssl.HAS_SNI` is true).

*New in version 3.2:* `data` can be an iterable object.
Changed in version 3.3: cadefault was added.

Changed in version 3.4.3: context was added.

urllib.request.\texttt{install\_opener}(opener)

Install an OpenerDirector instance as the default global opener. Installing an opener is only necessary if you want urlopen to use that opener; otherwise, simply call \texttt{OpenerDirector.open()} instead of \texttt{urlopen()}. The code does not check for a real OpenerDirector, and any class with the appropriate interface will work.

urllib.request.\texttt{build\_opener}([\texttt{handler}, ...])

Return an OpenerDirector instance, which chains the handlers in the order given. handlers can be either instances of BaseHandler, or subclasses of BaseHandler (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the handlers, unless the handlers contain them, instances of them or subclasses of them: ProxyHandler (if proxy settings are detected), UnknownHandler, HTTPDefaultErrorHandler, HTTPRedirectHandler, FTPHandler, FileHandler, HTTPErrorProcessor.

If the Python installation has SSL support (i.e., if the ssl module can be imported), HTTPSHandler will also be added.

A BaseHandler subclass may also change its handler_order attribute to modify its position in the handlers list.

urllib.request.\texttt{pathname2url}(path)

Convert the pathname path from the local syntax for a path to the
form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the \texttt{quote()} function.

\texttt{urllib.request.url2pathname(path)}  
Convert the path component \textit{path} from a percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses \texttt{unquote()} to decode \textit{path}.

\texttt{urllib.request.getproxies()}  
This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named \texttt{<scheme>_proxy}, in a case insensitive approach, for all operating systems first, and when it cannot find it, looks for proxy information from Mac OS X System Configuration for Mac OS X and Windows Systems Registry for Windows.

The following classes are provided:

\texttt{class urllib.request.Request(url, data=None, headers={}, origin_req_host=None, unverifiable=False, method=None)}  
This class is an abstraction of a URL request.

\texttt{url} should be a string containing a valid URL.

\texttt{data} must be a bytes object specifying additional data to send to the server, or None if no such data is needed. Currently HTTP requests are the only ones that use \texttt{data}; the HTTP request will be a POST instead of a GET when the \texttt{data} parameter is provided. \texttt{data} should be a buffer in the standard \texttt{application/x-www-form-urlencoded} format.

The \texttt{urllib.parse.urlencode()} function takes a mapping or
sequence of 2-tuples and returns a string in this format. It should be encoded to bytes before being used as the data parameter. The charset parameter in Content-Type header may be used to specify the encoding. If charset parameter is not sent with the Content-Type header, the server following the HTTP 1.1 recommendation may assume that the data is encoded in ISO-8859-1 encoding. It is advisable to use charset parameter with encoding used in Content-Type header with the Request.

headers should be a dictionary, and will be treated as if add_header() was called with each key and value as arguments. This is often used to “spoon” the User-Agent header, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11", while urllib's default user agent string is "Python-urllib/2.6" (on Python 2.6).

An example of using Content-Type header with data argument would be sending a dictionary like {"Content-Type": "application/x-www-form-urlencoded; charset=utf-8"}.

The final two arguments are only of interest for correct handling of third-party HTTP cookies:

origin_req_host should be the request-host of the origin transaction, as defined by RFC 2965. It defaults to http.cookiejar.request_host(self). This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the
page containing the image.

unverifiable should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to False. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

method should be a string that indicates the HTTP request method that will be used (e.g. 'HEAD'). If provided, its value is stored in the method attribute and is used by get_method(). Subclasses may indicate a default method by setting the method attribute in the class itself.

Changed in version 3.3: Request.method argument is added to the Request class.

Changed in version 3.4: Default Request.method may be indicated at the class level.

class urllib.request.OpenerDirector

The OpenerDirector class opens URLs via BaseHandlers chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.BaseHandler

This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib.request.HTTPDefaultErrorHandler

A class which defines a default handler for HTTP error responses; all responses are turned into HTTPError exceptions.
class urllib.request.HTTPRedirectHandler
    A class to handle redirections.

class urllib.request.HTTPCookieProcessor(cookiejar=None)
    A class to handle HTTP Cookies.

class urllib.request.ProxyHandler(proxies=None)
    Cause requests to go through a proxy. If proxies is given, it must be
    a dictionary mapping protocol names to URLs of proxies. The
default is to read the list of proxies from the environment variables
<protocol>_proxy. If no proxy environment variables are set,
then in a Windows environment proxy settings are obtained from
the registry's Internet Settings section, and in a Mac OS X
environment proxy information is retrieved from the OS X System
Configuration Framework.

    To disable autodetected proxy pass an empty dictionary.

class urllib.request.HTTPPasswordMgr
    Keep a database of (realm, uri) -> (user, password)
mappings.

class urllib.request.HTTPPasswordMgrWithDefaultRealm
    Keep a database of (realm, uri) -> (user, password)
mappings. A realm of None is considered a catch-all realm, which
is searched if no other realm fits.

class urllib.request.HTTPPasswordMgrWithPriorAuth
    A variant of HTTPPasswordMgrWithDefaultRealm that also
has a database of uri -> is_authenticated mappings. Can
be used by a BasicAuth handler to determine when to send
authentication credentials immediately instead of waiting for a 401 response first.

*New in version 3.5.*

class urllib.request.AbstractBasicAuthHandler(password_mngr=None)

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mngr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported. If `passwd_mgr` also provides `is_authenticated` and `update_authenticated` methods (see `HTTPPasswordMgrWithPriorAuth Objects`), then the handler will use the `is_authenticated` result for a given URI to determine whether or not to send authentication credentials with the request. If `is_authenticated` returns `True` for the URI, credentials are sent. If `is_authenticated` is `False`, credentials are not sent, and then if a 401 response is received the request is re-sent with the authentication credentials. If authentication succeeds, `update_authenticated` is called to set `is_authenticated` `True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

*New in version 3.5: Added `is_authenticated` support.*

class urllib.request.HTTPBasicAuthHandler(password_mngr=None)

Handle authentication with the remote host. `password_mngr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects`
for information on the interface that must be supported. HTTPBasicAuthHandler will raise a `ValueError` when presented with a wrong Authentication scheme.

class urllib.request.ProxyBasicAuthHandler(password_mgr=None)
    Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib.request.AbstractDigestAuthHandler(password_mgr=None)
    This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib.request.HTTPDigestAuthHandler(password_mgr=None)
    Handle authentication with the remote host. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a `ValueError` when presented with an authentication scheme other than Digest or Basic.
Changed in version 3.3: Raise `ValueError` on unsupported Authentication Scheme.

class urllib.request.ProxyDigestAuthHandler(password_mgr):
    Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib.request.HTTPHandler
    A class to handle opening of HTTP URLs.

class urllib.request.HTTPSHandler(debuglevel=0, context=None, check_hostname=None)
    A class to handle opening of HTTPS URLs. `context` and `check_hostname` have the same meaning as in `http.client.HTTPSConnection`.

    Changed in version 3.2: `context` and `check_hostname` were added.

class urllib.request.FileHandler
    Open local files.

class urllib.request.DataHandler
    Open data URLs.

    New in version 3.4.

class urllib.request.FTPHandler
    Open FTP URLs.

class urllib.request.CacheFTPHandler
    Open FTP URLs, keeping a cache of open FTP connections to
minimize delays.

`class urllib.request.UnknownHandler`
A catch-all class to handle unknown URLs.

`class urllib.request.HTTPErrorProcessor`
Process HTTP error responses.
21.6.1. Request Objects

The following methods describe `Request`'s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request.**full_url**

The original URL passed to the constructor.

*Changed in version 3.4.*

Request.full_url is a property with setter, getter and a deleter. Getting **full_url** returns the original request URL with the fragment, if it was present.

Request.**type**

The URI scheme.

Request.**host**

The URI authority, typically a host, but may also contain a port separated by a colon.

Request.**origin_req_host**

The original host for the request, without port.

Request.**selector**

The URI path. If the `Request` uses a proxy, then selector will be the full url that is passed to the proxy.

Request.**data**

The entity body for the request, or None if not specified.

*Changed in version 3.4:* Changing value of `Request.data` now
deletes “Content-Length” header if it was previously set or calculated.

Request.unverifiable

boolean, indicates whether the request is unverifiable as defined by RFC 2965.

Request.method

The HTTP request method to use. By default its value is None, which means that get_method() will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in get_method()) either by providing a default value by setting it at the class level in a Request subclass, or by passing a value in to the Request constructor via the method argument.

New in version 3.3.

Changed in version 3.4: A default value can now be set in subclasses; previously it could only be set via the constructor argument.

Request.get_method()

Return a string indicating the HTTP request method. If Request.method is not None, return its value, otherwise return 'GET' if Request.data is None, or 'POST' if it's not. This is only meaningful for HTTP requests.

Changed in version 3.3: get_method now looks at the value of Request.method.

Request.add_header(key, val)

Add another header to the request. Headers are currently ignored
by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the `key` collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request `.add_unredirected_header(key, header)`
Add a header that will not be added to a redirected request.

Request `.has_header(header)`
Return whether the instance has the named header (checks both regular and unredirected).

Request `.remove_header(header)`
Remove named header from the request instance (both from regular and unredirected headers).

*New in version 3.4.*

Request `.get_full_url()`
Return the URL given in the constructor.

*Changed in version 3.4.*

Returns `Request.full_url`

Request `.set_proxy(host, type)`
Prepare the request by connecting to a proxy server. The `host` and `type` will replace those of the instance, and the instance's selector will be the original URL given in the constructor.
Request.\texttt{get\_header}(header\_name, default=\texttt{None})

Return the value of the given header. If the header is not present, return the default value.

Request.\texttt{header\_items}()

Return a list of tuples (header\_name, header\_value) of the Request headers.

\textit{Changed in version 3.4:} The request methods \texttt{add\_data}, \texttt{has\_data}, \texttt{get\_data}, \texttt{get\_type}, \texttt{get\_host}, \texttt{get\_selector}, \texttt{get\_origin\_req\_host} and \texttt{is\_unverifiable} that were deprecated since 3.3 have been removed.
21.6.2. OpenerDirector Objects

**OpenerDirector** instances have the following methods:

**OpenerDirector.**`add_handler(handler)`

*handler* should be an instance of **BaseHandler**. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- **protocol_open()** — signal that the handler knows how to open protocol URLs.
- **http_error_type()** — signal that the handler knows how to handle HTTP errors with HTTP error code *type*.
- **protocol_error()** — signal that the handler knows how to handle errors from (non-http) protocol.
- **protocol_request()** — signal that the handler knows how to pre-process protocol requests.
- **protocol_response()** — signal that the handler knows how to post-process protocol responses.

**OpenerDirector.**`open(url, data=None[, timeout])`

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of `urlopen()` (which simply calls the `open()` method on the currently installed global **OpenerDirector**). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).
OpenerDirector.error(proto, *args)

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the http_error_*() methods of the handler classes.

Return values and exceptions raised are the same as those of urlopen().

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like protocol_request() has that method called to pre-process the request.

2. Handlers with a method named like protocol_open() are called to handle the request. This stage ends when a handler either returns a non-None value (ie. a response), or raises an exception (usually URLError). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named default_open(). If all such methods return None, the algorithm is repeated for methods named like protocol_open(). If all such methods return None, the algorithm is repeated for methods named unknown_open().

Note that the implementation of these methods may involve calls of the parent OpenerDirector instance's open() and error()
methods.

3. Every handler with a method named like `protocol_response()` has that method called to post-process the response.
21.6.3. BaseHandler Objects

BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

BaseHandler .add_parent(director)

Add a director as parent.

BaseHandler .close()

Remove any parents.

The following attribute and methods should only be used by classes derived from BaseHandler.

Note: The convention has been adopted that subclasses defining protocol_request() or protocol_response() methods are named *Processor; all others are named *Handler.

BaseHandler .parent

A valid OpenerDirector, which can be used to open using a different protocol, or handle errors.

BaseHandler .default_open(req)

This method is not defined in BaseHandler, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent OpenerDirector. It should return a file-like object as described in the return value of the open() of OpenerDirector, or None. It should raise URLError, unless a truly exceptional thing happens
(for example, MemoryError should not be mapped to URLError).

This method will be called before any protocol-specific open method.

BaseHandler.\texttt{protocol\_open}(\textit{req})
This method is \textit{not} defined in BaseHandler, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent OpenerDirector. Return values should be the same as for \texttt{default\_open}().

BaseHandler.\texttt{unknown\_open}(\textit{req})
This method is \textit{not} defined in BaseHandler, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent OpenerDirector. Return values should be the same as for \texttt{default\_open}().

BaseHandler.\texttt{http\_error\_default}(\textit{req}, \textit{fp}, \textit{code}, \textit{msg}, \textit{hdrs})
This method is \textit{not} defined in BaseHandler, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the OpenerDirector getting the error, and should not normally be called in other circumstances.

\textit{req} will be a Request object, \textit{fp} will be a file-like object with the HTTP error body, \textit{code} will be the three-digit code of the error, \textit{msg} will be the user-visible explanation of the code and \textit{hdrs} will be a
mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of `urlopen()`.

`BaseHandler.http_error_nnn(req, fp, code, msg, hdrs)`

`nnn` should be a three-digit HTTP error code. This method is also not defined in `BaseHandler`, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code `nnn` occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for `http_error_default()`.

`BaseHandler.protocol_request(req)`

This method is `not` defined in `BaseHandler`, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. `req` will be a `Request` object. The return value should be a `Request` object.

`BaseHandler.protocol_response(req, response)`

This method is `not` defined in `BaseHandler`, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. `req` will be a `Request` object. `response` will be an object implementing the same interface as the return value of
urlopen(). The return value should implement the same interface as the return value of urlopen().
21.6.4. HTTPRedirectHandler Objects

Note: Some HTTP redirecions require action from this module's client code. If this is the case, HTTPError is raised. See RFC 2616 for details of the precise meanings of the various redirection codes.

An HTTPError exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected url which is not an HTTP, HTTPS or FTP url.

HTTPRedirectHandler. redirect_request(req, fp, code, msg, hdrs, newurl)

Return a Request or None in response to a redirect. This is called by the default implementations of the http_error_30*() methods when a redirection is received from the server. If a redirection should take place, return a new Request to allow http_error_30*() to perform the redirect to newurl. Otherwise, raise HTTPError if no other handler should try to handle this URL, or return None if you can’t but another handler might.

Note: The default implementation of this method does not strictly follow RFC 2616, which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

HTTPRedirectHandler. http_error_301(req, fp, code, msg, hdrs)

Redirect to the Location: or URI: URL. This method is called by
the parent **OpenerDirector** when getting an HTTP 'moved permanently' response.

HTTPRedirectHandler.**http_error_302**(req, fp, code, msg, hdrs)

The same as **http_error_301()**, but called for the ‘found’ response.

HTTPRedirectHandler.**http_error_303**(req, fp, code, msg, hdrs)

The same as **http_error_301()**, but called for the ‘see other’ response.

HTTPRedirectHandler.**http_error_307**(req, fp, code, msg, hdrs)

The same as **http_error_301()**, but called for the ‘temporary redirect’ response.
21.6.5. HTTPCookieProcessor Objects

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor.**cookiejar**

The http.cookiejar.CookieJar in which cookies are stored.
21.6.6. ProxyHandler Objects

ProxyHandler.\texttt{protocol\_open}(\textit{request})

The \texttt{ProxyHandler} will have a method \texttt{protocol\_open()} for every \texttt{protocol} which has a proxy in the \texttt{proxies} dictionary given in the constructor. The method will modify requests to go through the proxy, by calling \texttt{request.set\_proxy()}, and call the next handler in the chain to actually execute the protocol.
21.6.7. HTTPPasswordMgr Objects

These methods are available on HTTPPasswordMgr and HTTPPasswordMgrWithDefaultRealm objects.

HTTPPasswordMgr.add_password(realm, uri, user, passwd)

uri can be either a single URI, or a sequence of URIs. realm, user and passwd must be strings. This causes (user, passwd) to be used as authentication tokens when authentication for realm and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.find_user_password(realm, authuri)

Get user/password for given realm and URI, if any. This method will return (None, None) if there is no matching user/password.

For HTTPPasswordMgrWithDefaultRealm objects, the realm None will be searched if the given realm has no matching user/password.
21.6.8. HTTPPasswordMgrWithPriorAuth Objects

This password manager extends HTTPPasswordMgrWithDefaultRealm to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.add_password(realm, uri, user, passwd, is_authenticated=False)

realm, uri, user, passwd are as for HTTPPasswordMgr.add_password(). is_authenticated sets the initial value of the is_authenticated flag for the given URI or list of URIs. If is_authenticated is specified as True, realm is ignored.

HTTPPasswordMgr.find_user_password(realm, authuri)

Same as for HTTPPasswordMgrWithDefaultRealm objects

HTTPPasswordMgrWithPriorAuth.update_authenticated(uri, is_authenticated=False)

Update the is_authenticated flag for the given uri or list of URIs.

HTTPPasswordMgrWithPriorAuth.is_authenticated(self, authuri)

Returns the current state of the is_authenticated flag for the given URI.
21.6.9. AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler.http_error_auth_reqed(authreq, host, req, headers)

Handle an authentication request by getting a user/password pair, and re-trying the request. authreq should be the name of the header where the information about the realm is included in the request, host specifies the URL and path to authenticate for, req should be the (failed) Request object, and headers should be the error headers.

host is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
21.6.10. HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler.\texttt{http\_error\_401}(req, \textit{fp}, \textit{code}, \textit{msg}, \textit{hdrs})

Retry the request with authentication information, if available.
21.6.11. ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.\texttt{http\_error\_407}(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.12. AbstractDigestAuthHandler

Objects

AbstractDigestAuthHandler.\texttt{http_error_auth_required}(\texttt{authreq}, \texttt{host}, \texttt{req}, \texttt{headers})

\texttt{authreq} should be the name of the header where the information about the realm is included in the request, \texttt{host} should be the host to authenticate to, \texttt{req} should be the (failed) \texttt{Request} object, and \texttt{headers} should be the error headers.
21.6.13. HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.\texttt{http\_error\_401}(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.

ProxyDigestAuthHandler.http_error_407(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.15. HTTPHandler Objects

HTTPHandler.\texttt{http\_open}(\texttt{req})
Send an HTTP request, which can be either GET or POST, depending on \texttt{req.has\_data}().
21.6.16. HTTPSHandler Objects

HTTPSHandler.\texttt{https\_open}(\textit{req})

Send an HTTPS request, which can be either GET or POST, depending on \textit{req}.\texttt{has\_data}().
21.6.17. FileHandler Objects

FileHandler.\texttt{\textbf{file\_open}}(\texttt{req})

Open the file locally, if there is no host name, or the host name is 'localhost'.

\textit{Changed in version 3.2:} This method is applicable only for local hostnames. When a remote hostname is given, an \texttt{URLError} is raised.
21.6.18. DataHandler Objects

DataHandler\texttt{.data\_open}(req)
Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in \texttt{RFC 2397}. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don’t mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise an \texttt{ValueError} in that case.
21.6.19. FTPHandler Objects

FTPHandler.\texttt{ftp\_open}(\textit{req})

Open the FTP file indicated by \textit{req}. The login is always done with empty username and password.
21.6.20. CacheFTPHandler Objects

CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler.\texttt{setTimeout}(t)

Set timeout of connections to $t$ seconds.

CacheFTPHandler.\texttt{setMaxConns}(m)

Set maximum number of cached connections to $m$. 
21.6.21. UnknownHandler Objects

UnknownHandler.\texttt{unknown\_open()}

Raise a \texttt{URLError} exception.
HTTPErrorProcessor Objects

HTTPErrorProcessor. `http_response()`
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the `protocol_error_code()` handler methods, via `OpenerDirector.error()`. Eventually, `HTTPDefaultErrorHandler` will raise an `HTTPError` if no other handler handles the error.

HTTPErrorProcessor. `https_response()`
Process HTTPS error responses.

The behavior is same as `http_response()`.
This example gets the python.org main page and displays the first 300 bytes of it.

```python
>>> import urllib.request

>>> with urllib.request.urlopen('http://www.python.org/') as f:
    print(f.read(300))
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the http server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, [http://www.w3.org/International/O-charset](http://www.w3.org/International/O-charset), lists the various ways in which a (X)HTML or a XML document could have specified its encoding information.

As the python.org website uses utf-8 encoding as specified in its meta tag, we will use the same for decoding the bytes object.

```python
>>> with urllib.request.urlopen('http://www.python.org/') as f:
    print(f.read(100).decode('utf-8'))
```
It is also possible to achieve the same result without using the context manager approach.

```python
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/)
>>> print(f.read(100).decode('utf-8'))
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" http://www.w3.org/TR/xhtml1/DTD/xhtml1-1.dtd>
...
```

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```python
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/cgi-bin/test.cgi'
... data=b'This data is passed to stdin of the CGI'
>>> with urllib.request.urlopen(req) as f:
... print(f.read().decode('utf-8'))
... Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is:

```python
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain

Got Data: "%s"
```
Use of Basic HTTP Authentication:

```python
import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                           uri='https://mahler:8092/site-updates.py',
                           user='klem',
                           passwd='kadidd!ehopper')
operator = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urllib.request.urlopen(opener)
urllib.request.urlopen('http://www.example.com/login.html')
```

`build_opener()` provides many handlers by default, including a `ProxyHandler`. By default, `ProxyHandler` uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the `http_proxy` environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default `ProxyHandler` with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with `ProxyBasicAuthHandler`.

```python
proxy_handler = urllib.request.ProxyHandler({'http':
                                           'https':
                                           proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'user'
```
Adding HTTP headers:

Use the `headers` argument to the `Request` constructor, or:

```python
import urllib.request
req = urllib.request.Request('http://www.example.com')
req.add_header('Referer', 'http://www.python.org/')
r = urllib.request.urlopen(req)
```

`OpenerDirector` automatically adds a `User-Agent` header to every `Request`. To change this:

```python
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/')
```

Also, remember that a few standard headers (`Content-Length`, `Content-Type` without charset parameter and `Host`) are added when the `Request` is passed to `urlopen()` (or `OpenerDirector.open()`).

Here is an example session that uses the GET method to retrieve a URL containing parameters:

```python
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'egg': 2})
>>> url = "http://www.musical.com/cgi-bin/query?%s"
```
The following example uses the POST method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```python
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs': 2})
>>> data = data.encode('utf-8')
>>> request = urllib.request.Request("http://requestb.in/xrbl82xr"
>>> # adding charset parameter to the Content-Type header.
>>> request.add_header("Content-Type","application/x-www-form-urlencoded; charset=utf-8")
>>> with urllib.request.urlopen(request, data) as f:
...    print(f.read().decode('utf-8'))
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> with opener.open("http://www.python.org") as f:
...    f.read().decode('utf-8')
```

The following example uses no proxies at all, overriding environment settings:

```python
>>> import urllib.request
```
>>> opener = urllib.request.FancyURLopener({})
>>> with opener.open("http://www.python.org/") as f:
...    f.read().decode('utf-8')
...
21.6.24. Legacy interface

The following functions and classes are ported from the Python 2 module urllib (as opposed to urllib2). They might become deprecated at some point in the future.

urllib.request.urlretrieve(url, filename=None, reporthook=None, data=None)

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple (filename, headers) where filename is the local file name under which the object can be found, and headers is whatever the info() method of the object returned by urlopen() returned (for a remote object). Exceptions are the same as for urlopen().

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be -1 on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```python
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve
>>> html = open(local_filename)
```
If the url uses the http: scheme identifier, the optional data argument may be given to specify a POST request (normally the request type is GET). The data argument must be a bytes object in standard application/x-www-form-urlencoded format; see the urllib.parse.urlencode() function.

urlretrieve() will raise ContentTooShortError when it detects that the amount of data available was less than the expected amount (which is the size reported by a Content-Length header). This can occur, for example, when the download is interrupted.

The Content-Length is treated as a lower bound: if there's more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the content attribute of the exception instance.

If no Content-Length header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

urllib.request.urlopen()

Cleans up temporary files that may have been left behind by previous calls to urlretrieve().

class urllib.request.URLopener(proxies=None, **x509)

Deprecated since version 3.3.
Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than http:, ftp:, or file:, you probably want to use FancyURLopener.

By default, the URLopener class sends a User-Agent header of urllib/VVV, where VVV is the urllib version number. Applications can define their own User-Agent header by subclassing URLopener or FancyURLopener and setting the class attribute version to an appropriate string value in the subclass definition.

The optional proxies parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is None, in which case environmental proxy settings will be used if present, as discussed in the definition of urlopen(), above.

Additional keyword parameters, collected in x509, may be used for authentication of the client when using the https: scheme. The keywords key_file and cert_file are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an OSError exception if the server returns an error code.

**open**(fullurl, data=None)

Open fullurl using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, open_unknown() is called. The data argument has the same meaning as the data
argument of `urlopen()`.

**open_unknown**(`fullurl`, `data=None`)

Overridable interface to open unknown URL types.

**retrieve**(`url`, `filename=None`, `reporthook=None`, `data=None`)

Retrieves the contents of `url` and places it in `filename`. The return value is a tuple consisting of a local filename and either an `email.message.Message` object containing the response headers (for remote URLs) or None (for local URLs). The caller must then open and read the contents of `filename`. If `filename` is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and `filename` is not given, the filename is the output of `tempfile.mktemp()` with a suffix that matches the suffix of the last path component of the input URL. If `reporthook` is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. `reporthook` is ignored for local URLs.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a POST request (normally the request type is GET). The `data` argument must in standard `application/x-www-form-urlencoded` format; see the `urllib.parse.urlencode()` function.

**version**

Variable that specifies the user agent of the opener object.
To get `urllib` to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.

```python
class urllib.request.FancyURLopener(...)
```

*Deprecated since version 3.3.*

`FancyURLopener` subclasses `URLopener` providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the `Location` header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the `maxtries` attribute, which defaults to 10.

For all other response codes, the method `http_error_default()` is called which you can override in subclasses to handle the error appropriately.

**Note:** According to the letter of [RFC 2616](https://tools.ietf.org/html/rfc2616), 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and `urllib` reproduces this behaviour.

The parameters to the constructor are the same as those for `URLopener`.

**Note:** When performing basic authentication, a `FancyURLopener` instance calls its `prompt_user_passwd()` method. The default implementation asks the users for the required information on the controlling terminal. A subclass may
override this method to support more appropriate behavior if needed.

The FancyURLopener class offers one additional method that should be overloaded to provide the appropriate behavior:

**prompt_user_passwd**(host, realm)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, (user, password), which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.
21.6.25. `urllib.request` Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  *Changed in version 3.4:* Added support for data URLs.

- The caching feature of `urllibretrieve()` has been disabled until someone finds the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The `urlopen()` and `urllibretrieve()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

- The data returned by `urlopen()` or `urllibretrieve()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `html.parser` to parse it.

- The code handling the FTP protocol cannot differentiate between
a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a /, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the `ftplib` module, subclassing `FancyURLopener`, or changing `_urloper` to meet your needs.
21.7. `urllib.response` — Response classes used by `urllib`

The `urllib.response` module defines functions and classes which define a minimal file like interface, including `read()` and `readline()`. The typical response object is an `addinfourl` instance, which defines an `info()` method and that returns headers and a `geturl()` method that returns the url. Functions defined by this module are used internally by the `urllib.request` module.
This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: file, ftp, gopher, hdl, http, https, imap, mailto, mms, news, nntp, prospero, rsync, rtsp, rtspu, sftp, shttp, sip, sips, snews, svn, svn+ssh, telnet, wais.

The urllib.parse module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.
21.8.1. URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

```
urllib.parse.urlparse(urlstring, scheme='', allow_fragments=True)
```

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the `path` component, which is retained if present. For example:

```
>>> from urllib.parse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')

>>> o.scheme
'http'

>>> o.port
80

>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in RFC 1808, urlparse recognizes a netloc only if it is properly introduced by '//'. Otherwise the input is presumed to be a relative URL and thus to start with a
from urllib.parse import urlparse

>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')

>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/%7Eguido/Python.html', params='', query='', fragment='')

>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', params='', query='', fragment='')

The `scheme` argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as `urlstring`, except that the default value '' is always allowed, and is automatically converted to b'' if appropriate.

If the `allow_fragments` argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and `fragment` is set to the empty string in the return value.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td><code>scheme parameter</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Network location</td>
<td></td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>part</td>
<td>empty string</td>
</tr>
<tr>
<td>--------</td>
<td>---</td>
<td>------</td>
<td>--------------</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>params</td>
<td>3</td>
<td>Parameters for last path element</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>4</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>5</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td>None</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td>None</td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

See section [Structured Parse Results](#) for more information on the result object.

*Changed in version 3.2:* Added IPv6 URL parsing capabilities.

*Changed in version 3.3:* The fragment is now parsed for all URL schemes (unless allow_fragment is false), in accordance with [RFC 3986](https://tools.ietf.org/html/rfc3986). Previously, a whitelist of schemes that support fragments existed.

```python
urllib.parse.parse_qs(qs, keep_blank_values=False, strict_parsing=False, encoding='utf-8', errors='replace')
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument `keep_blank_values` is a flag indicating
whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlencode()` function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

`Changed in version 3.2: Add encoding and errors parameters.`

`urllib.parse.parse_qsl(qs, keep_blank_values=False, strict_parsing=False, encoding='utf-8', errors='replace')`

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a list of name, value pairs.

The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.
The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlenconde()` function to convert such lists of pairs into query strings.

*Changed in version 3.2:* Add `encoding` and `errors` parameters.

`urllib.parse.urlunparse(parts)`

Construct a URL from a tuple as returned by `urlparse()`. The `parts` argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

`urllib.parse.urlsplit(urlstring, scheme='', allow_fragments=True)`

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the path portion of the URL (see RFC 2396) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience
attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>scheme parameter</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>3</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>4</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td>None</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td>None</td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

See section Structured Parse Results for more information on the result object.

urllib.parse.urlunsplit(parts)

Combine the elements of a tuple as returned by urlsplit() into a complete URL as a string. The parts argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

urllib.parse.urljoin(base, url, allow_fragments=True)

Construct a full (“absolute”) URL by combining a “base URL” (base)
with another URL (url). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```python
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'http://www.cwi.nl/%7Eguido/FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The allow_fragments argument has the same meaning and default as for urlparse().

**Note:** If url is an absolute URL (that is, starting with // or scheme://), the url's host name and/or scheme will be present in the result. For example:

```python
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the url with urlsplit() and urlunsplit(), removing possible scheme and netloc parts.

*Changed in version 3.5:* Behaviour updated to match the semantics defined in RFC 3986.

**urlib.parse.urldefrag(url)**

If url contains a fragment identifier, return a modified version of url with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in url, return url unmodified and an empty string.
The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>0</td>
<td>URL with no fragment</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>1</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
</tbody>
</table>

See section [Structured Parse Results](#) for more information on the result object.

*Changed in version 3.2:* Result is a structured object rather than a simple 2-tuple.
21.8.2. Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on bytes and bytearray objects in addition to str objects.

If str data is passed in, the result will also contain only str data. If bytes or bytearray data is passed in, the result will contain only bytes data.

Attempting to mix str data with bytes or bytearray in a single function call will result in a TypeError being raised, while attempting to pass in non-ASCII byte values will trigger UnicodeDecodeError.

To support easier conversion of result objects between str and bytes, all return values from URL parsing functions provide either an encode() method (when the result contains str data) or a decode() method (when the result contains bytes data). The signatures of these methods match those of the corresponding str and bytes methods (except that the default encoding is 'ascii' rather than 'utf-8'). Each produces a value of a corresponding type that contains either bytes data (for encode() methods) or str data (for decode() methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.
The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

*Changed in version 3.2:* URL parsing functions now accept ASCII encoded byte sequences
21.8.3. Structured Parse Results

The result objects from the `urlparse()`, `urlsplit()` and `urldefrag()` functions are subclasses of the `tuple` type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

`urllib.parse.SplitResult.geturl()`

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For `urldefrag()` results, only empty fragment identifiers will be removed. For `urlsplit()` and `urlparse()` results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```python
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured
parse results when operating on `str` objects:

```python
class urllib.parse.DefragResult(url, fragment)
    Concrete class for urldefrag() results containing `str` data. The encode() method returns a DefragResultBytes instance.

    New in version 3.2.
```

```python
class urllib.parse.ParseResult(scheme, netloc, path, params, query, fragment)
    Concrete class for urlparse() results containing `str` data. The encode() method returns a ParseResultBytes instance.

    New in version 3.2.
```

```python
class urllib.parse.SplitResult(scheme, netloc, path, query, fragment)
    Concrete class for urlsplit() results containing `str` data. The encode() method returns a SplitResultBytes instance.
```

The following classes provide the implementations of the parse results when operating on `bytes` or `bytearray` objects:

```python
class urllib.parse.DefragResultBytes(url, fragment)
    Concrete class for urldefrag() results containing `bytes` data. The decode() method returns a DefragResult instance.

    New in version 3.2.
```

```python
class urllib.parse.ParseResultBytes(scheme, netloc, path, params, query, fragment)
    Concrete class for urlparse() results containing `bytes` data. The decode() method returns a ParseResult instance.

    New in version 3.2.
```
class urllib.parse.SplitResultBytes(scheme, netloc, path, query, fragment)

Concrete class for urlsplit() results containing bytes data. The decode() method returns a SplitResult instance.

New in version 3.2.
21.8.4. URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

```
urllib.parse.quote(string, safe='/', encoding=None, errors=None)
```

Replace special characters in `string` using the `%xx` escape. Letters, digits, and the characters '_.-' are never quoted. By default, this function is intended for quoting the path section of URL. The optional `safe` parameter specifies additional ASCII characters that should not be quoted — its default value is '/'.

`string` may be either a `str` or a `bytes`.

The optional `encoding` and `errors` parameters specify how to deal with non-ASCII characters, as accepted by the `str.encode()` method. `encoding` defaults to 'utf-8'. `errors` defaults to 'strict', meaning unsupported characters raise a `UnicodeEncodeError`. `encoding` and `errors` must not be supplied if `string` is a `bytes`, or a `TypeError` is raised.

Note that `quote(string, safe, encoding, errors)` is equivalent to `quote_from_bytes(string.encode(encoding, errors), safe)`. 
Example: `quote('/El Niño/')` yields '/El%20Ni%C3%B1o/'.

`urllib.parse.quote_plus(string, safe='', encoding=None, errors=None)`

Like `quote()`, but also replace spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in `safe`. It also does not have `safe` default to '/'.

Example: `quote_plus('/El Niño/')` yields '%2FEl+Ni%C3%B1o%2F'.

`urllib.parse.quote_from_bytes(bytes, safe='')`  
Like `quote()`, but accepts a `bytes` object rather than a `str`, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields 'a%26%EF'.

`urllib.parse.unquote(string, encoding='utf-8', errors='replace')`  
Replace %xx escapes by their single-character equivalent. The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

`string` must be a `str`.

`encoding` defaults to 'utf-8'. `errors` defaults to 'replace', meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields '/El Niño/'.

urllib.parse.unquote_plus(string, encoding='utf-8', errors='replace')

Like unquote(), but also replace plus signs by spaces, as required for unquoting HTML form values.

string must be a str.

Example: unquote_plus('/El+Ni%C3%B1o/') yields '/El Niño/'.

urllib.parse.unquote_to_bytes(string)

Replace %xx escapes by their single-octet equivalent, and return a bytes object.

string may be either a str or a bytes.

If it is a str, unescaped non-ASCII characters in string are encoded into UTF-8 bytes.

Example: unquote_to_bytes('a%26%EF') yields b'a&\xef'.

urllib.parse.urlencode(query, doseq=False, safe='', encoding=None, errors=None, quote_via=quote_plus)

Convert a mapping object or a sequence of two-element tuples, which may contain str or bytes objects, to a “percent-encoded” string. If the resultant string is to be used as a data for POST operation with urlopen() function, then it should be properly encoded to bytes, otherwise it would result in a TypeError.

The resulting string is a series of key=value pairs separated by '&' characters, where both key and value are quoted using the quote_via function. By default, quote_plus() is used to quote
the values, which means spaces are quoted as a ' + ' character and '/' characters are encoded as %2F, which follows the standard for GET requests (application/x-www-form-urlencoded). An alternate function that can be passed as quote_via is quote(), which will encode spaces as %20 and not encode '/' characters. For maximum control of what is quoted, use quote and specify a value for safe.

When a sequence of two-element tuples is used as the query argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter doseq is evaluates to True, individual key=value pairs separated by '& ' are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

The safe, encoding, and errors parameters are passed down to quote_via (the encoding and errors parameters are only passed when a query element is a str).

To reverse this encoding process, parse_qs() and parse_qsl() are provided in this module to parse query strings into Python data structures.

Refer to urllib examples to find out how urlencode method can be used for generating query string for a URL or data for POST.

Changed in version 3.2: Query parameter supports bytes and string objects.

New in version 3.5: quote_via parameter.

**RFC 3986 - Uniform Resource Identifiers**  
This is the current standard (STD66). Any changes to urllib.parse module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732 - Format for Literal IPv6 Addresses in URL's.**  
This specifies the parsing requirements of IPv6 URLs.

**RFC 2396 - Uniform Resource Identifiers (URI): Generic Syntax**  
Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

**RFC 2368 - The mailto URL scheme.**  
Parsing requirements for mailto url schemes.

**RFC 1808 - Relative Uniform Resource Locators**  
This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 1738 - Uniform Resource Locators (URL)**  
This specifies the formal syntax and semantics of absolute URLs.
21.9. `urllib.error` — Exception classes raised by `urllib.request`

The `urllib.error` module defines the exception classes for exceptions raised by `urllib.request`. The base exception class is `URLError`.

The following exceptions are raised by `urllib.error` as appropriate:

**exception `urllib.error.URLError`**

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `OSError`.

**reason**

The reason for this error. It can be a message string or another exception instance.

*Changed in version 3.3: `URLError` has been made a subclass of `OSError` instead of `IOError`.*

**exception `urllib.error.HTTPError`**

Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

**code**

An HTTP status code as defined in RFC 2616. This numeric
value corresponds to a value found in the dictionary of codes as found in `http.server.BaseHTTPRequestHandler.responses`.

**reason**
This is usually a string explaining the reason for this error.

**headers**
The HTTP response headers for the HTTP request that caused the `HTTPError`.

*New in version 3.4.*

**exception `urllib.error.ContentTooShortError(msg, content)`**
This exception is raised when the `urlretrieve()` function detects that the amount of the downloaded data is less than the expected amount (given by the `Content-Length` header). The `content` attribute stores the downloaded (and supposedly truncated) data.
21.10. **urllib.robotparser** — Parser for robots.txt

This module provides a single class, `RobotFileParser`, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the robots.txt file. For more details on the structure of robots.txt files, see [http://www.robotstxt.org/orig.html](http://www.robotstxt.org/orig.html).

class urllib.robotparser.RobotFileParser(url='')

This class provides methods to read, parse and answer questions about the robots.txt file at `url`.

**set_url(url)**

Sets the URL referring to a robots.txt file.

**read()**

Reads the robots.txt URL and feeds it to the parser.

**parse(lines)**

Parses the lines argument.

**can_fetch(useragent, url)**

Returns True if the `useragent` is allowed to fetch the `url` according to the rules contained in the parsed robots.txt file.

**mtime()**

Returns the time the robots.txt file was last fetched. This is useful for long-running web spiders that need to check for new
robots.txt files periodically.

**modified()**

Sets the time the robots.txt file was last fetched to the current time.

The following example demonstrates basic use of the RobotFileParser class.

```python
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```
21.11. **http** — HTTP modules

**Source code:** Lib/http/__init__.py

http is a package that collects several modules for working with the HyperText Transfer Protocol:

- **http.client** is a low-level HTTP protocol client; for high-level URL opening use **urllib.request**
- **http.server** contains basic HTTP server classes based on **socketserver**
- **http.cookies** has utilities for implementing state management with cookies
- **http.cookiejar** provides persistence of cookies

http is also a module that defines a number of HTTP status codes and associated messages through the **http.HTTPStatus** enum:

**class** `http.HTTPStatus`

*New in version 3.5.*

A subclass of `enum.IntEnum` that defines a set of HTTP status codes, reason phrases and long descriptions written in English.

Usage:

```python
>>> from http import HTTPStatus
>>> HTTPStatus.OK
<HTTPStatus.OK: 200>
>>> HTTPStatus.OK == 200
True
>>> http.HTTPStatus.OK.value
200
```
HTTPStatus.OK.phrase
'OK'
HTTPStatus.OK.description
'Request fulfilled, document follows'
list(HTTPStatus)
[<HTTPStatus.CONTINUE: 100>, <HTTPStatus.SWITCHING_PROTOCOLS: 101>, ...]
21.11.1. HTTP status codes

Supported, IANA-registered status codes available in `http.HTTPStatus` are:

<table>
<thead>
<tr>

Source code: Lib/http/client.py

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module urllib.request uses it to handle URLs that use HTTP and HTTPS.

See also: The Requests package is recommended for a higher-level http client interface.

Note: HTTPS support is only available if Python was compiled with SSL support (through the ssl module).

The module provides the following classes:

```python
class http.client.HTTPConnection(host, port=None, [timeout, ]source_address=None)
```

An HTTPConnection instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form host:port, else the default HTTP port (80) is used. If the optional timeout parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional source_address parameter may be a tuple of a (host, port) to use as the source
address the HTTP connection is made from.

For example, the following calls all create instances that connect to the server at the same host and port:

```python
>>> h1 = http.client.HTTPConnection('www.python.org')
>>> h2 = http.client.HTTPConnection('www.python.org:80')
>>> h3 = http.client.HTTPConnection('www.python.org')
>>> h4 = http.client.HTTPConnection('www.python.org')
```

*Changed in version 3.2:* `source_address` was added.

*Changed in version 3.4:* The `strict` parameter was removed. HTTP 0.9-style “Simple Responses” are not longer supported.

class http.client.**HTTPSConnection**(host, port=None, key_file=None, cert_file=None, [timeout, ]source_address=None, *, context=None, check_hostname=None)

A subclass of **HTTPConnection** that uses SSL for communication with secure servers. Default port is 443. If `context` is specified, it must be a `ssl.SSLContext` instance describing the various SSL options.

`key_file` and `cert_file` are deprecated, please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system’s trusted CA certificates for you. The `check_hostname` parameter is also deprecated; the `ssl.SSLContext.check_hostname` attribute of `context` should be used instead.

Please read **Security considerations** for more information on best practices.
Changed in version 3.2: `source_address`, `context` and `check_hostname` were added.

Changed in version 3.2: This class now supports HTTPS virtual hosts if possible (that is, if `ssl.HAS_SNI` is true).

Changed in version 3.4: The `strict` parameter was removed. HTTP 0.9-style “Simple Responses” are no longer supported.

Changed in version 3.4.3: This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the `context` parameter.

class http.client.HTTPResponse(sock, debuglevel=0, method=None, url=None)

Class whose instances are returned upon successful connection. Not instantiated directly by user.

Changed in version 3.4: The `strict` parameter was removed. HTTP 0.9 style “Simple Responses” are no longer supported.

The following exceptions are raised as appropriate:

exception http.client.HTTPException

The base class of the other exceptions in this module. It is a subclass of `Exception`.

exception http.client.NotConnected

A subclass of `HTTPException`.

exception http.client.InvalidURL

A subclass of `HTTPException`, raised if a port is given and is
either non-numeric or empty.

_exception http.client.UnknownProtocol
   A subclass of HTTPException.

_exception http.client.UnknownTransferEncoding
   A subclass of HTTPException.

_exception http.client.UnimplementedFileMode
   A subclass of HTTPException.

_exception http.client.IncompleteRead
   A subclass of HTTPException.

_exception http.client.ImproperConnectionState
   A subclass of HTTPException.

_exception http.client.CannotSendRequest
   A subclass of ImproperConnectionState.

_exception http.client.CannotSendHeader
   A subclass of ImproperConnectionState.

_exception http.client.ResponseNotReady
   A subclass of ImproperConnectionState.

_exception http.client.BadStatusLine
   A subclass of HTTPException. Raised if a server responds with a HTTP status code that we don’t understand.

_exception http.client.LineTooLong
   A subclass of HTTPException. Raised if an excessively long line is received in the HTTP protocol from the server.
exception http.client.RemoteDisconnected
   A subclass of ConnectionResetError and BadStatusLine. Raised by HTTPConnection.getresponse() when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

   New in version 3.5: Previously, BadStatusLine('') was raised.

The constants defined in this module are:

http.client.HTTP_PORT
   The default port for the HTTP protocol (always 80).

http.client.HTTPS_PORT
   The default port for the HTTPS protocol (always 443).

http.client.responses
   This dictionary maps the HTTP 1.1 status codes to the W3C names.

   Example:
   http.client.responses[http.client.NOT_FOUND] is 'Not Found'.

See HTTP status codes for a list of HTTP status codes that are available in this module as constants.
21.12.1. HTTPConnection Objects

HTTPConnection instances have the following methods:

HTTPConnection.request(method, url, body=None, headers={})

This will send a request to the server using the HTTP request method method and the selector url.

If body is specified, the specified data is sent after the headers are finished. It may be a string, a bytes-like object, an open file object, or an iterable of bytes-like objects. If body is a string, it is encoded as ISO-8851-1, the default for HTTP. If it is a bytes-like object the bytes are sent as is. If it is a file object, the contents of the file is sent; this file object should support at least the read() method. If the file object has a mode attribute, the data returned by the read() method will be encoded as ISO-8851-1 unless the mode attribute contains the substring b, otherwise the data returned by read() is sent as is. If body is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The headers argument should be a mapping of extra HTTP headers to send with the request.

If headers does not contain a Content-Length item, one is added automatically if possible. If body is None, the Content-Length header is set to 0 for methods that expect a body (PUT, POST, and PATCH). If body is a string or bytes object, the Content-Length header is set to its length. If body is a file object and it works to call fstat() on the result of its fileno() method, then the Content-Length header is set to the st_size reported by the fstat call. Otherwise no Content-Length header is added.
New in version 3.2: body can now be an iterable.

`HTTPConnection.getresponse()`

Should be called after a request is sent to get the response from the server. Returns an `HTTPResponse` instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

*Changed in version 3.5:* If a `ConnectionError` or subclass is raised, the `HTTPConnection` object will be ready to reconnect when a new request is sent.

`HTTPConnection.set_debuglevel(level)`

Set the debugging level. The default debug level is 0, meaning no debugging output is printed. Any value greater than 0 will cause all currently defined debug output to be printed to stdout. The debuglevel is passed to any new `HTTPResponse` objects that are created.

*New in version 3.1.*

`HTTPConnection.set_tunnel(host, port=None, headers=None)`

Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The host and port arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, *not* the address of the proxy server).

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.
For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the `HTTPSConnection` constructor, and the address of the host that we eventually want to reach to the `set_tunnel()` method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("localhost")
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

*New in version 3.2.*

`HTTPConnection.connect()`

Connect to the server specified when the object was created. By default, this is called automatically when making a request if the client does not already have a connection.

`HTTPConnection.close()`

Close the connection to the server.

As an alternative to using the `request()` method described above, you can also send your request step by step, by using the four functions below.

`HTTPConnection.putrequest(request, selector, skip_host=False, skip_accept_encoding=False)`

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the `request` string, the `selector` string, and the HTTP version (HTTP/1.1). To disable automatic sending of Host: or Accept-Encoding: headers (for example to accept additional content encodings), specify `skip_host` or `skip_accept_encoding` with non-False values.
HTTPConnection.putheader(header, argument[, ...])

Send an **RFC 822**-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(message_body=None)

Send a blank line to the server, signalling the end of the headers. The optional `message_body` argument can be used to pass a message body associated with the request. The message body will be sent in the same packet as the message headers if it is string, otherwise it is sent in a separate packet.

HTTPConnection.send(data)

Send data to the server. This should be used directly only after the `endheaders()` method has been called and before `getresponse()` is called.
21.12.2. HTTPResponse Objects

An HTTPResponse instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

HTTPResponse.read([amt])
Reads and returns the response body, or up to the next amt bytes.

HTTPResponse.readinto(b)
Reads up to the next len(b) bytes of the response body into the buffer b. Returns the number of bytes read.

New in version 3.3.

HTTPResponse.getheader(name, default=None)
Return the value of the header name, or default if there is no header matching name. If there is more than one header with the name name, return all of the values joined by ‘,’. If ‘default’ is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.getheaders()
Return a list of (header, value) tuples.

HTTPResponse.fileno()
Return the fileno of the underlying socket.

HTTPResponse.msg
A http.client.HTTPMessage instance containing the response headers. http.client.HTTPMessage is a subclass of
email.message.Message.

HTTPResponse.version
    HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.status
    Status code returned by server.

HTTPResponse.reason
    Reason phrase returned by server.

HTTPResponse.debuglevel
    A debugging hook. If debuglevel is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse.closed
    Is True if the stream is closed.
21.12.3. Examples

Here is an example session that uses the GET method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while not r1.closed:
...    print(r1.read(200))  # 200 bytes
b'<!doctype html>\n
...# Example of an invalid request
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the HEAD method. Note that the HEAD method never returns any data.

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
```
Here is an example session that shows how to POST requests:

```python
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524})
>>> headers = {"Content-type": "application/x-www-form-urlencoded", "Accept": "text/plain"}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", ", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="http://bugs.python.org/issue12524">http://bugs.python.org/issue12524</a>'
>>> conn.close()
```

Client side HTTP PUT requests are very similar to POST requests. The difference lies only the server side where HTTP server will allow resources to be created via PUT request. It should be noted that custom HTTP methods are also handled in `urllib.request.Request` by sending the appropriate `+method` attribute. Here is an example session that shows how to do PUT request using `http.client`:

```python
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/file
```
>>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", &
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200, OK
21.12.4. HTTPMessage Objects

An http.client.HTTPMessage instance holds the headers from an HTTP response. It is implemented using the email.message.Message class.
21.13. ftplib — FTP protocol client

Source code: Lib/ftplib.py

This module defines the class FTP and a few related items. The FTP class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other ftp servers. It is also used by the module urllib.request to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here’s a sample session using the ftplib module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')  # connect to host
>>> ftp.login()                 # user anonymous
'230 Login successful.'
>>> ftp.cwd('debian')          # change into "debian" directory
>>> ftp.retrlines('LIST')      # list directory contents
-rw-rw-r-- 1 1176 1176 1063 Jun 15 10:18 README
...  
drwxr-sr-x 5 1176 1176 4096 Dec 19 2000 pool
drwxr-sr-x 4 1176 1176 4096 Nov 17 2008 project
drwxr-xr-x 3 1176 1176 4096 Oct 10 2012 tools
'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb'))
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:
class ftplib.**FTP**(*host*="", *user="", *passwd="", *acct="", *timeout=None, source_address=None*)

Return a new instance of the **FTP** class. When *host* is given, the method call `connect(host)` is made. When *user* is given, additionally the method call `login(user, passwd, acct)` is made (where *passwd* and *acct* default to the empty string when not given). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). *source_address* is a 2-tuple (*host*, *port*) for the socket to bind to as its source address before connecting.

The **FTP** class supports the **with** statement, e.g.:

```python
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
```

*Changed in version 3.2*: Support for the **with** statement was added.

*Changed in version 3.3*: *source_address* parameter was added.

class ftplib.**FTP_TLS**(*host="", *user="", *passwd="", *acct="", keyfile=None, certfile=None, context=None, timeout=None, source_address=None*)
A FTP subclass which adds TLS support to FTP as described in RFC 4217. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the prot_p() method. context is a ssl.SSLContext object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

New in version 3.2.

Changed in version 3.3: source_address parameter was added.

Changed in version 3.4: The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

Here’s a sample session using the FTP_TLS class:

```python
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
>>> ftps.prot_p()
'200 Data protection level set to "private"
>>> ftps.nlst()
['6jack', 'OpenBSD', 'antilink', 'blogbench', 'bs...]
```

exception ftplib.error_reply
Exception raised when an unexpected reply is received from the server.

*exception* `ftplib.error_temp`

Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

*exception* `ftplib.error_perm`

Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

*exception* `ftplib.error_proto`

Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

`ftplib.all_errors`

The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as `OSError`.

**See also:**

**Module netrc**

Parser for the `.netrc` file format. The file `.netrc` is typically used by FTP clients to load user authentication information before prompting the user.

The file `Tools/scripts/ftpmirror.py` in the Python source distribution is a script that can mirror FTP sites, or portions thereof, using the `ftplib` module. It can be used as an extended example that applies this module.
21.13.1. FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by lines for the text version or binary for the binary version.

FTP instances have the following methods:

`FTP.set_debuglevel(level)`

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

`FTP.connect(host='', port=0, timeout=None, source_address=None)`

Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt. If no `timeout` is passed, the global default timeout setting will be used. `source_address` is a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.

*Changed in version 3.3*: `source_address` parameter was added.
FTP. `getwelcome()`

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP. `login(user='anonymous', passwd='', acct='')`

Log in as the given `user`. The `passwd` and `acct` parameters are optional and default to the empty string. If no `user` is specified, it defaults to 'anonymous'. If `user` is 'anonymous', the default `passwd` is 'anonymous@'. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The `acct` parameter supplies “accounting information”; few systems implement this.

FTP. `abort()`

Abort a file transfer that is in progress. Using this does not always work, but it's worth a try.

FTP. `sendcmd(cmd)`

Send a simple command string to the server and return the response string.

FTP. `voidcmd(cmd)`

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise `error_reply` otherwise.

FTP. `retrbinary(cmd, callback, blocksize=8192, rest=None)`

Retrieve a file in binary transfer mode. `cmd` should be an
appropriate RETR command: 'RETR filename'. The callback function is called for each block of data received, with a single string argument giving the data block. The optional blocksize argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to callback). A reasonable default is chosen. rest means the same thing as in the transfercmd() method.

FTP.retrlines(cmd, callback=None)
Retrieve a file or directory listing in ASCII transfer mode. cmd should be an appropriate RETR command (see retrbinary()) or a command such as LIST or NLST (usually just the string 'LIST'). LIST retrieves a list of files and information about those files. NLST retrieves a list of file names. The callback function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default callback prints the line to sys.stdout.

FTP.set_pasv(boolean)
Enable “passive” mode if boolean is true, other disable passive mode. Passive mode is on by default.

FTP.storbinary(cmd, fp, blocksize=8192, callback=None, rest=None)
Store a file in binary transfer mode. cmd should be an appropriate STOR command: "STOR filename". fp is a file object (opened in binary mode) which is read until EOF using its read() method in blocks of size blocksize to provide the data to be stored. The blocksize argument defaults to 8192. callback is an optional single parameter callable that is called on each block of data after it is
sent. rest means the same thing as in the transfercmd() method.

*Changed in version 3.2: rest parameter added.*

**FTP. storlines(cmd, fp, callback=None)**

Store a file in ASCII transfer mode. cmd should be an appropriate STOR command (see storbinary()). Lines are read until EOF from the file object fp (opened in binary mode) using its readline() method to provide the data to be stored. callback is an optional single parameter callable that is called on each line after it is sent.

**FTP. transfercmd(cmd, rest=None)**

Initiate a transfer over the data connection. If the transfer is active, send an EPRT or PORT command and the transfer command specified by cmd, and accept the connection. If the server is passive, send an EPSV or PASV command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional rest is given, a REST command is sent to the server, passing rest as an argument. rest is usually a byte offset into the requested file, telling the server to restart sending the file’s bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that rest be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The transfercmd() method, therefore, converts rest to a string, but no check is performed on the string’s contents. If the server does not recognize the REST command, an error_reply exception will be raised. If this happens, simply call transfercmd() without a rest argument.
FTP. `nttransfercmd(cmd, rest=None)`

Like `transfercmd()`, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, `None` will be returned as the expected size. `cmd` and `rest` means the same thing as in `transfercmd()`.

FTP. `mlsd(path='', facts=[])`  

List a directory in a standardized format by using MLSD command (RFC 3659). If `path` is omitted the current directory is assumed. `facts` is a list of strings representing the type of information desired (e.g. ["type", "size", "perm"]). Return a generator object yielding a tuple of two elements for every file found in path. First element is the file name, the second one is a dictionary containing facts about the file name. Content of this dictionary might be limited by the `facts` argument but server is not guaranteed to return all requested facts.

*New in version 3.3.*

FTP. `nlst(argument[, ...])`  

Return a list of file names as returned by the NLST command. The optional `argument` is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the NLST command.

*Deprecated since version 3.3: use `mlsd()` instead.*

FTP. `dir(argument[, ...])`  

Produce a directory listing as returned by the LIST command, printing it to standard output. The optional `argument` is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the LIST command.
If the last argument is a function, it is used as a *callback* function as for `retrlines()`; the default prints to `sys.stdout`. This method returns None.

*Deprecated since version 3.3*: use `mlsd()` instead.

**FTP. rename(fromname, toname)**

Rename file *fromname* on the server to *toname*.

**FTP. delete(filename)**

Remove the file named *filename* from the server. If successful, returns the text of the response, otherwise raises `error_perm` on permission errors or `error_reply` on other errors.

**FTP. cwd(pathname)**

Set the current directory on the server.

**FTP. mkd(pathname)**

Create a new directory on the server.

**FTP. pwd()**

Return the pathname of the current directory on the server.

**FTP. rmd(dirname)**

Remove the directory named *dirname* on the server.

**FTP. size(filename)**

Request the size of the file named *filename* on the server. On success, the size of the file is returned as an integer, otherwise None is returned. Note that the SIZE command is not standardized, but is supported by many common server implementations.
FTP. **quit()**

Send a QUIT command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception if the server responds with an error to the QUIT command. This implies a call to the `close()` method which renders the FTP instance useless for subsequent calls (see below).

FTP. **close()**

Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to `quit()`. After this call the FTP instance should not be used any more (after a call to `close()` or `quit()` you cannot reopen the connection by issuing another `login()` method).
21.13.2. FTP_TLS Objects

**FTP_TLS** class inherits from **FTP**, defining these additional objects:

**FTP_TLS.ssl_version**
The SSL version to use (defaults to `ssl.PROTOCOL_SSLv23`).

**FTP_TLS.auth()**
Set up a secure control connection by using TLS or SSL, depending on what is specified in the `ssl_version` attribute.

*Changed in version 3.4:* The method now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

**FTP_TLS.ccc()**
Revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports.

*New in version 3.3.*

**FTP_TLS.prot_p()**
Set up secure data connection.

**FTP_TLS.prot_c()**
Set up clear text data connection.
21.14. poplib — POP3 protocol client

Source code: Lib/poplib.py

This module defines a class, POP3, which encapsulates a connection to a POP3 server and implements the protocol as defined in RFC 1939. The POP3 class supports both the minimal and optional command sets from RFC 1939. The POP3 class also supports the STLS command introduced in RFC 2595 to enable encrypted communication on an already established connection.

Additionally, this module provides a class POP3_SSL, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the imaplib.IMAP4 class, as IMAP servers tend to be better implemented.

The poplib module provides two classes:

```
class poplib.POP3(host, port=POP3_PORT[, timeout])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not
specified, the global default timeout setting will be used).

class poplib.POP3_SSL(host, port=POP3_SSL_PORT, keyfile=None, certfile=None, timeout=None, context=None)

This is a subclass of POP3 that connects to the server over an SSL encrypted socket. If port is not specified, 995, the standard POP3-over-SSL port is used. timeout works as in the POP3 constructor. context is an optional ssl.SSLContext object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context - they can point to PEM-formatted private key and certificate chain files, respectively, for the SSL connection.

Changed in version 3.2: context parameter added.

Changed in version 3.4: The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

One exception is defined as an attribute of the poplib module:

element poplib.error_proto

Exception raised on any errors from this module (errors from socket module are not caught). The reason for the exception is passed to the constructor as a string.

See also:

Module imaplib
The standard Python IMAP module.
<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>The FAQ for the <strong>fetchmail</strong> POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.</td>
</tr>
</tbody>
</table>
21.14.1. POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An POP3 instance has the following methods:

**POP3.set_debuglevel(level)**

Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**POP3.getwelcome()**

Returns the greeting string sent by the POP3 server.

**POP3.capa()**

Query the server's capabilities as specified in RFC 2449. Returns a dictionary in the form {'name': ['param'...]}.

_New in version 3.4._

**POP3.user(username)**

Send user command, response should indicate that a password is required.

**POP3.pass_(password)**

Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until quit() is called.
POP3. **apop**(user, secret)

Use the more secure APOP authentication to log into the POP3 server.

POP3. **rpop**(user)

Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

POP3. **stat()**

Get mailbox status. The result is a tuple of 2 integers: (message count, mailbox size).

POP3. **list([which])**

Request message list, result is in the form (response, ['mesg_num octets', ...], octets). If which is set, it is the message to list.

POP3. **retr**(which)

Retrieve whole message number which, and set its seen flag. Result is in form (response, ['line', ...], octets).

POP3. **dele**(which)

Flag message number which for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

POP3. **rset()**

Remove any deletion marks for the mailbox.

POP3. **noop()**

Do nothing. Might be used as a keep-alive.
**POP3.**\texttt{quit}()

Signoff: commit changes, unlock mailbox, drop connection.

**POP3.**\texttt{top}(\texttt{which}, \texttt{howmuch})

Retrieves the message header plus \textit{howmuch} lines of the message after the header of message number \texttt{which}. Result is in form (\texttt{response}, ['\texttt{line}', ...], \texttt{octets}).

The POP3 TOP command this method uses, unlike the RETR command, doesn’t set the message’s seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

**POP3.**\texttt{uidl}(\texttt{which}=\texttt{None})

Return message digest (unique id) list. If \texttt{which} is specified, result contains the unique id for that message in the form 'response \texttt{mesgnum uid}', otherwise result is list (\texttt{response}, ['\texttt{mesgnum uid}', ...], \texttt{octets}).

**POP3.**\texttt{utf8}()

Try to switch to UTF-8 mode. Returns the server response if successful, raises \texttt{error\_proto} if not. Specified in \texttt{RFC 6856}.

\textit{New in version 3.5.}

**POP3.**\texttt{stls}(\texttt{context}=\texttt{None})

Start a TLS session on the active connection as specified in \texttt{RFC 2595}. This is only allowed before user authentication

\texttt{context} parameter is a \texttt{ssl\_SSLContext} object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read \texttt{Security}
considerations for best practices.

This method supports hostname checking via `ssl.SSLContext.check_hostname` and `Server Name Indication` (see `ssl.HAS_SNI`).

*New in version 3.4.*

Instances of `POP3_SSL` have no additional methods. The interface of this subclass is identical to its parent.
21.14.2. POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.
This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in RFC 2060. It is backward compatible with IMAP4 (RFC 1730) servers, but note that the STATUS command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class:

```python
class imaplib.IMAP4(host='', port=IMAP4_PORT)
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If `host` is not specified, '' (the local host) is used. If `port` is omitted, the standard IMAP4 port (143) is used.

The `IMAP4` class supports the `with` statement. When used like this, the IMAP4 LOGOUT command is issued automatically when the `with` statement exits. E.g.:

```python
>>> from imaplib import IMAP4
>>> with IMAP4("domain.org") as M:
...     M.noop()
...```
Changed in version 3.5: Support for the `with` statement was added.

Three exceptions are defined as attributes of the `IMAP4` class:

*exception* `IMAP4.error`

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

*exception* `IMAP4.abort`

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

*exception* `IMAP4.readonly`

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of `IMAP4.error`. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There’s also a subclass for secure connections:

```python
class imaplib.IMAP4_SSL(host='', port=IMAP4_SSL_PORT, keyfile=None, certfile=None, ssl_context=None)
```

This is a subclass derived from `IMAP4` that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If `host` is not specified, '' (the local host) is used. If `port` is omitted, the standard IMAP4-over-SSL port (993) is used. `ssl_context` is a `ssl.SSLContext` object which
allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

`keyfile` and `certfile` are a legacy alternative to `ssl_context` - they can point to PEM-formatted private key and certificate chain files for the SSL connection. Note that the `keyfile/certfile` parameters are mutually exclusive with `ssl_context`, a `ValueError` is raised if `keyfile/certfile` is provided along with `ssl_context`.

*Changed in version 3.3:* `ssl_context` parameter added.

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and Server Name Indication (see `ssl.HAS_SNI`).

The second subclass allows for connections created by a child process:

```python
class imaplib.IMAP4_stream(command)
```

This is a subclass derived from `IMAP4` that connects to the stdin/stdout file descriptors created by passing `command` to `subprocess.Popen()`.

The following utility functions are defined:

```python
imaplib.Internaldate2tuple(datestr)
```

Parse an IMAP4 INTERNALDATE string and return corresponding local time. The return value is a `time.struct_time` tuple or None if the string has wrong format.

```python
imaplib.Int2AP(num)
```

Converts an integer into a string representation using characters
from the set [A .. P].

imaplib.ParseFlags(flagstr)
Converts an IMAP4 FLAGS response to a tuple of individual flags.

imaplib.Time2Internaldate(date_time)
Convert date_time to an IMAP4 INTERNALDATE representation. The return value is a string in the form: "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The date_time argument can be a number (int or float) representing seconds since epoch (as returned by time.time()), a 9-tuple representing local time an instance of time.struct_time (as returned by time.localtime()), an aware instance of datetime.datetime, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an EXPUNGE command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

See also: Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the University of Washington's IMAP Information Center (http://www.washington.edu/imap/).
21.15.1. IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn’t enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'("Deleted")').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: 'literal' value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3,6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:*').

An IMAP4 instance has the following methods:

IMAP4.append(mailbox, flags, date_time, message)

Append message to named mailbox.

IMAP4.authenticate(mechanism, authobject)
Authenticate command — requires response processing.

*mecanism* specifies which authentication mechanism is to be used - it should appear in the instance variable capabilities in the form AUTH=mecanism.

*authobject* must be a callable object:

```
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be bytes. It should return bytes *data* that will be base64 encoded and sent to the server. It should return None if the client abort response * should be sent instead.

*Changed in version 3.5:* string usernames and passwords are now encoded to utf-8 instead of being limited to ASCII.

**IMAP4.check()**

Checkpoint mailbox on server.

**IMAP4.close()**

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before LOGOUT.

**IMAP4.copy(message_set, new_mailbox)**

Copy *message_set* messages onto end of *new_mailbox*.

**IMAP4.create(mailbox)**

Create new mailbox named *mailbox*. 
IMAP4.\texttt{delete}(\texttt{mailbox})

Delete old mailbox named \texttt{mailbox}.

IMAP4.\texttt{deleteacl}(\texttt{mailbox}, \texttt{who})

Delete the ACLs (remove any rights) set for who on mailbox.

IMAP4.\texttt{enable}(\texttt{capability})

Enable \texttt{capability} (see \texttt{RFC 5161}). Most capabilities do not need to be enabled. Currently only the \texttt{UTF8=ACCEPT} capability is supported (see \texttt{RFC 6855}).

\textit{New in version 3.5}: The \texttt{enable()} method itself, and \texttt{RFC 6855} support.

IMAP4.\texttt{expunge}()

Permanently remove deleted items from selected mailbox. Generates an \texttt{EXPUNGE} response for each deleted message. Returned data contains a list of \texttt{EXPUNGE} message numbers in order received.

IMAP4.\texttt{fetch}(\texttt{message\_set}, \texttt{message\_parts})

Fetch (parts of) messages. \texttt{message\_parts} should be a string of message part names enclosed within parentheses, eg: "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

IMAP4.\texttt{getacl}(\texttt{mailbox})

Get the ACLs for \texttt{mailbox}. The method is non-standard, but is supported by the Cyrus server.

IMAP4.\texttt{getannotation}(\texttt{mailbox}, \texttt{entry}, \texttt{attribute})

Retrieve the specified \texttt{ANNOTATION}s for \texttt{mailbox}. The method is
non-standard, but is supported by the Cyrus server.

**IMAP4.** `getquota(root)`
Get the quota `root`'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4.** `getquotaroot(mailbox)`
Get the list of quota roots for the named `mailbox`. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4.** `list([directory[, pattern]])`
List mailbox names in `directory` matching `pattern`. `directory` defaults to the top-level mail folder, and `pattern` defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4.** `login(user, password)`
Identify the client using a plaintext password. The `password` will be quoted.

**IMAP4.** `login_cram_md5(user, password)`
Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server CAPABILITY response includes the phrase AUTH=CRAM-MD5.

**IMAP4.** `logout()`
Shutdown connection to server. Returns server BYE response.

**IMAP4.** `lsub(directory="", pattern="*")`
List subscribed mailbox names in directory matching pattern. `directory` defaults to the top level directory and `pattern` defaults to match any mailbox. Returned data are tuples of message part envelope and data.
**IMAP4.myrights(mailbox)**
Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

**IMAP4.namespace()**
Returns IMAP namespaces as defined in RFC2342.

**IMAP4.noop()**
Send NOOP to server.

**IMAP4.open(host, port)**
Opens socket to port at host. This method is implicitly called by the IMAP4 constructor. The connection objects established by this method will be used in the IMAP4.read(), IMAP4.readline(), IMAP4.send(), and IMAP4shutdown() methods. You may override this method.

**IMAP4.partial(message_num, message_part, start, length)**
Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4.proxyauth(user)**
Assume authentication as user. Allows an authorised administrator to proxy into any user’s mailbox.

**IMAP4.read(size)**
Reads size bytes from the remote server. You may override this method.

**IMAP4.readline()**
Reads one line from the remote server. You may override this method.
**IMAP4**. `recent()`  
Prompt server for an update. Returned data is `None` if no new messages, else value of RECENT response.

**IMAP4**. `rename(oldmailbox, newmailbox)`  
Rename mailbox named `oldmailbox` to `newmailbox`.

**IMAP4**. `response(code)`  
Return data for response `code` if received, or `None`. Returns the given code, instead of the usual type.

**IMAP4**. `search(charset, criterion[, ...])`  
Search mailbox for matching messages. `charset` may be `None`, in which case no CHARSET will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error. `charset` must be `None` if the UTF8=ACCEPT capability was enabled using the `enable()` command.

Example:

```python
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '"LDJ"')
# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

**IMAP4**. `select(mailbox='INBOX', readonly=False)`  
Select a mailbox. Returned data is the count of messages in `mailbox` (EXISTS response). The default `mailbox` is 'INBOX'. If the `readonly` flag is set, modifications to the mailbox are not allowed.
**IMAP4.send(data)**
Sends data to the remote server. You may override this method.

**IMAP4.setacl(mailbox, who, what)**
Set an ACL for mailbox. The method is non-standard, but is supported by the Cyrus server.

**IMAP4.setannotation(mailbox, entry, attribute[,...])**
Set ANNOTATIONs for mailbox. The method is non-standard, but is supported by the Cyrus server.

**IMAP4.setquota(root, limits)**
Set the quota root's resource limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4.shutdown()**
Close connection established in open. This method is implicitly called by IMAP4.logout(). You may override this method.

**IMAP4.socket()**
Returns socket instance used to connect to server.

**IMAP4.sort(sort_criteria, charset, search_criterion[,...])**
The sort command is a variant of search with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the search_criterion argument(s); a parenthesized list of sort_criteria, and the searching charset. Note that unlike search, the searching charset argument is mandatory. There is also a uid sort command which corresponds to sort
the way that uid search corresponds to search. The sort command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an IMAP4rev1 extension command.

**IMAP4.starttls**(*ssl_context=None*)

Send a STARTTLS command. The *ssl_context* argument is optional and should be a *ssl.SSLContext* object. This will enable encryption on the IMAP connection. Please read Security considerations for best practices.

*New in version 3.2.*

*Changed in version 3.4:* The method now supports hostname check with *ssl.SSLContext.check_hostname* and Server Name Indication (see *ssl.HAS_SNI*).

**IMAP4.status**(*mailbox, names*)

Request named status conditions for *mailbox*.

**IMAP4.store**(*message_set, command, flag_list*)

Alters flag dispositions for messages in mailbox. *command* is specified by section 6.4.6 of RFC 2060 as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of ”.SILENT”.

For example, to set the delete flag on all messages:

```python
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\\Deleted')
```
IMAP4. **subscribe**(mailbox)
   Subscribe to new mailbox.

IMAP4. **thread**(threading_algorithm, charset, search_criterion[, ...])
   The thread command is a variant of search with threading semantics for the results. Returned data contains a space separated list of thread members.

   Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

   Thread has two arguments before the search_criterion argument(s); a threading_algorithm, and the searching charset. Note that unlike search, the searching charset argument is mandatory. There is also a uid thread command which corresponds to thread the way that uid search corresponds to search. The thread command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

   This is an IMAP4rev1 extension command.

IMAP4. **uid**(command, arg[, ...])
   Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.
**IMAP4.** `unsubscribe(mailbox)`
Unsubscribe from old mailbox.

**IMAP4.** `xatom(name[, ...])`
Allow simple extension commands notified by server in CAPABILITY response.

The following attributes are defined on instances of **IMAP4**:

**IMAP4.** `PROTOCOL_VERSION`
The most recent supported protocol in the CAPABILITY response from the server.

**IMAP4.** `debug`
Integer value to control debugging output. The initialize value is taken from the module variable `Debug`. Values greater than three trace each command.

**IMAP4.** `utf8_enabled`
Boolean value that is normally False, but is set to True if an `enable()` command is successfully issued for the UTF8=ACCEPT capability.

*New in version 3.5.*
21.15.2. IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print('Message %s
%s
' % (num, data[0][1]))
M.close()
M.logout()
```
This module defines the class **NNTP** which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with **RFC 3977** as well as the older **RFC 977** and **RFC 2980**.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print('Group', name, 'has', count, 'articles, range', first, 'to', last)
Group gmane.comp.python.committers has 1096 articles, range 1 to 1096
>>> resp, overviews = s.overviews((last - 9, last))
>>> for id, over in overviews:
...     print(id, nntplib.decode_header(over['subject']))
1087 Re: Commit privileges for Łukasz Langa
1088 Re: 3.2 alpha 2 freeze
1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
```
To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```python
>>> s.quit()
'205 Bye!'
```

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

```python
class nntplib.NNTP(host, port=119, user=None, password=None,
readermode=None, usenetrc=False[, timeout])
```

Return a new NNTP object, representing a connection to the NNTP server running on host `host`, listening at port `port`. An optional `timeout` can be specified for the socket connection. If the optional `user` and `password` are provided, or if suitable credentials are present in `/.netrc` and the optional flag `usenetrc` is true, the AUTHINFO USER and AUTHINFO PASS commands are used to identify and authenticate the user to the server. If the optional flag `readermode` is true, then a `mode reader` command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as `group`. If you get unexpected `NNTPPermanentErrors`, you might need to set `readermode`. The `NNTP` class supports the `with` statement to unconditionally consume `OSError` exceptions and to close the
NNTP connection when done, e.g.:

```python
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.org') as n:
...     n.group('gmane.comp.python.committers')
... ('211 1755 1 1755 gmane.comp.python.committers',
```

*Changed in version 3.2:* `usenetrc` is now `False` by default.

*Changed in version 3.3:* Support for the `with` statement was added.

```python
class nntplib.NNTP_SSL(host, port=563, user=None, 
password=None, ssl_context=None, readermode=None, 
usenetrc=False[, timeout])
```

Return a new `NNTP_SSL` object, representing an encrypted connection to the NNTP server running on host `host`, listening at port `port`. `NNTP_SSL` objects have the same methods as `NNTP` objects. If `port` is omitted, port 563 (NNTPS) is used. `ssl_context` is also optional, and is a `SSLContext` object. Please read Security considerations for best practices. All other parameters behave the same as for `NNTP`.

Note that SSL-on-563 is discouraged per RFC 4642, in favor of STARTTLS as described below. However, some servers only support the former.

*New in version 3.2.*

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name*
Indication (see ssl.HAS_SNI).

**exception nntplib.NNTPError**

Derived from the standard exception `Exception`, this is the base class for all exceptions raised by the `nntplib` module. Instances of this class have the following attribute:

**response**

The response of the server if available, as a `str` object.

**exception nntplib.NNTPReplyError**

Exception raised when an unexpected reply is received from the server.

**exception nntplib.NNTPTemporaryError**

Exception raised when a response code in the range 400–499 is received.

**exception nntplib.NNTPPermanentError**

Exception raised when a response code in the range 500–599 is received.

**exception nntplib.NNTPProtocolError**

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

**exception nntplib.NNTPDataError**

Exception raised when there is some error in the response data.
21.16.1. NNTP Objects

When connected, NNTP and NNTP_SSL objects support the following methods and attributes.

21.16.1.1. Attributes

NNTP.nntp_version
An integer representing the version of the NNTP protocol supported by the server. In practice, this should be 2 for servers advertising RFC 3977 compliance and 1 for others.

New in version 3.2.

NNTP.nntp_implementation
A string describing the software name and version of the NNTP server, or None if not advertised by the server.

New in version 3.2.

21.16.1.2. Methods

The response that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument file. When the file argument is supplied, it must be either a file object opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the
server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

*Changed in version 3.2:* Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

**NNTP.quit()**

Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

**NNTP.getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**NNTP.getcapabilities()**

Return the RFC 3977 capabilities advertised by the server, as a `dict` instance mapping capability names to (possibly empty) lists of values. On legacy servers which don’t understand the CAPABILITIES command, an empty dictionary is returned instead.

```python
>>> s = NNTP('news.gmane.org')
>>> 'POST' in s.getcapabilities()
True
```

*New in version 3.2.*

**NNTP.login(user=None, password=None, usenetrc=True)**

Send AUTHINFO commands with the user name and password. If
user and password are None and usenetrc is true, credentials from ~/.netrc will be used if possible.

Unless intentionally delayed, login is normally performed during the NNTP object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set user or password when creating the object, and must set usenetrc to False.

New in version 3.2.

NNTP.starttls(ssl_context=None)
Send a STARTTLS command. This will enable encryption on the NNTP connection. The ssl_context argument is optional and should be a ssl.SSLContext object. Please read Security considerations for best practices.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a NNTP object initialization. See NNTP.login() for information on suppressing this behavior.

New in version 3.2.

Changed in version 3.4: The method now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

NNTP.newgroups(date, *, file=None)
Send a NEWGROUPS command. The date argument should be a datetime.date or datetime.datetime object. Return a pair (response, groups) where groups is a list representing the groups that are new since the given date. If file is supplied, though,
then groups will be empty.

```python
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today()) - timedelta
>>> len(groups)
85
>>> groups[0]
GroupInfo(group='gmane.network.tor.devel', last=''.
```

**NNTP .newnews(group, date, *, file=None)**

Send a NEWNEWS command. Here, group is a group name or ' * ', and date has the same meaning as for newgroups(). Return a pair (response, articles) where articles is a list of message ids.

This command is frequently disabled by NNTP server administrators.

**NNTP .list(group_pattern=None, *, file=None)**

Send a LIST or LIST ACTIVE command. Return a pair (response, list) where list is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string group_pattern. Each tuple has the form (group, last, first, flag), where group is a group name, last and first are the last and first article numbers, and flag usually takes one of these values:

- **y**: Local postings and articles from peers are allowed.
- **m**: The group is moderated and all postings must be approved.
- **n**: No local postings are allowed, only articles from peers.
- **j**: Articles from peers are filed in the junk group instead.
- **x**: No local postings, and articles from peers are ignored.
• =foo.bar: Articles are filed in the foo.bar group instead.

If flag has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if group_pattern is not specified. It is best to cache the results offline unless you really need to refresh them.

*Changed in version 3.2: group_pattern was added.*

**NNTP.descriptions(group_pattern)**

Send a LIST NEWSGROUPS command, where group_pattern is a wildmat string as specified in RFC 3977 (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair (response, descriptions), where descriptions is a dictionary mapping group names to textual descriptions.

```python
>>> resp, descs = s.descriptions('gmane.comp.python.*')
>>> len(descs)
295
>>> descs.popitem()
('gmane.comp.python.bio.general', 'BioPython discussion list (Moderated)')
```

**NNTP.description(group)**

Get a description for a single group group. If more than one group matches (if 'group' is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use descriptions().

**NNTP.group(name)**
Send a GROUP command, where name is the group name. The group is selected as the current group, if it exists. Return a tuple (response, count, first, last, name) where count is the (estimated) number of articles in the group, first is the first article number in the group, last is the last article number in the group, and name is the group name.

NNTP.over(message_spec, *, file=None)

Send an OVER command, or an XOVER command on legacy servers. message_spec can be either a string representing a message id, or a (first, last) tuple of numbers indicating a range of articles in the current group, or a (first, None) tuple indicating a range of articles starting from first to the last article in the current group, or None to select the current article in the current group.

Return a pair (response, overviews). overviews is a list of (article_number, overview) tuples, one for each article selected by message_spec. Each overview is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with ":"). The following items are guaranteed to be present by the NNTP specification:

- the subject, from, date, message-id and references headers
- the :bytes metadata: the number of bytes in the entire raw article (including headers and body)
- the :lines metadata: the number of lines in the article body

The value of each item is either a string, or None if not present.
It is advisable to use the `decode_header()` function on header values when they may contain non-ASCII characters:

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel')
>>> resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
>>> art_num
117216
>>> list(over.keys())
['xref', 'from', ':lines', ':bytes', 'references']
>>> over['from']
'=?UTF-8?B?Ik1hcnRpbjB2LiBm7Z3aXMi?= <martin@v.l
>>> nntplib.decode_header(over['from'])
'Martin v. Löwis' <martin@v.loewis.de>'
```

New in version 3.2.

**NNTP.**`.help(*, file=None)`

Send a HELP command. Return a pair `(response, list)` where `list` is a list of help strings.

**NNTP.stat**(message_spec=None)

Send a STAT command, where `message_spec` is either a message id (enclosed in '<' and '>') or an article number in the current group. If `message_spec` is omitted or `None`, the current article in the current group is considered. Return a triple `(response, number, id)` where `number` is the article number and `id` is the message id.

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel')
>>> resp, number, message_id = s.stat(first)
>>> number, message_id
(9099, '<20030112190404.GE29873@epoch.metaslash.com>')
```
NNTP.next()
    Send a NEXT command. Return as for stat().

NNTP.last()
    Send a LAST command. Return as for stat().

NNTP.article(message_spec=None, *, file=None)
    Send an ARTICLE command, where message_spec has the same
    meaning as for stat(). Return a tuple (response, info)
    where info is a namedtuple with three attributes number,
    message_id and lines (in that order). number is the article
    number in the group (or 0 if the information is not available),
    message_id the message id as a string, and lines a list of lines
    (without terminating newlines) comprising the raw message including
    headers and body.

>>> resp, info = s.article('<20030112190404.GE29873@epoch.metaslash.com>
>>> info.number
0
>>> info.message_id
'<20030112190404.GE29873@epoch.metaslash.com>'
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[-3:]
[b'There is a patch for 2.3 as well as 2.2.', b''

NNTP.head(message_spec=None, *, file=None)
    Same as article(), but sends a HEAD command. The lines
returned (or written to file) will only contain the message headers, not the body.

NNTP.body(message_spec=None, *, file=None)
Same as article(), but sends a BODY command. The lines returned (or written to file) will only contain the message body, not the headers.

NNTP.post(data)
Post an article using the POST command. The data argument is either a file object opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The post() method automatically escapes lines beginning with . and appends the termination line.

If the method succeeds, the server’s response is returned. If the server refuses posting, a NNTPReplyError is raised.

NNTP.ihave(message_id, data)
Send an IHAVE command. message_id is the id of the message to send to the server (enclosed in '<' and '>'). The data parameter and the return value are the same as for post().

NNTP.date()
Return a pair (response, date). date is a datetime object containing the current date and time of the server.

NNTP.slave()
Send a SLAVE command. Return the server’s response.

NNTP.set_debuglevel(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in RFC 2980. Some of them have been superseded by newer commands in RFC 3977.

**NNTP.xhdr**(hdr, str, *, file=None)

Send an XHDR command. The *hdr* argument is a header keyword, e.g. 'subject'. The *str* argument should have the form 'first-last' where *first* and *last* are the first and last article numbers to search. Return a pair (response, list), where *list* is a list of pairs (*id*, *text*), where *id* is an article number (as a string) and *text* is the text of the requested header for that article. If the *file* parameter is supplied, then the output of the XHDR command is stored in a file. If *file* is a string, then the method will open a file with that name, write to it then close it. If *file* is a *file object*, then it will start calling *write()* on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an empty list.

**NNTP.xover**(start, end, *, file=None)

Send an X0VER command. *start* and *end* are article numbers delimiting the range of articles to select. The return value is the same of for *over()* . It is recommended to use *over()* instead, since it will automatically use the newer OVER command if available.
NNTP.\texttt{xpath}(id)

Return a pair \((\texttt{resp}, \texttt{path})\), where \texttt{path} is the directory path to the article with message ID \textit{id}. Most of the time, this extension is not enabled by NNTP server administrators.

\textit{Deprecated since version 3.3}: The XPATH extension is not actively used.
21.16.2. Utility functions

The module also defines the following utility function:

\[ \text{nntplib.} \text{decode\_header}(header\_str) \]

Decode a header value, un-escaping any escaped non-ASCII characters. \textit{header\_str} must be a \texttt{str} object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

\[
\begin{align*}
>>> \text{decode\_header("Some subject")} \\
\text{'Some subject'} \\
>>> \text{decode\_header("=?ISO-8859-15?Q?D=E9buter\_en\_P\n\text'Débuter en Python'} \\
>>> \text{decode\_header("Re: =?UTF-8?B?cHJvYmzDqG1lIGRL\n\text'Re: problème de matrice'}
\end{align*}
\]

Created using Sphinx 1.3.1.
21.17. **smtplib — SMTP protocol client**

**Source code:** Lib/smtplib.py

The `smtplib` module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult **RFC 821** (Simple Mail Transfer Protocol) and **RFC 1869** (SMTP Service Extensions).

```python
class smtplib.SMTP(host='', port=0, local_hostname=None, timeout=None, source_address=None)
```

An SMTP instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the SMTP `connect()` method is called with those parameters during initialization. If specified, `local_hostname` is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using `socket.getfqdn()`. If the `connect()` call returns anything other than a success code, an `SMTPConnectError` is raised. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). If the timeout expires, `socket.timeout` is raised. The optional `source_address` parameter allows to bind to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple (host, port), for the socket to bind to as its source address.
before connecting. If omitted (or if host or port are '' and/or 0 respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/connect, sendmail(), and quit() methods. An example is included below.

The **SMTP** class supports the *with* statement. When used like this, the SMTP QUIT command is issued automatically when the *with* statement exits. E.g.:

```python
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...     smtp.noop()
... (250, b'0k')
```

*Changed in version 3.3:* Support for the *with* statement was added.

*Changed in version 3.3:* source_address argument was added.

*New in version 3.5:* The SMTPUTF8 extension (**RFC 6531**) is now supported.

```python
class smtplib.SMTP_SSL(host='', port=0, local_hostname=None, keyfile=None, certfile=None, [timeout, ]context=None, source_address=None)
```

An **SMTP_SSL** instance behaves exactly the same as instances of **SMTP**. **SMTP_SSL** should be used for situations where SSL is required from the beginning of the connection and using starttls() is not appropriate. If *host* is not specified, the local
host is used. If port is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments local_hostname, timeout and source_address have the same meaning as they do in the SMTP class. context, also optional, can contain a SSLContext and allows to configure various aspects of the secure connection. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context, and can point to a PEM formatted private key and certificate chain file for the SSL connection.

*Changed in version 3.3:* context was added.

*Changed in version 3.3:* source_address argument was added.

*Changed in version 3.4:* The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

class smtplib.LMTP(host='', port=LMTP_PORT, local_hostname=None, source_address=None)

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It's common to use Unix sockets for LMTP, so our connect() method must support that as well as a regular host:port server. The optional arguments local_hostname and source_address have the same meaning as they do in the SMTP class. To specify a Unix socket, you must use an absolute path for host, starting with a ‘/’.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don’t support or require any authentication, but your mileage might vary.
A nice selection of exceptions is defined as well:

```python
exception smtplib.SMTPException
```

Subclass of `OSError` that is the base exception class for all the other exceptions provided by this module.

*Changed in version 3.4:* SMTPException became subclass of `OSError`

```python
exception smtplib.SMTPServerDisconnected
```

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the SMTP instance before connecting it to a server.

```python
exception smtplib.SMTPResponseException
```

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

```python
exception smtplib.SMTPSenderRefused
```

Sender address refused. In addition to the attributes set by on all `SMTPResponseException` exceptions, this sets ‘sender’ to the string that the SMTP server refused.

```python
exception smtplib.SMTPRecipientsRefused
```

All recipient addresses refused. The errors for each recipient are accessible through the attribute `recipients`, which is a dictionary of exactly the same sort as `SMTP.sendmail()` returns.

```python
exception smtplib.SMTPDataError
```

The SMTP server refused to accept the message data.
exception smtplib.SMTPConnectError
Error occurred during establishment of a connection with the server.

exception smtplib.SMTPHeloError
The server refused our HELO message.

exception smtplib.SMTPNotSupportedError
The command or option attempted is not supported by the server.

New in version 3.5.

exception smtplib.SMTPAuthenticationError
SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

See also:

RFC 821 - Simple Mail Transfer Protocol
Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

RFC 1869 - SMTP Service Extensions
Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
21.17.1. SMTP Objects

An SMTP instance has the following methods:

SMTP.set_debuglevel(level)
Set the debug output level. A value of 1 or True for level results in debug messages for connection and for all messages sent to and received from the server. A value of 2 for level results in these messages being timestamped.

*Changed in version 3.5:* Added debuglevel 2.

SMTP.docmd(cmd, args="")
Send a command cmd to the server. The optional argument args is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, SMTPServerDisconnected will be raised.

SMTP.connect(host='localhost', port=0)
Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (':') followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This
method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

**SMTP.helo(name="")**
Identify yourself to the SMTP server using HELO. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the helo_resp attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

**SMTP.ehlo(name="")**
Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by `has_extn()`. Also sets several informational attributes: the message returned by the server is stored as the ehlo_resp attribute, does_esmtp is set to true or false depending on whether the server supports ESMTP, and esmtp_features will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

**SMTP.ehlo_or_helo_if_needed()**
This method call `ehlo()` and or `helo()` if there has been no previous EHLO or HELO command this session. It tries ESMTP
EHLO first.

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTP**.has_extn(name)

Return True if name is in the set of SMTP service extensions returned by the server, False otherwise. Case is ignored.

**SMTP**.verify(address)

Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

**Note:** Many sites disable SMTP VRFY in order to foil spammers.

**SMTP**.login(user, password, *, initial_response_ok=True)

Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTPAuthenticationError**

The server didn’t accept the username/password combination.

**SMTPNotSupportedError**

The AUTH command is not supported by the server.
SMTPException

No suitable authentication method was found.

Each of the authentication methods supported by `smtplib` are tried in turn if they are advertised as supported by the server. See `auth()` for a list of supported authentication methods. `initial_response_ok` is passed through to `auth()`.

Optional keyword argument `initial_response_ok` specifies whether, for authentication methods that support it, an “initial response” as specified in RFC 4954 can be sent along with the AUTH command, rather than requiring a challenge/response.

*Changed in version 3.5:* `SMTPNotSupportedError` may be raised, and the `initial_response_ok` parameter was added.

```python
SMTP.auth(mechanism, authobject, *, initial_response_ok=True)
```

Issue an SMTP AUTH command for the specified authentication `mechanism`, and handle the challenge response via `authobject`.

`mechanism` specifies which authentication mechanism is to be used as argument to the AUTH command; the valid values are those listed in the `auth` element of `esmtp_features`.

`authobject` must be a callable object taking an optional single argument:

```
data = authobject(challenge=None)
```

If optional keyword argument `initial_response_ok` is true, `authobject()` will be called first with no argument. It can return the RFC 4954 “initial response” bytes which will be encoded and sent with the AUTH command as below. If the `authobject()`
does not support an initial response (e.g. because it requires a challenge), it should return None when called with challenge=None. If `initial_response_ok` is false, then `authobject()` will not be called first with None.

If the initial response check returns None, or if `initial_response_ok` is false, `authobject()` will be called to process the server's challenge response; the `challenge` argument it is passed will be a bytes. It should return bytes `data` that will be base64 encoded and sent to the server.

The SMTP class provides authobjects for the CRAM-MD5, PLAIN, and LOGIN mechanisms; they are named `SMTP.auth_cram_md5`, `SMTP.auth_plain`, and `SMTP.auth_login` respectively. They all require that the user and password properties of the SMTP instance are set to appropriate values.

User code does not normally need to call auth directly, but can instead call the `login()` method, which will try each of the above mechanisms in turn, in the order listed. auth is exposed to facilitate the implementation of authentication methods not (or not yet) supported directly by smtplib.

New in version 3.5.

**SMTP.starttls(keyfile=None, certfile=None, context=None)**

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call `ehlo()` again.

If `keyfile` and `certfile` are provided, these are passed to the `socket`
module's `ssl()` function.

Optional `context` parameter is a `ssl.SSLContext` object; This is an alternative to using a keyfile and a certfile and if specified both `keyfile` and `certfile` should be None.

If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first.

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTPNotSupportedError**

The server does not support the STARTTLS extension.

**RuntimeError**

SSL/TLS support is not available to your Python interpreter.

*Changed in version 3.3:* `context` was added.

*Changed in version 3.4:* The method now supports hostname check with `SSLContext.check_hostname` and `Server Name Indicator` (see `HAS_SNI`).

*Changed in version 3.5:* The error raised for lack of STARTTLS support is now the `SMTPNotSupportedError` subclass instead of the base `SMTPException`.

```python
SMTP.sendmail(from_addr, to_addrs, msg, mail_options=[], rcpt_options=[])
```

Send mail. The required arguments are an RFC 822 from-address string, a list of RFC 822 to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as 8bitmime) to be used
in MAIL FROM commands as mail_options. ESMTP options (such as DSN commands) that should be used with all RCPT commands can be passed as rcpt_options. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as mail(), rcpt() and data() to send the message.)

**Note:** The from_addr and to_addrs parameters are used to construct the message envelope used by the transport agents. sendmail does not modify the message headers in any way.

`msg` may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone \r and \n characters are converted to \r\n characters. A byte string is not modified.

If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If EHLO fails, HELO will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

If SMTPUTF8 is included in mail_options, and the server supports it, from_addr and to_addr may contain non-ASCII characters.
This method may raise the following exceptions:

**SMTPRecipientsRefused**
All recipients were refused. Nobody got the mail. The recipients attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**SMTPHeloError**
The server didn’t reply properly to the HELO greeting.

**SMTPSenderRefused**
The server didn’t accept the `from_addr`.

**SMTPDataError**
The server replied with an unexpected error code (other than a refusal of a recipient).

**SMTPNotSupportedError**
SMTPUTF8 was given in the `mail_options` but is not supported by the server.

Unless otherwise noted, the connection will be open even after an exception is raised.

*Changed in version 3.2:* `msg` may be a byte string.

*Changed in version 3.5:* SMTPUTF8 support added, and `SMTPNotSupportedError` may be raised if SMTPUTF8 is specified but the server does not support it.

**SMTP.send_message**(`msg`, `from_addr=None`, `to_addrs=None`, `mail_options=[], rcpt_options=[]`)
This is a convenience method for calling `sendmail()` with the message represented by an `email.message.Message` object. The arguments have the same meaning as for `sendmail()`,
except that msg is a Message object.

If from_addr is None or to_addrs is None, send_message fills those arguments with addresses extracted from the headers of msg as specified in RFC 5322: from_addr is set to the Sender field if it is present, and otherwise to the From field. to_addresses combines the values (if any) of the To, Cc, and Bcc fields from msg. If exactly one set of Resent-* headers appear in the message, the regular headers are ignored and the Resent-* headers are used instead. If the message contains more than one set of Resent-* headers, a ValueError is raised, since there is no way to unambiguously detect the most recent set of Resent-headers.

send_message serializes msg using BytesGenerator with \r\n as the linesep, and calls sendmail() to transmit the resulting message. Regardless of the values of from_addr and to_addrs, send_message does not transmit any Bcc or Resent-Bcc headers that may appear in msg. If any of the addresses in from_addr and to_addrs contain non-ASCII characters and the server does not advertise SMTPUTF8 support, an SMTPNotSupported error is raised. Otherwise the Message is serialized with a clone of its policy with the utf8 attribute set to True, and SMTPUTF8 and BODY=8BITMIME are added to mail_options.

New in version 3.2.

New in version 3.5: Support for internationalized addresses (SMTPUTF8).

SMTP.quit()
Terminate the SMTP session and close the connection. Return the result of the SMTP QUIT command.

Low-level methods corresponding to the standard SMTP/ESMTP commands HELP, RSET, NOOP, MAIL, RCPT, and DATA are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
21.17.2. SMTP Example

This example prompts the user for addresses needed in the message envelope (‘To’ and ‘From’ addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn’t do any processing of the RFC 822 headers. In particular, the ‘To’ and ‘From’ addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs  = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows):")

# Add the From: and To: headers at the start!
msg = ("From: %s\n\nTo: %s\n\n" % (fromaddr, ", ".join(toaddrs)))

while True:
    try:
        line = input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print("Message length is", len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
```
server.quit()

**Note:** In general, you will want to use the `email` package's features to construct an email message, which you can then send via `send_message()`; see `email: Examples`. 
21.18. `smtpd` — SMTP Server

**Source code:** Lib/smtpd.py

This module offers several classes to implement SMTP (email) servers.

Several server implementations are present; one is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

Additionally the SMTPChannel may be extended to implement very specific interaction behaviour with SMTP clients.

The code supports RFC 5321, plus the RFC 1870 SIZE and RFC 6531 SMTPUTF8 extensions.
21.18.1. SMTPServer Objects

```python
class smtplib.SMTPServer(localaddr, remoteaddr, 
data_size_limit=33554432, map=None, enable_SMTPUTF8=False, 
decode_data=True)
```

Create a new SMTPServer object, which binds to local address `localaddr`. It will treat `remoteaddr` as an upstream SMTP relayer. It inherits from `asyncore.dispatcher`, and so will insert itself into `asyncore`'s event loop on instantiation.

`data_size_limit` specifies the maximum number of bytes that will be accepted in a DATA command. A value of None or 0 means no limit.

`map` is the socket map to use for connections (an initially empty dictionary is a suitable value). If not specified the `asyncore` global socket map is used.

`enable_SMTPUTF8` determines whether the SMTPUTF8 extension (as defined in RFC 6531) should be enabled. The default is False. If set to True, `decode_data` must be False (otherwise an error is raised). When True, SMTPUTF8 is accepted as a parameter to the MAIL command and when present is passed to `process_message()` in the `kwargs['mail_options']` list.

`decode_data` specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. The default is True for backward compatibility reasons, but will change to False in Python 3.6; specify the keyword value explicitly to avoid the DeprecationWarning. When `decode_data` is set to False the server advertises the 8BITMIME extension (RFC 6152), accepts
the BODY=8BITMIME parameter to the MAIL command, and when present passes it to \texttt{process_message()} in the \texttt{kwargs['mail_options']} list.

\textbf{process_message}(\textit{peer, mailfrom, rcpttos, data, **kwargs})

Raise a \texttt{NotImplementedError} exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as \texttt{remoteaddr} will be available as the \texttt{_remoteaddr} attribute. \textit{peer} is the remote host's address, \textit{mailfrom} is the envelope originator, \textit{rcpttos} are the envelope recipients and \textit{data} is a string containing the contents of the e-mail (which should be in \texttt{RFC 5321} format).

If the \texttt{decode_data} constructor keyword is set to \texttt{True}, the \textit{data} argument will be a unicode string. If it is set to \texttt{False}, it will be a bytes object.

\texttt{kwargs} is a dictionary containing additional information. It is empty unless at least one of \texttt{decode_data=False} or \texttt{enable_SMTPUTF8=True} was given as an init parameter, in which case it contains the following keys:

- \textit{mail_options}:
  a list of all received parameters to the MAIL command (the elements are uppercase strings; example: \texttt{['BODY=8BITMIME', 'SMTPUTF8']}).

- \textit{rcpt_options}:
  same as \textit{mail_options} but for the RCPT command. Currently no RCPT TO options are supported, so for now this will always be an empty list.

Implementations of \texttt{process_message} should use the
**kwargs signature to accept arbitrary keyword arguments, since future feature enhancements may add keys to the kwargs dictionary.

Return None to request a normal 250 Ok response; otherwise return the desired response string in RFC 5321 format.

**channel_class**

Override this in subclasses to use a custom SMTPChannel for managing SMTP clients.

*New in version 3.4:* The map constructor argument.

*Changed in version 3.5:* localaddr and remoteaddr may now contain IPv6 addresses.

*New in version 3.5:* the decode_data and enable_SMTPUTF8 constructor arguments, and the kwargs argument to process_message() when one or more of these is specified.
21.18.2. DebuggingServer Objects

class smtpd.DebuggingServer(localaddr, remoteaddr)

Create a new debugging server. Arguments are as per SMTPServer. Messages will be discarded, and printed on stdout.
21.18.3. PureProxy Objects

class smtPD.PureProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.4. MailmanProxy Objects

class smtpd.MailmanProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.5. SMTPChannel Objects

```python
class smtplib.SMTPChannel(server, conn, addr,
data_size_limit=33554432, map=None, enable_SMTPUTF8=False,
decode_data=True)
```

Create a new `SMTPChannel` object which manages the communication between the server and a single SMTP client.

`conn` and `addr` are as per the instance variables described below.

`data_size_limit` specifies the maximum number of bytes that will be accepted in a DATA command. A value of None or 0 means no limit.

`enable_SMTPUTF8` determines whether the SMTPUTF8 extension (as defined in RFC 6531) should be enabled. The default is False. A `ValueError` is raised if both `enable_SMTPUTF8` and `decode_data` are set to True at the same time.

A dictionary can be specified in `map` to avoid using a global socket map.

`decode_data` specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. The default is True for backward compatibility reasons, but will change to False in Python 3.6. Specify the keyword value explicitly to avoid the `DeprecationWarning`.

To use a custom SMTPChannel implementation you need to override the `SMTPServer.channel_class` of your `SMTPServer`. 
Changed in version 3.5: the `decode_data` and `enable_SMTPUTF8` arguments were added.

The `SMTPChannel` has the following instance variables:

**smtp_server**
- Holds the `SMTPServer` that spawned this channel.

**conn**
- Holds the socket object connecting to the client.

**addr**
- Holds the address of the client, the second value returned by `socket.accept`

**received_lines**
- Holds a list of the line strings (decoded using UTF-8) received from the client. The lines have their "\r\n" line ending translated to "\n".

**smtp_state**
- Holds the current state of the channel. This will be either `COMMAND` initially and then `DATA` after the client sends a “DATA” line.

**seen_greeting**
- Holds a string containing the greeting sent by the client in its “HELO”.

**mailfrom**
- Holds a string containing the address identified in the “MAIL FROM:” line from the client.
rcpttos
Holds a list of strings containing the addresses identified in the "RCPT TO:" lines from the client.

received_data
Holds a string containing all of the data sent by the client during the DATA state, up to but not including the terminating "\r\n\r\n".

fqdn
Holds the fully-qualified domain name of the server as returned by socket.getfqdn().

peer
Holds the name of the client peer as returned by conn.getpeername() where conn is conn.

The SMTPChannel operates by invoking methods named smtp_<command> upon reception of a command line from the client. Built into the base SMTPChannel class are methods for handling the following commands (and responding to them appropriately):

<table>
<thead>
<tr>
<th>Command</th>
<th>Action taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>HELO</td>
<td>Accepts the greeting from the client and stores it in seen_greeting. Sets server to base command mode.</td>
</tr>
<tr>
<td>EHLO</td>
<td>Accepts the greeting from the client and stores it in seen_greeting. Sets server to extended command mode.</td>
</tr>
<tr>
<td>NOOP</td>
<td>Takes no action.</td>
</tr>
<tr>
<td>QUIT</td>
<td>Closes the connection cleanly.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>MAIL</td>
<td>Accepts the “MAIL FROM:” syntax and stores the supplied address as <code>mailfrom</code>. In extended command mode, accepts the RFC 1870 SIZE attribute and responds appropriately based on the value of <code>data_size_limit</code>.</td>
</tr>
<tr>
<td>RCPT</td>
<td>Accepts the “RCPT TO:” syntax and stores the supplied addresses in the <code>rcpttos</code> list.</td>
</tr>
<tr>
<td>RSET</td>
<td>Resets the <code>mailfrom</code>, <code>rcpttos</code>, and <code>received_data</code>, but not the greeting.</td>
</tr>
<tr>
<td>DATA</td>
<td>Sets the internal state to DATA and stores remaining lines from the client in <code>received_data</code> until the terminator &quot;\r\n\r\n&quot; is received.</td>
</tr>
<tr>
<td>HELP</td>
<td>Returns minimal information on command syntax</td>
</tr>
<tr>
<td>VRFY</td>
<td>Returns code 252 (the server doesn’t know if the address is valid)</td>
</tr>
<tr>
<td>EXPN</td>
<td>Reports that the command is not implemented.</td>
</tr>
</tbody>
</table>

Last updated on Dec 06, 2015. Found a bug?
Created using Sphinx 1.3.1.
The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in arpa/telnet.h, with the leading TEL0PT_ removed. For symbolic names of options which are traditionally not included in arpa/telnet.h, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

```python
class telnetlib.Telnet(host=None, port=0[, timeout])
```

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor too, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).
Do not reopen an already connected instance.

This class has many read_*( ) methods. Note that some of them raise EOFError when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

See also:

**RFC 854 - Telnet Protocol Specification**
Definition of the Telnet protocol.
21.19.1. Telnet Objects

**Telnet** instances have the following methods:

**Telnet**.read_until*(expected, timeout=None)*

Read until a given byte string, *expected*, is encountered or until *timeout* seconds have passed.

When no match is found, return whatever is available instead, possibly empty bytes. Raise **EOFError** if the connection is closed and no cooked data is available.

**Telnet**.read_all()

Read all data until EOF as bytes; block until connection closed.

**Telnet**.read_some()

Read at least one byte of cooked data unless EOF is hit. Return b'' if EOF is hit. Block if no data is immediately available.

**Telnet**.read_very_eager()

Read everything that can be without blocking in I/O (eager).

Raise **EOFError** if connection closed and no cooked data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

**Telnet**.read_eager()

Read readily available data.

Raise **EOFError** if connection closed and no cooked data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
Telnet.read_lazy()

Process and return data already in the queues (lazy).

Raise EOFError if connection closed and no data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_very_lazy()

Return any data available in the cooked queue (very lazy).

Raise EOFError if connection closed and no data available. Return b'' if no cooked data available otherwise. This method never blocks.

Telnet.read_sb_data()

Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

Telnet.open(host, port=0[, timeout])

Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

Telnet.msg(msg, *args)

Print a debug message when the debug level is > 0. If extra arguments are present, they are substituted in the message using the standard string formatting operator.
Telnet.set_debuglevel(debuglevel)
   Set the debug level. The higher the value of debuglevel, the more debug output you get (on sys.stdout).

Telnet.close()
   Close the connection.

Telnet.get_socket()
   Return the socket object used internally.

Telnet.fileno()
   Return the file descriptor of the socket object used internally.

Telnet.write(buffer)
   Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise OSError if the connection is closed.

   Changed in version 3.3: This method used to raise socket.error, which is now an alias of OSError.

Telnet.interact()
   Interaction function, emulates a very dumb Telnet client.

Telnet.mt_interact()
   Multithreaded version of interact().

Telnet.expect(list, timeout=None)
   Read until one from a list of a regular expressions matches.

   The first argument is a list of regular expressions, either compiled (regex objects) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block
Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise **EOFError**. Otherwise, when nothing matches, return (-1, None, data) where *data* is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as .* ) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

**Telnet.set_option_negotiation_callback** *(callback)*

Each time a telnet option is read on the input flow, this *callback* (if set) is called with the following parameters: callback(telnet socket, command (DO/DONT/WILL/WONT), option). No other action is done afterwards by telnetlib.
21.19.2. Telnet Example

A simple example illustrating typical use:

```python
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)
	nn.read_until(b"login: ")

tn.write(user.encode('ascii') + b"\n")

if password:
    tn.read_until(b"Password: ")
    tn.write(password.encode('ascii') + b"\n")

tn.write(b"ls\n")

tn.write(b"exit\n")

print(tn.read_all().decode('ascii'))
```
21.20. **uuid** — UUID objects according to RFC 4122

This module provides immutable UUID objects (the **UUID** class) and the functions `uuid1()`, `uuid3()`, `uuid4()`, `uuid5()` for generating version 1, 3, 4, and 5 UUIDs as specified in **RFC 4122**.

If all you want is a unique ID, you should probably call `uuid1()` or `uuid4()`. Note that `uuid1()` may compromise privacy since it creates a UUID containing the computer's network address. `uuid4()` creates a random UUID.

```python
class uuid.UUID(hex=None, bytes=None, bytes_le=None, fields=None, int=None, version=None):
    Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the bytes argument, a string of 16 bytes in little-endian order as the bytes_le argument, a tuple of six integers (32-bit time_low, 16-bit time_mid, 16-bit time_hi_version, 8-bit clock_seq_hi_variant, 8-bit clock_seq_low, 48-bit node) as the fields argument, or a single 128-bit integer as the int argument. When a string of hex digits is given, curly braces, hyphens, and aURN prefix are all optional. For example, these expressions all yield the same UUID:
```

```
UUID( '{12345678-1234-5678-1234-567812345678}' )
UUID( '12345678123456781234567812345678' )
UUID( 'urn:uuid:12345678-1234-5678-1234-567812345678' )
UUID( bytes=b'\x12\x34\x56\x78'*4 )
UUID( bytes_le=b'\x78\x56\x34\x12\x34\x12\x78\x56' b'\x12\x34\x56\x78\x12\x34\x56\x78' )
UUID( fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x
```
Exactly one of `hex`, `bytes`, `bytes_le`, `fields`, or `int` must be given. The `version` argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given `hex`, `bytes`, `bytes_le`, `fields`, or `int`.

**UUID** instances have these read-only attributes:

**UUID.bytes**

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.bytes_le**

The UUID as a 16-byte string (with `time_low`, `time_mid`, and `time_hi_version` in little-endian byte order).

**UUID.fields**

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>time_low</td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td>time_mid</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>time_hi_version</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_hi_variant</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_low</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>node</td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td>time</td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td>clock_seq</td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>
The UUID as a 32-character hexadecimal string.

The UUID as a 128-bit integer.

The UUID as aURN as specified in RFC 4122.

The UUID variant, which determines the internal layout of the UUID. This will be one of the integer constants RESERVED_NCS, RFC_4122, RESERVED_MICROSOFT, or RESERVED_FUTURE.

The UUID version number (1 through 5, meaningful only when the variant is RFC_4122).

The uuid module defines the following functions:

\section*{uuid\texttt{.getnode}()}

Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

\section*{uuid\texttt{.uuid1}(node=None, clock_seq=None)}

Generate a UUID from a host ID, sequence number, and the current time. If \texttt{node} is not given, \texttt{getnode()} is used to obtain the
hardware address. If \textit{clock_seq} is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

\texttt{uuid.uuid3}(\textit{namespace}, \textit{name})

Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

\texttt{uuid.uuid4()}

Generate a random UUID.

\texttt{uuid.uuid5}(\textit{namespace}, \textit{name})

Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The \texttt{uuid} module defines the following namespace identifiers for use with \texttt{uuid3()} or \texttt{uuid5()}.

\texttt{uuid.NAMESPACE_DNS}

When this namespace is specified, the \textit{name} string is a fully-qualified domain name.

\texttt{uuid.NAMESPACE_URL}

When this namespace is specified, the \textit{name} string is a URL.

\texttt{uuid.NAMESPACE_OID}

When this namespace is specified, the \textit{name} string is an ISO OID.

\texttt{uuid.NAMESPACE_X500}

When this namespace is specified, the \textit{name} string is an X.500 DN in DER or a text output format.

The \texttt{uuid} module defines the following constants for the possible values of the variant attribute:
uuid.**RESERVED_NCS**
Reserved for NCS compatibility.

uuid.**RFC_4122**

uuid.**RESERVED_MICROSOFT**
Reserved for Microsoft compatibility.

uuid.**RESERVED_FUTURE**
Reserved for future definition.

**See also:**

[RFC 4122 - A Universally Unique IDentifier (UUID) URN Namespace](https://tools.ietf.org/html/rfc4122)
This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
21.20.1. Example

Here are some examples of typical usage of the `uuid` module:

```python
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\0b\0c\r

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
```
21.21. socketserver — A framework for network servers

Source code: Lib/socketserver.py

The socketserver module simplifies the task of writing network servers.

There are four basic server classes: TCPServer uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. UDPServer uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The more infrequently used UnixStreamServer and UnixDatagramServer classes are similar, but use Unix domain sockets; they're not available on non-Unix platforms. For more details on network programming, consult a book such as W. Richard Steven's UNIX Network Programming or Ralph Davis's Win32 Network Programming.

These four classes process requests synchronously; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the ForkingMixIn and ThreadingMixIn mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a
request handler class by subclassing the BaseRequestHandler class and overriding its handle() method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server's address and the request handler class. Then call the handle_request() or serve_forever() method of the server object to process one or many requests. Finally, call server_close() to close the socket.

When inheriting from ThreadingMixIn for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The ThreadingMixIn class defines an attribute daemon_threads, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is False, meaning that Python will not exit until all threads created by ThreadingMixIn have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.
21.21.1. Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+
| BaseServer |
+------------+
    |
    v
+------------+------------------+
| TCPServer  |------->| UnixStreamServer |
+------------+------------------+
    |
    v
+------------+------------------+
| UDPServer  |------->| UnixDatagramServer |
+------------+------------------+
```

Note that UnixDatagramServer derives from UDPServer, not from UnixStreamServer — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

Forking and threading versions of each type of server can be created using the ForkingMixIn and ThreadingMixIn mix-in classes. For instance, a threading UDP server class is created as follows:

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer):
```

The mix-in class must come first, since it overrides a method defined in UDPServer. Setting the various attributes also change the behavior of the underlying server mechanism.
To implement a service, you must derive a class from BaseRequestHandler and redefine its handle() method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses StreamRequestHandler or DatagramRequestHandler.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class handle() method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor fork() (or where these are too expensive or inappropriate for the service) is to maintain
an explicit table of partially finished requests and to use selectors to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See asyncore for another way to manage this.
21.21.2. Server Objects

class socketserver.BaseServer

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses.

BaseServer.fileno()

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to selectors, to allow monitoring multiple servers in the same process.

BaseServer.handle_request()

Process a single request. This function calls the following methods in order: get_request(), verify_request(), and process_request(). If the user-provided handle() method of the handler class raises an exception, the server's handle_error() method will be called. If no request is received within self.timeout seconds, handle_timeout() will be called and handle_request() will return.

BaseServer.serve_forever(poll_interval=0.5)

Handle requests until an explicit shutdown() request. Poll for shutdown every poll_interval seconds. Ignores self.timeout. It also calls service_actions(), which may be used by a subclass or mixin to provide actions specific to a given service. For example, the ForkingMixIn class uses service_actions() to clean up zombie child processes.

Changed in version 3.3: Added service_actions call to the serve_forever method.
BaseServer\texttt{.service\_actions()}

This is called in the \texttt{serve\_forever()} loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

\textit{New in version 3.3.}

BaseServer\texttt{.shutdown()}

Tell the \texttt{serve\_forever()} loop to stop and wait until it does.

BaseServer\texttt{.server\_close()}

Clean up the server. May be overridden.

\textit{New in version 2.6.}

BaseServer\texttt{.address\_family}

The family of protocols to which the server’s socket belongs. Common examples are \texttt{socket.AF_INET} and \texttt{socket.AF_UNIX}.

BaseServer\texttt{.RequestHandlerClass}

The user-provided request handler class; an instance of this class is created for each request.

BaseServer\texttt{.server\_address}

The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the socket module for details. For Internet protocols, this is a tuple containing a string giving the address, and an integer port number: (\texttt{'127.0.0.1', 80}), for example.

BaseServer\texttt{.socket}

The socket object on which the server will listen for incoming
requests.

The server classes support the following class variables:

**BaseServer**. `allow_reuse_address`  
Whether the server will allow the reuse of an address. This defaults to `False`, and can be set in subclasses to change the policy.

**BaseServer**. `request_queue_size`  
The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to `request_queue_size` requests. Once the queue is full, further requests from clients will get a “Connection denied” error. The default value is usually 5, but this can be overridden by subclasses.

**BaseServer**. `socket_type`  
The type of socket used by the server; `socket.SOCK_STREAM` and `socket.SOCK_DGRAM` are two common values.

**BaseServer**. `timeout`  
Timeout duration, measured in seconds, or `None` if no timeout is desired. If `handle_request()` receives no incoming requests within the timeout period, the `handle_timeout()` method is called.

There are various server methods that can be overridden by subclasses of base server classes like TCPServer; these methods aren't useful to external users of the server object.

**BaseServer**. `finish_request()`  
Actually processes the request by instantiating `RequestHandlerClass` and calling its `handle()` method.
**BaseServer.get_request()**

Must accept a request from the socket, and return a 2-tuple containing the new socket object to be used to communicate with the client, and the client’s address.

**BaseServer.handle_error(request, client_address)**

This function is called if the RequestHandlerClass's handle() method raises an exception. The default action is to print the traceback to standard output and continue handling further requests.

**BaseServer.handle_timeout()**

This function is called when the timeout attribute has been set to a value other than None and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**BaseServer.process_request(request, client_address)**

Calls finish_request() to create an instance of the RequestHandlerClass. If desired, this function can create a new process or thread to handle the request; the ForkingMixIn and ThreadingMixIn classes do this.

**BaseServer.server_activate()**

Called by the server’s constructor to activate the server. The default behavior just listen()s to the server’s socket. May be overridden.

**BaseServer.server_bind()**

Called by the server’s constructor to bind the socket to the desired address. May be overridden.
BaseServer.**verify_request**(request, client_address)

Must return a Boolean value; if the value is **True**, the request will be processed, and if it's **False**, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns **True**.
21.21.3. RequestHandler Objects

The request handler class must define a new handle() method, and can override any of the following methods. A new instance is created for each request.

RequestHandler.finish()
Called after the handle() method to perform any clean-up actions required. The default implementation does nothing. If setup() raises an exception, this function will not be called.

RequestHandler.handle()
This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as self.request; the client address as self.client_address; and the server instance as self.server, in case it needs access to per-server information.

The type of self.request is different for datagram or stream services. For stream services, self.request is a socket object; for datagram services, self.request is a pair of string and socket. However, this can be hidden by using the request handler subclasses StreamRequestHandler or DatagramRequestHandler, which override the setup() and finish() methods, and provide self.rfile and self.wfile attributes. self.rfile and self.wfile can be read or written, respectively, to get the request data or return data to the client.

RequestHandler.setup()
Called before the handle() method to perform any initialization
actions required. The default implementation does nothing.
21.21.4. Examples

21.21.4.1. socketserver.TCPServer Example

This is the server side:

```python
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    ""
    The RequestHandler class for our server.

    It is instantiated once per connection to the server, and must
    override the handle() method to implement communication with
    a client.
    ""

    def handle(self):
        # self.request is the TCP socket connected to the
        # client.
        self.data = self.request.recv(1024).strip()
        print("{} wrote:").format(self.client_address)
        print(self.data)
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    server = socketserver.TCPServer((HOST, PORT), MyTCPHandler)

    # Activate the server; this will keep running until
    # interrupt the program with Ctrl-C
    server.serve_forever()
```
An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```python
class MyTCPHandler(socketserver.StreamRequestHandler):
    def handle(self):
        # self.rfile is a file-like object created by the handler;
        # we can now use e.g. readline() instead of
        self.data = self.rfile.readline().strip()
        print("{} wrote:").format(self.client_address)
        print(self.data)
        # Likewise, self.wfile is a file-like object
        # to the client
        self.wfile.write(self.data.upper())
```

The difference is that the readline() call in the second handler will call recv() multiple times until it encounters a newline character, while the single recv() call in the first handler will just return what has been sent from the client in one sendall() call.

This is the client side:

```python
import socket
import sys
HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
try:
    # Connect to server and send data
    sock.connect((HOST, PORT))
```
sock.sendall(bytes(data + "\n", "utf-8"))

# Receive data from the server and shut down
received = str(sock.recv(1024), "utf-8")

finally:
    sock.close()

print("Sent: {}".format(data))
print("Received: {}".format(received))

The output of the example should look something like this:

Server:

$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'

Client:

$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE

21.21.4.2. socketserver.UDPServer Example

This is the server side:

import socketserver
class MyUDPHandler(socketserver.BaseRequestHandler):
    ""
    This class works similar to the TCP handler class.
    self.request consists of a pair of data and client.
    there is no connection the client address must be
    when sending data back via sendto().
    ""

    def handle(self):
        data = self.request[0].strip()
        socket = self.request[1]
        print('{} wrote:'.format(self.client_address)
        print(data)
        socket.sendto(data.upper(), self.client_address)

if __name__ == '__main__':
    HOST, PORT = "localhost", 9999
    server = socketserver.UDPServer((HOST, PORT), MyUDPHandler)
    server.serve_forever()

This is the client side:

import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:]):

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has
# Instead, data is directly sent to the recipient via
sock.sendto(bytes(data + "\n", "utf-8"), (HOST, PORT))
received = str(sock.recv(1024), "utf-8")
The output of the example should look exactly like for the TCP server example.

21.21.4.3. Asynchronous Mixins

To build asynchronous handlers, use the ThreadingMixIn and ForkingMixIn classes.

An example for the ThreadingMixIn class:

```python
import socket
import threading
import socketserver

class ThreadedTCPRequestHandler(socketserver.BaseRequestHandler):
    def handle(self):
        data = str(self.request.recv(1024), 'ascii')
        cur_thread = threading.current_thread()
        response = bytes(f'{}: {{}}'.format(cur_thread), 'ascii')
        self.request.sendall(response)

class ThreadedTCPServer(socketserver.ThreadingMixIn, socketserver.TCPServer):
    pass
def client(ip, port, message):
    sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    sock.connect((ip, port))
    try:
        sock.sendall(bytes(message, 'ascii'))
        response = str(sock.recv(1024), 'ascii')
```

```
print("Received: {}".format(response))

finally:
    sock.close()

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    ip, port = server.server_address

    # Start a thread with the server -- that thread
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)

    # Exit the server thread when the main thread terminates
    server_thread.daemon = True
    server_thread.start()

    print("Server loop running in thread:", server_thread)

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()
    server.server_close()

The output of the example should look something like this:

```
$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3
```

The ForkingMixIn class is used in the same way, except that the server will spawn a new process for each request.
This module defines classes for implementing HTTP servers (Web servers).

One class, `HTTPServer`, is a `socketserver.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=HTTPServer, handler_class=BaseHTTPRequestHandler, server_address=('', 8000)):
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

```python
class http.server.HTTPServer(server_address, RequestHandlerClass):
    This class builds on the TCPServer class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler’s server instance variable.
```

The `HTTPServer` must be given a `RequestHandlerClass` on instantiation, of which this module provides three different variants:

```python
class http.server.BaseHTTPRequestHandler(request, client_address, server)
```
This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). `BaseHTTPRequestHandler` provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method SPAM, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

`BaseHTTPRequestHandler` has the following instance variables:

**client_address**
Contains a tuple of the form `(host, port)` referring to the client's address.

**server**
Contains the server instance.

**close_connection**
Boolean that should be set before `handle_one_request()` returns, indicating if another request may be expected, or if the connection should be shut down.

**requestline**
Contains the string representation of the HTTP request line. The terminating CRLF is stripped. This attribute should be set by `handle_one_request()`. If no valid request line was processed, it should be set to the empty string.
command
Contains the command (request type). For example, 'GET'.

path
Contains the request path.

request_version
Contains the version string from the request. For example, 'HTTP/1.0'.

headers
Holds an instance of the class specified by the MessageClass class variable. This instance parses and manages the headers in the HTTP request. The parse_headers() function from http.client is used to parse the headers and it requires that the HTTP request provide a valid RFC 2822 style header.

rfile
Contains an input stream, positioned at the start of the optional input data.

wfile
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream.

BaseHTTPRequestHandler has the following class variables:

server_version
Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.
**sys_version**

Contains the Python system version, in a form usable by the `version_string` method and the `server_version` class variable. For example, 'Python/1.4'.

**error_message_format**

 Specifies a format string for building an error response to the client. It uses parenthesized, keyed format specifiers, so the format operand must be a dictionary. The `code` key should be an integer, specifying the numeric HTTP error code value. `message` should be a string containing a (detailed) error message of what occurred, and `explain` should be an explanation of the error code number. Default `message` and `explain` values can be found in the `responses` class variable.

**error_content_type**

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

**protocol_version**

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server must then include an accurate Content-Length header (using `send_header()`) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

**MessageClass**

Specifies an `email.message.Message`-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to `http.client.HTTPMessage`. 
responses

This variable contains a mapping of error code integers to two-element tuples containing a short and long message. For example, \{code: (shortmessage, longmessage)\}. The shortmessage is usually used as the message key in an error response, and longmessage as the explain key (see the error_message_format class variable).

A BaseHTTPRequestHandler instance has the following methods:

**handle()**

Calls handle_one_request() once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate do_*() methods.

**handle_one_request()**

This method will parse and dispatch the request to the appropriate do_*() method. You should never need to override it.

**handle_expect_100()**

When a HTTP/1.1 compliant server receives an Expect: 100-continue request header it responds back with a 100 Continue followed by 200 OK headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can chose to send 417 Expectation Failed as a response header and return False.

*New in version 3.2.*
**send_error**(*code, message=None, explain=None*)

Sends and logs a complete error reply to the client. The numeric *code* specifies the HTTP error code, with *message* as an optional, short, human readable description of the error. The *explain* argument can be used to provide more detailed information about the error; it will be formatted using the *error_message_format* class variable and emitted, after a complete set of headers, as the response body. The *responses* class variable holds the default values for *message* and *explain* that will be used if no value is provided; for unknown codes the default value for both is the string `???`.

*Changed in version 3.4:* The error response includes a Content-Length header. Added the *explain* argument.

**send_response**(*code, message=None*)

Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the internal buffer, followed by *Server* and *Date* headers. The values for these two headers are picked up from the *version_string()* and *date_time_string()* methods, respectively. If the server does not intend to send any other headers using the *send_header()* method, then *send_response()* should be followed by an *end_headers()* call.

*Changed in version 3.3:* Headers are stored to an internal buffer and *end_headers()* needs to be called explicitly.

**send_header**(*keyword, value*)

Adds the HTTP header to an internal buffer which will be written to the output stream when either *end_headers()* or
flush_headers() is invoked. keyword should specify the header keyword, with value specifying its value. Note that, after the send_header calls are done, end_headers() MUST BE called in order to complete the operation.

Changed in version 3.2: Headers are stored in an internal buffer.

send_response_only(code, message=None)
Sends the response header only, used for the purposes when 100 Continue response is sent by the server to the client. The headers not buffered and sent directly the output stream. If the message is not specified, the HTTP message corresponding the response code is sent.

New in version 3.2.

default_headers()}

end_headers()
Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls flush_headers().

Changed in version 3.2: The buffered headers are written to the output stream.

flush_headers()
Finally send the headers to the output stream and flush the internal headers buffer.

New in version 3.3.

log_request(code='-', size='-')
Logs an accepted (successful) request. code should specify the numeric HTTP code associated with the response. If a size of
the response is available, then it should be passed as the size parameter.

**log_error(...)**
Logs an error when a request cannot be fulfilled. By default, it passes the message to `log_message()`, so it takes the same arguments (`format` and additional values).

**log_message(format, ...)**
Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The `format` argument is a standard printf-style format string, where the additional arguments to `log_message()` are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

**version_string()**
Returns the server software’s version string. This is a combination of the `server_version` and `sys_version` class variables.

**date_time_string(timestamp=None)**
Returns the date and time given by `timestamp` (which must be None or in the format returned by `time.time()`), formatted for a message header. If `timestamp` is omitted, it uses the current date and time. The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.

**log_date_time_string()**
Returns the current date and time, formatted for logging.
address_string()

Returns the client address.

Changed in version 3.3: Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

class http.server.SimpleHTTPRequestHandler(request, client_address, server)

This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class BaseHTTPRequestHandler. This class implements the do_GET() and do_HEAD() functions.

The following are defined as class-level attributes of SimpleHTTPRequestHandler:

server_version

This will be "SimpleHTTP/" + __version__, where __version__ is defined at the module level.

extensions_map

A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be application/octet-stream. The mapping is used case-insensitively, and so should contain only lower-cased keys.

The SimpleHTTPRequestHandler class defines the following methods:

do_HEAD()
This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the do_GET() method for a more complete explanation of the possible headers.

**do_GET()**

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named index.html or index.htm (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the list_directory() method. This method uses os.listdir() to scan the directory, and returns a 404 error response if the listdir() fails.

If the request was mapped to a file, it is opened and the contents are returned. Any OSError exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the guess_type() method, which in turn uses the extensions_map variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file's MIME type starts with text/ the file is opened in text mode; otherwise
binary mode is used.

For example usage, see the implementation of the `test()` function invocation in the `http.server` module.

The `SimpleHTTPRequestHandler` class can be used in the following manner in order to create a very basic webserver serving files relative to the current directory:

```python
import http.server
import socketserver

PORT = 8000
Handler = http.server.SimpleHTTPRequestHandler
httpd = socketserver.TCPServer(("", PORT), Handler)
print("serving at port", PORT)
httpd.serve_forever()
```

`http.server` can also be invoked directly using the `-m` switch of the interpreter with a `port` number argument. Similar to the previous example, this serves files relative to the current directory:

```bash
python -m http.server 8000
```

By default, server binds itself to all interfaces. The option `-b/`--bind` specifies a specific address to which it should bind. For example, the following command causes the server to bind to localhost only:

```bash
python -m http.server 8000 --bind 127.0.0.1
```

New in version 3.4: `--bind` argument was introduced.
class http.server.CGIHTTPRequestHandler(request, client_address, server)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in SimpleHTTPRequestHandler.

Note: CGI scripts run by the CGIHTTPRequestHandler class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The do_GET() and do_HEAD() functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the cgi_directories path.

The CGIHTTPRequestHandler defines the following data member:

cgi_directories

This defaults to ['/cgi-bin', '/htbin'] and describes directories to treat as containing CGI scripts.

The CGIHTTPRequestHandler defines the following method:

do_POST()

This method serves the 'POST' request type, only allowed for CGI scripts. Error 501, "Can only POST to CGI scripts", is
output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

**CGIHTTPRequestHandler** can be enabled in the command line by passing the **--cgi** option:

```
python -m http.server --cgi 8000
```
21.23. **http.cookies** — HTTP state management

**Source code:** `Lib/http/cookies.py`

The `http.cookies` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](https://tools.ietf.org/html/rfc2109) and [RFC 2068](https://tools.ietf.org/html/rfc2068) specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters`, `string.digits` and `!#$%&'*+-.^_`~: denote the set of valid characters allowed by this module in Cookie name (as key).

*Changed in version 3.3:* Allowed `:` as a valid Cookie name character.

**Note:** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

```exception
http.cookies.CookieError
```

Exception failing because of [RFC 2109](https://tools.ietf.org/html/rfc2109) invalidity: incorrect
attributes, incorrect *Set-Cookie* header, etc.

```python
class http.cookies.BaseCookie([input])
```

This class is a dictionary-like object whose keys are strings and whose values are *Morsel* instances. Note that upon setting a key to a value, the value is first converted to a *Morsel* containing the key and the value.

If `input` is given, it is passed to the `load()` method.

```python
class http.cookies.SimpleCookie([input])
```

This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

---

See also:

**Module http.cookiejar**

HTTP cookie handling for web *clients*. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**

This is the state management specification implemented by this module.
21.23.1. Cookie Objects

BaseCookie.value_decode(val)

Return a decoded value from a string representation. Return value can be any type. This method does nothing in BaseCookie — it exists so it can be overridden.

BaseCookie.value_encode(val)

Return an encoded value. val can be any type, but return value must be a string. This method does nothing in BaseCookie — it exists so it can be overridden.

In general, it should be the case that value_encode() and value_decode() are inverses on the range of value_decode.

BaseCookie.output(attrs=None, header='Set-Cookie:', sep='\r\n')

Return a string representation suitable to be sent as HTTP headers. attrs and header are sent to each Morsel's output() method. sep is used to join the headers together, and is by default the combination '\r\n' (CRLF).

BaseCookie.js_output(attrs=None)

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for attrs is the same as in output().

BaseCookie.load(rawdata)

If rawdata is a string, parse it as an HTTP_COOKIE and add the values found there as Morsels. If it is a dictionary, it is equivalent
for k, v in rawdata.items():
    cookie[k] = v
21.23.2. Morsel Objects

```python
class http.cookies.Morsel
    Abstract a key/value pair, which has some RFC 2109 attributes.

    Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

    • expires
    • path
    • comment
    • domain
    • max-age
    • secure
    • version
    • httponly

    The attribute httponly specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

    The keys are case-insensitive.

    Changed in version 3.5: __eq__() now takes key and value into account.

Morsel.value
    The value of the cookie.

    Deprecated since version 3.5: assigning to value; use set() instead.
```
**Morsel.coded_value**

The encoded value of the cookie — this is what should be sent.

*Deprecated since version 3.5:* assigning to `coded_value`; use `set()` instead.

**Morsel.key**

The name of the cookie.

*Deprecated since version 3.5:* assigning to `key`; use `set()` instead.

**Morsel.set(key, value, coded_value)**

Set the `key`, `value` and `coded_value` attributes.

*Deprecated since version 3.5:* The undocumented `LegalChars` parameter is ignored and will be removed in a future version.

**Morsel.isReservedKey(K)**

Whether `K` is a member of the set of keys of a `Morsel`.

**Morsel.output(attr=None, header='Set-Cookie: ')**

Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless `attr` is given, in which case it should be a list of attributes to use. `header` is by default "Set-Cookie: ".

**Morsel.js_output(attr=None)**

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for `attr` is the same as in `output()`.
Morsel.**OutputString**(attrs=None)

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for `attrs` is the same as in `output()`.

Morsel.**update**(values)

Update the values in the Morsel dictionary with the values in the dictionary `values`. Raise an error if any of the keys in the `values` dict is not a valid **RFC 2109** attribute.

*Changed in version 3.5:* an error is raised for invalid keys.

Morsel.**copy**(value)

Return a shallow copy of the Morsel object.

*Changed in version 3.5:* return a Morsel object instead of a dict.

Morsel.**setdefault**(key, value=None)

Raise an error if key is not a valid **RFC 2109** attribute, otherwise behave the same as `dict.setdefault()`.
21.23.3. Example

The following example demonstrates how to use the `http.cookies` module.

```python
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C)  # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output())  # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger")  # load from
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
>>> C.load('keebler="E=everybody; L="Loves"; fudge')
>>> print(C)
Set-Cookie: keebler="E=everybody; L="Loves"; fudge
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print(C)
```
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'
>>> C = cookies.SimpleCookie()
>>> C["number"] = 7 # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
>>> C["string"].value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
21.24. **http.cookiejar** — Cookie handling for HTTP clients

**Source code:** [Lib/http/cookiejar.py](http://lib/http/cookiejar.py)

The `http.cookiejar` module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by **RFC 2965** are handled. RFC 2965 handling is switched off by default. **RFC 2109** cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the 'policy' in effect. Note that the great majority of cookies on the Internet are Netscape cookies. `http.cookiejar` attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the `max-age` and `port` cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in `Set-Cookie` and `Set-Cookie2` headers (eg. `domain` and `expires`) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.

The module defines the following exception:
exception http.cookiejar.LoadError

Instances of FileCookieJar raise this exception on failure to load cookies from a file. LoadError is a subclass of OSError.

Changed in version 3.3: LoadError was made a subclass of OSError instead of IOError.

The following classes are provided:

class http.cookiejar.CookieJar(policy=None)

    policy is an object implementing the CookiePolicy interface.

    The CookieJar class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. CookieJar instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

class http.cookiejar.FileCookieJar(filename, delayload=None, policy=None)

    policy is an object implementing the CookiePolicy interface. For the other arguments, see the documentation for the corresponding attributes.

    A CookieJar which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are NOT loaded from the named file until either the load() or revert() method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.

class http.cookiejar.CookiePolicy

    This class is responsible for deciding whether each cookie should be accepted from / returned to the server.
class http.cookiejar.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=http.cookiejar.DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)

Constructor arguments should be passed as keyword arguments only. blocked_domains is a sequence of domain names that we never accept cookies from, nor return cookies to. allowed_domains if not None, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for CookiePolicy and DefaultCookiePolicy objects.

DefaultCookiePolicy implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or rfc2109_as_netscape is True, RFC 2109 cookies are 'downgraded' by the CookieJar instance to Netscape cookies, by setting the version attribute of the Cookie instance to 0. DefaultCookiePolicy also provides some parameters to allow some fine-tuning of policy.

class http.cookiejar.Cookie

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of http.cookiejar construct their own Cookie instances. Instead, if necessary, call make_cookies() on a CookieJar instance.
See also:

**Module urllib.request**
URL opening with automatic cookie handling.

**Module http.cookies**
HTTP cookie classes, principally useful for server-side code. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

[http://curl.haxx.se/rfc/cookie_spec.html](http://curl.haxx.se/rfc/cookie_spec.html)
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and `http.cookiejar`) only bears a passing resemblance to the one sketched out in cookie_spec.html.

**RFC 2109 - HTTP State Management Mechanism**
Obsoleted by RFC 2965. Uses `Set-Cookie` with version=1.

**RFC 2965 - HTTP State Management Mechanism**
The Netscape protocol with the bugs fixed. Uses `Set-Cookie2` in place of `Set-Cookie`. Not widely used.

[http://kristol.org/cookie/errata.html](http://kristol.org/cookie/errata.html)
Unfinished errata to RFC 2965.

**RFC 2964** - Use of HTTP State Management

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.add_cookie_header(request)
Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar's CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The request object (usually a urllib.request.Request instance) must support the methods get_full_url(), get_host(), get_type(), unverifiable(), has_header(), get_header(), header_items(), add_unredirected_header() and origin_req_host attribute as documented by urllib.request.

Changed in version 3.3: request object needs origin_req_host attribute. Dependency on a deprecated method get_origin_req_host() has been removed.

CookieJar.extract_cookies(response, request)
Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-
Cookie2 headers in the response argument, and store cookies as appropriate (subject to the CookiePolicy.set_ok() method's approval).

The response object (usually the result of a call to urllib.request.urlopen(), or similar) should support an info() method, which returns an email.message.Message instance.

The request object (usually a urllib.request.Request instance) must support the methods get_full_url(), get_host(), unverifiable(), and origin_req_host attribute, as documented by urllib.request. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

Changed in version 3.3: request object needs origin_req_host attribute. Dependency on a deprecated method get_origin_req_host() has been removed.

CookieJar.set_policy(policy)

Set the CookiePolicy instance to be used.

CookieJar.make_cookies(response, request)

Return sequence of Cookie objects extracted from response object.

See the documentation for extract_cookies() for the interfaces required of the response and request arguments.

CookieJar.set_cookie_if_ok(cookie, request)

Set a Cookie if policy says it's OK to do so.
CookieJar.set_cookie(cookie)
    Set a Cookie, without checking with policy to see whether or not it should be set.

CookieJar.clear([domain[, path[, name]]])
    Clear some cookies.
    If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that domain will be removed. If given two arguments, cookies belonging to the specified domain and URL path are removed. If given three arguments, then the cookie with the specified domain, path and name is removed.
    Raises KeyError if no matching cookie exists.

CookieJar.clear_session_cookies()
    Discard all session cookies.
    Discards all contained cookies that have a true discard attribute (usually because they had either no max-age or expires cookie-attribute, or an explicit discard cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.
    Note that the save() method won’t save session cookies anyway, unless you ask otherwise by passing a true ignore_discard argument.

FileCookieJar implements the following additional methods:

FileCookieJar.save(filename=None, ignore_discard=False, ignoreExpires=False)
    Save cookies to a file.
This base class raises `NotImplementedError`. Subclasses may leave this method unimplemented.

`filename` is the name of file in which to save cookies. If `filename` is not specified, `self.filename` is used (whose default is the value passed to the constructor, if any); if `self.filename` is `None`, `ValueError` is raised.

`ignore_discard`: save even cookies set to be discarded. `ignore_expires`: save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the `load()` or `revert()` methods.

FileCookieJar.**load**(filename=None, ignore_discard=False, ignore_expires=False)

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for `save()`.

The named file must be in the format understood by the class, or `LoadError` will be raised. Also, `OSError` may be raised, for example if the file does not exist.

*Changed in version 3.3:* `IOError` used to be raised, it is now an alias of `OSError`.

FileCookieJar.**revert**(filename=None, ignore_discard=False, ignore_expires=False)

Clear all cookies and reload cookies from a saved file.
revert() can raise the same exceptions as load(). If there is a failure, the object's state will not be altered.

FileCookieJar instances have the following public attributes:

FileCookieJar.filename
Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayload
If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A CookieJar object may ignore it. None of the FileCookieJar classes included in the standard library lazily loads cookies.
21.24.2. FileCookieJar subclasses and cooperation with web browsers

The following CookieJar subclasses are provided for reading and writing.

```python
class http.cookiejar.MozillaCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in the Mozilla cookies.txt file format (which is also used by the Lynx and Netscape browsers).

**Note:** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as port.

**Warning:** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

```python
class http.cookiejar.LWPCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in format compatible with the libwww-perl library's Set-Cookie3 file format. This is convenient if you want to store cookies in a human-readable file.
21.24.3. CookiePolicy Objects

Objects implementing the `CookiePolicy` interface have the following methods:

**CookiePolicy.set_ok(cookie, request)**

Return boolean value indicating whether cookie should be accepted from server.

*cookie* is a `Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.extract_cookies()`.

**CookiePolicy.return_ok(cookie, request)**

Return boolean value indicating whether cookie should be returned to server.

*cookie* is a `Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.add_cookie_header()`.

**CookiePolicy.domain_return_ok(domain, request)**

Return false if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from `domain_return_ok()` and `path_return_ok()` leaves all the work to `return_ok()`.

If `domain_return_ok()` returns true for the cookie domain, `path_return_ok()` is called for the cookie path. Otherwise,
path_return_ok() and return_ok() are never called for that cookie domain. If path_return_ok() returns true, return_ok() is called with the Cookie object itself for a full check. Otherwise, return_ok() is never called for that cookie path.

Note that domain_return_ok() is called for every cookie domain, not just for the request domain. For example, the function might be called with both ".example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for path_return_ok().

The request argument is as documented for return_ok().

CookiePolicy.path_return_ok(path, request)
Return false if cookies should not be returned, given cookie path.
See the documentation for domain_return_ok().

In addition to implementing the methods above, implementations of the CookiePolicy interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy.netscape
Implement Netscape protocol.

CookiePolicy.rfc2965
Implement RFC 2965 protocol.

CookiePolicy.hide_cookie2
Don’t add Cookie2 header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).
The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of the methods above. `CookiePolicy` itself may be used as a ‘null policy’ to allow setting and receiving any and all cookies (this is unlikely to be useful).
21.24.4. DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import http.cookiejar

class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the CookiePolicy interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the blocked_domains constructor argument, and blocked_domains() and set_blocked_domains() methods (and the corresponding argument and methods for allowed_domains). If you set a whitelist,
you can turn it off again by setting it to None.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.blocked_domains()

   Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.set_blocked_domains(blocked_domains)

   Set the sequence of blocked domains.

DefaultCookiePolicy.isBlocked(domain)

   Return whether domain is on the blacklist for setting or receiving cookies.

DefaultCookiePolicy.allowed_domains()

   Return None, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.set_allowed_domains(allowed_domains)

   Set the sequence of allowed domains, or None.
DefaultCookiePolicy.is_not_allowed(domain)

Return whether domain is not on the whitelist for setting or receiving cookies.

DefaultCookiePolicy instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

DefaultCookiePolicy.rfc2109_as_netscape

If true, request that the CookieJar instance downgrade RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the Cookie instance to 0. The default value is None, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

General strictness switches:

DefaultCookiePolicy.strict_domain

Don’t allow sites to set two-component domains with country-code top-level domains like .co.uk, .gov.uk, .co.nz etc. This is far from perfect and isn’t guaranteed to work!

RFC 2965 protocol strictness switches:

DefaultCookiePolicy.strict_rfc2965_unverifiable

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are never blocked on the basis of verifiability

Netscape protocol strictness switches:
DefaultCookiePolicy.\texttt{strict\_ns\_unverifiable}

Apply RFC 2965 rules on unverifiable transactions even to Netscape cookies.

DefaultCookiePolicy.\texttt{strict\_ns\_domain}

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

DefaultCookiePolicy.\texttt{strict\_ns\_set\_initial\_dollar}

Ignore cookies in Set-Cookie: headers that have names starting with '\$'.

DefaultCookiePolicy.\texttt{strict\_ns\_set\_path}

Don’t allow setting cookies whose path doesn’t path-match request URI.

\texttt{strict\_ns\_domain} is a collection of flags. Its value is constructed by or-ing together (for example, DomainStrictNoDots|DomainStrictNonDomain means both flags are set).

DefaultCookiePolicy.\texttt{DomainStrictNoDots}

When setting cookies, the ‘host prefix’ must not contain a dot (eg. www.foo.bar.com can’t set a cookie for .bar.com, because www.foo contains a dot).

DefaultCookiePolicy.\texttt{DomainStrictNonDomain}

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. spam.example.com won’t be returned cookies from example.com that had no domain cookie-attribute).

DefaultCookiePolicy.\texttt{DomainRFC2965Match}
When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy. **DomainLiberal**
Equivalent to 0 (i.e. all of the above Netscape domain strictness flags switched off).

DefaultCookiePolicy. **DomainStrict**
Equivalent to **DomainStrictNoDots|DomainStrictNonDomain**.
21.24.5. Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by http.cookiejar from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie.version
   Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that http.cookiejar may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie.name
   Cookie name (a string).

Cookie.value
   Cookie value (a string), or None.

Cookie.port
   String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie.path
Cookie path (a string, eg. `/acme/rocket_launchers`).

**Cookie.secure**
True if cookie should only be returned over a secure connection.

**Cookie.expires**
Integer expiry date in seconds since epoch, or None. See also the is_expired() method.

**Cookie.discard**
True if this is a session cookie.

**Cookie.comment**
String comment from the server explaining the function of this cookie, or None.

**Cookie.comment_url**
URL linking to a comment from the server explaining the function of this cookie, or None.

**Cookie.rfc2109**
True if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a Set-Cookie header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because http.cookiejar may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

**Cookie.port_specified**
True if a port or set of ports was explicitly specified by the server (in the Set-Cookie / Set-Cookie2 header).

**Cookie.domain_specified**
True if a domain was explicitly specified by the server.

Cookie.domain_initial_dot
   True if the domain explicitly specified by the server began with a dot (\'\.\').

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

Cookie.has_nonstandard_attr(name)
   Return true if cookie has the named cookie-attribute.

Cookie.get_nonstandard_attr(name, default=None)
   If cookie has the named cookie-attribute, return its value. Otherwise, return default.

Cookie.set_nonstandard_attr(name, value)
   Set the value of the named cookie-attribute.

The Cookie class also defines the following method:

Cookie.is_expired(now=None)
   True if cookie has passed the time at which the server requested it should expire. If now is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
21.24.6. Examples

The first example shows the most common usage of `http.cookiejar`:

```python
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.UserAgent(cj))
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".netscape/cookies征求"))
opener = urllib.request.build_opener(urllib.request.UserAgent(cj))
r = opener.open("http://example.com/")
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```python
import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStrict
)
blocked_domains=["ads.net", ".ads.net"]
cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.UserAgent(cj))
r = opener.open("http://example.com/")
```
r = opener.open("http://example.com/")
21.25. xmlrpc — XMLRPC server and client modules

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data.

xmlrpc is a package that collects server and client modules implementing XML-RPC. The modules are:

- xmlrpc.client
- xmlrpc.server
21.26. `xmlrpc.client` — XML-RPC client access

**Source code:** [Lib/xmlrpc/client.py](https://docs.python.org/3/library/xmlrpc/client.html)

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

**Warning:** The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](https://docs.python.org/3/library/xmlrpc/client.html).

*Changed in version 3.5:* For https URIs, `xmlrpc.client` now performs all the necessary certificate and hostname checks by default.

```python
class xmlrpc.client.ServerProxy(uri, transport=None, encoding=None, verbose=False, allow_none=False, use_datetime=False, use_builtin_types=False, *, context=None)
```

*Changed in version 3.3:* The `use_builtin_types` flag was added.

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal
SafeTransport instance for https: URLs and an internal HTTP Transport instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag. If allow_none is true, the Python constant None will be translated into XML; the default behaviour is for None to raise a TypeError. This is a commonly-used extension to the XML-RPC specification, but isn’t supported by all clients and servers; see http://ontosys.com/xml-rpc/extensions.php for a description. The use_builtin_types flag can be used to cause date/time values to be presented as datetime.datetime objects and binary data to be presented as bytes objects; this flag is false by default. datetime.datetime and bytes objects may be passed to calls.

The obsolete use_datetime flag is similar to use_builtin_types but it applies only to date/time values.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: http://user:pass@host:port/path. The user:pass portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password. If an HTTPS url is provided, context may be ssl.SSLContext and configures the SSL settings of the underlying HTTPS connection.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.
ServerProxy instance methods take Python basic types and objects as arguments and return Python basic types and classes. Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>The <code>True</code> and <code>False</code> constants</td>
</tr>
<tr>
<td>integers</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>floating-point</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>numbers</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>strings</td>
<td>Pass in directly</td>
</tr>
<tr>
<td>arrays</td>
<td>Any Python sequence type containing conformable elements. Arrays are returned as lists</td>
</tr>
<tr>
<td>structures</td>
<td>A Python dictionary. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.</td>
</tr>
<tr>
<td>dates</td>
<td>In seconds since the epoch. Pass in an instance of the DateTime class or a <code>datetime.datetime</code> instance.</td>
</tr>
<tr>
<td>binary data</td>
<td>Pass in an instance of the Binary wrapper class or a <code>bytes</code> instance.</td>
</tr>
</tbody>
</table>

This is the full set of data types supported by XML-RPC. Method calls may also raise a special Fault instance, used to signal XML-RPC server errors, or ProtocolError used to signal an error in the HTTP/HTTPS transport layer. Both Fault and
ProtocolError derive from a base class called Error. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.

When passing strings, characters special to XML such as <, >, and & will be automatically escaped. However, it’s the caller’s responsibility to ensure that the string is free of characters that aren’t allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn’t well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use the bytes class or the class:Binary wrapper class described below.

Server is retained as an alias for ServerProxy for backwards compatibility. New code should use ServerProxy.

*Changed in version 3.5:* Added the context argument.

**See also:**

**XML-RPC HOWTO**

A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

**XML-RPC Introspection**

Describes the XML-RPC protocol extension for introspection.

**XML-RPC Specification**

The official specification.

**Unofficial XML-RPC Errata**

Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best
practices’ to use when designing your own XML-RPC implementations.”

A ServerProxy instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a Fault or ProtocolError object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved system attribute:

ServerProxy.system.listMethods()

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

ServerProxy.system.methodSignature(name)

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.
If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

**ServerProxy.system.methodHelp(name)**

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

*Changed in version 3.5:* Instances of `ServerProxy` support the **context manager** protocol for closing the underlying transport.

A working example follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

def is_even(n):
    return n%2 == 0

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client

with xmlrpc.client.ServerProxy("http://localhost:8000") as proxy:
    print("3 is even: %s" % str(proxy.is_even(3)))
    print("100 is even: %s" % str(proxy.is_even(100)))
```
21.26.2. DateTime Objects

This class may be initialized with seconds since the epoch, a time
tuple, an ISO 8601 time/date string, or a `datetime.datetime`
instance. It has the following methods, supported mainly for internal
use by the marshalling/unmarshalling code:

DateTime. `decode(string)`
Accept a string as the instance's new time value.

DateTime. `encode(out)`
Write the XML-RPC encoding of this DateTime item to the `out`
stream object.

It also supports certain of Python's built-in operators through rich
comparison and `__repr__()` methods.

A working example follows. The server code:

```python
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:
import xmlrpc.client
import datetime

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, "%Y-%m-%d %H:%M:%S")

print("Today: %s" % converted.strftime("%d.%m.%Y, %H:%M"))
21.26.3. Binary Objects

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

**Binary.data**

The binary data encapsulated by the Binary instance. The data is provided as a `bytes` object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

**Binary.decode**(bytes)

Accept a base64 `bytes` object and decode it as the instance's new data.

**Binary.encode**(out)

Write the XML-RPC base 64 encoding of this binary item to the output stream object.

The encoded data will have newlines every 76 characters as per [RFC 2045 section 6.8](https://tools.ietf.org/html/rfc2045), which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python's built-in operators through `__eq__() and __ne__()` methods.

Example usage of the binary objects. We're going to transfer an image over XMLRPC:

```python
from xmlrpc.server import SimpleXMLRPCServer
```
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(('localhost', 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')

server.serve_forever()

The client gets the image and saves it to a file:

import xmlrpc.client

with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
21.26.4. Fault Objects

A Fault object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

**Fault.faultCode**
A string indicating the fault type.

**Fault.faultString**
A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a Fault by returning a complex type object. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a complex number
def add(x, y):
    return x + y + 0j

server = SimpleXMLRPCServer(('localhost', 8000))
print('Listening on port 8000...')
sERVER.register_function(add, 'add')

server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client

try:
```
proxy.add(2, 5)

```
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
```
21.26.5. ProtocolError Objects

A ProtocolError object describes a protocol error in the underlying transport layer (such as a 404 ‘not found’ error if the server named by the URI does not exist). It has the following attributes:

**ProtocolError.** **url**
The URI or URL that triggered the error.

**ProtocolError.** **errcode**
The error code.

**ProtocolError.** **errmsg**
The error message or diagnostic string.

**ProtocolError.** **headers**
A dict containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we’re going to intentionally cause a ProtocolError by providing an invalid URI:

```python
import xmlrpc.client

# create a ServerProxy with an URI that doesn't respond
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
    print("URL: %s" % err.url)
    print("HTTP/HTTPS headers: %s" % err.headers)
    print("Error code: %d" % err.errcode)
```
print("Error message: \%s" % err.errmsg)
21.26.6. MultiCall Objects

The **MultiCall** object provides a way to encapsulate multiple calls to a remote server into a single request [1].

```python
class xmlrpc.client.MultiCall(server):
    Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.
```

A usage example of this class follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y

def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_multicall_functions()
```
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()

The client code for the preceding server:

```
import xmlrpc.client

multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```
21.26.7. Convenience Functions

```python
xmlrpc.client.dumps(params, methodname=None, methodresponse=None, encoding=None, allow_none=False)
```

Convert `params` into an XML-RPC request. or into a response if `methodresponse` is true. `params` can be either a tuple of arguments or an instance of the Fault exception class. If `methodresponse` is true, only a single value can be returned, meaning that `params` must be of length 1. `encoding`, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python’s `None` value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for `allow_none`.

```python
xmlrpc.client.loads(data, use_datetime=False, use_builtin_types=False)
```

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. `params` is a tuple of argument; `methodname` is a string, or None if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a Fault exception. The `use_builtin_types` flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default.

The obsolete `use_datetime` flag is similar to `use_builtin_types` but it applies only to date/time values.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```
# simple test program (from the XML-RPC specification)
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000")  # local server

with ServerProxy("http://betty.userland.com") as proxy:
    print(proxy)

    try:
        print(proxy.examples.getStateName(41))
    except Error as v:
        print("ERROR", v)
```

To access an XML-RPC server through a proxy, you need to define a custom transport. The following example shows how:

```
import xmlrpc.client, http.client

class ProxiedTransport(xmlrpc.client.Transport):
    def set_proxy(self, proxy):
        self.proxy = proxy
    def make_connection(self, host):
        self.realhost = host
        h = http.client.HTTP(self.proxy)
        return h
    def send_request(self, connection, handler, request_body):
        connection.putrequest("POST", 'http://%s%s'
    def send_host(self, connection, host):
        connection.putheader('Host', self.realhost)

p = ProxiedTransport()
p.set_proxy('proxy-server:8080')
```
print(server.currentTime.getCurrentTime())
21.26.9. Example of Client and Server Usage

See SimpleXMLRPCServer Example.

Footnotes

[1] This approach has been first presented in a discussion on xmlrpc.com.
The `xmlrpc.server` module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using `SimpleXMLRPCServer`, or embedded in a CGI environment, using `CGIXMLRPCRequestHandler`.

**Warning:** The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

```python
class xmlrpc.server.SimpleXMLRPCServer(addr, requestHandler=SimpleXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=False)
```

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The `requestHandler` parameter should be a factory for request handler instances; it defaults to `SimpleXMLRPCRequestHandler`. The `addr` and `requestHandler` parameters are passed to the `socketserver.TCPServer` constructor. If `logRequests` is true (the default), requests will be logged; setting this parameter to false will turn off logging. The `allow_none` and `encoding` parameters are passed on to `xmlrpc.client` and control the XML-RPC responses that will be returned from the server. The `bind_and_activate` parameter
controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

class xmlrpc.server.CGIXMLRPCRequestHandler(allow_none=False, encoding=None, use_builtin_types=False)

Create a new instance to handle XML-RPC requests in a CGI environment. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

class xmlrpc.server.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the logRequests parameter to the SimpleXMLRPCServer constructor parameter is honored.
21.27.1. SimpleXMLRPCServer Objects

The **SimpleXMLRPCServer** class is based on socketserver.TCPServer and provides a means of creating simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.register_function(function, name=None)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise *function*.__name__ will be used. *name* can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

SimpleXMLRPCServer.register_instance(instance, allow_dotted_names=False)

Register an object which is used to expose method names which have not been registered using register_function(). If *instance* contains a _dispatch() method, it is called with the requested method name and the parameters from the request. Its API is def _dispatch(self, method, params) (note that params does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as func(*params), expanding the parameter list. The return value from _dispatch() is returned to the client as the result. If *instance* does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method.

If the optional allow_dotted_names argument is true and the instance does not have a _dispatch() method, then if the requested method name contains periods, each component of the
method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the *allow_dotted_names* option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

SimpleXMLRPCServer.*register_introspection_functions*()  
Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

SimpleXMLRPCServer.*register_multicall_functions*()  
Registers the XML-RPC multicall function `system.multicall`.

SimpleXMLRPCRequestHandler.*rpc_paths*  
An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 “no such page” HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

**21.27.1.1. SimpleXMLRPCServer Example**

Server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler
```
The following client code will call the methods made available by the preceding server:

```python
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2, 3))  # Returns 2**3 = 8
```
print(s.add(2,3)) # Returns 5
print(s.mul(5,2)) # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())

The following example included in the Lib/xmlrpc/server.py module shows a server allowing dotted names and registering a multicall function.

**Warning:** Enabling the *allow_dotted_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this example only within a secure, closed network.

```python
import datetime

class ExampleService:
    def getData(self):
        return '42'

class currentTime:
    @staticmethod
    def getCurrentTime():
        return datetime.datetime.now()

server = SimpleXMLRPCServer(("localhost", 8000))
server.register_function(pow)
server.register_function(lambda x,y: x+y, 'add')
server.register_instance(ExampleService(), allow_dot)
server.register_multicall_functions()
print('Serving XML-RPC on localhost port 8000')
try:
    server.serve_forever()
```
except KeyboardInterrupt:
    print("Keyboard interrupt received, exiting.")
server.server_close()
sys.exit(0)

This ExampleService demo can be invoked from the command line:

```
python -m xmlrpc.server
```

The client that interacts with the above server is included in `Lib/xmlrpc/client.py`:

```python
server = ServerProxy("http://localhost:8000")

try:
    print(server.currentTime.getCurrentTime())
except Error as v:
    print("ERROR", v)

multi = MultiCall(server)
multi.getData()
multi.pow(2, 9)
multi.add(1, 2)

try:
    for response in multi():
        print(response)
except Error as v:
    print("ERROR", v)
```

This client which interacts with the demo XMLRPC server can be invoked as:

```
python -m xmlrpc.client
```
21.27.2. CGIXMLRPCRequestHandler

The CGIXMLRPCRequestHandler class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.register_function(function, name=None)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with function, otherwise *function.__name__* will be used. *name* can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

CGIXMLRPCRequestHandler.register_instance(instance)

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.register_introspection_functions

Register the XML-RPC introspection functions system.listMethods, system.methodHelp and system.methodSignature.
CGIXMLRPCRequestHandler.register_multicall_function
Register the XML-RPC multicall function system.multicall.

CGIXMLRPCRequestHandler.handle_request(request_text=None)
Handle a XML-RPC request. If request_text is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

```python
class MyFuncs:
    def mul(self, x, y):
        return x * y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```
21.27.3. Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using `DocXMLRPCServer`, or embedded in a CGI environment, using `DocCGIXMLRPCRequestHandler`.

```python
class xmlrpc.server.DocXMLRPCServer(addr, requestHandler=DocXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=True)
```

Create a new server instance. All parameters have the same meaning as for `SimpleXMLRPCServer`; `requestHandler` defaults to `DocXMLRPCRequestHandler`.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```python
class xmlrpc.server.DocCGIXMLRPCRequestHandler
```

Create a new instance to handle XML-RPC requests in a CGI environment.

```python
class xmlrpc.server.DocXMLRPCRequestHandler
```

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the `logRequests` parameter to the `DocXMLRPCServer` constructor parameter is honored.
21.27.4. DocXMLRPCServer Objects

The `DocXMLRPCServer` class is derived from `SimpleXMLRPCServer` and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

`DocXMLRPCServer.set_server_title(server_title)`

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

`DocXMLRPCServer.set_server_name(server_name)`

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

`DocXMLRPCServer.set_server_documentation(server_doc)`

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.27.5. DocCGIXMLRPCRequestHandler

The DocCGIXMLRPCRequestHandler class is derived from CGIXMLRPCRequestHandler and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocCGIXMLRPCRequestHandler.set_server_title(server_title)
Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocCGIXMLRPCRequestHandler.set_server_name(server_name)
Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocCGIXMLRPCRequestHandler.set_server_documentation()
Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.28. ipaddress — IPv4/IPv6 manipulation library

Source code: Lib/ipaddress.py

`ipaddress` provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference—for an overview and introduction, see An introduction to the ipaddress module.

*New in version 3.3.*
21.28.1. Convenience factory functions

The `ipaddress` module provides factory functions to conveniently create IP addresses, networks and interfaces:

`ipaddress.ip_address(address)`

Return an `IPv4Address` or `IPv6Address` object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than $2^{32}$ will be considered to be IPv4 by default. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address.

```python
>>> ipaddress.ip_address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

`ipaddress.ip_network(address, strict=True)`

Return an `IPv4Network` or `IPv6Network` object depending on the IP address passed as argument. `address` is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than $2^{32}$ will be considered to be IPv4 by default. `strict` is passed to `IPv4Network` or `IPv6Network` constructor. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```python
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

`ipaddress.ip_interface(address)`

Return an `IPv4Interface` or `IPv6Interface` object depending
on the IP address passed as argument. *address* is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than 2**32 will be considered to be IPv4 by default. A *ValueError* is raised if *address* does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don't know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.
21.28.2. IP Addresses

21.28.2.1. Address objects

The IPv4Address and IPv6Address objects share a lot of common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by IPv4Address objects, in order to make it easier to write code that handles both IP versions correctly.

```python
class ipaddress.IPv4Address(address)
    Construct an IPv4 address. An AddressValueError is raised if address is not a valid IPv4 address.
```

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0-255, separated by dots (e.g. 192.168.0.1). Each integer represents an octet (byte) in the address. Leading zeroes are tolerated only for values less than 8 (as there is no ambiguity between the decimal and octal interpretations of such strings).
2. An integer that fits into 32 bits.
3. An integer packed into a bytes object of length 4 (most significant octet first).

```python
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\xC0\xA8\x00\x01')
IPv4Address('192.168.0.1')
```
The appropriate version number: 4 for IPv4, 6 for IPv6.

**max_prefixlen**

The total number of bits in the address representation for this version: 32 for IPv4, 128 for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

**compressed**

**exploded**

The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

**packed**

The binary representation of this address - a `bytes` object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

**reverse_pointer**

The name of the reverse DNS PTR record for the IP address, e.g.:

```python
>>> ipaddress.ip_address("127.0.0.1").reverse_pointer
'1.0.0.127.in-addr.arpa'
>>> ipaddress.ip_address("2001:db8::1").reverse_pointer
'1::1.in-addr.arpa'
```
This is the name that could be used for performing a PTR lookup, not the resolved hostname itself.

_New in version 3.5._

**is_multicast**
True if the address is reserved for multicast use. See [RFC 3171](https://tools.ietf.org/html/rfc3171) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).

**is_private**
True if the address is allocated for private networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-special-registry) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-special-registry) (for IPv6).

**is_global**
True if the address is allocated for public networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-special-registry) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-special-registry) (for IPv6).

_New in version 3.4._

**is_unspecified**

**is_reserved**
True if the address is otherwise IETF reserved.

**is_loopback**
True if this is a loopback address. See [RFC 3330](https://tools.ietf.org/html/rfc3330) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).
is_link_local

True if the address is reserved for link-local usage. See RFC 3927.

class ipaddress.IPv6Address(address)

Construct an IPv6 address. An AddressValueError is raised if address is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an exploded (longhand) notation. The string can also be compressed (shorthand notation) by various means. See RFC 4291 for details. For example, "0000:0000:0000:0000:0000:0abc:0007:0def" can be compressed to "::abc:7:def".
2. An integer that fits into 128 bits.
3. An integer packed into a bytes object of length 16, big-endian.

>>> ipaddress.IPv6Address('2001:db8::1000')
IPv6Address('2001:db8::1000')

compressed

The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by str(addr) for IPv6 addresses.

e xpl o ded

The long form of the address representation, with all leading
For the following attributes, see the corresponding documentation of the IPv4Address class:

- packed
- reverse_pointer
- version
- max_prefixlen
- is_multicast
- is_private
- is_global
- is_unspecified
- is_reserved
- is_loopback
- is_link_local
  
  New in version 3.4: is_global

- is_site_local
  
  True if the address is reserved for site-local usage. Note that the site-local address space has been deprecated by RFC 3879. Use is_private to test if this address is in the space of unique local addresses as defined by RFC 4193.

- ipv4_mapped
  
  For addresses that appear to be IPv4 mapped addresses (starting with ::FFFF/96), this property will report the
embedded IPv4 address. For any other address, this property will be None.

**sixtofour**
For addresses that appear to be 6to4 addresses (starting with 2002::/16) as defined by RFC 3056, this property will report the embedded IPv4 address. For any other address, this property will be None.

**teredo**
For addresses that appear to be Teredo addresses (starting with 2001::/32) as defined by RFC 4380, this property will report the embedded (server, client) IP address pair. For any other address, this property will be None.

### 21.28.2.2. Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is handled using the `str()` and `int()` built-in functions:

```
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
>>> str(ipaddress.IPv6Address('::1'))
'::1'
>>> int(ipaddress.IPv6Address('::1'))
1
```

### 21.28.2.3. Operators
Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.2.3.1. Comparison operators

Address objects can be compared with the usual set of comparison operators. Some examples:

```python
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
```

21.28.2.3.2. Arithmetic operators

Integers can be added to or subtracted from address objects. Some examples:

```python
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32)
```

21.28.3. IP Network definitions

The IPv4Network and IPv6Network objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a mask and a network address, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask 255.255.255.0 and the network address 192.168.1.0 consists of IP addresses in the inclusive range 192.168.1.0 to 192.168.1.255.

21.28.3.1. Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A prefix /<nbits> is a notation that denotes how many high-order bits are set in the network mask. A net mask is an IP address with some number of high-order bits set. Thus the prefix /24 is equivalent to the net mask 255.255.255.0 in IPv4, or ffff:ff00:: in IPv6. In addition, a host mask is the logical inverse of a net mask, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to /24 in IPv4 is 0.0.0.255.

21.28.3.2. Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement additional attributes. All of these are common between IPv4Network and IPv6Network, so to avoid duplication they are only documented for IPv4Network.
class `ipaddress.IPv4Network(address, strict=True)`

Construct an IPv4 network definition. `address` can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a *prefix*, or a string representation of an IPv4 address. If it’s the latter, the mask is interpreted as a *net mask* if it starts with a non-zero field, or as a *host mask* if it starts with a zero field. If no mask is provided, it’s considered to be /32.

   For example, the following `address` specifications are equivalent:
   
   192.168.1.0/24, 192.168.1.0/255.255.255.0 and 192.168.1.0/0.0.0.255.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being `address` and the mask being /32.

3. An integer packed into a `bytes` object of length 4, big-endian. The interpretation is similar to an integer `address`.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 32-bits integer, a 4-bytes packed integer, or an existing IPv4Address object; and the netmask is either an integer representing the prefix length (e.g. 24) or a string representing the prefix mask (e.g. 255.255.255.0).

An `AddressValueError` is raised if `address` is not a valid IPv4
address. A `NetmaskValueError` is raised if the mask is not valid for an IPv4 address.

If `strict` is True and host bits are set in the supplied address, then `ValueError` is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Unless stated otherwise, all network methods accepting other network/address objects will raise `TypeError` if the argument’s IP version is incompatible to `self`

*Changed in version 3.5:* Added the two-tuple form for the `address` constructor parameter.

**version**

**max_prefixlen**

Refer to the corresponding attribute documentation in `IPv4Address`

**is_multicast**

**is_private**

**is_unspecified**

**is_reserved**

**is_loopback**

**is_link_local**

These attributes are true for the network as a whole if they are true for both the network address and the broadcast address

**network_address**

The network address for the network. The network address and
the prefix length together uniquely define a network.

**broadcast_address**
The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

**hostmask**
The host mask, as a string.

**with_prefixlen**
**compressed**
**exploded**
A string representation of the network, with the mask in prefix notation.

with_prefixlen and compressed are always the same as str(network). exploded uses the exploded form the network address.

**with_netmask**
A string representation of the network, with the mask in net mask notation.

**with_hostmask**
A string representation of the network, with the mask in host mask notation.

**num_addresses**
The total number of addresses in the network.

**prefixlen**
Length of the network prefix, in bits.

hosts()
Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address.

```python
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2.2'), IPv4Address('192.0.2.3'), IPv4Address('192.0.2.4'), IPv4Address('192.0.2.5'), IPv4Address('192.0.2.6')]
```

overlaps(other)
True if this network is partly or wholly contained in other or other is wholly contained in this network.

address_exclude(network)
Computes the network definitions resulting from removing the given network from this one. Returns an iterator of network objects. Raises ValueError if network is not completely contained in this network.

```python
>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.0.2.4/30'), IPv4Network('192.0.2.2/31'), IPv4Network('192.0.2.0/32')]
```

subnets(prefixlen_diff=1, new_prefix=None)
The subnets that join to make the current network definition, depending on the argument values. prefixlen_diff is the amount
our prefix length should be increased by. \textit{new\_prefix} is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of \textit{prefixlen\_diff} and \textit{new\_prefix} must be set. Returns an iterator of network objects.

\begin{verbatim}
>>> list(ip_network('192.0.2.0/24').subnets())
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]

>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=1, new_prefix=None))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    raise ValueError('new prefix must be longer than the prefix length used to create this network')
ValueError: new prefix must be longer

>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=1, new_prefix='192.0.2.0/25'))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
\end{verbatim}

\textbf{supernet}(prefixlen\_diff=1, new\_prefix=None)

The supernet containing this network definition, depending on the argument values. \textit{prefixlen\_diff} is the amount our prefix length should be decreased by. \textit{new\_prefix} is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of \textit{prefixlen\_diff} and \textit{new\_prefix} must be set. Returns a single network object.

\begin{verbatim}
>>> ip_network('192.0.2.0/24').supernet()
IPv4Network('192.0.2.0/23')

>>> ip_network('192.0.2.0/24').supernet(prefixlen_diff=1)
IPv4Network('192.0.0.0/22')

>>> ip_network('192.0.2.0/24').supernet(new_prefix='192.0.0.0/22')
IPv4Network('192.0.2.0/25')
\end{verbatim}
**IPv4Network('192.0.0.0/20')**

**compare_networks(other)**

Compare this network to other. In this comparison only the network addresses are considered; host bits aren’t. Returns either -1, 0 or 1.

```python
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32')) -1
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32')) 1
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32')) 0
```

**class ipaddress.IPv6Network(address, strict=True)**

Construct an IPv6 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a prefix, or a string representation of an IPv6 address. If it's the latter, the mask is interpreted as a net mask. If no mask is provided, it's considered to be /128.

   For example, the following address specifications are equivalent: 2001:db00::0/24 and 2001:db00::0/ffff:ff00:..

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being address and the mask being /128.
3. An integer packed into a bytes object of length 16, big-endian. The interpretation is similar to an integer address.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 128-bits integer, a 16-bytes packed integer, or an existing IPv4Address object; and the netmask is an integer representing the prefix length.

An AddressValueError is raised if address is not a valid IPv6 address. A NetmaskValueError is raised if the mask is not valid for an IPv6 address.

If strict is True and host bits are set in the supplied address, then ValueError is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

*Changed in version 3.5:* Added the two-tuple form for the address constructor parameter.

    These attribute is true for the network as a whole if it is true for both the network address and the broadcast address

21.28.3.3. Operators
Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

**21.28.3.3.1. Logical operators**

Network objects can be compared with the usual set of logical operators, similarly to address objects.

**21.28.3.3.2. Iteration**

Network objects can be iterated to list all the addresses belonging to the network. For iteration, all hosts are returned, including unusable hosts (for usable hosts, use the `hosts()` method). An example:

```python
>>> for addr in IPv4Network('192.0.2.0/28'):
...   addr
...  IPv4Address('192.0.2.0')
  IPv4Address('192.0.2.1')
  IPv4Address('192.0.2.2')
  IPv4Address('192.0.2.3')
  IPv4Address('192.0.2.4')
  IPv4Address('192.0.2.5')
  IPv4Address('192.0.2.6')
  IPv4Address('192.0.2.7')
  IPv4Address('192.0.2.8')
  IPv4Address('192.0.2.9')
  IPv4Address('192.0.2.10')
  IPv4Address('192.0.2.11')
  IPv4Address('192.0.2.12')
  IPv4Address('192.0.2.13')
  IPv4Address('192.0.2.14')
  IPv4Address('192.0.2.15')
```
21.28.3.3.3. Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```python
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/28')
True
>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/28')
False
```
21.28.4. Interface objects

```python
class ipaddress.IPv4Interface(address)
Construct an IPv4 interface. The meaning of address is as in the
constructor of IPv4Network, except that arbitrary host addresses
are always accepted.

IPv4Interface is a subclass of IPv4Address, so it inherits all
the attributes from that class. In addition, the following attributes
are available:

ip
The address (IPv4Address) without network information.

```  
```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.ip
IPv4Address('192.0.2.5')
```

network
The network (IPv4Network) this interface belongs to.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.network
IPv4Network('192.0.2.0/24')
```

with_prefixlen
A string representation of the interface with the mask in prefix
notation.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_prefixlen
'192.0.2.5/24'
```
**with_netmask**

A string representation of the interface with the network as a net mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'
```

**with_hostmask**

A string representation of the interface with the network as a host mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'
```

class `ipaddress.IPV6Interface(address)`

Construct an IPv6 interface. The meaning of `address` is as in the constructor of `IPv6Network`, except that arbitrary host addresses are always accepted.

`IPv6Interface` is a subclass of `IPv6Address`, so it inherits all the attributes from that class. In addition, the following attributes are available:

- `ip`
- `network`
- `with_prefixlen`
- `with_netmask`
- `with_hostmask`

Refer to the corresponding attribute documentation in
IPv4Interface.
21.28.5. Other Module Level Functions

The module also provides the following module level functions:

\[\text{ipaddress.v4\_int\_to\_packed(address)}\]

Represent an address as 4 packed bytes in network (big-endian) order. \(\text{address}\) is an integer representation of an IPv4 IP address. A \text{ValueError} is raised if the integer is negative or too large to be an IPv4 IP address.

\[
\begin{align*}
\text{>>> ipaddress.ip\_address(3221225985)} & \quad \text{IPv4Address('192.0.2.1')} \\
\text{>>> ipaddress.v4\_int\_to\_packed(3221225985)} & \quad \text{b'\xc0\x00\x02\x01'}
\end{align*}
\]

\[\text{ipaddress.v6\_int\_to\_packed(address)}\]

Represent an address as 16 packed bytes in network (big-endian) order. \(\text{address}\) is an integer representation of an IPv6 IP address. A \text{ValueError} is raised if the integer is negative or too large to be an IPv6 IP address.

\[\text{ipaddress.summarize\_address\_range(first, last)}\]

Return an iterator of the summarized network range given the first and last IP addresses. \(\text{first}\) is the first \text{IPv4Address} or \text{IPv6Address} in the range and \(\text{last}\) is the last \text{IPv4Address} or \text{IPv6Address} in the range. A \text{TypeError} is raised if \(\text{first}\) or \(\text{last}\) are not IP addresses or are not of the same version. A \text{ValueError} is raised if \(\text{last}\) is not greater than \(\text{first}\) or if \(\text{first}\) address version is not 4 or 6.

\[
\begin{align*}
\text{>>> [ipaddr for ipaddr in ipaddress.summarize_add... ipaddress.IPv4Address('192.0.2.0')},
\end{align*}
\]
ipaddress.collapse_addresses(addresses)

Return an iterator of the collapsed IPv4Network or IPv6Network objects. addresses is an iterator of IPv4Network or IPv6Network objects. A TypeError is raised if addresses contains mixed version objects.

>>> [ipaddr for ipaddr in ...
ipaddress.collapse_addresses([ipaddress.IPv4Network('192.0.2.128/25')])]
[IPv4Network('192.0.2.0/24')]

ipaddress.get_mixed_type_key(obj)

Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they're fundamentally different, so the expression:

IPv4Address('192.0.2.0') <= IPv4Network('192.0.2.0')

doesn't make sense. There are some times however, where you may wish to have ipaddress sort these anyway. If you need to do this, you can use this function as the key argument to sorted().

obj is either a network or address object.
21.28.6. Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

exception ipaddress.AddressValueError(ValorError)

  Any value error related to the address.

exception ipaddress.NetmaskValueError(ValorError)

  Any value error related to the netmask.
22. Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **22.1. audioop** — Manipulate raw audio data
- **22.2. aifc** — Read and write AIFF and AIFC files
- **22.3. sunau** — Read and write Sun AU files
  - 22.3.1. AU_read Objects
  - 22.3.2. AU_write Objects
- **22.4. wave** — Read and write WAV files
  - 22.4.1. Wave_read Objects
  - 22.4.2. Wave_write Objects
- **22.5. chunk** — Read IFF chunked data
- **22.6. colorsys** — Conversions between color systems
- **22.7. imghdr** — Determine the type of an image
- **22.8. sndhdr** — Determine type of sound file
- **22.9. ossaudiodev** — Access to OSS-compatible audio devices
  - 22.9.1. Audio Device Objects
  - 22.9.2. Mixer Device Objects
22.1. audioop — Manipulate raw audio data

The audioop module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16, 24 or 32 bits wide, stored in bytes-like objects. All scalar items are integers, unless specified otherwise.

*Changed in version 3.4:* Support for 24-bit samples was added. All functions now accept any bytes-like object. String input now results in an immediate error.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

*exception* audioop.error

This exception is raised on all errors, such as unknown number of bytes per sample, etc.

audioop.add(fragment1, fragment2, width)

Return a fragment which is the addition of the two samples passed as parameters. width is the sample width in bytes, either 1, 2, 3 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.
audioop.adpcm2lin(adpcmfragment, width, state)
Decide an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of lin2adpcm() for details on ADPCM coding. Return a tuple (sample, newstate) where the sample has the width specified in width.

audioop.alaw2lin(fragment, width)
Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so width refers only to the sample width of the output fragment here.

audioop.avg(fragment, width)
Return the average over all samples in the fragment.

audioop.avgpp(fragment, width)
Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop.bias(fragment, width, bias)
Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

audioop.byteswap(fragment, width)
“Byteswap” all samples in a fragment and returns the modified fragment. Converts big-endian samples to little-endian and vice versa.

New in version 3.4.

audioop.cross(fragment, width)
Return the number of zero crossings in the fragment passed as an argument.
audioop.**findfactor**(fragment, reference)

Return a factor \( F \) such that \( \text{rms}(\text{add}(\text{fragment}, \text{mul}(\text{reference}, -F))) \) is minimal, i.e., return the factor with which you should multiply \text{reference} to make it match as well as possible to \text{fragment}. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to \text{len(fragment)}.

audioop.**findfit**(fragment, reference)

Try to match \text{reference} as well as possible to a portion of \text{fragment} (which should be the longer fragment). This is (conceptually) done by taking slices out of \text{fragment}, using **findfactor()** to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple \((\text{offset}, \text{factor})\) where \text{offset} is the (integer) offset into \text{fragment} where the optimal match started and \text{factor} is the (floating-point) factor as per **findfactor()**.

audioop.**findmax**(fragment, length)

Search \text{fragment} for a slice of length \text{length} samples (not bytes!) with maximum energy, i.e., return \( i \) for which \( \text{rms}(\text{fragment}[i*2:(i+\text{length})*2]) \) is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to \text{len(fragment)}.

audioop.**getsample**(fragment, width, index)

Return the value of sample \text{index} from the fragment.

audioop.**lin2adpcm**(fragment, width, state)
Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

`state` is a tuple containing the state of the coder. The coder returns a tuple `(adpcmfrag, newstate)`, and the `newstate` should be passed to the next call of `lin2adpcm()`. In the initial call, None can be passed as the state. `adpcmfrag` is the ADPCM coded fragment packed 2 4-bit values per byte.

**audioop.**lin2alaw(*fragment, width*)

Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

**audioop.**lin2lin(*fragment, width, newwidth*)

Convert samples between 1-, 2-, 3- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16, 24 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```python
new_frames = audioop.lin2lin(frames, old_width,
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16, 24 or 32 bit width samples.
audioop.\texttt{lin2ulaw}(\texttt{fragment, width})

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop.\texttt{max}(\texttt{fragment, width})

Return the maximum of the \textit{absolute value} of all samples in a fragment.

audioop.\texttt{maxpp}(\texttt{fragment, width})

Return the maximum peak-peak value in the sound fragment.

audioop.\texttt{minmax}(\texttt{fragment, width})

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop.\texttt{mul}(\texttt{fragment, width, factor})

Return a fragment that has all samples in the original fragment multiplied by the floating-point value \textit{factor}. Samples are truncated in case of overflow.

audioop.\texttt{ratecv}(\texttt{fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]]})

Convert the frame rate of the input fragment.

\textit{state} is a tuple containing the state of the converter. The converter returns a tuple (newfragment, newstate), and \textit{newstate} should be passed to the next call of \texttt{ratecv()}. The initial call should pass None as the state.

The \textit{weightA} and \textit{weightB} arguments are parameters for a simple
digital filter and default to 1 and 0 respectively.

audioop.reverse(fragment, width)
Reverse the samples in a fragment and returns the modified fragment.

audioop.rms(fragment, width)
Return the root-mean-square of the fragment, i.e. \( \sqrt{\text{sum}(S_i^2)/n} \).

This is a measure of the power in an audio signal.

audioop.tomono(fragment, width, ifactor, rfactor)
Convert a stereo fragment to a mono fragment. The left channel is multiplied by \( ifactor \) and the right channel by \( rfactor \) before adding the two channels to give a mono signal.

audioop.tostereo(fragment, width, ifactor, rfactor)
Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by \( ifactor \) and right channel samples by \( rfactor \).

audioop.ulaw2lin(fragment, width)
Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so \( width \) refers only to the sample width of the output fragment here.

Note that operations such as \texttt{mul()} or \texttt{max()} make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)

If you use the ADPCM coder to build network packets and you want
your protocol to be stateless (i.e. to be able to tolerate packet loss)
you should not only transmit the data but also the state. Note that you
should send the initial state (the one you passed to lin2adpcm())
along to the decoder, not the final state (as returned by the coder). If
you want to use struct.Struct to store the state in binary you can
code the first element (the predicted value) in 16 bits and the second
(the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM
coders, only against themselves. It could well be that I misinterpreted
the standards in which case they will not be interoperable with the
respective standards.

The find*() routines might look a bit funny at first sight. They are
primarily meant to do echo cancellation. A reasonably fast way to do
this is to pick the most energetic piece of the output sample, locate
that in the input sample and subtract the whole output sample from the
input sample:

def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one
gen_test = outputdata[pos*2:]
in_test = inputdata[pos*2:]

ipos, factor = audioop.findfit(in_test, out_test)
# Optional (for better cancellation):
# factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)],
# out_test)
prefill = '\0'*(pos+ipos)*2
postfill = '\0'*(len(inputdata)-len(prefill)-len(outputdata) + len(prefill))
outputdata = prefill + audioop.mul(outputdata, 2,
return audioop.add(inputdata, outputdata, 2)
22.2. aifc — Read and write AIFF and AIFC files

Source code: Lib/aifc.py

This module provides support for reading and writing AIFF and AIFF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

Note: Some operations may only work under IRIX; these will raise ImportError when attempting to import the c1 module, which is only available on IRIX.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of nchannels * samplesize bytes, and a second's worth of audio consists of nchannels * samplesize * framerate bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second's worth occupies 2*2*44100 bytes (176,400 bytes).

Module aifc defines the following function:
aifc.open(file, mode=None)

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument file is either a string naming a file or a file object. mode must be 'r' or 'rb' when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, file.mode is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use writeframesraw() and setnframes(). The open() function may be used in a with statement. When the with block completes, the close() method is called.

Changed in version 3.4: Support for the with statement was added.

Objects returned by open() when a file is opened for reading have the following methods:

aifc.getnchannels()

Return the number of audio channels (1 for mono, 2 for stereo).

aifc.getsampwidth()

Return the size in bytes of individual samples.

aifc.getframerate()

Return the sampling rate (number of audio frames per second).

aifc.getnframes()

Return the number of audio frames in the file.

aifc.getcomptype()
Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is b'NONE'.

aifc.getcompname()
Return a bytes array convertible to a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is b'not compressed'.

aifc.getparams()
Returns a namedtuple() (nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to output of the get*() methods.

aifc.getmarkers()
Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

aifc.getmark(id)
Return the tuple as described in getmarkers() for the mark with the given id.

aifc.readframes(nframes)
Read and return the next nframes frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

aifc.rewind()
Rewind the read pointer. The next readframes() will start from the beginning.
aifc.setpos(pos)
    Seek to the specified frame number.

aifc.tell()
    Return the current frame number.

aifc.close()
    Close the AIFF file. After calling this method, the object can no
    longer be used.

Objects returned by open() when a file is opened for writing have all
the above methods, except for readframes() and setpos(). In
addition the following methods exist. The get*() methods can only
be called after the corresponding set*() methods have been called.
Before the first writeframes() or writeframesraw(), all
parameters except for the number of frames must be filled in.

aifc.aiff()
    Create an AIFF file. The default is that an AIFF-C file is created,
    unless the name of the file ends in '.aiff' in which case the
default is an AIFF file.

aifc.aifc()
    Create an AIFF-C file. The default is that an AIFF-C file is created,
    unless the name of the file ends in '.aiff' in which case the
default is an AIFF file.

aifc.setnchannels(nchannels)
    Specify the number of channels in the audio file.

aifc.setsampwidth(width)
    Specify the size in bytes of audio samples.
aifc.setframerate(rate)
   Specify the sampling frequency in frames per second.

aifc.setnframes(nframes)
   Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

aifc.setcomptype(type, name)
   Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: b'NONE', b'ULAW', b'ALAW', b'G722'.

aifc.setparams(nchannels, sampwidth, framerate, comptype, compname)
   Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a getparams() call as argument to setparams().

aifc.setmark(id, pos, name)
   Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before close().

aifc.tell()
   Return the current write position in the output file. Useful in combination with setmark().
aifc.writeframes(data)
  Write data to the output file. This method can only be called after
  the audio file parameters have been set.

  Changed in version 3.4: Any bytes-like object is now accepted.

aifc.writeframesraw(data)
  Like writeframes(), except that the header of the audio file is
  not updated.

  Changed in version 3.4: Any bytes-like object is now accepted.

aifc.close()
  Close the AIFF file. The header of the file is updated to reflect the
  actual size of the audio data. After calling this method, the object
  can no longer be used.
22.3. sunau — Read and write Sun AU files

Source code: Lib/sunau.py

The sunau module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules aifc and wave.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes . snd.</td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes).</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The sunau module defines the following functions:

sunau. open(file, mode)
If `file` is a string, open the file by that name, otherwise treat it as a seekable file-like object. `mode` can be any of

'`r`'
Read only mode.

'`w`'
Write only mode.

Note that it does not allow read/write files.

A `mode` of 'r' returns an AU_read object, while a `mode` of 'w' or 'wb' returns an AU_write object.

sunau.openfp(file, mode)
A synonym for `open()`, maintained for backwards compatibility.

The `sunau` module defines the following exception:

`exception sunau.Error`
An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The `sunau` module defines the following data items:

sunau.AUDIO_FILE_MAGIC
An integer every valid Sun AU file begins with, stored in big-endian form. This is the string `.snd` interpreted as an integer.

sunau.AUDIO_FILE_ENCODING_MULAW_8
sunau.AUDIO_FILE_ENCODING_LINEAR_8
sunau.AUDIO_FILE_ENCODING_LINEAR_16
sunau.AUDIO_FILE_ENCODING_LINEAR_24
sunau.AUDIO_FILE_ENCODING_LINEAR_32
sunau.AUDIO_FILE_ENCODING_ALAW_8
Values of the encoding field from the AU header which are supported by this module.

sunau.\texttt{AUDIO\_FILE\_ENCODING\_FLOAT}

sunau.\texttt{AUDIO\_FILE\_ENCODING\_DOUBLE}

sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G721}

sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G722}

sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_3}

sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_5}

Additional known values of the encoding field from the AU header, but which are not supported by this module.
22.3.1. AU_read Objects

AU_read objects, as returned by `open()` above, have the following methods:

**AU_read.close()**
Close the stream, and make the instance unusable. (This is called automatically on deletion.)

**AU_read.getnchannels()**
Returns number of audio channels (1 for mono, 2 for stereo).

**AU_read.getsampwidth()**
Returns sample width in bytes.

**AU_read.getframerate()**
Returns sampling frequency.

**AU_read.getnframes()**
Returns number of audio frames.

**AU_read.getcomptype()**
Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

**AU_read.getcomppname()**
Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

**AU_read.getparams()**
Returns a `namedtuple()` (nchannels, sampwidth,
framerate, nframes, comtype, compname), equivalent to output of the get*( ) methods.

**AU_read.readframes(n)**
Reads and returns at most n frames of audio, as a string of bytes. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

**AU_read.rewind()**
Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

**AU_read.setpos(pos)**
Set the file pointer to the specified position. Only values returned from tell( ) should be used for pos.

**AU_read.tell()**
Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the aifc, and don’t do anything interesting.

**AU_read.getmarkers()**
Returns None.

**AU_read.getmark(id)**
Raise an error.
22.3.2. AU_write Objects

AU_write objects, as returned by open() above, have the following methods:

\texttt{AU\_write.setnchannels(n)}
Set the number of channels.

\texttt{AU\_write.setsampwidth(n)}
Set the sample width (in bytes.)

\textit{Changed in version 3.4:} Added support for 24-bit samples.

\texttt{AU\_write.setframerate(n)}
Set the frame rate.

\texttt{AU\_write.setnframes(n)}
Set the number of frames. This can be later changed, when and if more frames are written.

\texttt{AU\_write.setcomptype(type, name)}
Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

\texttt{AU\_write.setparams(tuple)}
The \textit{tuple} should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

\texttt{AU\_write.tell()}
Return current position in the file, with the same disclaimer for the \texttt{AU\_read.tell()} and \texttt{AU\_read.setpos()} methods.
AU_write.writeframesraw(data)
Write audio frames, without correcting nframes.

Changed in version 3.4: Any bytes-like object is now accepted.

AU_write.writeframes(data)
Write audio frames and make sure nframes is correct.

Changed in version 3.4: Any bytes-like object is now accepted.

AU_write.close()
Make sure nframes is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw().
22.4. `wave` — Read and write WAV files

**Source code:** Lib/wave.py

The `wave` module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The `wave` module defines the following function and exception:

```python
wave.open(file, mode=None)
```

If `file` is a string, open the file by that name, otherwise treat it as a file-like object. `mode` can be:

- `'rb'`
  
  Read only mode.

- `'wb'`
  
  Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'rb'` returns a `Wave_read` object, while a `mode` of `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode`.

If you pass in a file-like object, the `wave` object will not close it when its `close()` method is called; it is the caller’s responsibility to close the file object.
The open() function may be used in a with statement. When the with block completes, the Wave_read.close() or Wave_write.close() method is called.

*Changed in version 3.4:* Added support for unseekable files.

wave.openfp(file, mode)

A synonym for open(), maintained for backwards compatibility.

exception wave.Error

An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.
22.4.1. Wave_read Objects

Wave_read objects, as returned by open(), have the following methods:

Wave_read.close()
   Close the stream if it was opened by wave, and make the instance unusable. This is called automatically on object collection.

Wave_read.getnchannels()
   Returns number of audio channels (1 for mono, 2 for stereo).

Wave_read.getsampwidth()
   Returns sample width in bytes.

Wave_read.getframerate()
   Returns sampling frequency.

Wave_read.getnframes()
   Returns number of audio frames.

Wave_read.getcomptype()
   Returns compression type ('NONE' is the only supported type).

Wave_read.getcompname()
   Human-readable version of getcomptype(). Usually 'not compressed' parallels 'NONE'.

Wave_read.getparams()
   Returns a namedtuple() (nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to
output of the get*() methods.

Wave_read.readframes(n)
  Reads and returns at most n frames of audio, as a string of bytes.

Wave_read.rewind()
  Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the aifc module, and don’t do anything interesting.

Wave_read.getmarkers()
  Returns None.

Wave_read.getmark(id)
  Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

Wave_read.setpos(pos)
  Set the file pointer to the specified position.

Wave_read.tell()
  Return current file pointer position.
22.4.2. Wave_write Objects

For seekable output streams, the wave header will automatically be updated to reflect the number of frames actually written. For unseekable streams, the nframes value must be accurate when the first frame data is written. An accurate nframes value can be achieved either by calling setnframes() or setparams() with the number of frames that will be written before close() is called and then using writeframesraw() to write the frame data, or by calling writeframes() with all of the frame data to be written. In the latter case writeframes() will calculate the number of frames in the data and set nframes accordingly before writing the frame data.

Wave_write objects, as returned by open(), have the following methods:

*Changed in version 3.4:* Added support for unseekable files.

Wave_write.close()

Make sure nframes is correct, and close the file if it was opened by wave. This method is called upon object collection. It will raise an exception if the output stream is not seekable and nframes does not match the number of frames actually written.

Wave_write.setnchannels(n)

Set the number of channels.

Wave_write.setsampwidth(n)

Set the sample width to n bytes.

Wave_write.setframerate(n)
Set the frame rate to \( n \).

*Changed in version 3.2:* A non-integral input to this method is rounded to the nearest integer.

**Wave_write.setnframes(\( n \))**
Set the number of frames to \( n \). This will be changed later if the number of frames actually written is different (this update attempt will raise an error if the output stream is not seekable).

**Wave_write.setcomptype(type, name)**
Set the compression type and description. At the moment, only compression type NONE is supported, meaning no compression.

**Wave_write.setparams(tuple)**
The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Sets all parameters.

**Wave_write.tell()**
Return current position in the file, with the same disclaimer for the Wave_read.tell() and Wave_read.setpos() methods.

**Wave_write.writeframesraw(data)**
Write audio frames, without correcting nframes.

*Changed in version 3.4:* Any bytes-like object is now accepted.

**Wave_write.writeframes(data)**
Write audio frames and make sure nframes is correct. It will raise an error if the output stream is not seekable and the total number of frames that have been written after data has been written does not match the previously set value for nframes.
Changed in version 3.4: Any bytes-like object is now accepted.

Note that it is invalid to set any parameters after calling `writeframes()` or `writeframesraw()`, and any attempt to do so will raise `wave.Error`.
22.5. **chunk — Read IFF chunked data**

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>(n)</td>
<td>Data bytes, where (n) is the size given in the preceding field</td>
</tr>
<tr>
<td>8 + (n)</td>
<td>0 or 1</td>
<td>Pad byte needed if (n) is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the **Chunk** class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an **EOFError** exception.
**class** chunk.

**Chunk(file, align=True, bigendian=True, inclheader=False)**

Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don’t raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument *align* is true, chunks are assumed to be aligned on 2-byte boundaries. If *align* is false, no alignment is assumed. The default value is true. If the optional argument *bigendian* is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument *inclheader* is true, the size given in the chunk header includes the size of the header. The default value is false.

A **Chunk** object supports the following methods:

**getname()**

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

**getsize()**

Returns the size of the chunk.

**close()**

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise **OSError** if called after the **close()** method has been called. Before Python 3.3, they used to raise **IOError**, now an alias of **OSError**.
**isatty()**

Returns False.

**seek(pos, whence=0)**

Set the chunk's current position. The *whence* argument is optional and defaults to 0 (absolute file positioning); other values are 1 (seek relative to the current position) and 2 (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

**tell()**

Return the current position into the chunk.

**read(size=-1)**

Read at most size bytes from the chunk (less if the read hits the end of the chunk before obtaining size bytes). If the *size* argument is negative or omitted, read all data until the end of the chunk. An empty bytes object is returned when the end of the chunk is encountered immediately.

**skip()**

Skip to the end of the chunk. All further calls to *read()* for the chunk will return b' '. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

**Footnotes**

22.6. `colorsys` — Conversions between color systems

**Source code:** Lib/colorsys.py

The `colorsys` module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

**See also:** More information about color spaces can be found at [http://www.poynton.com/ColorFAQ.html](http://www.poynton.com/ColorFAQ.html) and [http://www.cambridgeincolour.com/tutorials/color-spaces.htm](http://www.cambridgeincolour.com/tutorials/color-spaces.htm).

The `colorsys` module defines the following functions:

- `colorsys.rgb_to_yiq(r, g, b)`
  Convert the color from RGB coordinates to YIQ coordinates.

- `colorsys.yiq_to_rgb(y, i, q)`
  Convert the color from YIQ coordinates to RGB coordinates.

- `colorsys.rgb_to_hls(r, g, b)`
  Convert the color from RGB coordinates to HLS coordinates.

- `colorsys.hls_to_rgb(h, l, s)`
Convert the color from HLS coordinates to RGB coordinates.

```
colorsys.rgb_to_hsv(r, g, b)
```

Convert the color from RGB coordinates to HSV coordinates.

```
colorsys.hsv_to_rgb(h, s, v)
```

Convert the color from HSV coordinates to RGB coordinates.

Example:

```
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```
22.7. **imghdr** — Determine the type of an image

**Source code:** Lib/imghdr.py

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

```
imghdr.what(filename, h=None)
```

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pnm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>'rast'</td>
<td>SunRaster Files</td>
</tr>
<tr>
<td></td>
<td>Description</td>
</tr>
<tr>
<td>---</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
<tr>
<td>'webp'</td>
<td>WebP files</td>
</tr>
<tr>
<td>'exr'</td>
<td>OpenEXR Files</td>
</tr>
</tbody>
</table>

New in version 3.5: The exr and webp formats were added.

You can extend the list of file types `imghdr` can recognize by appending to this variable:

`imghdr.tests`

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be None.

The test function should return a string describing the image type if the test succeeded, or None if it failed.

Example:

```
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```
Last updated on Dec 06, 2015. Found a bug?
Created using Sphinx 1.3.1.
22.8. sndhdr — Determine type of sound file

Source code: Lib/sndhdr.py

The sndhdr provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a namedtuple(), containing five attributes: (filetype, framerate, nchannels, nframes, sampwidth). The value for type indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The sampling rate will be either the actual value or 0 if unknown or difficult to decode. Similarly, channels will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for frames will be either the number of frames or -1. The last item in the tuple, bits_per_sample, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

sndhdr.what(filename)

Determines the type of sound data stored in the file filename using whathdr(). If it succeeds, returns a namedtuple as described above, otherwise None is returned.

Changed in version 3.5: Result changed from a tuple to a namedtuple.

sndhdr.whathdr(filename)

Determines the type of sound data stored in a file based on the file
header. The name of the file is given by *filename*. This function returns a namedtuple as described above on success, or None.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.
22.9. ossaudiodev — Access to OSS-compatible audio devices

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

Changed in version 3.3: Operations in this module now raise OSError where IOError was raised.

See also:

Open Sound System Programmer's Guide
the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see <sys/soundcard.h> on either Linux or FreeBSD for a listing.

ossaudiodev defines the following variables and functions:

exception ossaudiodev.OSSAudioError

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If ossaudiodev receives an error from a system call such as open(), write(), or ioctl(), it raises OSError. Errors detected directly by ossaudiodev result in OSSAudioError.)

(For backwards compatibility, the exception class is also available
ossaudiodev.error.

**ossaudiodev.open**(mode)

**ossaudiodev.open**(device, mode)

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as read(), write(), and fileno() (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

*device* is the audio device filename to use. If it is not specified, this module first looks in the environment variable AUDIODEV for a device to use. If not found, it falls back to /dev/dsp.

*mode* is one of 'r' for read-only (record) access, 'w' for write-only (playback) access and 'rw' for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the first argument is optional, and the second is required. This is a historical artifact for compatibility with the older linuxaudiodev module which ossaudiodev supersedes.

ossaudiodev.openmixer([device])

Open a mixer device and return an OSS mixer device object. *device* is the mixer device filename to use. If it is not specified, this module first looks in the environment variable MIXERDEV for a device to use. If not found, it falls back to /dev/mixer.
22.9.1. Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

`oss_audio_device.close()`

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`

Return the file descriptor associated with the device.

`oss_audio_device.read(size)`

Read `size` bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

`oss_audio_device.write(data)`

Write a bytes-like object `data` to the audio device and return the
number of bytes written. If the audio device is in blocking mode (the default), the entire data is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written — see `writeall()`.

`oss_audio_device.writeall(data)`

Write a bytes-like object `data` to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until `data` has been completely written. If the device is in blocking mode (the default), this has the same effect as `write()`; `writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

*Changed in version 3.2:* Audio device objects also support the context management protocol, i.e. they can be used in a `with` statement.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` ioctl, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise `OSError`.

`oss_audio_device.nonblock()`

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

`oss_audio_device.getfmts()`

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:
<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMT.IMA.ADPCM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
<tr>
<td>AFMT_U8</td>
<td>Unsigned, 8-bit audio</td>
</tr>
<tr>
<td>AFMT.S16.LE</td>
<td>Signed, 16-bit audio, little-endian byte order (as used by Intel processors)</td>
</tr>
<tr>
<td>AFMT.S16.BE</td>
<td>Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)</td>
</tr>
<tr>
<td>AFMT_S8</td>
<td>Signed, 8 bit audio</td>
</tr>
<tr>
<td>AFMT.U16.LE</td>
<td>Unsigned, 16-bit little-endian audio</td>
</tr>
<tr>
<td>AFMT.U16.BE</td>
<td>Unsigned, 16-bit big-endian audio</td>
</tr>
</tbody>
</table>

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support AFMT_U8; the most common format used today is AFMT_S16_LE.

**oss_audio_device.setfmt(format)**

Try to set the current audio format to *format*—see *getfmts()* for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of AFMT_QUERY.

**oss_audio_device.channels(nchannels)**

Set the number of output channels to *nchannels*. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may
have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

**oss_audio_device.speed(samplerate)**

Try to set the audio sampling rate to *samplerate* samples per second. Returns the rate actually set. Most sound devices don’t support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>default rate for /dev/audio</td>
</tr>
<tr>
<td>11025</td>
<td>speech recording</td>
</tr>
<tr>
<td>22050</td>
<td></td>
</tr>
<tr>
<td>44100</td>
<td>CD quality audio (at 16 bits/sample and 2 channels)</td>
</tr>
<tr>
<td>96000</td>
<td>DVD quality audio (at 24 bits/sample)</td>
</tr>
</tbody>
</table>

**oss_audio_device.sync()**

Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using `sync()`.

**oss_audio_device.reset()**

Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling `reset()`.

**oss_audio_device.post()**

Tell the driver that there is likely to be a pause in the output,
making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctl's, or one ioctl and some simple calculations.

oss_audio_device.setparameters(format, nchannels, samplerate[, strict=False])
Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. format, nchannels, and samplerate should be as specified in the setfmt(), channels(), and speed() methods. If strict is true, setparameters() checks to see if each parameter was actually set to the requested value, and raises OSSAudioError if not. Returns a tuple (format, nchannels, samplerate) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of setfmt(), channels(), and speed()).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, channels, samplerate)
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(rate)
```

oss_audio_device.bufsize()
Returns the size of the hardware buffer, in samples.
oss_audio_device.\textbf{obufcount}()
   Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.\textbf{obuffree}()
   Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.\textbf{closed}
   Boolean indicating whether the device has been closed.

oss_audio_device.\textbf{name}
   String containing the name of the device file.

oss_audio_device.\textbf{mode}
   The I/O mode for the file, either "r", "rw", or "w".
22.9.2. Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an OSError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

Changed in version 3.2: Mixer objects also support the context management protocol.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_* constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIX
    # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that
uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, SOUND_MIXER_VOLUME does not exist.

oss_mixer_device.stereocontrols()
Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with controls() to determine which).

See the code example for the controls() function for an example of getting data from a bitmask.

oss_mixer_device.reccontrols()
Returns a bitmask specifying the mixer controls that may be used to record. See the code example for controls() for an example of reading from a bitmask.

oss_mixer_device.get(control)
Returns the volume of a given mixer control. The returned volume is a 2-tuple (left_volume, right_volume). Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises OSSAudioError if an invalid control is specified, or OSError if an unsupported control is specified.

oss_mixer_device.set(control, (left, right))
Sets the volume for a given mixer control to (left, right). left and right must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple.
Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises **OSSAudioError** if an invalid mixer control was specified, or if the specified volumes were out-of-range.

**oss_mixer_device.get_recsrc()**

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

**oss_mixer_device.set_recsrc(bitmask)**

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises **OSError** if an invalid source was specified. To set the current recording source to the microphone input:

```python
mixer.setrecesrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```
23. Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **23.1. gettext — Multilingual internationalization services**
  - 23.1.1. GNU gettext API
  - 23.1.2. Class-based API
    - 23.1.2.1. The NullTranslations class
    - 23.1.2.2. The GNUTranslations class
    - 23.1.2.3. Solaris message catalog support
    - 23.1.2.4. The Catalog constructor
  - 23.1.3. Internationalizing your programs and modules
    - 23.1.3.1. Localizing your module
    - 23.1.3.2. Localizing your application
    - 23.1.3.3. Changing languages on the fly
    - 23.1.3.4. Deferred translations
  - 23.1.4. Acknowledgements

- **23.2. locale — Internationalization services**
  - 23.2.1. Background, details, hints, tips and caveats
  - 23.2.2. For extension writers and programs that embed Python
  - 23.2.3. Access to message catalogs
23.1. gettext — Multilingual internationalization services

Source code: Lib/gettext.py

The gettext module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU gettext message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
23.1.1. GNU gettext API

The gettext module defines the following API, which is very similar to the GNU gettext API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

`gettext.bindtextdomain(domain, localedir=None)`

Bind the `domain` to the locale directory `localedir`. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix):
```
localedir/language/LC_MESSAGES/domain.mo
```
where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or `None`, then the current binding for `domain` is returned. [1]

`gettext.bind_textdomain_codeset(domain, codeset=None)`

Bind the `domain` to `codeset`, changing the encoding of strings returned by the `gettext()` family of functions. If `codeset` is omitted, then the current binding is returned.

`gettext.textdomain(domain=None)`

Change or query the current global domain. If `domain` is `None`, then the current global domain is returned, otherwise the global domain is set to `domain`, which is returned.
**gettext.gettext(message)**

Return the localized translation of `message`, based on the current global domain, language, and locale directory. This function is usually aliased as `_()` in the local namespace (see examples below).

**gettext.lgettext(message)**

Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

**gettext.dgettext(domain, message)**

Like `gettext()`, but look the message up in the specified `domain`.

**gettext.ldgettext(domain, message)**

Equivalent to `dgettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

**gettext.ngettext(singular, plural, n)**

Like `gettext()`, but consider plural forms. If a translation is found, apply the plural formula to `n`, and return the resulting message (some languages have more than two plural forms). If no translation is found, return `singular` if `n` is 1; return `plural` otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable `n`; the expression evaluates to the index of the plural in the catalog. See the [GNU gettext documentation](https://www.gnu.org/software/gettext/manual/html_node/) for the precise syntax to be used in `.po` files and the formulas for a variety of languages.

**gettext.lngettext(singular, plural, n)**
Equivalent to `ngettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

```python
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my
gettext.textdomain('myapplication')
_ = gettextgettext
# ...
print(_('This is a translatable string.'))
```

`gettext.dngettext(domain, singular, plural, n)`

Like `ngettext()`, but look the message up in the specified `domain`.

`gettext.ldngettext(domain, singular, plural, n)`

Equivalent to `dngettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `bind_textdomain_codeset()`.

Note that GNU `gettext` also defines a `dcgettext()` method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:
23.1.2. Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function _().

`gettext.find(domain, localedir=None, languages=None, all=False)`

This function implements the standard .mo file search algorithm. It takes a domain, identical to what textdomain() takes. Optional localedir is as in bindtextdomain() Optional languages is a list of strings, where each string is a language code.

If localedir is not given, then the default system locale directory is used. [2] If languages is not given, then the following environment variables are searched: LANGUAGE, LC_ALL, LC_MESSAGES, and LANG. The first one returning a non-empty value is used for the languages variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

`localedir/language/LC_MESSAGES/domain.mo`
The first such file name that exists is returned by `find()`. If no such file is found, then `None` is returned. If `all` is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

```python
gettext.translation(domain, localedir=None, languages=None, class_=None, fallback=False, codeset=None)
```

Return a `Translations` instance based on the `domain`, `localedir`, and `languages`, which are first passed to `find()` to get a list of the associated `.mo` file paths. Instances with identical `.mo` file names are cached. The actual class instantiated is either `class_` if provided, otherwise `GNUTranslations`. The class's constructor must take a single `file object` argument. If provided, `codeset` will change the charset used to encode translated strings in the `gettext()` and `lngettext()` methods.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, `copy.copy()` is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no `.mo` file is found, this function raises `OSError` if `fallback` is false (which is the default), and returns a `NullTranslations` instance if `fallback` is true.

*Changed in version 3.3:* `IOError` used to be raised instead of `OSError`.

```python
gettext.install(domain, localedir=None, codeset=None, names=None)
```

This installs the function `_( )` in Python's builtins namespace, based on `domain`, `localedir`, and `codeset` which are passed to the
function translation().

For the names parameter, please see the description of the translation object's install() method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the _() function, like this:

```
print(_('This string will be translated.'))
```

For convenience, you want the _() function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

23.1.2.1. The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is NullTranslations; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of NullTranslations:

class gettext.NullTranslations(fp=None)

Takes an optional file object fp, which is ignored by the base class. Initializes “protected” instance variables _info and _charset which are set by derived classes, as well as _fallback, which is set through add_fallback(). It then calls self._parse(fp) if fp is not None.

_parse(fp)

No-op’d in the base class, this method takes file object fp, and
reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add_fallback(fallback)**

Add *fallback* as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext(message)**

If a fallback has been set, forward `gettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lgettext(message)**

If a fallback has been set, forward `lgettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**ngettext(singular, plural, n)**

If a fallback has been set, forward `ngettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lngettext(singular, plural, n)**

If a fallback has been set, forward `lngettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**info()**

Return the “protected” `_info` variable.
charset()
Return the “protected” _charset variable, which is the encoding of the message catalog file.

output_charset()
Return the “protected” _output_charset variable, which defines the encoding used to return translated messages in lgettext() and lngettext().

set_output_charset(charset)
Change the “protected” _output_charset variable, which defines the encoding used to return translated messages.

install(names=None)
This method installs self.gettext() into the built-in namespace, binding it to _.

If the names parameter is given, it must be a sequence containing the names of functions you want to install in the builtin namespace in addition to _. Supported names are 'gettext' (bound to self.gettext()), 'ngettext' (bound to self.ngettext()), 'lgettext' and 'lngettext'.

Note that this is only one way, albeit the most convenient way, to make the _() function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install _. Instead, they should use this code to make _() available to their module:

```python
import gettext
```
This puts `_()` only in the module's global namespace and so only affects calls within this module.

### 23.1.2.2. The GNUTranslations class

The `gettext` module provides one additional class derived from `NullTranslations`: `GNUTranslations`. This class overrides `_parse()` to enable reading GNU `gettext` format `.mo` files in both big-endian and little-endian format.

`GNUTranslations` parses optional meta-data out of the translation catalog. It is convention with GNU `gettext` to include meta-data as the translation for the empty string. This meta-data is in RFC 822-style key: value pairs, and should contain the `Project-Id-Version` key. If the key `Content-Type` is found, then the charset property is used to initialize the “protected” `_charset` instance variable, defaulting to `None` if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII encoding is assumed.

Since message ids are read as Unicode strings too, all `*gettext()` methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” `_info` instance variable.

If the `.mo` file's magic number is invalid, the major version number is unexpected, or if other problems occur while reading the file,
instantiating a GNUTranslations class can raise OSError.

The following methods are overridden from the base class implementation:

**GNUTranslations.gettext**(message)

Look up the *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id, and a fallback has been set, the look up is forwarded to the fallback's gettext() method. Otherwise, the *message* id is returned.

**GNUTranslations.lgettext**(message)

Equivalent to gettext(), but the translation is returned as a bytestring encoded in the selected output charset, or in the preferred system encoding if no encoding was explicitly set with set_output_charset().

**GNUTranslations.ngettext**(singular, plural, n)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback’s ngettext() method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
```
message = cat.ngettext(
'There is %(num)d file in this directory',
'There are %(num)d files in this directory',
n) % {'num': n}

GNUTranslations.\texttt{lngettext}(\textit{singular}, \textit{plural}, \textit{n})
Equivalent to \texttt{gettext()}, but the translation is returned as a bytestring encoded in the selected output charset, or in the preferred system encoding if no encoding was explicitly set with set_output_charset().

23.1.2.3. Solaris message catalog support

The Solaris operating system defines its own binary .mo file format, but since no documentation can be found on this format, it is not supported at this time.

23.1.2.4. The Catalog constructor

GNOME uses a version of the \texttt{gettext} module by James Henstridge, but this version has a slightly different API. Its documented usage was:

\begin{verbatim}
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print(_('hello world'))
\end{verbatim}

For compatibility with this older module, the function Catalog() is an alias for the translation() function described above.

One difference between this module and Henstridge’s: his catalog objects supported access through a mapping API, but this appears to
be unused and so is not currently supported.
23.1.3. Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the gettext module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_('...')` — that is, a call to the function `_()`. For example:

```python
filename = 'mylog.txt'
message = _('writing a log message')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

In this example, the string 'writing a log message' is marked as a candidate for translation, while the strings 'mylog.txt' and 'w' are not.
There are a few tools to extract the strings meant for translation. The original GNU gettext only supported C or C++ source code but its extended version xgettext scans code written in a number of languages, including Python, to find strings marked as translatable. Babel is a Python internationalization library that includes a pybabel script to extract and compile message catalogs. François Pinard's program called xpot does a similar job and is available as part of his po-utils package.

(Python also includes pure-Python versions of these programs, called pygettext.py and msgfmt.py; some Python distributions will install them for you. pygettext.py is similar to xgettext, but only understands Python source code and cannot handle other programming languages such as C or C++. pygettext.py supports a command-line interface similar to xgettext; for details on its use, run pygettext.py --help. msgfmt.py is binary compatible with GNU msgfmt. With these two programs, you may not need the GNU gettext package to internationalize your Python applications.)

xgettext, pygettext, and similar tools generate .po files that are message catalogs. They are structured human-readable files that contain every marked string in the source code, along with a placeholder for the translated versions of these strings.

Copies of these .po files are then handed over to the individual human translators who write translations for every supported natural language. They send back the completed language-specific versions as a <language-name>.po file that's compiled into a machine-readable .mo binary catalog file using the msgfmt program. The .mo files are used by the gettext module for the actual translation processing at run-time.
How you use the gettext module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.

### 23.1.3.1. Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU gettext API but instead the class-based API.

Let's say your module is called “spam” and the module's various natural language translation .mo files reside in /usr/share/locale in GNU gettext format. Here's what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.lgettext
```

### 23.1.3.2. Localizing your application

If you are localizing your application, you can install the _( ) function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use _( '...' ) without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
ggettext.install('myapplication')
```
If you need to set the locale directory, you can pass it into the `install()` function:

```python
import gettext
gettext.install('myapplication', '/usr/share/locale')
```

### 23.1.3.3. Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', language='en')
lang2 = gettext.translation('myapplication', language='fr')
lang3 = gettext.translation('myapplication', language='es')

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

### 23.1.3.4. Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:
animals = ['mollusk',
            'albatross',
            'rat',
            'penguin',
            'python',
          ]

# ...
for a in animals:
    print(a)

Here, you want to mark the strings in the animals list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

def _(message):  return message

animals = [_( exceed'),
            _( 'albatross'),
            _( 'rat'),
            _( 'penguin'),
            _( 'python'),
          ]

del _

# ...
for a in animals:
    print(_(a))

This works because the dummy definition of _() simply returns the string unchanged. And this dummy definition will temporarily override any definition of _() in the built-in namespace (until the del command). Take care, though if you have a previous definition of _() in the local namespace.
Note that the second use of \_() will not identify “a” as being translatable to the \gettext program, because the parameter is not a string literal.

Another way to handle this is with the following example:

```python
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'),  ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function \N_(), which won’t conflict with any definition of \_(). However, you will need to teach your message extraction program to look for translatable strings marked with \N_(). \xgettext, \pygettext, pybabel extract, and \xpot all support this through the use of the -k command-line switch. The choice of \N_() here is totally arbitrary; it could just as easily have been MarkThisStringForTranslation().
23.1.4. Acknowledgements

The following people contributed code, feedback, design suggestions, previous implementations, and valuable experience to the creation of this module:

- Peter Funk
- James Henstridge
- Juan David Ibáñez Palomar
- Marc-André Lemburg
- Martin von Löwis
- François Pinard
- Barry Warsaw
- Gustavo Niemeyer

Footnotes

The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call bindtextdomain() with an explicit absolute path at the start of your application.

[1] The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call bindtextdomain() with an explicit absolute path at the start of your application.

[2] See the footnote for bindtextdomain() above.
23.2. locale — Internationalization services

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

`exception locale.Error`
Exception raised when the locale passed to `setlocale()` is not recognized.

`locale.setlocale(category, locale=None)`
If `locale` is given and not None, `setlocale()` modifies the locale setting for the `category`. The available categories are listed in the data description below. `locale` may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user’s default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If `locale` is omitted or None, the current setting for `category` is returned.
**setlocale()** is not thread-safe on most systems. Applications typically start with a call of

```python
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

**locale.localeconv()**

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LC_NUMERIC</strong></td>
<td>'decimal_point'</td>
<td>Decimal point character.</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td>Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. If the sequence terminates with a character, the last group size is repeatedly used.</td>
</tr>
<tr>
<td></td>
<td>'thousands_sep'</td>
<td>Character used further grouping is performed.</td>
</tr>
</tbody>
</table>

```
<table>
<thead>
<tr>
<th><strong>LC_MONETARY</strong></th>
<th>'int_curr_symbol'</th>
<th>International currency symbol.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
</tr>
<tr>
<td></td>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether currency symbol precedes the value (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether currency symbol is separated from the value (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
</tr>
<tr>
<td></td>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
</tr>
<tr>
<td></td>
<td>'int_frac_digits'</td>
<td>Number of fractional digits used in international formatting of monetary values.</td>
</tr>
<tr>
<td></td>
<td>'mon_thousands_sep'</td>
<td>Group separator used for monetary values.</td>
</tr>
<tr>
<td></td>
<td>'mon_grouping'</td>
<td>Equivalent to 'grouping' for monetary values.</td>
</tr>
</tbody>
</table>
The `positive_sign` symbol is used to annotate a positive monetary value.

The `negative_sign` symbol is used to annotate a negative monetary value.

The `p_sign_posn/n_sign_posn` value specifies the position of the sign (for positive resp. negative values), see below.

All numeric values can be set to `CHAR_MAX` to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
<tr>
<td>1</td>
<td>The sign should precede the value and currency symbol.</td>
</tr>
<tr>
<td>2</td>
<td>The sign should follow the value and currency symbol.</td>
</tr>
<tr>
<td>3</td>
<td>The sign should immediately precede the value.</td>
</tr>
<tr>
<td>4</td>
<td>The sign should immediately follow the value.</td>
</tr>
<tr>
<td><code>CHAR_MAX</code></td>
<td>Nothing is specified in this locale.</td>
</tr>
</tbody>
</table>

`locale.nl_langinfo(option)`

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might
also vary across platforms. The possible argument values are
numbers, for which symbolic constants are available in the locale
module.

The `nl_langinfo()` function accepts one of the following keys. Most
descriptions are taken from the corresponding description in
the GNU C library.

**locale.CODSET**
Get a string with the name of the character encoding used in
the selected locale.

**locale.D_T_FMT**
Get a string that can be used as a format string for
`time.strftime()` to represent date and time in a locale-
specific way.

**locale.D_FMT**
Get a string that can be used as a format string for
`time.strftime()` to represent a date in a locale-specific
way.

**locale.T_FMT**
Get a string that can be used as a format string for
`time.strftime()` to represent a time in a locale-specific
way.

**locale.T_FMT_AMPM**
Get a format string for `time.strftime()` to represent time in
the am/pm format.

**DAY_1 ... DAY_7**
Get the name of the n-th day of the week.
Note: This follows the US convention of DAY_1 being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

**ABDAY_1 . . . ABDAY_7**
Get the abbreviated name of the n-th day of the week.

**MON_1 . . . MON_12**
Get the name of the n-th month.

**ABMON_1 . . . ABMON_12**
Get the abbreviated name of the n-th month.

**locale.RADIXCHAR**
Get the radix character (decimal dot, decimal comma, etc.).

**locale.THOUSEP**
Get the separator character for thousands (groups of three digits).

**locale.YESEXPR**
Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

Note: The expression is in the syntax suitable for the `regex()` function from the C library, which might differ from the syntax used in `re`.

**locale.NOEXPR**
Get a regular expression that can be used with the `regex(3)` function to recognize a negative response to a yes/no question.

**locale.CRNCYSTR**
Get the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.

`locale.ERA`

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the E modifier in their format strings causes the `time.strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

`locale.ERA_D_T_FMT`

Get a format string for `time.strftime()` to represent date and time in a locale-specific era-based way.

`locale.ERA_D_FMT`

Get a format string for `time.strftime()` to represent a date in a locale-specific era-based way.

`locale.ERA_T_FMT`

Get a format string for `time.strftime()` to represent a time in a locale-specific era-based way.

`locale.ALT_DIGITS`

Get a representation of up to 100 values used to represent the values 0 to 99.
locale.getdefaultlocale([envvars])

Tries to determine the default locale settings and returns them as a tuple of the form (language code, encoding).

According to POSIX, a program which has not called setlocale(LC_ALL, '') runs using the portable 'C' locale. Calling setlocale(LC_ALL, '') lets it use the default locale as defined by the LANG variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the LANG variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. envvars defaults to the search path used in GNU gettext; it must always contain the variable name 'LANG'. The GNU gettext search path contains 'LC_ALL', 'LC_CTYPE', 'LANG' and 'LANGUAGE', in that order.

Except for the code 'C', the language code corresponds to RFC 1766. language code and encoding may be None if their values cannot be determined.

locale.getlocale(category=LC_CTYPE)

Returns the current setting for the given locale category as sequence containing language code, encoding. category may be one of the LC_* values except LC_ALL. It defaults to LC_CTYPE.

Except for the code 'C', the language code corresponds to RFC 1766. language code and encoding may be None if their values cannot be determined.
locale.getpreferredencoding(do_setlocale=True)

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke setlocale() to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, do_setlocale should be set to False.

locale.normalize(localename)

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with setlocale(). If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like setlocale().

locale.resetlocale(category=LC_ALL)

Sets the locale for category to the default setting.

The default setting is determined by calling getdefaultlocale(). category defaults to LC_ALL.

locale.strcoll(string1, string2)

Compares two strings according to the current LC_COLLATE setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether string1 collates before or after string2 or is equal to it.

locale.strxfrm(string)
Transforms a string to one that can be used in locale-aware comparisons. For example, `strxfrm(s1) < strxfrm(s2)` is equivalent to `strcoll(s1, s2) < 0`. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

`locale.format(format, val, grouping=False, monetary=False)`

Formats a number `val` according to the current `LC_NUMERIC` setting. The format follows the conventions of the `%` operator. For floating point values, the decimal point is modified if appropriate. If `grouping` is true, also takes the grouping into account.

If `monetary` is true, the conversion uses monetary thousands separator and grouping strings.

Please note that this function will only work for exactly one `%char` specifier. For whole format strings, use `format_string()`.

`locale.format_string(format, val, grouping=False)`

Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

`locale.currency(val, symbol=True, grouping=False, international=False)`

Formats a number `val` according to the current `LC_MONETARY` settings.

The returned string includes the currency symbol if `symbol` is true, which is the default. If `grouping` is true (which is not the default), grouping is done with the value. If `international` is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have
to set a locale via `setlocale()` first.

`locale.str(float)`
Forms a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

`locale.delocalize(string)`
Converts a string into a normalized number string, following the `LC_NUMERIC` settings.

*New in version 3.5.*

`locale.atof(string)`
Converts a string to a floating point number, following the `LC_NUMERIC` settings.

`locale.atoi(string)`
Converts a string to an integer, following the `LC_NUMERIC` conventions.

`locale.LC_CTYPE`
Locale category for the character type functions. Depending on the settings of this category, the functions of module `string` dealing with case change their behaviour.

`locale.LC_COLLATE`
Locale category for sorting strings. The functions `strcoll()` and `strxfrm()` of the `locale` module are affected.

`locale.LC_TIME`
Locale category for the formatting of time. The function `time.strftime()` follows these conventions.
locale.LC_MONETARY
Locate category for formatting of monetary values. The available options are available from the `localeconv()` function.

locale.LC_MESSAGES
Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by `os.strerror()` might be affected by this category.

locale.LC_NUMERIC
Locale category for formatting numbers. The functions `format()`, `atoi()`, `atof()` and `str()` of the `locale` module are affected by that category. All other numeric formatting operations are not affected.

locale.LC_ALL
Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale.CHAR_MAX
This is a symbolic constant used for different values returned by `localeconv()`.

Example:

```python
>>> import locale
>>> loc = locale.getlocale() # get current locale
# use German locale; name might vary with platform
```
>>> locale.setlocale(locale.LC_ALL, 'de_DE')
>>> locale.strcoll('f\xe4n', 'foo')  # compare a string containing an umlaut
>>> locale.setlocale(locale.LC_ALL, '')  # use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, 'C')  # use default (C) locale
>>> locale.setlocale(locale.LC_ALL, loc)  # restore saved locale
23.2.1. Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. There is one exception: the LC_CTYPE category is changed at startup to set the current locale encoding to the user’s preferred locale encoding. The program must explicitly say that it wants the user’s preferred locale settings for other categories by calling setlocale(LC_ALL, '').

It is generally a bad idea to call setlocale() in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with time.strftime()), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: atof(), atoi(),
There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.
23.2.2. For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn’t want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
23.2.3. Access to message catalogs

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions gettext(), dgettext(), dcgettext(), textdomain(), bindtextdomain(), and bind_textdomain_codeset(). These are similar to the same functions in the gettext module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use gettext instead. A known exception to this rule are applications that link with additional C libraries which internally invoke gettext() or dcgettext(). For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
24. Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

- **24.1. turtle — Turtle graphics**
  - 24.1.1. Introduction
  - 24.1.2. Overview of available Turtle and Screen methods
    - 24.1.2.1. Turtle methods
    - 24.1.2.2. Methods of TurtleScreen/Screen
  - 24.1.3. Methods of RawTurtle/Turtle and corresponding functions
    - 24.1.3.1. Turtle motion
    - 24.1.3.2. Tell Turtle's state
    - 24.1.3.3. Settings for measurement
    - 24.1.3.4. Pen control
      - 24.1.3.4.1. Drawing state
      - 24.1.3.4.2. Color control
      - 24.1.3.4.3. Filling
      - 24.1.3.4.4. More drawing control

24.1. *turtle* — Turtle graphics
24.1.1. Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an `import turtle`, give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.right(25)`, and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The `turtle` module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the -n switch.

The turtle module provides turtle graphics primitives, in both object-
oriented and procedure-oriented ways. Because it uses tkinter for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The TurtleScreen class defines graphics windows as a playground for the drawing turtles. Its constructor needs a tkinter.Canvas or a ScrolledCanvas as argument. It should be used when turtle is used as part of some application.

   The function Screen() returns a singleton object of a TurtleScreen subclass. This function should be used when turtle is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

   All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. RawTurtle (alias: RawPen) defines Turtle objects which draw on a TurtleScreen. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

   Derived from RawTurtle is the subclass Turtle (alias: Pen), which draws on “the” Screen instance which is automatically created, if not already present.

   All methods of RawTurtle/Turtle also exist as functions, i.e. part of the procedure-oriented interface.
The procedural interface provides functions which are derived from the methods of the classes `Screen` and `Turtle`. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

**Note:** In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
24.1.2. Overview of available Turtle and Screen methods

24.1.2.1. Turtle methods

Turtle motion
  Move and draw

  \texttt{forward()} | \texttt{fd()}
  \texttt{backward()} | \texttt{bk() | back()}
  \texttt{right()} | \texttt{rt()}
  \texttt{left()} | \texttt{lt()}
  \texttt{goto()} | \texttt{setpos()} | \texttt{setposition()}
  \texttt{setx()}
  \texttt{sety()}
  \texttt{setheading()} | \texttt{seth()}
  \texttt{home()}
  \texttt{circle()}
  \texttt{dot()}
  \texttt{stamp()}
  \texttt{clearstamp()}
  \texttt{clearstamps()}
  \texttt{undo()}
  \texttt{speed()}

Tell Turtle's state

  \texttt{position()} | \texttt{pos()}
  \texttt{towards()}
  \texttt{xcor()}
  \texttt{ycor()}
  \texttt{heading()}
  \texttt{distance()}
Setting and measurement

\begin{verbatim}
  degrees()
  radians()
\end{verbatim}

Pen control

Drawing state

\begin{verbatim}
  pendown() | pd() | down()
  penup()  | pu()  | up()
  pensize() | width()
  pen()
  isdown()
\end{verbatim}

Color control

\begin{verbatim}
  color()
  pencolor()
  fillcolor()
\end{verbatim}

Filling

\begin{verbatim}
  filling()
  begin_fill()
  end_fill()
\end{verbatim}

More drawing control

\begin{verbatim}
  reset()
  clear()
  write()
\end{verbatim}

Turtle state

Visibility

\begin{verbatim}
  showturtle() | st()
\end{verbatim}
hideturtle() | ht() 
isvisible() 

Appearance 

shape() 
resizemode() 
shapesize() | turtlesize() 
shearfactor() 
settiltangle() 
tiltangle() 
tilt() 
shapetransform() 
get_shapepoly() 

Using events 

onclick() 
onrelease() 
ondrag() 

Special Turtle methods 

begin_poly() 
end_poly() 
get_poly() 
clone() 
getturtle() | getpen() 
getscreenshot() 
setundobuffer() 
undobufferentries() 

24.1.2.2. Methods of TurtleScreen/Screen 

Window control
bgcolor()
bgpic()
clear()|clearscreen()
reset()|resetscreen()
screensize()
setworldcoordinates()

Animation control

delay()
tracer()
update()

Using screen events

listen()
onkey()|onkeyrelease()
onkeypress()
onclick()|onscreenclick()
ontimer()
mainloop()|done()

Settings and special methods

mode()
colormode()
getcanvas()
getshapes()
register_shape()|addshape()
turtles()
window_height()
window_width()

Input methods

textinput()
numinput()

Methods specific to Screen

bye()
exitonclick()
setup()
title()
24.1.3. Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

24.1.3.1. Turtle motion

turtle.\texttt{forward}(distance)
turtle.\texttt{fd}(distance)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>distance – a number (integer or float)</th>
</tr>
</thead>
</table>

Move the turtle forward by the specified distance, in the direction the turtle is headed.

```python
>>> turtle.position()
(0.00, 0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00, 0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00, 0.00)
```

turtle.\texttt{back}(distance)
turtle.\texttt{bk}(distance)
turtle.\texttt{backward}(distance)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>distance – a number</th>
</tr>
</thead>
</table>

Move the turtle backward by distance, opposite to the direction the turtle is headed. Do not change the turtle's heading.
```python
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
```

turtle.right\(\text{angle}\)
turtle.rt\(\text{angle}\)

**Parameters:**  
\textbf{angle} – a number (integer or float)

Turn turtle right by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.  

```python
>>> turtle.heading()
22.0
>>> turtle.right(45)
>>> turtle.heading()
337.0
```

turtle.left\(\text{angle}\)
turtle.lt\(\text{angle}\)

**Parameters:**  
\textbf{angle} – a number (integer or float)

Turn turtle left by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.  

```python
>>> turtle.heading()
22.0
>>> turtle.left(45)
>>> turtle.heading()
67.0
```
turtle.goto(x, y=None)
turtle.setpos(x, y=None)
turtle.setPosition(x, y=None)

Parameters:
- x – a number or a pair/vector of numbers
- y – a number or None

If y is None, x must be a pair of coordinates or a Vec2D (e.g. as returned by pos()).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```python
>>> tp = turtle.pos()
>>> tp
(0.00, 0.00)
>>> turtle.setpos(60, 30)
>>> turtle.pos()
(60.00, 30.00)
>>> turtle.setpos((20, 80))
>>> turtle.pos()
(20.00, 80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00, 0.00)
```

turtle.setx(x)

Parameters:
- x – a number (integer or float)

Set the turtle's first coordinate to x, leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00, 240.00)
>>> turtle.setx(10)
```
turtle.sety(y)

Parameters:  
- **y** – a number (integer or float)

Set the turtle’s second coordinate to \( y \), leave first coordinate unchanged.

```
>>> turtle.position()
(10.00,240.00)
>>> turtle.sety(10)
>>> turtle.position()
(0.00,340.00)
```

turtle.setheading(to_angle)
turtle.seth(to_angle)

Parameters:  
- **to_angle** – a number (integer or float)

Set the orientation of the turtle to \( to\_angle \). Here are some common directions in degrees:

<table>
<thead>
<tr>
<th>standard mode</th>
<th>logo mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - east</td>
<td>0 - north</td>
</tr>
<tr>
<td>90 - north</td>
<td>90 - east</td>
</tr>
<tr>
<td>180 - west</td>
<td>180 - south</td>
</tr>
<tr>
<td>270 - south</td>
<td>270 - west</td>
</tr>
</tbody>
</table>

```
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```
turtle.home()

Move turtle to the origin – coordinates (0, 0) – and set its heading to its start-orientation (which depends on the mode, see `mode()`).

```python
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00, -10.00)
>>> turtle.home()
>>> turtle.position()
(0.00, 0.00)
>>> turtle.heading()
0.0
```

turtle.circle(radius, extent=None, steps=None)

Parameters:
- `radius` – a number
- `extent` – a number (or None)
- `steps` – an integer (or None)

Draw a circle with given `radius`. The center is `radius` units left of the turtle; `extent` – an angle – determines which part of the circle is drawn. If `extent` is not given, draw the entire circle. If `extent` is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if `radius` is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of `extent`.

As the circle is approximated by an inscribed regular polygon, `steps` determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```python
>>> turtle.home()
>>> turtle.position()
```
turtle.**heading**()
0.0

turtle.**circle**(50)

turtle.**position**()
(-0.00,0.00)

turtle.**heading**()
0.0

turtle.**circle**(120, 180)  # draw a semicircle

turtle.**position**()
(0.00,240.00)

turtle.**heading**()
180.0

turtle.**dot**(*size=None, *color*)

**Parameters:**

- **size** – an integer $\geq 1$ (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter **size**, using **color**. If **size** is not given, the maximum of pensize+4 and 2*pensize* is used.

turtle.**home**()

turtle.**dot**()

turtle.**fd**(50); turtle.**dot**(20, "blue"); turtle

turtle.**position**()
(100.00,-0.00)

turtle.**heading**()
0.0

turtle.**stamp**()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling clearstamp(stamp_id).
turtle.color("blue")
turtle.stamp()
turtle.fd(50)

turtle.clearstamp(stampid)

Parameters:

- **stampid** – an integer, must be return value of previous `stamp()` call

Delete stamp with given `stampid`.

turtle.clearstamps(n=None)

Parameters:

- **n** – an integer (or None)

Delete all or first/last n of turtle’s stamps. If n is None, delete all stamps, if n > 0 delete first n stamps, else if n < 0 delete last n stamps.

```python
>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
13
14
15
16
```
turtle.clearstamps(2)
turtle.clearstamps(-2)
turtle.clearstamps()

turtle.undo()
Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

for i in range(4):
    ... turtle.fd(50); turtle.lt(80)

for i in range(8):
    ... turtle.undo()

turtle.speed(speed=None)

Parameters:

| speed | an integer in the range 0..10 or a speedstring (see below) |

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speed values as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1

Speeds from 1 to 10 enforce increasingly faster animation of line
drawing and turtle turning.

Attention: \textit{speed} = 0 means that \textit{no} animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

\begin{verbatim}
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
\end{verbatim}

24.1.3.2. Tell Turtle's state

turtle.\underline{position}()
turtle.\underline{pos}()

Return the turtle's current location (x,y) (as a \texttt{Vec2D} vector).

\begin{verbatim}
>>> turtle.pos()
(440.00,-0.00)
\end{verbatim}

turtle.\underline{towards}(x, y=None)

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \textbullet\ x – a number or a pair/vector of numbers or a turtle instance \\
& \textbullet\ y – a number if \textit{x} is a number, else None \\
\hline
\end{tabular}

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - “standard”/"world" or “logo”).
turtle.goto(10, 10)
turtle.towards(0, 0)
225.0

turtle.xcor()
Return the turtle's x coordinate.

>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28, 76.60)
>>> print(round(turtle.xcor(), 5))
64.27876

turtle.ycor()
Return the turtle's y coordinate.

>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.pos())
(50.00, 86.60)
>>> print(round(turtle.ycor(), 5))
86.60254

turtle.heading()
Return the turtle's current heading (value depends on the turtle mode, see mode()).

>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
67.0
turtle.distance(x, y=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• x – a number or a pair/vector of numbers or a turtle instance</td>
<td></td>
</tr>
<tr>
<td>• y – a number if x is a number, else None</td>
<td></td>
</tr>
</tbody>
</table>

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.home()
>>> turtle.distance(30,40)
50.0
>>> turtle.distance((30,40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

24.1.3.3. Settings for measurement

turtle.degrees(fullcircle=360.0)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>fullcircle – a number</td>
<td></td>
</tr>
</tbody>
</table>

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
```

Change angle measurement unit to grad (also known grade, or gradian and equals 1/100-th of the right

```python
>>> turtle.degrees(400.0)
```
turtle.**radians**()

Set the angle measurement units to radians. Equivalent to degrees(2*\(\text{math.pi}\)).

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
>>> turtle.radians()
>>> turtle.heading()
1.5707963267948966
```

24.1.3.4. Pen control

24.1.3.4.1. Drawing state

turtle.**pendown**()
turtle.**pd**()
turtle.**down**()

Pull the pen down – drawing when moving.

turtle.**penup**()
turtle.**pu**()
turtle.**up**()

Pull the pen up – no drawing when moving.

turtle.**pensize**(width=None)
turtle.width(width=None)

**Parameters:**
- **width** – a positive number

Set the line thickness to `width` or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> turtle.pensize(10)  # from here on lines of # from here on lines of
```

turtle.pen(pen=None, **pendict)

**Parameters:**
- **pen** – a dictionary with some or all of the below listed keys
- **pendict** – one or more keyword-arguments with the below listed keys as keywords

Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number

This dictionary can be used as argument for a subsequent call to
pen() to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
>>> turtle.pen(fillcolor="black", pencolor="red",
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencol ('pendown', True), ('pensize', 10), ('resizemode ('shearfactor', 0.0), ('shown', True), ('speed', ('stretchfactor', (1.0, 1.0)), ('tilt', 0.0)]
```

```python
>>> penstate=turtle.pen()
>>> turtle.color("yellow", ")
>>> turtle.penup()
>>> sorted(turtle.pen().items())[3]
[('fillcolor', ''), ('outline', 1), ('pencolor',
```

```python
turtle.isdown()
Return True if pen is down, False if it's up.

```python
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```

24.1.3.4.2. Color control

turtle.pencolor(*args)
Return or set the pencolor.
Four input formats are allowed:

`pencolor()`
Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

`pencolor(colorstring)`
Set pencolor to `colorstring`, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

`pencolor((r, g, b))`
Set pencolor to the RGB color represented by the tuple of `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode, where colormode is either 1.0 or 255 (see `colormode()`).

`pencolor(r, g, b)`
Set pencolor to the RGB color represented by `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```python
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
```
turtle.pencolor('violet')
>>> turtle.pencolor()
(50.0, 193.0, 143.0)

turtle.fillcolor(*args)
Return or set the fillcolor.

Four input formats are allowed:

fillcolor()
    Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

fillcolor(colorstring)
    Set fillcolor to colorstring, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

fillcolor((r, g, b))
    Set fillcolor to the RGB color represented by the tuple of r, g, and b. Each of r, g, and b must be in the range 0..colormode, where colormode is either 1.0 or 255 (see colormode()).

fillcolor(r, g, b)
    Set fillcolor to the RGB color represented by r, g, and b. Each of r, g, and b must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> col = turtle.pencolor()
>>> col
(50.0, 193.0, 143.0)
turtle.fillcolor(col)
>>> turtle.fillcolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor('#ffffff')
>>> turtle.fillcolor()
(255.0, 255.0, 255.0)

turtle.color(*args)
Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()
Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by pencolor() and fillcolor().

color(colorstring), color((r,g,b)), color(r,g,b)
Inputs as in pencolor(), set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))
Equivalent to pencolor(colorstring1) and fillcolor(colorstring2) and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

>>> turtle.color("red", "green")
>>> turtle.color()
('red', 'green')
>>> color("#285078", "#a0c8f0")
See also: Screen method `colormode()`.

24.1.3.4.3. Filling

`turtle.filling()`

Return fillstate (True if filling, False else).

```python
turtle.begin_fill()
>>> if turtle.filling():
...    turtle.pensize(5)
...    else:
...    turtle.pensize(3)
```  

`turtle.begin_fill()`

To be called just before drawing a shape to be filled.

`turtle.end_fill()`

Fill the shape drawn after the last call to `begin_fill()`.

```python
turtle.color("black", "red")
turtle.begin_fill()
turtle.circle(80)
turtle.end_fill()
```  

24.1.3.4.4. More drawing control

`turtle.reset()`

Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.
turtle.goto(0,-22)
turtle.left(100)
turtle.position()
(0.00,-22.00)
turtle.heading()
100.0
turtle.reset()
turtle.position()
(0.00,0.00)
turtle.heading()
0.0
turtle.clear()

Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.write(arg, move=False, align="left", font=("Arial", 8, "normal"))

Parameters:
- **arg** – object to be written to the TurtleScreen
- **move** – True/False
- **align** – one of the strings “left”, “center” or right"
- **font** – a triple (fontname, fontsize, fonttype)

Write text - the string representation of *arg* - at the current turtle position according to *align* (“left”, “center” or right”) and with the given font. If *move* is true, the pen is moved to the bottom-right corner of the text. By default, *move* is False.

>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
24.1.3.5. Turtle state

24.1.3.5.1. Visibility

```python
turtle.hideturtle()
turtle.ht()
```

Make the turtle invisible. It’s a good idea to do this while you’re in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```python
turtle.hideturtle()
```

```python
turtle.showturtle()
turtle.st()
```

Make the turtle visible.

```python
turtle.showturtle()
```

```python
turtle.isvisible()
```

Return True if the Turtle is shown, False if it’s hidden.

```python
turtle.isvisible()
turtle.hideturtle()
turtle.isvisible()
False
turtle.showturtle()
turtle.isvisible()
True
```

24.1.3.5.2. Appearance

```python
turtle.shape(name=None)
```

**Parameters:** `name` – a string which is a valid shapename
Set turtle shape to shape with given name or, if name is not given, return name of current shape. Shape with name must exist in the TurtleScreen’s shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”, “triangle”, “classic”. To learn about how to deal with shapes see Screen method register_shape().

```python
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.resizemode(rmode=None)

| Parameters: | rmode – one of the strings “auto”, “user”, “noresize” |

Set resizemode to one of the values: “auto”, “user”, “noresize”. If rmode is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by shapesize().
- “noresize”: no adaption of the turtle’s appearance takes place.

resizemode(“user”) is called by shapesize() when used with arguments.

```python
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
```
turtle.shapesize(stretch_wid=None, stretch_len=None, outline=None)
turtle.turtlesize(stretch_wid=None, stretch_len=None, outline=None)

Parameters:
- stretch_wid – positive number
- stretch_len – positive number
- outline – positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set resizemode to “user”. If and only if resizemode is set to “user”, the turtle will be displayed stretched according to its stretchfactors: stretch_wid is stretchfactor perpendicular to its orientation, stretch_len is stretchfactor in direction of its orientation, outline determines the width of the shape's outline.

turtle.shearfactor(shear=None)

Parameters: shear – number (optional)

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of
the shear angle. Do not change the turtle's heading (direction of movement). If shear is not given: return the current shearfactor, i.e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```python
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()
0.5
```

turtle.tilt(angle)

**Parameters:**  
angle – a number

Rotate the turtleshape by angle from its current tilt-angle, but do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.settiltangle(angle)

**Parameters:**  
angle – a number

Rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
```
```python
>>> turtle.shapesize(5, 2)
>>> turtle.settiltangle(45)
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)
```

*Deprecated since version 3.1.*

**turtle.tiltangle**(angle=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>angle – a number (optional)</th>
</tr>
</thead>
</table>

Set or return the current tilt-angle. If angle is given, rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do *not* change the turtle’s heading (direction of movement). If angle is not given: return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0
```

**turtle.shapetransform**(t11=None, t12=None, t21=None, t22=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• t11 – a number (optional)</td>
</tr>
<tr>
<td>• t12 – a number (optional)</td>
</tr>
<tr>
<td>• t21 – a number (optional)</td>
</tr>
<tr>
<td>• t22 – a number (optional)</td>
</tr>
</tbody>
</table>

Set or return the current transformation matrix of the turtleshape.
If none of the matrix elements are given, return the transformation matrix as a tuple of 4 elements. Otherwise set the given elements and transform the turtleshape according to the matrix consisting of first row t11, t12 and second row t21, 22. The determinant $t_{11} \times t_{22} - t_{12} \times t_{21}$ must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```python
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4,2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform()
(4.0, -1.0, 0.0, 2.0)
```

turtle.get_shapepoly()

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```python
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

24.1.3.6. Using events

turtle.onclick(fun, btn=1, add=None)

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults
to 1 (left mouse button)

- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is None, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```python
>>> def turn(x, y):
...     left(180)
...
>>> onclick(turn)  # Now clicking into the turtle
>>> onclick(None)  # event-binding will be removed
```

```python
turtle.onrelease(*fun*, *btn=1*, *add=None*)
```

**Parameters:**

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is None, existing bindings are removed.

```python
>>> class MyTurtle(Turtle):
...     def glow(self, x, y):
...         self.fillcolor("red")
...     def unglow(self, x, y):
...         self.fillcolor("")
```
turtle.ondrag(fun, btn=1, add=None)

Parameters:
- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is None, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```python
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

### 24.1.3.7. Special Turtle methods

**turtle.begin_poly()**

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

**turtle.end_poly()**
Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

turtle.get_poly()
Return the last recorded polygon.

```python
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

turtle.clone()
Create and return a clone of the turtle with same position, heading and turtle properties.

```python
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle.getturtle()
turtle.getpen()
Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```
turtle.getscreen()

Return the TurtleScreen object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```python
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

turtle.setundobuffer(size)

Parameters:  

- **size** – an integer or None

Set or disable undobuffer. If size is an integer an empty undobuffer of given size is installed. size gives the maximum number of turtle actions that can be undone by the undo() method/function. If size is None, the undobuffer is disabled.

```python
>>> turtle.setundobuffer(42)
```

turtle.undobufferentries()

Return number of entries in the undobuffer.

```python
>>> while undobufferentries():
...     undo()
```

24.1.3.8. Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class Shape explicitly as described below:

1. Create an empty Shape object of type “compound”.
2. Add as many components to this object as desired, using the `addcomponent()` method.

For example:

```python
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
```

3. Now add the Shape to the Screen’s shapelist and use it:

```python
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note:** The `Shape` class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the Shape class only when using compound shapes like shown above!
24.1.4. Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called screen.

24.1.4.1. Window control

turtle.bgcolor(*args)

| Parameters: | **args** – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers |

Set or return background color of the TurtleScreen.

```python
>>> screen.bgcolor("orange")
'orange'
>>> screen.bgcolor()
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()
(128.0, 0.0, 128.0)
```

turtle.bgpic(picname=None)

| Parameters: | **picname** – a string, name of a gif-file or "nopic", or None |

Set background image or return name of current background image. If **picname** is a filename, set the corresponding image as background. If **picname** is "nopic", delete background image, if present. If **picname** is None, return the filename of the current background image.
turtle.**clear**()

turtle.**clearscreen**()

Delete all drawings and all turtles from the TurtleScreen. Reset the newly empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

**Note:** This TurtleScreen method is available as a global function only under the name clearscreen. The global function clear is a different one derived from the Turtle method clear.

turtle.**reset**()

turtle.**resetscreen**()

Reset all Turtles on the Screen to their initial state.

**Note:** This TurtleScreen method is available as a global function only under the name resetscreen. The global function reset is another one derived from the Turtle method reset.

turtle.**screensize**(*canvwidth=None, canvheight=None, bg=None*)

**Parameters:**

- **canvwidth** – positive integer, new width of canvas in pixels
- **canvheight** – positive integer, new height of canvas in pixels
- **bg** – colorstring or color-tuple, new background color
If no arguments are given, return current (canvaswidth, canvashight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```python
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000, 1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle ;-)

turtle.setworldcoordinates(llx, lly, urx, ury)

**Parameters:**
- **llx** – a number, x-coordinate of lower left corner of canvas
- **lly** – a number, y-coordinate of lower left corner of canvas
- **urx** – a number, x-coordinate of upper right corner of canvas
- **ury** – a number, y-coordinate of upper right corner of canvas

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION:** in user-defined coordinate systems angles may appear distorted.
24.1.4.2. Animation control

turtle.\texttt{delay}(\texttt{delay} = \texttt{None})

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>\texttt{delay} – positive integer</th>
</tr>
</thead>
</table>

Set or return the drawing \texttt{delay} in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```python
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

turtle.\texttt{tracer}(\texttt{n} = \texttt{None}, \texttt{delay} = \texttt{None})

| Parameters: | • \texttt{n} – nonnegative integer  
• \texttt{delay} – nonnegative integer |
|-------------|-----------------------------------|

Turn turtle animation on/off and set delay for update drawings. If \texttt{n} is given, only each n-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value.
of n. Second argument sets delay value (see \texttt{delay()}).

\begin{verbatim}
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...     fd(dist)
...     rt(90)
>>> dist += 2
\end{verbatim}

\texttt{turtle.update()}

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method \texttt{speed()}. 

\subsection*{24.1.4.3. Using screen events}

\texttt{turtle.listen}(\texttt{xdummy=None, ydummy=None})

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass \texttt{listen()} to the onclick method.

\texttt{turtle.onkey}(\texttt{fun, key})
\texttt{turtle.onkeyrelease}(\texttt{fun, key})

\begin{table}[h]
\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \begin{itemize}
\item \texttt{fun} – a function with no arguments or None
\item \texttt{key} – a string: key (e.g. “a”) or key-symbol (e.g. “space”)
\end{itemize}
\hline
\end{tabular}
\end{table}

Bind \texttt{fun} to key-release event of key. If \texttt{fun} is None, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method \texttt{listen()}. )
```python
>>> def f():
...    fd(50)
...    lt(60)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

**turtle.onkeypress**(*fun*, *key=None*)

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fun</strong></td>
<td>a function with no arguments or None</td>
<td></td>
</tr>
<tr>
<td><strong>key</strong></td>
<td>a string: key (e.g. “a”) or key-symbol (e.g. “space”)</td>
<td></td>
</tr>
</tbody>
</table>

Bind *fun* to key-press event of key if key is given, or to any key-press-event if no key is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method *listen()*.)

```python
>>> def f():
...    fd(50)
...    lt(60)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

**turtle.onclick**(*fun*, *btn=1, add=None*)

**turtle.onscreenclick**(*fun*, *btn=1, add=None*)

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fun</strong></td>
<td>a function with two arguments which will be called with the coordinates of the clicked point on the canvas</td>
<td></td>
</tr>
<tr>
<td><strong>num</strong></td>
<td>number of the mouse-button, defaults to 1 (left mouse button)</td>
<td></td>
</tr>
<tr>
<td><strong>add</strong></td>
<td>True or False – if True, a new binding will be added, otherwise it will replace a former binding</td>
<td></td>
</tr>
</tbody>
</table>
Bind `fun` to mouse-click events on this screen. If `fun` is None, existing bindings are removed.

Example for a TurtleScreen instance named `screen` and a Turtle instance named `turtle`:

```python
>>> screen.onclick(turtle.goto)  # Subsequently clicking into the TurtleScreen will make the turtle move to the clicked point.
>>> screen.onclick(None)  # remove event binding again
```

**Note:** This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

`turtle.ontimer(fun, t=0)`

**Parameters:**
- `fun` – a function with no arguments
- `t` – a number $\geq 0$

Install a timer that calls `fun` after `t` milliseconds.

```python
>>> running = True
>>> def f():
...    if running:
...        fd(50)
...        lt(60)
...        screen.ontimer(f, 250)
>>> f()  # makes the turtle march around
>>> running = False
```

`turtle.mainloop()`

`turtle.done()`
Starts event loop - calling Tkinter’s mainloop function. Must be the last statement in a turtle graphics program. Must *not* be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```python
>>> screen.mainloop()
```

### 24.1.4.4. Input methods

**turtle.textinput**(title, prompt)

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>title – string</td>
</tr>
<tr>
<td>prompt – string</td>
</tr>
</tbody>
</table>

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, prompt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return None.

```python
>>> screen.textinput("NIM", "Name of first player:")
```

**turtle.numinput**(title, prompt, default=None, minval=None, maxval=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>title – string</td>
</tr>
<tr>
<td>prompt – string</td>
</tr>
<tr>
<td>default – number (optional)</td>
</tr>
<tr>
<td>minval – number (optional)</td>
</tr>
<tr>
<td>maxval – number (optional)</td>
</tr>
</tbody>
</table>

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value
for input, maxval: maximum value for input The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return None.

```python
>>> screen.numinput("Poker", "Your stakes:", 1000
```

24.1.4.5. Settings and special methods

turtle.**mode**(mode=None)

**Parameters:**

mode – one of the strings “standard”, “logo” or “world”

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old turtle. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention:** in this mode angles appear distorted if x/y unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>“standard”</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>“logo”</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```python
>>> mode("logo")    # resets turtle heading to nor
>>> mode()           # resets turtle heading to nor
'logo'
```

turtle.**colormode**(cmode=None)
Parameters:  
cmode – one of the values 1.0 or 255  

Return the colormode or set it to 1.0 or 255. Subsequently r, g, b values of color triples have to be in the range 0..cmode.

```python
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
 ...  
TurtleGraphicsError: bad color sequence: (240, 16
```  
```python
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> screen.colormode()
255
>>> turtle.pencolor(240,160,80)
```

turtle.getcanvas()  
Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```python
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas object ...>
```

turtle.getshapes()  
Return a list of names of all currently available turtle shapes.

```python
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

turtle.register_shape(name, shape=None)  
turtle.addshape(name, shape=None)  
There are three different ways to call this function:
1. *name* is the name of a gif-file and *shape* is None: Install the corresponding image shape.

```python
>>> screen.register_shape("turtle.gif")
```

**Note:** Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```python
>>> screen.register_shape("triangle", ((5, -3),
```

3. *name* is an arbitrary string and shape is a (compound) *Shape* object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen’s shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

```python
turtle.turtles()
```

Return the list of turtles on the screen.

```python
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

```python
turtle.window_height()
```

Return the height of the turtle window.

```python
>>> screen.window_height()
480
```

```python
turtle.window_width()
```
Return the width of the turtle window.

```python
>>> screen.window_width()
640
```

### 24.1.4.6. Methods specific to Screen, not inherited from TurtleScreen

**turtle**. `bye()`  
Shut the turtlegraphics window.

**turtle**. `exitonclick()`  
Bind `bye()` method to mouse clicks on the Screen.

If the value “using_IDLE” in the configuration dictionary is False (default value), also enter mainloop. Remark: If IDLE with the `-n` switch (no subprocess) is used, this value should be set to True in `turtle.cfg`. In this case IDLE’s own mainloop is active also for the client script.

**turtle**. `setup(width=_CFG["width"], height=_CFG["height"],
                    startx=_CFG["leftright"], starty=_CFG["topbottom"])`  
Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

- **width** – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen  
- **height** – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
### Parameters:

- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if None, center window horizontally
- **starty** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if None, center window vertically

```python
goldenrod
>>> screen.setup (width=200, height=200, startx=0)
# sets window to 200x200 pixels,
>>> screen.setup(width=.75, height=0.5, startx=None)
# sets window to 75% of screen b
```

### turtle.title(titlestring)

**Parameters:**
- **titlestring** – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```python
>>> screen.title("Welcome to the turtle zoo!")
```
24.1.5. Public classes

class turtle.RawTurtle(canvas)
class turtle.RawPen(canvas)

| Parameters: | canvas – a tkinter.Canvas, a ScrolledCanvas or a TurtleScreen |

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

class turtle.Turtle
Subclass of RawTurtle, has the same interface but draws on a default Screen object created automatically when needed for the first time.

class turtle.TurtleScreen(cv)

| Parameters: | cv – a tkinter.Canvas |

Provides screen oriented methods like setbg() etc. that are described above.

class turtle.Screen
Subclass of TurtleScreen, with four methods added.

class turtle.ScrolledCanvas(master)

| Parameters: | master – some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added |

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.
class turtle.Shape(type_, data)

Parameters:
- **type_** – one of the strings “polygon”, “image”, “compound”

Data structure modeling shapes. The pair (type_, data) must follow this specification:

<table>
<thead>
<tr>
<th>type_</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the addcomponent() method)</td>
</tr>
</tbody>
</table>

addcomponent(poly, fill, outline=None)

Parameters:
- **poly** – a polygon, i.e. a tuple of pairs of numbers
- **fill** – a color the poly will be filled with
- **outline** – a color for the poly’s outline (if given)

Example:

```python
>>> poly = ((0, 0), (10, -5), (0, 10), (-10, -5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

See Compound shapes.

class turtle.Turtles.Vec2D(x, y)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics
programs too. Derived from tuple, so a vector is a tuple!

Provides (for $a$, $b$ vectors, $k$ number):

- $a + b$ vector addition
- $a - b$ vector subtraction
- $a \times b$ inner product
- $k \times a$ and $a \times k$ multiplication with scalar
- $\text{abs}(a)$ absolute value of $a$
- $a\.\text{rotate}(\text{angle})$ rotation
24.1.6. Help and configuration

24.1.6.1. How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.

- Calling help() on methods or functions displays the docstrings:

```python
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen

    Arguments (if given): a color string or three numbers in
    the range 0..colormode or a 3-tuple of such numbers.

>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
```
Aliases: penup | pu | up

No argument

>>> turtle.penup()

The docstrings of the functions which are derived from methods have a modified form:

>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range
    0..colormode or a 3-tuple of such numbers.

Example::

    >>> bgcolor("orange")
    >>> bgcolor()
    "orange"
    >>> bgcolor(0.5,0,0.5)
    >>> bgcolor()
    "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up
These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

24.1.6.2. Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```
turtle.write_docstringdict(filename="turtle_docstringdict")
```

**Parameters:**  
 filename – a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script `filename.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use `turtle` with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.
At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

24.1.6.3. How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file turtle.cfg which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following turtle.cfg:

```plaintext
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
```
Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg-file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`.
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE`: Set this to True if you regularly work with IDLE and its -n switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The Lib/turtledemo directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos
(preferably not from within the demo-viewer).
24.1.7. turtledemo — Demo scripts

The turtledemo package includes a set of demo scripts. These scripts can be run and viewed using the supplied demo viewer as follows:

```
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```
python -m turtledemo.bytedesign
```

The turtledemo package directory contains:

- A demo viewer __main__.py which can be used to view the sourcecode of the scripts and run them at the same time.
- Multiple scripts demonstrating different features of the turtle module. Examples can be accessed via the Examples menu. They can also be run standalone.
- A turtle.cfg file which serves as an example of how to write and use such files.

The demo scripts are:

Have fun!
24.1.8. Changes since Python 2.6

- The methods `Turtle.tracer()`, `Turtle.window_width()` and `Turtle.window_height()` have been eliminated. Methods with these names and functionality are now available only as methods of Screen. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding `TurtleScreen/Screen`-methods.)
- The method `Turtle.fill()` has been eliminated. The behaviour of `begin_fill()` and `end_fill()` have changed slightly: now every filling-process must be completed with an `end_fill()` call.
- A method `Turtle.filling()` has been added. It returns a boolean value: True if a filling process is under way, False otherwise. This behaviour corresponds to a `fill()` call without arguments in Python 2.6.
24.1.9. Changes since Python 3.0

- The methods `Turtle.shearfactor()`, `Turtle.shapetransform()` and `Turtle.get_shapepoly()` have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes.
- `Turtle.tiltangle()` has been enhanced in functionality: it now can be used to get or set the tiltangle.
- `Turtle.settiltangle()` has been deprecated.
- The method `Screen.onkeypress()` has been added as a complement to `Screen.onkey()` which in fact binds actions to the keyrelease event. Accordingly the latter has got an alias: `Screen.onkeyrelease()`.
- The method `Screen.mainloop()` has been added. So when working only with `Screen` and `Turtle` objects one must not additionally import `mainloop()` anymore.
- Two input methods have been added `Screen.textinput()` and `Screen.numinput()`. These popup input dialogs and return strings and numbers respectively.
- Two example scripts `tdemo_nim.py` and `tdemo_round_dance.py` have been added to the `Lib/turtledemo` directory.
24.2. cmd — Support for line-oriented command interpreters

Source code: Lib/cmd.py

The Cmd class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

```
class cmd.Cmd(completekey='tab', stdin=None, stdout=None)
```

A Cmd instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate Cmd itself; rather, it’s useful as a superclass of an interpreter class you define yourself in order to inherit Cmd’s methods and encapsulate action methods.

The optional argument completekey is the readline name of a completion key; it defaults to Tab. If completekey is not None and readline is available, command completion is done automatically.

The optional arguments stdin and stdout specify the input and output file objects that the Cmd instance or subclass instance will use for input and output. If not specified, they will default to sys.stdin and sys.stdout.

If you want a given stdin to be used, make sure to set the instance's use_rawinput attribute to False, otherwise stdin will
be ignored.
24.2.1. Cmd Objects

A `Cmd` instance has the following methods:

`Cmd.cmdloop(intro= None)`

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the `intro` class attribute).

If the `readline` module is loaded, input will automatically inherit `bash`-like history-list editing (e.g. Control-P scrolls back to the last command, Control-N forward to the next one, Control-F moves the cursor to the right non-destructively, Control-B moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string 'EOF'.

An interpreter instance will recognize a command name foo if and only if it has a method `do_foo()`. As a special case, a line beginning with the character '?' is dispatched to the method `do_help()`. As another special case, a line beginning with the character '!' is dispatched to the method `do_shell()` (if such a method is defined).

This method will return when the `postcmd()` method returns a true value. The `stop` argument to `postcmd()` is the return value from the command's corresponding `do_*()` method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling complete_foo() with arguments text, line, begidx, and endidx. text is the string prefix we are attempting to match: all returned matches must begin with it. line is the current input line with leading whitespace removed, begidx and endidx are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of Cmd inherit a predefined do_help(). This method, called with an argument 'bar', invokes the corresponding method help_bar(), and if that is not present, prints the docstring of do_bar(), if available. With no argument, do_help() lists all available help topics (that is, all commands with corresponding help_*() methods or commands that have docstrings), and also lists any undocumented commands.

Cmd.onecmd(str)

Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the precmd() and postcmd() methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a do_*( ) method for the command str, the return value of that method is returned, otherwise the return value from the default() method is returned.

Cmd.emptyline()

Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.
Cmd. **default**(line)

Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

Cmd. **completesdefault**(text, line, begidx, endidx)

Method called to complete an input line when no command-specific complete_*() method is available. By default, it returns an empty list.

Cmd. **precmd**(line)

Hook method executed just before the command line line is interpreted, but after the input prompt is generated and issued. This method is a stub in Cmd; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the onecmd() method; the precmd() implementation may re-write the command or simply return line unchanged.

Cmd. **postcmd**(stop, line)

Hook method executed just after a command dispatch is finished. This method is a stub in Cmd; it exists to be overridden by subclasses. line is the command line which was executed, and stop is a flag which indicates whether execution will be terminated after the call to postcmd(); this will be the return value of the onecmd() method. The return value of this method will be used as the new value for the internal flag which corresponds to stop; returning false will cause interpretation to continue.

Cmd. **preloop()**

Hook method executed once when cmdloop() is called. This method is a stub in Cmd; it exists to be overridden by subclasses.
**Cmd.postloop()**

Hook method executed once when `cmdloop()` is about to return. This method is a stub in `Cmd`; it exists to be overridden by subclasses.

Instances of `Cmd` subclasses have some public instance variables:

**Cmd.prompt**

The prompt issued to solicit input.

**Cmd.identchars**

The string of characters accepted for the command prefix.

**Cmd.lastcmd**

The last nonempty command prefix seen.

**Cmd.cmdqueue**

A list of queued input lines. The cmdqueue list is checked in `cmdloop()` when new input is needed; if it is nonempty, its elements will be processed in order, as if entered at the prompt.

**Cmd.intro**

A string to issue as an intro or banner. May be overridden by giving the `cmdloop()` method an argument.

**Cmd.doc_header**

The header to issue if the help output has a section for documented commands.

**Cmd.misc_header**

The header to issue if the help output has a section for miscellaneous help topics (that is, there are `help_*()` methods
without corresponding do_*() methods).

Cmd. **undoc_header**
The header to issue if the help output has a section for undocumented commands (that is, there are do_*() methods without corresponding help_*() methods).

Cmd. **ruler**
The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to '='.

Cmd. **use_rawinput**
A flag, defaulting to true. If true, cmdloop() uses input() to display a prompt and read the next command; if false, sys.stdout.write() and sys.stdin.readline() are used. (This means that by importing readline, on systems that support it, the interpreter will automatically support Emacs-like line editing and command-history keystrokes.)
24.2.2. Cmd Example

The `cmd` module is mainly useful for building custom shells that let a user work with a program interactively.

This section presents a simple example of how to build a shell around a few of the commands in the `turtle` module.

Basic turtle commands such as `forward()` are added to a `Cmd` subclass with method named `do_forward()`. The argument is converted to a number and dispatched to the turtle module. The docstring is used in the help utility provided by the shell.

The example also includes a basic record and playback facility implemented with the `precmd()` method which is responsible for converting the input to lowercase and writing the commands to a file. The `do_playback()` method reads the file and adds the recorded commands to the `cmdqueue` for immediate playback:

```python
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = 'Welcome to the turtle shell. Type help or ? to list commands.

    prompt = '(turtle) '
    file = None

    # ----- basic turtle commands -----
    def do_forward(self, arg):
        'Move the turtle forward by the specified distance:
        forward(*parse(arg))

    def do_right(self, arg):
        'Turn turtle right by given number of degrees:
```
right(*parse(arg))

def do_left(self, arg):
    'Turn turtle left by given number of degrees'
    left(*parse(arg))

def do_goto(self, arg):
    'Move turtle to an absolute position with changing orientation.'
    goto(*parse(arg))

def do_home(self, arg):
    'Return turtle to the home position: HOME'
    home()

def do_circle(self, arg):
    'Draw circle with given radius and options'  
    circle(*parse(arg))

def do_position(self, arg):
    'Print the current turtle position: POSITION'
    print('Current position is %d %d\n' % position)

def do_heading(self, arg):
    'Print the current turtle heading in degrees:'
    print('Current heading is %d\n' % (heading()))

def do_color(self, arg):
    'Set the color: COLOR BLUE'
    color(arg.lower())

def do_undo(self, arg):
    'Undo (repeatedly) the last turtle action(s)'

def do_reset(self, arg):
    'Clear the screen and return turtle to center'
    reset()

def do_bye(self, arg):
    'Stop recording, close the turtle window, and exit'
    print('Thank you for using Turtle')
    self.close()
    bye()
    return True

# ----- record and playback -----  
def do_record(self, arg):
    'Save future commands to filename: RECORD rose.cmd'
self.file = open(arg, 'w')

def do_playback(self, arg):
    'Playback commands from a file: PLAYBACK records commands from
    a file and replays them.
    '    self.close()
    with open(arg) as f:
        self.cmdqueue.extend(f.read().splitlines)

def precmd(self, line):
    line = line.lower()
    if self.file and 'playback' not in line:
        print(line, file=self.file)
        return line

def close(self):
    if self.file:
        self.file.close()
        self.file = None

def parse(arg):
    'Convert a series of zero or more numbers to an argument tuple'
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()

Here is a sample session with the turtle shell showing the help functions, using blank lines to repeat commands, and the simple record and playback facility:

Welcome to the turtle shell. Type help or ? to list commands.
(turtle) ?

Documented commands (type help <topic>):
bye  color  goto  home  playback  record  right  circle  forward  heading  left  position  reset  undo
Move the turtle forward by the specified distance:

```
(turtle) forward 10
(turtle) record spiral.cmd
(turtle) position
Current position is 0 0

(turtle) heading
Current heading is 0

(turtle) reset
(turtle) circle 20
(turtle) right 30
(turtle) circle 40
(turtle) right 30
(turtle) circle 60
(turtle) right 30
(turtle) circle 80
(turtle) right 30
(turtle) circle 100
(turtle) right 30
(turtle) circle 120
(turtle) right 30
(turtle) circle 120
(turtle) heading
Current heading is 180

(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 500
(turtle) right 90
(turtle) forward 400
```
(turtle) right 90
(turtle) forward 300
(turtle) playback spiral.cmd
Current position is 0 0

Current heading is 0

Current heading is 180

(turtle) bye
Thank you for using Turtle
24.3. `shlex` — Simple lexical analysis

**Source code:** Lib/shlex.py

The `shlex` class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

The `shlex` module defines the following functions:

```python
shlex.split(s, comments=False, posix=True)
```

Split the string `s` using shell-like syntax. If `comments` is `False` (the default), the parsing of comments in the given string will be disabled (setting the `commenters` attribute of the `shlex` instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the `posix` argument is false.

**Note:** Since the `split()` function instantiates a `shlex` instance, passing `None` for `s` will read the string to split from standard input.

```python
shlex.quote(s)
```

Return a shell-escaped version of the string `s`. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe:
```python
>>> filename = 'somefile; rm -rf ~'
>>> command = 'ls -l {}'.format(filename)
>>> print(command)  # executed by a shell: boom!
ls -l somefile; rm -rf ~
```

`quote()` lets you plug the security hole:

```python
>>> command = 'ls -l {}'.format(quote(filename))
>>> print(command)
ls -l 'somefile; rm -rf ~'
>>> remote_command = 'ssh home {}'.format(quote(command))
>>> print(remote_command)
ssh home 'ls -l """somefile; rm -rf ~"""'
```

The quoting is compatible with UNIX shells and with `split()`:

```python
>>> remote_command = split(remote_command)
>>> remote_command
['ssh', 'home', 'ls -l """somefile; rm -rf ~"""
>>> command = split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
```

*New in version 3.3.*

The `shlex` module defines the following class:

```python
class shlex.**shlex**(instream=None, infile=None, posix=False)
```

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string. If no argument is given, input will be taken from `sys.stdin`. The second optional
argument is a filename string, which sets the initial value of the `inFILE` attribute. If the `inSTREAM` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument defines the operational mode: when `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules.

**See also:**

**Module** `configparser`

Parser for configuration files similar to the Windows `.ini` files.
24.3.1. shlex Objects

A shlex instance has the following methods:

shlex.get_token()
Return a token. If tokens have been stacked using push_token(), pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, eof is returned (the empty string ('') in non-POSIX mode, and None in POSIX mode).

shlex.push_token(str)
Push the argument onto the token stack.

shlex.read_token()
Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

shlex.sourcehook(filename)
When shlex detects a source request (see source below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as sys.stdin), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles
#include "file.h").

The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with open() called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding ‘close’ hook, but a shlex instance will call the close() method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the push_source() and pop_source() methods.

shlex.push_source(newstream, newfile=None)

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the sourcehook() method.

shlex.pop_source()

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

shlex.error_leader(infile=None, lineno=None)

This method generates an error message leader in the format of a Unix C compiler error label; the format is ""%s", line %d: ", where the %s is replaced with the name of the current source file and the %d with the current input line number (the optional
arguments can be used to override these).

This convenience is provided to encourage `shlex` users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of `shlex` subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

**shlex.commenters**

The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just '#' by default.

**shlex.wordchars**

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore.

**shlex.whitespace**

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

**shlex.escape**

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.

**shlex.quotes**

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.
shlex.**escapedquotes**
Characters in *quotes* that will interpret escape characters defined in *escape*. This is only used in POSIX mode, and includes just `'"' by default.

shlex.**whitespace_split**
If True, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with *shlex*, getting tokens in a similar way to shell arguments.

shlex.**infile**
The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

shlex.**instream**
The input stream from which this *shlex* instance is reading characters.

shlex.**source**
This attribute is None by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion request similar to the source keyword in various shells. That is, the immediately following token will opened as a filename and input taken from that stream until EOF, at which point the *close()* method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

shlex.**debug**
If this attribute is numeric and 1 or more, a *shlex* instance will print verbose progress output on its behavior. If you need to use
this, you can read the module source code to learn the details.

**shlex.lineno**

Source line number (count of newlines seen so far plus one).

**shlex.token**

The token buffer. It may be useful to examine this when catching exceptions.

**shlex.eof**

Token used to determine end of file. This will be set to the empty string (''), in non-POSIX mode, and to None in POSIX mode.
24.3.2. Parsing Rules

When operating in non-POSIX mode, `shlex` will try to obey to the following rules.

- Quote characters are not recognized within words (Do"Not"Separate is parsed as the single word Do"Not"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do"Separate is parsed as "Do" and Separate);
- If `whitespace_split` is False, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is True, `shlex` will only split words in whitespaces;
- EOF is signaled with an empty string (' ');
- It’s not possible to parse empty strings, even if quoted.

When operating in POSIX mode, `shlex` will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do"Not"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of `escapedquotes` (e.g. '""") preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of
escapedquotes (e.g. "'"') preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a None value;
- Quoted empty strings ("'") are allowed.
25. Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the `tkinter` package, and its extension, the `tkinter.tix` and the `tkinter.ttk` modules.

The `tkinter` package is a thin object-oriented layer on top of Tcl/Tk. To use `tkinter`, you don't need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. `tkinter` is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module `_tkinter` provides a threadsafe mechanism which allows Python and Tcl to interact.

`tkinter`'s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. `tkinter` is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the Other Graphical User Interface Packages section.

25.1. **tkinter — Python interface to Tcl/Tk**

The `tkinter` package ("Tk interface") is the standard Python interface to the Tk GUI toolkit. Both Tk and `tkinter` are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.) You can check that `tkinter` is properly installed on your system by running `python -m tkinter` from the command line; this should open a window demonstrating a simple Tk interface.

**Python and Tkinter Programming**

25.1.1. Tkinter Modules

Most of the time, tkinter is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named _tkinter. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, tkinter includes a number of Python modules, tkinter.constants being one of the most important. Importing tkinter will automatically import tkinter.constants, so, usually, to use Tkinter all you need is a simple import statement:

```python
import tkinter
```

Or, more often:

```python
from tkinter import *
```

class tkinter.Tk(screenName=None, baseName=None, className='Tk', useTk=1)

The Tk class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

tkinter.Tcl(screenName=None, baseName=None, className='Tk', useTk=0)

The Tcl() function is a factory function which creates an object much like that created by the Tk class, except that it does not
initialize the Tk subsystem. This is most often useful when driving
the Tcl interpreter in an environment where one doesn’t want to
create extraneous toplevel windows, or where one cannot (such as
Unix/Linux systems without an X server). An object created by the
Tcl() object can have a Toplevel window created (and the Tk
subsystem initialized) by calling its loadtk() method.

Other modules that provide Tk support include:

**tkinter.scrolledtext**
Text widget with a vertical scroll bar built in.

**tkinter.colorchooser**
Dialog to let the user choose a color.

**tkinter.commondialog**
Base class for the dialogs defined in the other modules listed here.

**tkinter.filedialog**
Common dialogs to allow the user to specify a file to open or save.

**tkinter.font**
Utilities to help work with fonts.

**tkinter.messagebox**
Access to standard Tk dialog boxes.

**tkinter.simpledialog**
Basic dialogs and convenience functions.

**tkinter.dnd**
Drag-and-drop support for tkinter. This is experimental and
should become deprecated when it is replaced with the Tk DND.

**turtle**
Turtle graphics in a Tk window.
25.1.2. Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tk was written by John Ousterhout while at Berkeley.
- Tkinter was written by Steen Lumholt and Guido van Rossum.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The HTML rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

25.1.2.1. How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do"blah” in straight Tk, and then convert this back into the corresponding `tkinter` call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists.
Here are some hints:

- The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the manN directory are most useful. The man3 man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
- Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
- tkinter/__init__.py is a last resort for most, but can be a good place to go when nothing else makes sense.

25.1.2.2. A Simple Hello World Program

```python
import tkinter as tk

class Application(tk.Frame):
    def __init__(self, master=None):
        tk.Frame.__init__(self, master)
        self.pack()
        self.createWidgets()
```
```python
def createWidgets(self):
    self.hi_there = tk.Button(self)
    self.hi_there['text'] = 'Hello World
    (click me)
    self.hi_there['command'] = self.say_hi
    self.hi_there.pack(side="top")

    self.QUIT = tk.Button(self, text="QUIT", fg=
                             command=self.quit)
    self.QUIT.pack(side="bottom")

    def say_hi(self):
        print("hi there, everyone!")

root = tk.Tk()
app = Application(master=root)
app.mainloop()
```
25.1.3. A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren’t meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

```
classCommand newPathname options
```
classCommand
denotes which kind of widget to make (a button, a label, a menu...)

newPathname
is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with pathnames, just like files in a file system. The top level widget, the root, is called . (period) and children are delimited by more periods. For example, .myApp.controlPanel.okButton might be the name of a widget.

options
configure the widget’s appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

```
button .fred -fg red -text "hi there"
          ^          ^                  \______________________/
           |          |                  /         |
        class    new        options
    command  widget  (-opt val -opt val ...)
```

Once created, the pathname to the widget becomes a new command. This new widget command is the programmer’s handle for getting the new widget to perform some action. In C, you’d express this as someAction(fred, someOptions), in C++, you would express this as fred.someAction(someOptions), and in Tk, you say:

```
.fred someAction someOptions
```

Note that the object name, .fred, starts with a dot.
As you’d expect, the legal values for *someAction* will depend on the widget’s class: `.fred disable` works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of *someOptions* is action dependent. Some actions, like disable, require no arguments, others, like a text-entry box’s delete command, would need arguments to specify what range of text to delete.
25.1.4. Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```
button .fred          ===>  fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```
button .panel.fred    ===>  fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

```
button .fred -fg red  ===>  fred = Button(panel)
.fred configure -fg red ===>  fred["fg"] = red
OR ===>  fred.config(fg=
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in tkinter/__init__.py.

```
.fred invoke          ===>  fred.invoke()
```

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this
functionality, and the various forms of the pack command are implemented as methods. All widgets in tkinter are subclassed from the Packer, and so inherit all the packing methods. See the tkinter.tix module documentation for additional information on the Form geometry manager.

```python
def pack(fred, side='left')
```

```
pack .fred -side left ======> fred.pack(side='left')
```
25.1.5. How Tk and Tkinter are Related

From the top down:

Your App Here (Python)
A Python application makes a tkinter call.

tkinter (Python Package)
This call (say, for example, creating a button widget), is implemented in the tkinter package, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

ltkinter (C)
These commands and their arguments will be passed to a C function in the _tkinter - note the underscore - extension module.

Tk Widgets (C and Tcl)
This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python tkinter package is imported. (The user never sees this stage).

Tk (C)
The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)
the Xlib library to draw graphics on the screen.
25.1.6. Handy Reference

25.1.6.1. Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg="red", bg="blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the config() method to update multiple attrs subsequent to object creation

```python
fred.config(fg="red", bg="blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the options(3) man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a command option, labels do not.
The options supported by a given widget are listed in that widget’s man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, 'relief') and whose values are 5-tuples.

Some options, like bg are synonyms for common options with long names (bg is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not a 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as ('bg', 'background')).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print(fred.config())
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

25.1.6.2. The Packer
The packer is one of Tk’s geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual master. In contrast to the more cumbersome placer (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - above, to the left of, filling, etc - and works everything out to determine the exact placement coordinates for you.

The size of any master widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It’s a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s pack() method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
fred.pack()  # defaults to side =
fred.pack(side="left")
fred.pack(expand=1)
```

25.1.6.3. Packer Options
For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

anchor
   Anchor type. Denotes where the packer is to place each slave in its parcel.

expand
   Boolean, 0 or 1.

fill
   Legal values: 'x', 'y', 'both', 'none'.

ipadx and ipady
   A distance - designating internal padding on each side of the slave widget.

padx and pady
   A distance - designating external padding on each side of the slave widget.

side
   Legal values are: 'left', 'right', 'top', 'bottom'.

25.1.6.4. Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are variable, textvariable, onvalue, offvalue, and value. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of tkinter it is not possible to hand over an arbitrary Python variable to a widget through
a variable or textvariable option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in tkinter.

There are many useful subclasses of Variable already defined: StringVar, IntVar, DoubleVar, and BooleanVar. To read the current value of such a variable, call the get() method on it, and to change its value you call the set() method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return
        # we will have the program print out the value of
        # application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
                                self.print_contents)

def print_contents(self, event):
25.1.6.5. The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In `tkinter`, these commands have been implemented as methods on the `Wm` class. Toplevel widgets are subclassed from the `Wm` class, and so can call the `Wm` methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won't represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
from tkinter import *
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

# create the application
myapp = App()
```

```python
print("hi. contents of entry is now -->", self.contents.get())
```
here are method calls to the window manager class

myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()

25.1.6.6. Tk Option Data Types

anchor
Legal values are points of the compass: "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

bitmap
There are eight built-in, named bitmaps: 'error', 'gray25', 'gray50', 'hourglass', 'info', 'questhead', 'question', 'warning'. To specify an X bitmap filename, give the full path to the file, preceded with an @, as in '@/usr/contrib/bitmap/gumby.bit'.

boolean
You can pass integers 0 or 1 or the strings "yes" or "no".

callback
This is any Python function that takes no arguments. For example:

```python
def print_it():
    print("hi there")
fred["command"] = print_it
```

color
Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: "#RGB", 8 bit: "#RRGGBB", 12 bit "#RRRGGGGBBB", or 16 bit "#RRRRGGGGGBBBB"

cursor
The standard X cursor names from cursorfont.h can be used, without the XC_ prefix. For example to get a hand cursor (XC_hand2), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

font
Tk uses a list font name format, such as {courier 10 bold}. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry
This is a string of the form widthxheight, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: fred["geometry"] = "200x100".

justify
Legal values are the strings: "left", "center", "right", and "fill".

region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.
relief
Determines what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

scrollcommand
This is almost always the set() method of some scrollbar widget, but can be any widget method that takes a single argument.

wrap:
Must be one of: "none", "char", or "word".

25.1.6.7. Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:

```python
def bind(self, sequence, func, add=' '):
```

where:

sequence
is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout's book for details).

func
is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as callbacks.)

add
is optional, either '' or '+' . Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.
def turnRed(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turnRed)

Notice how the widget field of the event is being accessed in the turnRed() callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
<td>%A</td>
<td>char</td>
</tr>
<tr>
<td>%h</td>
<td>height</td>
<td>%E</td>
<td>send_event</td>
</tr>
<tr>
<td>%k</td>
<td>keycode</td>
<td>%K</td>
<td>keysym</td>
</tr>
<tr>
<td>%s</td>
<td>state</td>
<td>%N</td>
<td>keysym_num</td>
</tr>
<tr>
<td>%t</td>
<td>time</td>
<td>%T</td>
<td>type</td>
</tr>
<tr>
<td>%w</td>
<td>width</td>
<td>%W</td>
<td>widget</td>
</tr>
<tr>
<td>%x</td>
<td>x</td>
<td>%X</td>
<td>x_root</td>
</tr>
<tr>
<td>%y</td>
<td>y</td>
<td>%Y</td>
<td>y_root</td>
</tr>
</tbody>
</table>

25.1.6.8. The index Parameter

A number of widgets require “index” parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)
Entry widgets have options that refer to character positions in the text being displayed. You can use these tkinter functions to access these special points in text widgets:

Text widget indexes
The index notation for Text widgets is very rich and is best described in the Tk man pages.

Menu indexes (menu.invoke(), menu.entryconfig(), etc.)
Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string "active", which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu’s coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

25.1.6.9. Images
Bitmap/ Pixelmap images can be created through the subclasses of
tkinter.Image:

- BitmapImage can be used for X11 bitmap data.
- PhotoImage can be used for GIF and PPM/PGM color bitmaps.

Either type of image is created through either the file or the data option (other options are available as well).

The image object can then be used wherever an image option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
25.1.7. File Handlers

Tk allows you to register and unregister a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. Only one handler may be registered per file descriptor. Example code:

```python
import tkinter
widget = tkinter.Tk()
mask = tkinter.READABLE | tkinter.WRITABLE
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

This feature is not available on Windows.

Since you don’t know how many bytes are available for reading, you may not want to use the `BufferedIOBase` or `TextIOBase` `read()` or `readline()` methods, since these will insist on reading a predefined number of bytes. For sockets, the `recv()` or `recvfrom()` methods will work fine; for other files, use raw reads or `os.read(file.fileno(), maxbytecount)`. 

`Widget.tk.createfilehandler(file, mask, func)`

Registers the file handler callback function `func`. The `file` argument may either be an object with a `fileno()` method (such as a file or socket object), or an integer file descriptor. The `mask` argument is an ORed combination of any of the three constants below. The callback is called as follows:

```python
callback(file, mask)
```
Widget.tk.deletefilehandler(file)

Unregisters a file handler.

tkinter.READABLE
tkinter.WRITABLE
tkinter.EXCEPTION

Constants used in the mask arguments.
25.2. **tkinter.ttk** — Tk themed widgets

The `tkinter.ttk` module provides access to the Tk themed widget set, introduced in Tk 8.5. If Python has not been compiled against Tk 8.5, this module can still be accessed if *Tile* has been installed. The former method using Tk 8.5 provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for `tkinter.ttk` is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

**See also:**

**Tk Widget Styling Support**
A document introducing theming support for Tk
25.2.1. Using Ttk

To start using Ttk, import its module:

```python
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```python
from tkinter import *
from tkinter.ttk import *
```

That code causes several `tkinter.ttk` widgets (Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Instead, use the `ttk.Style` class for improved styling effects.

**See also:**

**Converting existing applications to use Tile widgets**

A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.
25.2.2. Ttk Widgets

Ttk comes with 17 widgets, eleven of which already existed in tkinter: Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar. The other six are new: Combobox, Notebook, Progressbar, Separator, Sizegrip and Treeview. And all them are subclasses of Widget.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```python
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```python
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling, see the Style class documentation.
25.2.3. Widget

ttk.Widget defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

25.2.3.1. Standard Options

All the ttk Widgets accepts the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This option is read-only, and may only be specified when the window is created.</td>
</tr>
<tr>
<td>cursor</td>
<td>Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.</td>
</tr>
<tr>
<td>takefocus</td>
<td>Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.</td>
</tr>
<tr>
<td>style</td>
<td>May be used to specify a custom widget style.</td>
</tr>
</tbody>
</table>

25.2.3.2. Scrollable Widget Options
The following options are supported by widgets that are controlled by a scrollbar.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xscrollcommand</td>
<td>Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method Scrollbar.set() of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.</td>
</tr>
<tr>
<td>yscrollcommand</td>
<td>Used to communicate with vertical scrollbars. For some more information, see above.</td>
</tr>
</tbody>
</table>

25.2.3.3. Label Options

The following options are supported by labels, buttons and other button-like widgets.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Specifies a text string to be displayed inside the widget.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value will be used in place of the text option resource.</td>
</tr>
<tr>
<td>underline</td>
<td>If set, specifies the index (0-based) of a character to underline in the text string. The underline</td>
</tr>
</tbody>
</table>
character is used for mnemonic activation.

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>image</td>
<td>Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list if a sequence of statespec/value pairs as defined by Style.map(), specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.</td>
</tr>
<tr>
<td>compound</td>
<td>Specifies how to display the image relative to the text, in the case both text and images options are present. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>- text: display text only</td>
</tr>
<tr>
<td></td>
<td>- image: display image only</td>
</tr>
<tr>
<td></td>
<td>- top, bottom, left, right: display image above, below, left of, or right of the text, respectively.</td>
</tr>
<tr>
<td></td>
<td>- none: the default. display the image if present, otherwise the text.</td>
</tr>
<tr>
<td>width</td>
<td>If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.</td>
</tr>
</tbody>
</table>

25.2.3.4. Compatibility Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the Widget.state() method does not affect this option.</td>
</tr>
</tbody>
</table>
25.2.3.5. Widget States

The widget state is a bitmap of independent state flags.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>The mouse cursor is over the widget and pressing a mouse button will cause some action to occur</td>
</tr>
<tr>
<td>disabled</td>
<td>Widget is disabled under program control</td>
</tr>
<tr>
<td>focus</td>
<td>Widget has keyboard focus</td>
</tr>
<tr>
<td>pressed</td>
<td>Widget is being pressed</td>
</tr>
<tr>
<td>selected</td>
<td>“On”, “true”, or “current” for things like Checkbuttons and radiobuttons</td>
</tr>
<tr>
<td>background</td>
<td>Windows and Mac have a notion of an “active” or foreground window. The background state is set for widgets in a background window, and cleared for those in the foreground window</td>
</tr>
<tr>
<td>readonly</td>
<td>Widget should not allow user modification</td>
</tr>
<tr>
<td>alternate</td>
<td>A widget-specific alternate display format</td>
</tr>
<tr>
<td>invalid</td>
<td>The widget’s value is invalid</td>
</tr>
</tbody>
</table>

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

25.2.3.6. ttk.Widget

Besides the methods described below, the ttk.Widget supports the methods tkinter.Widget.cget() and tkinter.Widget.configure().
class tkinter.ttk.Widget

identify(x, y)

Returns the name of the element at position x y, or the empty string if the point does not lie within any element.

x and y are pixel coordinates relative to the widget.

instate(statespec, callback=None, *args, **kw)

Test the widget's state. If a callback is not specified, returns True if the widget state matches statespec and False otherwise. If callback is specified then it is called with args if widget state matches statespec.

state(statespec=None)

Modify or inquire widget state. If statespec is specified, sets the widget state according to it and return a new statespec indicating which flags were changed. If statespec is not specified, returns the currently-enabled state flags.

statespec will usually be a list or a tuple.
25.2.4. Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget`: `Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()` and `Widget.state()`, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.inset()`, `Entry.selection()`, `Entry.xview()`, it has some other methods, described at `ttk.Combobox`.

25.2.4.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exportselection</td>
<td>Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).</td>
</tr>
<tr>
<td>justify</td>
<td>Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the height of the pop-down listbox, in rows.</td>
</tr>
<tr>
<td>postcommand</td>
<td>A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.</td>
</tr>
</tbody>
</table>
One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the “normal” state, the text field is directly editable. In the “disabled” state, no interaction is possible.

Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See tkinter.StringVar.

Specifies the list of values to display in the drop-down listbox.

Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget’s font.

25.2.4.2. Virtual events

The combobox widgets generates a <<ComboboxSelected>> virtual event when the user selects an element from the list of values.

25.2.4.3. ttk.Combobox

class tkinter.ttk.Combobox
current(newindex=None)

If newindex is specified, sets the combobox value to the element position newindex. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

get()

Returns the current value of the combobox.
set(value)

Sets the value of the combobox to value.
25.2.5. Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

25.2.5.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.</td>
</tr>
<tr>
<td>width</td>
<td>If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.</td>
</tr>
</tbody>
</table>

25.2.5.2. Tab Options

There are also specific options for tabs:
<table>
<thead>
<tr>
<th><strong>state</strong></th>
<th>Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If “hidden”, then the tab is not shown.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>sticky</strong></td>
<td>Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the <code>grid()</code> geometry manager.</td>
</tr>
<tr>
<td><strong>padding</strong></td>
<td>Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.</td>
</tr>
<tr>
<td><strong>text</strong></td>
<td>Specifies a text to be displayed in the tab.</td>
</tr>
<tr>
<td><strong>image</strong></td>
<td>Specifies an image to display in the tab. See the option image described in <code>Widget</code>.</td>
</tr>
<tr>
<td><strong>compound</strong></td>
<td>Specifies how to display the image relative to the text, in the case both options text and image are present. See <code>Label Options</code> for legal values.</td>
</tr>
<tr>
<td><strong>underline</strong></td>
<td>Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if <code>Notebook.enable_traversal()</code> is called.</td>
</tr>
</tbody>
</table>

### 25.2.5.3. Tab Identifiers

The `tab_id` present in several methods of `ttk.Notebook` may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form “@x,y”, which identifies the tab
The literal string “current”, which identifies the currently-selected tab

The literal string “end”, which returns the number of tabs (only valid for Notebook.index())

25.2.5.4. Virtual Events

This widget generates a <<NotebookTabChanged>> virtual event after a new tab is selected.

25.2.5.5. ttk.Notebook

class tkinter.ttk.Notebook

    add(child, **kw)

    Adds a new tab to the notebook.

    If window is currently managed by the notebook but hidden, it is restored to its previous position.

    See Tab Options for the list of available options.

    forget(tab_id)

    Removes the tab specified by tab_id, unmaps and unmanages the associated window.

    hide(tab_id)

    Hides the tab specified by tab_id.

    The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the add() command.
identify\((x, y)\)

Returns the name of the tab element at position \(x, y\), or the empty string if none.

index\((tab_id)\)

Returns the numeric index of the tab specified by \(tab_id\), or the total number of tabs if \(tab_id\) is the string “end”.

insert\((pos, child, **kw)\)

Inserts a pane at the specified position.

\(pos\) is either the string “end”, an integer index, or the name of a managed child. If \(child\) is already managed by the notebook, moves it to the specified position.

See Tab Options for the list of available options.

select\((tab_id=\text{None})\)

Selects the specified \(tab_id\).

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If \(tab_id\) is omitted, returns the widget name of the currently selected pane.

tab\((tab_id, option=\text{None}, **kw)\)

Query or modify the options of the specific \(tab_id\).

If \(kw\) is not given, returns a dictionary of the tab option values. If \(option\) is specified, returns the value of that \(option\). Otherwise, sets the options to the corresponding values.

tabs()
Returns a list of windows managed by the notebook.

**enable_traversal()**

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- **Control-Tab**: selects the tab following the currently selected one.
- **Shift-Control-Tab**: selects the tab preceding the currently selected one.
- **Alt-K**: where K is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.
25.2.6. Progressbar

The `ttk.Progressbar` widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

25.2.6.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).</td>
</tr>
<tr>
<td>mode</td>
<td>One of “determinate” or “indeterminate”.</td>
</tr>
<tr>
<td>maximum</td>
<td>A number specifying the maximum value. Defaults to 100.</td>
</tr>
<tr>
<td>value</td>
<td>The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo <code>maximum</code>; that is, the progress bar completes one “cycle” when its value increases by <code>maximum</code>.</td>
</tr>
<tr>
<td>variable</td>
<td>A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.</td>
</tr>
<tr>
<td></td>
<td>Read-only option. The widget periodically</td>
</tr>
</tbody>
</table>

phase

increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

25.2.6.2. ttk.Progressbar

class tkinter.ttk.Progressbar

start(interval=None)

Begin autoincrement mode: schedules a recurring timer event that calls Progressbar.step() every interval milliseconds. If omitted, interval defaults to 50 milliseconds.

step(amount=None)

Increments the progress bar’s value by amount.

amount defaults to 1.0 if omitted.

stop()

Stop autoincrement mode: cancels any recurring timer event initiated by Progressbar.start() for this progress bar.
25.2.7. Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

25.2.7.1. Options

This widget accepts the following specific option:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the separator.</td>
</tr>
</tbody>
</table>
25.2.8. Sizegrip

The `ttk.Sizegrip` widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from `ttk.Widget`.

25.2.8.1. Platform-specific notes

- On MacOS X, toplevel windows automatically include a built-in size grip by default. Adding a `Sizegrip` is harmless, since the built-in grip will just mask the widget.

25.2.8.2. Bugs

- If the containing toplevel’s position was specified relative to the right or bottom of the screen (e.g. ...), the `Sizegrip` widget will not resize the window.
- This widget supports only “southeast” resizing.
25.2.9. Treeview

The ttk.Treeview widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option displaycolumns. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by an unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named {}. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods Treeview.xview() and Treeview.yview().

25.2.9.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>A list of column identifiers, specifying the number of columns and their names.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>displaycolumns</td>
<td>A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the internal padding for the widget. The padding is a list of up to four length specifications.</td>
</tr>
<tr>
<td>selectmode</td>
<td>Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.</td>
</tr>
</tbody>
</table>
| show       | A list containing zero or more of the following values, specifying which elements of the tree to display.  

- tree: display tree labels in column #0.  
- headings: display the heading row.  

The default is “tree headings”, i.e., show all elements. |
**Note:** Column #0 always refers to the tree column, even if show="tree" is not specified.

25.2.9.2. Item Options

The following item options may be specified for items in the insert and item widget commands.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The textual label to display for the item.</td>
</tr>
<tr>
<td>image</td>
<td>A Tk Image, displayed to the left of the label.</td>
</tr>
<tr>
<td>values</td>
<td>The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.</td>
</tr>
<tr>
<td>open</td>
<td>True/False value indicating whether the item's children should be displayed or hidden.</td>
</tr>
<tr>
<td>tags</td>
<td>A list of tags associated with this item.</td>
</tr>
</tbody>
</table>

25.2.9.3. Tag Options

The following options may be specified on tags:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground</td>
<td>Specifies the text foreground color.</td>
</tr>
<tr>
<td>background</td>
<td>Specifies the cell or item background color.</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>font</td>
<td>Specifies the font to use when drawing text.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies the item image, in case the item’s image option is empty.</td>
</tr>
</tbody>
</table>

### 25.2.9.4. Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer n, specifying the nth data column.
- A string of the form #n, where n is an integer, specifying the nth display column.

**Notes:**

- Item’s option values may be displayed in a different order than the order in which they are stored.
- Column #0 always refers to the tree column, even if show="tree" is not specified.

A data column number is an index into an item’s option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column #0. If option displaycolumns is not set, then data column n is displayed in column #n+1. Again, **column #0 always refers to the tree column**.

### 25.2.9.5. Virtual Events

The Treeview widget generates the following virtual events.
The `Treeview.focus()` and `Treeview.selection()` methods can be used to determine the affected item or items.

### 25.2.9.6. `ttk.Treeview`

#### `bbox`(*item*, `column=None`)

Returns the bounding box (relative to the treeview widget's window) of the specified `item` in the form `(x, y, width, height)`.

If `column` is specified, returns the bounding box of that cell. If the `item` is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

#### `get_children`(*item=None*)

Returns the list of children belonging to `item`.

If `item` is not specified, returns root children.

#### `set_children`(*item*, `*newchildren*)

Replaces `item`'s child with `newchildren`.

Children present in `item` that are not present in `newchildren` are detached from the tree. No items in `newchildren` may be an ancestor of `item`. Note that not specifying `newchildren` results in
detaching item's children.

**column**(*column*, *option=None, **kw*)

Query or modify the options for the specified *column*.

If *kw* is not given, returns a dict of the column option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **id**
  Returns the column name. This is a read-only option.

- **anchor**: One of the standard Tk anchor values.
  Specifies how the text in this column should be aligned with respect to the cell.

- **minwidth**: width
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- **stretch**: True/False
  Specifies whether the column’s width should be adjusted when the widget is resized.

- **width**: width
  The width of the column in pixels.

To configure the tree column, call this with column = “#0”

**delete**(*items*)
Delete all specified *items* and all their descendants.

The root item may not be deleted.

**detach(*items*)**
Unlinks all of the specified *items* from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

**exists(item)**
Returns True if the specified *item* is present in the tree.

**focus(item=None)**
If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or ‘ ’ if there is none.

**heading(column, option=None, **kw)**
Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **text: text**
  The text to display in the column heading.

- **image: imageName**
  Specifies an image to display to the right of the column
heading.

- anchor: anchor
  Specifies how the heading text should be aligned. One of the standard Tk anchor values.

- command: callback
  A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = “#0”.

**identify**(component, x, y)
Returns a description of the specified component under the point given by x and y, or the empty string if no such component is present at that position.

**identify_row**(y)
Returns the item ID of the item at position y.

**identify_column**(x)
Returns the data column identifier of the cell at position x.

The tree column has ID #0.

**identify_region**(x, y)
Returns one of:

<table>
<thead>
<tr>
<th>region</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>Tree heading area.</td>
</tr>
<tr>
<td>separator</td>
<td>Space between two columns headings.</td>
</tr>
<tr>
<td>tree</td>
<td>The tree area.</td>
</tr>
<tr>
<td>cell</td>
<td>A data cell.</td>
</tr>
</tbody>
</table>

Availability: Tk 8.6.

**identify_element**(\(x, y\))
Returns the element at position \(x, y\).

Availability: Tk 8.6.

**index**(\(item\))
Returns the integer index of \(item\) within its parent’s list of children.

**insert**(\(parent, index, iid=None, **kw\))
Creates a new item and returns the item identifier of the newly created item.

\(parent\) is the item ID of the parent item, or the empty string to create a new top-level item. \(index\) is an integer, or the value “end”, specifying where in the list of parent’s children to insert the new item. If \(index\) is less than or equal to zero, the new node is inserted at the beginning; if \(index\) is greater than or equal to the current number of children, it is inserted at the end. If \(iid\) is specified, it is used as the item identifier; \(iid\) must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

**item**(\(item, option=None, **kw\))
Query or modify the options for the specified \(item\).

If no options are given, a dict with options/values for the item is returned. If \(option\) is specified then the value for that option is
returned. Otherwise, sets the options to the corresponding values as given by *kw*.

**move**(item, parent, index)

Moves *item* to position *index* in *parent*'s list of children.

It is illegal to move an item under one of its descendants. If *index* is less than or equal to zero, *item* is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If *item* was detached it is reattached.

**next**(item)

Returns the identifier of *item*'s next sibling, or "" if *item* is the last child of its parent.

**parent**(item)

Returns the ID of the parent of *item*, or "" if *item* is at the top level of the hierarchy.

**prev**(item)

Returns the identifier of *item*'s previous sibling, or "" if *item* is the first child of its parent.

**reattach**(item, parent, index)

An alias for *Treeview.move()*.

**see**(item)

Ensure that *item* is visible.

Sets all of *item*'s ancestors open option to True, and scrolls the widget if necessary so that *item* is within the visible portion of the tree.
selection selop=None, items=None
If selop is not specified, returns selected items. Otherwise, it will act according to the following selection methods.

selection_set(items)
items becomes the new selection.

selection_add(items)
Add items to the selection.

selection_remove(items)
Remove items from the selection.

selection_toggle(items)
Toggle the selection state of each item in items.

set(item, column=None, value=None)
With one argument, returns a dictionary of column/value pairs for the specified item. With two arguments, returns the current value of the specified column. With three arguments, sets the value of given column in given item to the specified value.

tag_bind(tagname, sequence=None, callback=None)
Bind a callback for the given event sequence to the tag tagname. When an event is delivered to an item, the callbacks for each of the item’s tags option are called.

tag_configure(tagname, option=None, **kw)
Query or modify the options for the specified tagname.
If kw is not given, returns a dict of the option settings for tagname. If option is specified, returns the value for that option for the specified tagname. Otherwise, sets the options to the
corresponding values for the given *tagname*.

**tag_has(tagname, item=None)**

If *item* is specified, returns 1 or 0 depending on whether the specified *item* has the given *tagname*. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

**xview(**args**)**

Query or modify horizontal position of the treeview.

**yview(**args**)**

Query or modify vertical position of the treeview.
25.2.10. Ttk Styling

Each widget in ttk is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class name of a widget, use the method Misc.winfo_class() (somewidget.winfo_class()).

See also:

Tcl'2004 conference presentation
   This document explains how the theme engine works

```python
class tkinter.ttk.Style
   This class is used to manipulate the style database.

configure(style, query_opt=None, **kw)
   Query or set the default value of the specified option(s) in style.

   Each key in kw is an option and each value is a string identifying the value for that option.

   For example, to change every default button to be a flat button with some padding and a different background color:

   from tkinter import ttk
   import tkinter

   root = tkinter.Tk()```
```python
ttk.Style().configure("TButton", padding=6, relief="flat", background="#ccc")
btn = ttk.Button(text="Sample")
btn.pack()
root.mainloop()
```

The `map` function:
```
map(style, query_opt=None, **kw)
```

Query or sets dynamic values of the specified option(s) in `style`.

Each key in `kw` is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```python
import tkinter
from tkinter import ttk
root = tkinter.Tk()
style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active',
    background=[('pressed', '!disabled', 'black')
]
colored_btn = ttk.Button(text="Test", style="C.
root.mainloop()
```

Note that the order of the `(states, value)` sequences for an
option does matter, if the order is changed to [('active', 'blue'), ('pressed', 'red')] in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

**lookup(style, option, state=None, default=None)**

Returns the value specified for `option` in `style`.

If `state` is specified, it is expected to be a sequence of one or more states. If the `default` argument is set, it is used as a fallback value in case no specification for `option` is found.

To check what font a Button uses by default:

```python
from tkinter import ttk

print(ttk.Style().lookup("TButton", "font"))
```

**layout(style, layoutspec=None)**

Define the widget layout for given `style`. If `layoutspec` is omitted, return the layout specification for given `style`.

`layoutspec`, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
style = ttk.Style()  
style.layout("TMenubutton", [  
    ("Menubutton.background", None),  
    ("Menubutton.button", {"children":  
        [("Menubutton.focus", {"children":  
            [("Menubutton.padding", {"children":  
                ["Menubutton.label", {"side": "}  
            }  
        }  
    }  
])  
mbtn = ttk.Menubutton(text='Text')  
mbtn.pack()  
root.mainloop()
```

**element_create(elementname, etype, *args, **kw)**

Create a new element in the current theme, of the given *etype* which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, *args* should contain the default image name followed by statespec/value pairs (this is the imagespec), and *kw* may have the following options:

- **border=padding**
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- **height=height**
  Specifies a minimum height for the element. If less than zero, the base image's height is used as a
• padding=padding
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

• sticky=spec
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

• width=width
  Specifies a minimum width for the element. If less than zero, the base image’s width is used as a default.

If “from” is used as the value of etype, element_create() will clone an existing element. args is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. kw is discarded.

**element_names()**
Returns the list of elements defined in the current theme.

**element_options(elementname)**
Returns the list of elementname's options.

**theme_create(themename, parent=None, settings=None)**
Create a new theme.

It is an error if themename already exists. If parent is specified,
the new theme will inherit styles, elements and layouts from the parent theme. If settings are present they are expected to have the same syntax used for `theme_settings()`.

**theme_settings**(themename, settings)
Temporarily sets the current theme to themename, apply specified settings and then restore the previous theme.

Each key in settings is a style and each value may contain the keys ‘configure’, ‘map’, ‘layout’ and ‘element create’ and they are expected to have the same format as specified by the methods `Style.configure()`, `Style.map()`, `Style.layout()` and `Style.element_create()` respectively.

As an example, let’s change the Combobox for the default theme a bit:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": [("active", "green2"),
                           ("!disabled", "green4"),
                          "fieldbackground": [("!disabled", "green3"),
                                              "foreground": [("focus", "OliveDrab1"),
                                                             ("!disabled", "OliveDrab2")]
                                      }
        }
    }
})
```
```python
combo = ttk.Combobox().pack()
root.mainloop()
```

**theme_names()**

Returns a list of all known themes.

**theme_use(themename=None)**

If `themename` is not given, returns the theme in use. Otherwise, sets the current theme to `themename`, refreshes all widgets and emits a `<<ThemeChanged>>` event.

### 25.2.10.1. Layouts

A layout can be just `None`, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:

- **side**: `whichside`
  
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- **sticky**: `nswe`
  
  Specifies where the element is placed inside its allocated parcel.

- **unit**: `0` or `1`
  
  If set to `1`, causes the element and all of its descendants
to be treated as a single element for the purposes of `Widget.identify()` et al. It's used for things like scrollbar thumbs with grips.

- **children: [sublayout...]**
  Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a `Layout`.
25.3. `tkinter.tix` — Extension widgets for Tk

The `tkinter.tix` (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The `tkinter.tix` library provides most of the commonly needed widgets that are missing from standard Tk: `HList`, `ComboBox`, `Control` (a.k.a. SpinBox) and an assortment of scrollable widgets. `tkinter.tix` also includes many more widgets that are generally useful in a wide range of applications: `NoteBook`, `FileEntry`, `PanedWindow`, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

   On-line version of the man pages and reference material.

[Tix Programming Guide](#)
   On-line version of the programmer’s reference material.

[Tix Development Applications](#)
Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include TixInspect, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
25.3.1. Using Tix

class tkinter.tix.Tk(screenName=None, baseName=None, className='Tix')

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the tkinter.tix module subclasses the classes in the tkinter. The former imports the latter, so to use tkinter.tix with Tkinter, all you need to do is to import one module. In general, you can just import tkinter.tix, and replace the toplevel call to tkinter.Tk with tix.Tk:

```python
from tkinter import tix
from tkinter.constants import *
root = tix.Tk()
```

To use tkinter.tix, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```python
from tkinter import tix
root = tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (tix8183.dll or libtix8183.so) in the same directory that contains your Tk dynamic object library (tk8183.dll or libtk8183.so). The directory with the dynamic
object library should also have a file called pkgIndex.tcl (case sensitive), which contains the line:

```tcl
package ifneeded Tix 8.1 [list load "$[file join $dir tix8183.dll]"
```
25.3.2. Tix Widgets

Tix introduces over 40 widget classes to the tkinter repertoire.

25.3.2.1. Basic Widgets

*class tkinter.tix.Balloon*

A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

*class tkinter.tix.ButtonBox*

The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

*class tkinter.tix.ComboBox*

The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

*class tkinter.tix.Control*

The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

*class tkinter.tix.LabelEntry*

The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.
class tkinter.tix.LabelFrame

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

class tkinter.tix.Meter

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

class tkinter.tix.OptionMenu

The OptionMenu creates a menu button of options.

class tkinter.tix.PopupMenu

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

class tkinter.tix.Select

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class tkinter.tix.StdButtonBox

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

25.3.2.2. File Selectors

class tkinter.tix.DirList

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the
directories displayed in the list or change to another directory.

**class tkinter.tix.DirTree**

The `DirTree` widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class tkinter.tix.DirSelectDialog**

The `DirSelectDialog` widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

**class tkinter.tix.DirSelectBox**

The `DirSelectBox` is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class tkinter.tix.ExFileSelectBox**

The `ExFileSelectBox` widget is usually embedded in a tixExFileSelectDialog widget. It provides an convenient method for the user to select files. The style of the `ExFileSelectBox` widget is very similar to the standard file dialog on MS Windows 3.1.

**class tkinter.tix.FileSelectBox**

The `FileSelectBox` is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class tkinter.tix.FileEntry**

The `FileEntry` widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the
button widget that sits next to the entry, which will bring up a file selection dialog.

### 25.3.2.3. Hierarchical ListBox

*class* `tkinter.tix.HList`

The *HList* widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

*class* `tkinter.tix.CheckList`

The *CheckList* widget displays a list of items to be selected by the user. *CheckList* acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

*class* `tkinter.tix.Tree`

The *Tree* widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

### 25.3.2.4. Tabular ListBox

*class* `tkinter.tix.TList`

The *TList* widget can be used to display data in a tabular format. The list entries of a *TList* widget are similar to the entries in the Tk listbox widget. The main differences are (1) the *TList* widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.
25.3.2.5. Manager Widgets

class tkinter.tix.PanedWindow
The PanedWindow widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

class tkinter.tix.ListNoteBook
The ListNoteBook widget is very similar to the TixNoteBook widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the hlist subwidget.

class tkinter.tix.NoteBook
The NoteBook widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

25.3.2.6. Image Types

The tkinter.tix module adds:

- **Pixmap** capabilities to all tkinter.tix and tkinter widgets to create color images from XPM files.
- **Compound** image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from
left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

25.3.2.7. Miscellaneous Widgets

class tkinter.tix.InputOnly

The InputOnly widgets are to accept inputs from the user, which can be done with the bind command (Unix only).

25.3.2.8. Form Geometry Manager

In addition, tkinter.tix augments tkinter by providing:

class tkinter.tix.Form

The Form geometry manager based on attachment rules for all Tk widgets.
25.3.3. Tix Commands

class tkinter.tix.tixCommand

The tix commands provide access to miscellaneous elements of Tix's internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```python
from tkinter import tix
root = tix.Tk()
print(root.tix_configure())
```

tixCommand.tix_configure(cnf=None, **kw)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(option)

Returns the current value of the configuration option given by option. Option may be any of the configuration options.

tixCommand.tix_getbitmap(name)

Locates a bitmap file of the name name.xpm or name in one of the
bitmap directories (see the tix_addbitmapdir() method). By using tix_getbitmap(), you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character @. The returned value can be used to configure the bitmap option of the Tk and Tix widgets.

\begin{tixcommand}
\texttt{tix_addbitmapdir(directory)}
\end{tixcommand}

Tix maintains a list of directories under which the tix_getimage() and tix_getbitmap() methods will search for image files. The standard bitmap directory is \$TIX_LIBRARY/bitmaps. The tix_addbitmapdir() method adds directory into this list. By using this method, the image files of an applications can also be located using the tix_getimage() or tix_getbitmap() method.

\begin{tixcommand}
\texttt{tix_filedialog([dlgclass])}
\end{tixcommand}

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to tix_filedialog(). An optional dlgclass parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are tix, FileSelectDialog or tixExFileSelectDialog.

\begin{tixcommand}
\texttt{tix_getimage(self, name)}
\end{tixcommand}

Locates an image file of the name name.xpm, name.xbm or name.ppm in one of the bitmap directories (see the tix_addbitmapdir() method above). If more than one file with the same name (but different extensions) exist, then the image type
is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are chosen on color displays. By using \texttt{tix\_getimage()}, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the image option of the Tk and Tix widgets.

\begin{verbatim}
tixCommand.tix\_option\_get(name)
\end{verbatim}

Gets the options maintained by the Tix scheme mechanism.

\begin{verbatim}
tixCommand.tix\_resetoptions(newScheme, newFontSet[, newScmPrio])
\end{verbatim}

Resets the scheme and fontset of the Tix application to \textit{newScheme} and \textit{newFontSet}, respectively. This affects only those widgets created after this call. Therefore, it is best to call the resetoptions method before the creation of any widgets in a Tix application.

The optional parameter \textit{newScmPrio} can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and inited, it is not possible to reset the color schemes and font sets using the \texttt{tix\_config()} method. Instead, the \texttt{tix\_resetoptions()} method must be used.
25. Graphical User Interfaces with Tk
25.4. `tkinter.scrolledtext` — Scrolled Text Widget

The `tkinter.scrolledtext` module provides a class of the same name which implements a basic text widget which has a vertical scrollbar configured to do the “right thing.” Using the ScrolledText class is a lot easier than setting up a text widget and scroll bar directly. The constructor is the same as that of the `tkinter.Text` class.

The text widget and scrollbar are packed together in a Frame, and the methods of the Grid and Pack geometry managers are acquired from the Frame object. This allows the ScrolledText widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

**ScrolledText.frame**

The frame which surrounds the text and scroll bar widgets.

**ScrolledText.vbar**

The scroll bar widget.
25.5. IDLE

IDLE is Python's Integrated Development and Learning Environment.

IDLE has the following features:

- coded in 100% pure Python, using the tkinter GUI toolkit
- cross-platform: works mostly the same on Windows, Unix, and Mac OS X
- Python shell window (interactive interpreter) with colorizing of code input, output, and error messages
- multi-window text editor with multiple undo, Python colorizing, smart indent, call tips, auto completion, and other features
- search within any window, replace within editor windows, and search through multiple files (grep)
- debugger with persistent breakpoints, stepping, and viewing of global and local namespaces
- configuration, browsers, and other dialogs
25.5.1. Menus

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. Output windows, such as used for Edit / Find in Files, are a subtype of edit window. They currently have the same top menu as Editor windows but a different default title and context menu.

IDLE’s menus dynamically change based on which window is currently selected. Each menu documented below indicates which window type it is associated with.

25.5.1.1. File menu (Shell and Editor)

New File
  Create a new file editing window.

Open...
  Open an existing file with an Open dialog.

Recent Files
  Open a list of recent files. Click one to open it.

Open Module...
  Open an existing module (searches sys.path).

Class Browser
  Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

Path Browser
  Show sys.path directories, modules, functions, classes and methods in a tree structure.

Save
  Save the current window to the associated file, if there is one.
Windows that have been changed since being opened or last saved have a * before and after the window title. If there is no associated file, do Save As instead.

Save As...
Save the current window with a Save As dialog. The file saved becomes the new associated file for the window.

Save Copy As...
Save the current window to different file without changing the associated file.

Print Window
Print the current window to the default printer.

Close
Close the current window (ask to save if unsaved).

Exit
Close all windows and quit IDLE (ask to save unsaved windows).

25.5.1.2. Edit menu (Shell and Editor)

Undo
Undo the last change to the current window. A maximum of 1000 changes may be undone.

Redo
Redo the last undone change to the current window.

Cut
Copy selection into the system-wide clipboard; then delete the selection.

Copy
Copy selection into the system-wide clipboard.

Paste
Insert contents of the system-wide clipboard into the current
The clipboard functions are also available in context menus.

Select All
Select the entire contents of the current window.

Find...
Open a search dialog with many options

Find Again
Repeat the last search, if there is one.

Find Selection
Search for the currently selected string, if there is one.

Find in Files...
Open a file search dialog. Put results in an new output window.

Replace...
Open a search-and-replace dialog.

Go to Line
Move cursor to the line number requested and make that line visible.

Show Completions
Open a scrollable list allowing selection of keywords and attributes. See Completions in the Tips sections below.

Expand Word
Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

Show call tip
After an unclosed parenthesis for a function, open a small window with function parameter hints.

Show surrounding parens
Highlight the surrounding parenthesis.
25.5.1.3. Format menu (Editor window only)

Indent Region
   Shift selected lines right by the indent width (default 4 spaces).

Dedent Region
   Shift selected lines left by the indent width (default 4 spaces).

Comment Out Region
   Insert ## in front of selected lines.

Uncomment Region
   Remove leading # or ## from selected lines.

Tabify Region
   Turn leading stretches of spaces into tabs. (Note: We recommend using 4 space blocks to indent Python code.)

Untabify Region
   Turn all tabs into the correct number of spaces.

Toggle Tabs
   Open a dialog to switch between indenting with spaces and tabs.

New Indent Width
   Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

Format Paragraph
   Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

Strip trailing whitespace
   Remove any space characters after the last non-space character of a line.

25.5.1.4. Run menu (Editor window only)
Python Shell
Open or wake up the Python Shell window.

Check Module
Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

Run Module
Do Check Module (above). If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of print or write. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with python -i file at a command line.

25.5.1.5. Shell menu (Shell window only)

View Last Restart
Scroll the shell window to the last Shell restart.

Restart Shell
Restart the shell to clean the environment.

25.5.1.6. Debug menu (Shell window only)

Go to File/Line
Look on the current line, with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also
available in the context menu of the Shell window and Output windows.

Debugger (toggle)
When actived, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

Stack Viewer
Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

Auto-open Stack Viewer
Toggle automatically opening the stack viewer on an unhandled exception.

25.5.1.7. Options menu (Shell and Editor)

Configure IDLE
Open a configuration dialog and change preferences for the following: fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions (see below). On OS X, open the configuration dialog by selecting Preferences in the application menu. To use a new built-in color theme (IDLE Dark) with older IDLEs, save it as a new custom theme.

Non-default user settings are saved in a .idlerc directory in the user’s home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in .idlerc.

Code Context (toggle)(Editor Window only)
Open a pane at the top of the edit window which shows the block
context of the code which has scrolled above the top of the window.

25.5.1.8. Window menu (Shell and Editor)

Zoom Height
Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog.

The rest of this menu lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

25.5.1.9. Help menu (Shell and Editor)

About IDLE
Display version, copyright, license, credits, and more.

IDLE Help
Display a help file for IDLE detailing the menu options, basic editing and navigation, and other tips.

Python Docs
Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

Turtle Demo
Run the turtledemo module with example python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE dialog under the General tab.

25.5.1.10. Context Menus
Open a context menu by right-clicking in a window (Control-click on OS X). Context menus have the standard clipboard functions also on the Edit menu.

Cut

  Copy selection into the system-wide clipboard; then delete the selection.

Copy

  Copy selection into the system-wide clipboard.

Paste

  Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user’s .idlerc directory.

Set Breakpoint

  Set a breakpoint on the current line.

Clear Breakpoint

  Clear the breakpoint on that line.

Shell and Output windows have the following.

Go to file/line

  Same as in Debug menu.
25.5.2. Editing and navigation

In this section, ‘C’ refers to the Control key on Windows and Unix and the Command key on Mac OS X.

- Backspace deletes to the left; Del deletes to the right
- C-Backspace delete word left; C-Del delete word to the right
- Arrow keys and Page Up/Page Down to move around
- C-LeftArrow and C-RightArrow moves by words
- Home/End go to begin/end of line
- C-Home/C-End go to begin/end of file
- Some useful Emacs bindings are inherited from Tcl/Tk:
  - C-a beginning of line
  - C-e end of line
  - C-k kill line (but doesn’t put it in clipboard)
  - C-l center window around the insertion point
  - C-b go backwards one character without deleting (usually you can also use the cursor key for this)
  - C-f go forward one character without deleting (usually you can also use the cursor key for this)
  - C-p go up one line (usually you can also use the cursor key for this)
  - C-d delete next character

Standard keybindings (like C-c to copy and C-v to paste) may work. Keybindings are selected in the Configure IDLE dialog.
25.5.2.1. Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, Backspace deletes up to 4 spaces if they are there. Tab inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands in the edit menu.

25.5.2.2. Completions

Completions are supplied for functions, classes, and attributes of classes, both built-in and user-defined. Completions are also provided for filenames.

The AutoCompleteWindow (ACW) will open after a predefined delay (default is two seconds) after a ‘.’ or (in a string) an os.sep is typed. If after one of those characters (plus zero or more other characters) a tab is typed the ACW will open immediately if a possible continuation is found.

If there is only one possible completion for the characters entered, a Tab will supply that completion without opening the ACW.

‘Show Completions’ will force open a completions window, by default the C-space will open a completions window. In an empty string, this will contain the files in the current directory. On a blank line, it will contain the built-in and user-defined functions and classes in the current name spaces, plus any modules imported. If some characters
have been entered, the ACW will attempt to be more specific.

If a string of characters is typed, the ACW selection will jump to the entry most closely matching those characters. Entering a tab will cause the longest non-ambiguous match to be entered in the Editor window or Shell. Two tab in a row will supply the current ACW selection, as will return or a double click. Cursor keys, Page Up/Down, mouse selection, and the scroll wheel all operate on the ACW.

“Hidden” attributes can be accessed by typing the beginning of hidden name after a ‘.’, e.g. ‘_’. This allows access to modules with __all__ set, or to class-private attributes.

Completions and the ‘Expand Word’ facility can save a lot of typing!

Completions are currently limited to those in the namespaces. Names in an Editor window which are not via __main__ and sys.modules will not be found. Run the module once with your imports to correct this situation. Note that IDLE itself places quite a few modules in sys.modules, so much can be found by default, e.g. the re module.

If you don’t like the ACW popping up unbidden, simply make the delay longer or disable the extension.

25.5.2.3. Calltips

A calltip is shown when one types ( after the name of an accessible function. A name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or ) is typed. When the cursor is in the argument part of a definition, the menu or shortcut display a calltip.

A calltip consists of the function signature and the first line of the
docstring. For builtins without an accessible signature, the calltip consists of all lines up the fifth line or the first blank line. These details may change.

The set of accessible functions depends on what modules have been imported into the user process, including those imported by Idle itself, and what definitions have been run, all since the last restart.

For example, restart the Shell and enter `import itertools`. A calltip appears because Idle imports itertools into the user process for its own use. (This could change.) Enter `turtle.write()` and nothing appears. Idle does not import turtle. The menu or shortcut do nothing either. Enter `import turtle` and then `turtle.write()` will work.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing the import statements at the top, or immediately run an existing file before editing.

25.5.2.4. Python Shell window

- `C-c` interrupts executing command
- `C-d` sends end-of-file; closes window if typed at a `>>>` prompt
- `Alt-/` (Expand word) is also useful to reduce typing

Command history

- `Alt-p` retrieves previous command matching what you have typed. On OS X use `C-p`.
- `Alt-n` retrieves next. On OS X use `C-n`.
- `Return` while on any previous command retrieves that command
25.5.2.5. Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, builtin class and function names, names following class and def, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

Text coloring is done in the background, so uncolorized text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.
25.5.3. Startup and code execution

Upon startup with the -s option, IDLE will execute the file referenced by the environment variables IDLESTARTUP or PYTHONSTARTUP. IDLE first checks for IDLESTARTUP; if IDLESTARTUP is present the file referenced is run. If IDLESTARTUP is not present, IDLE checks for PYTHONSTARTUP. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is .Idle.py and is looked for in the user’s home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE’s Python shell.

25.5.3.1. Command line usage

```
idle.py [-c command] [-d] [-e] [-h] [-i] [-r file] [arg...]

-c command  run command in the shell window
-d           enable debugger and open shell window
-e           open editor window
-h           print help message with legal combinations
-i           open shell window
-r file      run file in shell window
-s           run $IDLESTARTUP or $PYTHONSTARTUP first
-t title     set title of shell window
-            run stdin in shell (- must be last option)
```
If there are arguments:

- If `-`, `-c`, or `-r` is used, all arguments are placed in `sys.argv[1:...]` and `sys.argv[0]` is set to `'`, `-c`, or `-r`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

25.5.3.2. IDLE-console differences

As much as possible, the result of executing Python code with IDLE is the same as executing the same code in a console window. However, the different interface and operation occasionally affects results.

For instance, IDLE normally executes user code in a separate process from the IDLE GUI itself. The IDLE versions of `sys.stdin`, `stdout`, and `stderr` in the execution process get input from and send output to the GUI process, which keeps control of the keyboard and screen. This is normally transparent, but code that access these object will see different attribute values. Also, functions that directly access the keyboard and screen will not work.

With IDLE’s Shell, one enters, edits, and recalls complete statements. Some consoles only work with a single physical line at a time.

25.5.3.3. Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the Internet. If firewall software complains anyway, you can ignore it.
If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the -n command line switch.

If IDLE is started with the -n command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must reload() the affected modules and re-import any specific items (e.g. from foo import baz) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

*Deprecated since version 3.4.*
25.5.4. Help and preferences

25.5.4.1. Additional help sources

IDLE includes a help menu entry called “Python Docs” that will open the extensive sources of help, including tutorials, available at docs.python.org. Selected URLs can be added or removed from the help menu at any time using the Configure IDLE dialog. See the IDLE help option in the help menu of IDLE for more information.

25.5.4.2. Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Keys can be user defined; IDLE ships with four built in key sets. In addition a user can create a custom key set in the Configure IDLE dialog under the keys tab.

25.5.4.3. Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with Configure Extensions. See the beginning of config-extensions.def in the idlelib directory for further information. The default extensions are currently:

- FormatParagraph
- AutoExpand
- ZoomHeight
- ScriptBinding
- CallTips
- ParenMatch
- AutoComplete
- CodeContext
- RstripExtension
25.6. Other Graphical User Interface Packages

Major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits are available for Python:

See also:

**PyGObject**
provides introspection bindings for C libraries using GObject. One of these libraries is the GTK+ 3 widget set. GTK+ comes with many more widgets than Tkinter provides. An online Python GTK+ 3 Tutorial is available.

**PyGTK** provides bindings for an older version of the library, GTK+ 2. It provides an object oriented interface that is slightly higher level than the C one. There are also bindings to GNOME. An online tutorial is available.

**PyQt**
PyQt is a sip-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. sip is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python. The PyQt3 bindings have a book, GUI Programming with Python: QT Edition by Boudewijn Rempt. The PyQt4 bindings also have a book, Rapid GUI Programming with Python and Qt, by Mark Summerfield.

**PySide**
is a newer binding to the Qt toolkit, provided by Nokia. Compared to PyQt, its licensing scheme is friendlier to non-open source applications.
wxPython is a cross-platform GUI toolkit for Python that is built around the popular wxWidgets (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules. wxPython has a book, wxPython in Action, by Noel Rappin and Robin Dunn.

PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the GUI Programming page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
26. Development Tools

The modules described in this chapter help you write software. For example, the `pydoc` module takes a module and generates documentation based on the module's contents. The `doctest` and `unittest` modules contain frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. `2to3` can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **26.1. typing — Support for type hints**
  - 26.1.1. Type aliases
  - 26.1.2. Callable
  - 26.1.3. Generics
  - 26.1.4. User-defined generic types
  - 26.1.5. The `Any` type
  - 26.1.6. Classes, functions, and decorators
- **26.2. pydoc — Documentation generator and online help system**
- **26.3. doctest — Test interactive Python examples**
  - 26.3.1. Simple Usage: Checking Examples in Docstrings
  - 26.3.2. Simple Usage: Checking Examples in a Text File
  - 26.3.3. How It Works
    - 26.3.3.1. Which Docstrings Are Examined?
    - 26.3.3.2. How are Docstring Examples Recognized?
    - 26.3.3.3. What's the Execution Context?
    - 26.3.3.4. What About Exceptions?
    - 26.3.3.5. Option Flags
    - 26.3.3.6. Directives
    - 26.3.3.7. Warnings
  - 26.3.4. Basic API
26.3.5. Unittest API
26.3.6. Advanced API
  ■ 26.3.6.1. DocTest Objects
  ■ 26.3.6.2. Example Objects
  ■ 26.3.6.3. DocTestFinder objects
  ■ 26.3.6.4. DocTestParser objects
  ■ 26.3.6.5. DocTestRunner objects
  ■ 26.3.6.6. OutputChecker objects
26.3.7. Debugging
26.3.8. Soapbox

• 26.4. unittest — Unit testing framework
  ■ 26.4.1. Basic example
  ■ 26.4.2. Command-Line Interface
    ■ 26.4.2.1. Command-line options
  ■ 26.4.3. Test Discovery
  ■ 26.4.4. Organizing test code
  ■ 26.4.5. Re-using old test code
  ■ 26.4.6. Skipping tests and expected failures
  ■ 26.4.7. Distinguishing test iterations using subtests
  ■ 26.4.8. Classes and functions
    ■ 26.4.8.1. Test cases
      ■ 26.4.8.1.1. Deprecated aliases
    ■ 26.4.8.2. Grouping tests
    ■ 26.4.8.3. Loading and running tests
      ■ 26.4.8.3.1. load_tests Protocol
  ■ 26.4.9. Class and Module Fixtures
    ■ 26.4.9.1. setUpClass and tearDownClass
    ■ 26.4.9.2. setUpModule and tearDownModule
  ■ 26.4.10. Signal Handling

• 26.5. unittest.mock — mock object library
  ■ 26.5.1. Quick Guide
  ■ 26.5.2. The Mock Class
    ■ 26.5.2.1. Calling
    ■ 26.5.2.2. Deleting Attributes
- 26.5.2.3. Mock names and the name attribute
- 26.5.2.4. Attaching Mocks as Attributes

- 26.5.3. The patchers
  - 26.5.3.1. patch
  - 26.5.3.2. patch.object
  - 26.5.3.3. patch.dict
  - 26.5.3.4. patch.multiple
  - 26.5.3.5. patch methods: start and stop
  - 26.5.3.6. patch builtins
  - 26.5.3.7. TEST_PREFIX
  - 26.5.3.8. Nesting Patch Decorators
  - 26.5.3.9. Where to patch
  - 26.5.3.10. Patching Descriptors and Proxy Objects

- 26.5.4. MagicMock and magic method support
  - 26.5.4.1. Mocking Magic Methods
  - 26.5.4.2. Magic Mock

- 26.5.5. Helpers
  - 26.5.5.1. sentinel

26.1. typing — Support for type hints

Source code: Lib/typing.py

This module supports type hints as specified by PEP 484. The most fundamental support consists of the type Any, Union, Tuple, Callable, TypeVar, and Generic. For full specification please see PEP 484. For a simplified introduction to type hints see PEP 483.

The function below takes and returns a string and is annotated as follows:

```python
def greeting(name: str) -> str:
    return 'Hello ' + name
```

In the function greeting, the argument name is expected to by of type str and the return type str. Subtypes are accepted as arguments.
26.1.1. Type aliases

A type alias is defined by assigning the type to the alias:

```
Vector = List[float]
```
26.1.2. Callable

Frameworks expecting callback functions of specific signatures might be type hinted using `Callable[[Arg1Type, Arg2Type], ReturnType]`.

For example:

```python
from typing import Callable

def feeder(get_next_item: Callable[[], str]) -> None:
    # Body

def async_query(on_success: Callable[[int], None],
                 on_error: Callable[[int, Exception],
                                 None],
                 # Body
```

It is possible to declare the return type of a callable without specifying the call signature by substituting a literal ellipsis for the list of arguments in the type hint: `Callable[... , ReturnType]`. None as a type hint is a special case and is replaced by `type(None)`. 
26.1.3. Generics

Since type information about objects kept in containers cannot be statically inferred in a generic way, abstract base classes have been extended to support subscription to denote expected types for container elements.

```python
from typing import Mapping, Sequence

def notify_by_email(employees: Sequence[Employee], overrides: Mapping[str, str]) -> ...
```

Generics can be parametrized by using a new factory available in typing called `TypeVar`.

```python
from typing import Sequence, TypeVar

T = TypeVar('T')  # Declare type variable

def first(l: Sequence[T]) -> T:  # Generic function
    return l[0]
```
26.1.4. User-defined generic types

A user-defined class can be defined as a generic class.

```python
from typing import TypeVar, Generic
from logging import Logger

T = TypeVar('T')

class LoggedVar(Generic[T]):
    def __init__(self, value: T, name: str, logger: Logger):
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('{}: {}'.format(self.name, message))
```

Generic[T] as a base class defines that the class LoggedVar takes a single type parameter T. This also makes T valid as a type within the class body.

The Generic base class uses a metaclass that defines `__getitem__()` so that LoggedVar[t] is valid as a type:

```python
from typing import Iterable
```
```python
def zero_all_vars(vars: Iterable[LoggedVar[int]]) ->
    for var in vars:
        var.set(0)
```

A generic type can have any number of type variables, and type variables may be constrained:

```python
from typing import TypeVar, Generic...

T = TypeVar('T')
S = TypeVar('S', int, str)

class StrangePair(Generic[T, S]): ...
```

Each type variable argument to `Generic` must be distinct. This is thus invalid:

```python
from typing import TypeVar, Generic...

T = TypeVar('T')

class Pair(Generic[T, T]):    # INVALID ...
```

You can use multiple inheritance with `Generic`:

```python
from typing import TypeVar, Generic, Sized

T = TypeVar('T')

class LinkedList(Sized, Generic[T]):
```
When inheriting from generic classes, some type variables could be fixed:

```python
from typing import TypeVar, Mapping

T = TypeVar('T')

class MyDict(Mapping[str, T]):
...
```

In this case `MyDict` has a single parameter, `T`.

Subclassing a generic class without specifying type parameters assumes `Any` for each position. In the following example, `MyIterable` is not generic but implicitly inherits from `Iterable[Any]`:

```python
from typing import Iterable

class MyIterable(Iterable):  # Same as Iterable[Any]
...
```

The metaclass used by `Generic` is a subclass of `abc.ABCMeta`. A generic class can be an ABC by including abstract methods or properties, and generic classes can also have ABCs as base classes without a metaclass conflict. Generic metaclasses are not supported.
26.1.5. The *Any* type

A special kind of type is *Any*. Every type is a subtype of *Any*. This is also true for the builtin type object. However, to the static type checker these are completely different.

When the type of a value is *object*, the type checker will reject almost all operations on it, and assigning it to a variable (or using it as a return value) of a more specialized type is a type error. On the other hand, when a value has type *Any*, the type checker will allow all operations on it, and a value of type *Any* can be assigned to a variable (or used as a return value) of a more constrained type.
26.1.6. Classes, functions, and decorators

The module defines the following classes, functions and decorators:

```python
class typing.Any
    Special type indicating an unconstrained type.
    
    - Any object is an instance of `Any`.
    - Any class is a subclass of `Any`.
    - As a special case, `Any` and `object` are subclasses of each other.

class typing.TypeVar
    Type variable.
```

Usage:

```python
T = TypeVar('T')  # Can be anything
A = TypeVar('A', str, bytes)  # Must be str or by
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function definitions. See class Generic for more information on generic types. Generic functions work as follows:

```python
def repeat(x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x""
    return [x] * n

def longest(x: A, y: A) -> A:
    """Return the longest of two strings.""
    return x if len(x) >= len(y) else y
```

```
The latter example’s signature is essentially the overloading of (str, str) -> str and (bytes, bytes) -> bytes. Also note that if the arguments are instances of some subclass of str, the return type is still plain str.

At runtime, isinstance(x, T) will raise TypeError. In general, isinstance() and issubclass() should not be used with types.

Type variables may be marked covariant or contravariant by passing covariant=True or contravariant=True. See PEP 484 for more details. By default type variables are invariant. Alternatively, a type variable may specify an upper bound using bound=<type>. This means that an actual type substituted (explicitly or implicitly) for the type variable must be a subclass of the boundary type, see PEP 484.

class typing.Union
Union type; Union[X, Y] means either X or Y.

To define a union, use e.g. Union[int, str]. Details:

- The arguments must be types and there must be at least one.

- Unions of unions are flattened, e.g.:

  ```python
  Union[Union[int, str], float] == Union[int, str]
  ```

- Unions of a single argument vanish, e.g.:

  ```python
  Union[int] == int  # The constructor actually
  ```
- Redundant arguments are skipped, e.g.:

  ```python
  Union[int, str, int] == Union[int, str]
  ```

- When comparing unions, the argument order is ignored, e.g.:

  ```python
  Union[int, str] == Union[str, int]
  ```

- If `Any` is present it is the sole survivor, e.g.:

  ```python
  Union[int, Any] == Any
  ```

- You cannot subclass or instantiate a union.

- You cannot write `Union[X][Y]`.

- You can use `Optional[X]` as a shorthand for `Union[X, None]`.

```python
class typing.Optional

Optional type.

Optional[X] is equivalent to Union[X, type(None)].
```

```python
class typing.Tuple

Tuple type; Tuple[X, Y] is the is the type of a tuple of two items with the first item of type X and the second of type Y.

Example: Tuple[T1, T2] is a tuple of two elements corresponding to type variables T1 and T2. Tuple[int, float, str] is a tuple of an int, a float and a string.

To specify a variable-length tuple of homogeneous type, use literal ellipsis, e.g. Tuple[int, ...].
```
class typing.Callable
Callable type; Callable[[int], str] is a function of (int) -> str.

The subscription syntax must always be used with exactly two values: the argument list and the return type. The argument list must be a list of types; the return type must be a single type.

There is no syntax to indicate optional or keyword arguments, such function types are rarely used as callback types. Callable[...], ReturnType] could be used to type hint a callable taking any number of arguments and returning ReturnType. A plain Callable is equivalent to Callable[...], Any].

class typing.Generic
Abstract base class for generic types.

A generic type is typically declared by inheriting from an instantiation of this class with one or more type variables. For example, a generic mapping type might be defined as:

class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.

This class can then be used as follows:

X = TypeVar('X')
Y = TypeVar('Y')

def lookup_name(mapping: Mapping[X, Y], key: X, d:
    try:
        return mapping[key]
except KeyError:
    return default

class typing.Iterable(Generic[T_co])
    A generic version of the collections.abc.Iterable.

class typing.Iterator(Iterable[T_co])
    A generic version of the collections.abc.Iterator.

class typing.SupportsInt
    An ABC with one abstract method __int__.

class typing.SupportsFloat
    An ABC with one abstract method __float__.

class typing.SupportsAbs
    An ABC with one abstract method __abs__ that is covariant in its return type.

class typing.SupportsRound
    An ABC with one abstract method __round__ that is covariant in its return type.

class typing.Reversible
    An ABC with one abstract method __reversed__ returning an Iterator[T_co].

class typing.Container(Generic[T_co])
    A generic version of collections.abc.Container.

class typing.AbstractSet(Sized, Iterable[T_co], Container[T_co])
A generic version of `collections.abc.Set`.

```python
class typing.MutableSet(AbstractSet[T])
```
A generic version of `collections.abc.MutableSet`.

```python
class typing.Mapping(Sized, Iterable[KT], Container[KT], Generic[VT_co])
```
A generic version of `collections.abc.Mapping`.

```python
class typing.MutableMapping(Mapping[KT, VT])
```
A generic version of `collections.abc.MutableMapping`.

```python
class typing.Sequence(Sized, Iterable[T_co], Container[T_co])
```
A generic version of `collections.abc.Sequence`.

```python
class typing.MutableSequence(Sequence[T])
```
A generic version of `collections.abc.MutableSequence`.

```python
class typing.ByteString(Sequence[int])
```
A generic version of `collections.abc.ByteString`.

This type represents the types `bytes`, `bytearray`, and `memoryview`.

As a shorthand for this type, `bytes` can be used to annotate arguments of any of the types mentioned above.

```python
class typing.List(list, MutableSequence[T])
```
Generic version of `list`. Useful for annotating return types. To annotate arguments it is preferred to use abstract collection types such as `Mapping`, `Sequence`, or `AbstractSet`.

This type may be used as follows:
\[ T = \text{TypeVar}'T', \text{int}, \text{float} \]

def vec2(x: T, y: T) -> List[T]:
    return [x, y]

def slice__to_4(vector: Sequence[T]) -> List[T]:
    return vector[0:4]

class typing.AbstractSet(set, MutableSet[T])
    A generic version of collections.abc.Set.

class typing.MappingView(Sized, Iterable[T_co])
    A generic version of collections.abc.MappingView.

class typing.KeysView(MappingView[KT_co], AbstractSet[KT_co])
    A generic version of collections.abc.KeysView.

class typing.ItemsView(MappingView[KT_co], Generic[KT_co, VT_co])
    A generic version of collections.abc.ItemsView.

class typing.ValuesView(MappingView[VT_co])
    A generic version of collections.abc.ValuesView.

class typing.Dict(dict, MutableMapping[KT, VT])
    A generic version of dict. The usage of this type is as follows:

def get_position_in_index(word_list: Dict[str, int]):
    return word_list[word]

class typing.Generator(Iterator[T_co], Generic[T_co, T_contra, V_co])
class typing.io
Wrapper namespace for I/O stream types.

This defines the generic type IO[AnyStr] and aliases TextIO and BinaryIO for respectively IO[str] and IO[bytes]. These representing the types of I/O streams such as returned by open().

class typing.re
Wrapper namespace for regular expression matching types.

This defines the type aliases Pattern and Match which correspond to the return types from re.compile() and re.match(). These types (and the corresponding functions) are generic in AnyStr and can be made specific by writing Pattern[str], Pattern[bytes], Match[str], or Match[bytes].

typing.NamedTuple(typename, fields)
Typed version of namedtuple.

Usage:

```
Employee = typing.NamedTuple('Employee', [('name', str), ('age', int)])
```

This is equivalent to:

```
Employee = collections.namedtuple('Employee', ['name', 'age'])
```

The resulting class has one extra attribute: _field_types, giving a dict mapping field names to types. (The field names are in the _fields attribute, which is part of the namedtuple API.)
typing.cast(typ, val)
Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don’t check anything (we want this to be as fast as possible).

typing.get_type_hints(obj)
Return type hints for a function or method object.

This is often the same as obj.__annotations__, but it handles forward references encoded as string literals, and if necessary adds Optional[t] if a default value equal to None is set.

@typing.no_type_check(arg)
Decorator to indicate that annotations are not type hints.

The argument must be a class or function; if it is a class, it applies recursively to all methods defined in that class (but not to methods defined in its superclasses or subclasses).

This mutates the function(s) in place.

@typing.no_type_check_decorator(decorator)
Decorator to give another decorator the no_type_check() effect.

This wraps the decorator with something that wraps the decorated function in no_type_check().
The Python Software Foundation is a non-profit corporation. Please donate.

Last updated on Dec 06, 2015. Found a bug?

Created using Sphinx 1.3.1.
26.2. **pydoc** — Documentation generator and online help system

**Source code**: Lib/pydoc.py

The **pydoc** module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, **pydoc** tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function `help()` invokes the online help system in the interactive interpreter, which uses **pydoc** to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running **pydoc** as a script at the operating system’s command prompt. For example, running

```bash
pydoc sys
```

at a shell prompt will display documentation on the `sys` module, in a style similar to the manual pages shown by the Unix `man` command. The argument to **pydoc** can be the name of a function, module, or
package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to pydoc looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

**Note:** In order to find objects and their documentation, pydoc imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an if

```python
__name__ == '__main__':
```

guard to only execute code when a file is invoked as a script and not just imported.

When printing output to the console, pydoc attempts to paginate the output for easier reading. If the PAGER environment variable is set, pydoc will use its value as a pagination program.

Specifying a -w flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a -k flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix man command. The synopsis line of a module is the first line of its documentation string.

You can also use pydoc to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. pydoc -p 1234 will start a HTTP server on port 1234, allowing you to browse the documentation at http://localhost:1234/ in your preferred Web browser. Specifying 0 as the port number will select an arbitrary unused port.
pydoc -b will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can Get help on an individual item, Search all modules with a keyword in their synopsis line, and go to the Module index, Topics and Keywords pages.

When pydoc generates documentation, it uses the current environment and path to locate modules. Thus, invoking pydoc spam documents precisely the version of the module you would get if you started the Python interpreter and typed import spam.

Module docs for core modules are assumed to reside in https://docs.python.org/X.Y/library/ where X and Y are the major and minor version numbers of the Python interpreter. This can be overridden by setting the PYTHONDONTCS environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

*Changed in version 3.2:* Added the -b option.

*Changed in version 3.3:* The -g command line option was removed.

*Changed in version 3.4:* pydoc now uses inspect.signature() rather than inspect.getfullargspec() to extract signature information from callables.
26.3. doctest — Test interactive Python examples

The doctest module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
"""
This is the "example" module.

The example module supplies one function, factorial().

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >

>>> [factorial(n) for n in range(6)]
[1, 1, 2, 6, 24, 120]
```
>>> factorial(30)
2652528598121910586363084800000000
>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must
>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer
>>> factorial(30.0)
2652528598121910586363084800000000

It must also not be ridiculously large:
>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result
If you run `example.py` directly from the command line, `doctest` works its magic:

```bash
$ python example.py
$ 
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```bash
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```bash
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
      ...
    OverflowError: n too large
ok
```
2 items passed all tests:
  1 tests in __main__
  8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$

That's all you need to know to start making productive use of \texttt{doctest}! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file \texttt{Lib/test/test_doctest.py}. 
26.3.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module M with:

```python
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

doctest then examines docstrings in module M.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```bash
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is ***Test Failed*** N failures., where N is the number of examples that failed.

Run it with the -v switch instead:

```bash
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing verbose=True to testmod(), or prohibit it by passing verbose=False. In either of those cases, sys.argv is not examined by testmod() (so passing -
v or not has no effect).

There is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import example.py as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section Basic API.
26.3.2. Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn’t need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
======================

Using ``factorial``
-----------------

This is an example text file in reStructuredText for ``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the error
As with \texttt{testmod()}, \texttt{testfile()} won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as \texttt{testmod()}.

By default, \texttt{testfile()} looks for files in the calling module's directory. See section \texttt{Basic API} for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like \texttt{testmod()}, \texttt{testfile()}'s verbosity can be set with the \texttt{-v} command-line switch or with the optional keyword argument \texttt{verbose}.

There is also a command line shortcut for running \texttt{testfile()}. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

\begin{verbatim}
python -m doctest -v example.txt
\end{verbatim}

Because the file name does not end with \texttt{.py}, \texttt{doctest} infers that it must be run with \texttt{testfile()}, not \texttt{testmod()}.

For more information on \texttt{testfile()}, see section \texttt{Basic API}. 
26.3.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

26.3.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if M.__test__ exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from M.__test__ are searched, and strings are treated as if they were docstrings. In output, a key K in M.__test__ appears with name

<name of M>.__test__.K

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

**CPython implementation detail:** Prior to version 3.4, extension modules written in C were not fully searched by doctest.

26.3.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session
works fine, but doctest isn't trying to do an exact emulation of any specific Python shell.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print("yes")
... else:
...     print("no")
...     print("NO")
...     print("NO!!!")
no
NO
NO!!!
```
NORMALIZE_WHITESPACE option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom DocTestParser class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

  ```python
  >>> def f(x):
  ...     r'''Backslashes in a raw docstring: m\n'''
  >>> print(f.__doc__)
  Backslashes in a raw docstring: m
  ```

  Otherwise, the backslash will be interpreted as part of the string. For example, the \n above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

  ```python
  >>> def f(x):
  ...     '''Backslashes in a raw docstring: m\n'''
  >>> print(f.__doc__)
  Backslashes in a raw docstring: m
  ```

- The starting column doesn’t matter:
```python
>>> assert "Easy!"
>>> import math
>>> math.floor(1.9)
1
```

and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

26.3.3.3. What’s the Execution Context?

By default, each time doctest finds a docstring to test, it uses a shallow copy of M’s globals, so that running tests doesn’t change the module’s real globals, and so that one test in M can’t leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing globs=your_dict to testmod() or testfile() instead.

26.3.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:
That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi
 line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: multi
 line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception’s type and detail, and the rest are ignored.
Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```python
>>> raise ValueError('multi
   line\ndetail')
ValueError: multi
   line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of ... is independent of doctest's ELLIPSIS option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
• When the **IGNORE_EXCEPTION_DETAIL** doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.

• The interactive shell omits the traceback header line for some *SyntaxErrors*. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a *SyntaxError* that omits the traceback header, you will need to manually add the traceback header line to your test example.

• For some *SyntaxErrors*, Python displays the character position of the syntax error, using a ^ marker:

```python
>>> 1 1
    File "<stdin>", line 1
    1 1
^  
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the ^ marker in the wrong location:

```python
>>> 1 1
    File "<stdin>", line 1
    1 1
^  
SyntaxError: invalid syntax
```

26.3.3.5. Option Flags
A number of option flags control various aspects of doctest’s behavior. Symbolic names for the flags are supplied as module constants, which can be or’ed together and passed to various functions. The names can also be used in doctest directives, and may be passed to the doctest command line interface via the -o option.

New in version 3.4: The -o command line option.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example’s expected output:

**doctest.**

**DONT_ACCEPT_TRUE_FOR_1**

By default, if an expected output block contains just 1, an actual output block containing just 1 or just True is considered to be a match, and similarly for 0 versus False. When **DONT_ACCEPT_TRUE_FOR_1** is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest.**

**DONT_ACCEPT_BLANKLINE**

By default, if an expected output block contains a line containing only the string <BLANKLINE>, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When **DONT_ACCEPT_BLANKLINE** is specified, this substitution is not allowed.

**doctest.**

**NORMALIZE_WHITESPACE**

When specified, all sequences of whitespace (blanks and
newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. NORMALIZE_WHITESPACE is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

doctest.ELLIPSIS
When specified, an ellipsis marker (...) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that .* is prone to in regular expressions.

doctest.IGNORE_EXCEPTION_DETAIL
When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting ValueError: 42 will pass if the actual exception raised is ValueError: 3*14, but will fail, e.g., if TypeError is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```python
>>> raise CustomError('message')
Traceback (most recent call last):
  CustomError: message

>>> raise CustomError('message')
Traceback (most recent call last):
```
my_module.CustomError: message

Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using **IGNORE_EXCEPTION_DETAIL** and the details from Python 2.3 is also the only clear way to write a doctest that doesn’t care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support doctest directives and ignore them as irrelevant comments). For example:

```
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say “does not” instead of “doesn’t”.

*Changed in version 3.2:* **IGNORE_EXCEPTION_DETAIL** now also ignores any information relating to the module containing the exception under test.

**doctest.SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out”
doctest.COMPARISON_FLAGS

A bitmask or‘ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.REPORT_UDIFF

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.REPORT_CDIFF

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.REPORT_NDIFF

When specified, differences are computed by difflib.Differ, using the same algorithm as the popular ndiff.py utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

doctest.REPORT_ONLY_FIRST_FAILURE

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When REPORT_ONLY_FIRST_FAILURE is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.
`doctest.FAIL_FAST`
When specified, exit after the first failing example and don’t attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won’t even produce debugging output.

The doctest command line accepts the option `-f` as a shorthand for `-o FAIL_FAST`.

*New in version 3.4.*

`doctest.REPORTING_FLAGS`
A bitmask or’ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn’t useful unless you intend to extend `doctest` internals via subclassing:

`doctest.register_optionflag(name)`
Create a new option flag with a given name, and return the new flag’s integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```python
MY_FLAG = register_optionflag('MY_FLAG')
```

### 26.3.3.6. Directives

Doctest directives may be used to modify the option flags for an individual example. Doctest directives are special Python comments
following an example's source code:

```
directive ::= "#" "doctest:" directive
directive_options ::= directive_option ("," directive_option)*
directive_option ::= on_or_off directive_option_name
on_or_off ::= "+" | "-
directive_option_name ::= "DONT_ACCEPT_BLANKLINE" | "NORMALIZE_WHITESPACE" |
...
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

For example, this test passes:

```
>>> print(list(range(20)))  # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
```

If multiple directive comments are used for a single example, then they are combined:

```python
>>> print(list(range(20)))  # doctest: +ELLIPSIS
...  # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add ... lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```python
>>> print(list(range(5)) + list(range(10, 20)) + list(... # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via + in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via - in a directive can be useful.

### 26.3.3.7. Warnings

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn’t match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn’t guarantee about output. For example, when printing a dict, Python doesn’t guarantee that the key-value pairs will be
printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = sorted(foo().items())
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds
<__main__.C instance at 0x00AC18F0>
```

The ELLIPSIS directive gives a nice approach for the last example:

```python
>>> C()  # doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for
float formatting, and C libraries vary widely in quality here.

```python
>>> 1./7  # risky
0.14285714285714285
>>> print(1./7)  # safer
0.142857142857
>>> print(round(1./7, 6))  # much safer
0.142857
```

Numbers of the form I/2.**J are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```python
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.
26.3.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

```python
import doctest
doctest.testfile(filename, module_relative=True, name=None, package=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, parser=DocTestParser(), encoding=None)
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.  

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is True (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is False, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.
Optional argument *name* gives the name of the test; by default, or if None, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is False.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if None, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if None, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if None, it's true if and only if '-v' is in `sys.argv`.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).
Optional argument *optionflags* (default value 0) takes the bitwise-or of option flags. See section *Option Flags*.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a DocTestParser (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., DocTestParser()).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

doctest.testmod(m=None, name=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, exclude_empty=False)

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is None), starting with *m.__doc__*.  

Also test examples reachable from dict *m.__test__*, if it exists and is not None. *m.__test__* maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (*failure_count*, *test_count*).
Optional argument *name* gives the name of the module; by default, or if None, `m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The *exclude_empty* argument to the newer `DocTestFinder` constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise_on_error*, and *globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

```python
doctest.run_docstring_examples(f, globs, verbose=False, name="NoName", compileflags=None, optionflags=0)
```

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By
default, or if None, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function *testfile()* above.
26.3.5. Unittest API

As your collection of doctest’ed modules grows, you’ll want a way to run all their doctests systematically. `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

`doctest.DocFileSuite(*paths, module_relative=True, package=None, setUp=None, tearDown=None, globs=None, optionflags=0, parser=DocTestParser(), encoding=None)`

- Convert doctest tests from one or more text files to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the `unittest` framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.
Options may be provided as keyword arguments:

Optional argument `module_relative` specifies how the filenames in `paths` should be interpreted:

- If `module_relative` is `True` (the default), then each filename in `paths` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then each filename in `paths` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in `paths`. If no package is specified, then the calling module’s directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `setUp` specifies a set-up function for the test suite. This is called before running the tests in each file. The `setUp` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The `tearDown` function can access the test globals as the `globs` attribute of the test passed.
Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section *Option Flags*. See function *set_unittest_reportflags()* below for a better way to set reporting options.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global __file__ is added to the globals provided to doctests loaded from a text file using *DocFileSuite()*.

doctest.*DocTestSuite*(module=None, globs=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None)

Convert doctest tests for a module to a *unittest.TestSuite*.

The returned *unittest.TestSuite* is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a *failureException* exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not
specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the `DocTestFinder` object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function `DocFileSuite()` above.

This function uses the same search technique as `testmod()`.

*Changed in version 3.5:* `DocTestSuite()` returns an empty `unittest.TestSuite` if *module* contains no docstrings instead of raising `ValueError`.

Under the covers, `DocTestSuite()` creates a `unittest.TestSuite` out of doctest.DoctestCase instances, and `DocTestCase` is a subclass of `unittest.TestCase`. `DocTestCase` isn’t documented here (it’s an internal detail), but studying its code can answer questions about the exact details of `unittest` integration.

Similarly, `DocFileSuite()` creates a `unittest.TestSuite` out of doctest.DocFileCase instances, and `DocFileCase` is a subclass of `DocTestCase`. 
So both ways of creating a `unittest.TestSuite` run instances of DocTestCase. This is important for a subtle reason: when you run doctest functions yourself, you can control the doctest options in use directly, by passing option flags to doctest functions. However, if you're writing a unittest framework, unittest ultimately controls when and how tests get run. The framework author typically wants to control doctest reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through unittest to doctest test runners.

For this reason, doctest also supports a notion of doctest reporting flags specific to unittest support, via this function:

```python
doctest.set_unittest_reportflags(flags)

Set the doctest reporting flags to use.

Argument flags takes the bitwise-or of option flags. See section Option Flags. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module unittest: the runTest() method of DocTestCase looks at the option flags specified for the test case when the DocTestCase instance was constructed. If no reporting flags were specified (which is the typical and expected case), doctest's unittest reporting flags are or’ed into the option flags, and the option flags so augmented are passed to the DocTestRunner instance created to run the doctest. If any reporting flags were specified when the DocTestCase instance was constructed, doctest's unittest reporting flags are ignored.

The value of the unittest reporting flags in effect before the function was called is returned by the function.
26.3.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python **statement**, paired with its expected output.
- **DocTest**: A collection of **Examples**, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a **DocTestParser** to create a **DocTest** from every docstring that contains interactive examples.
- **DocTestParser**: Creates a **DocTest** object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a **DocTest**, and uses an **OutputChecker** to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
26.3.6.1. DocTest Objects

class doctest.DocTest(examples, globs, name, filename, lineno, docstring)

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

DocTest defines the following attributes. They are initialized by the constructor, and should not be modified directly.

examples
A list of Example objects encoding the individual interactive Python examples that should be run by this test.

globs
The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in globs after the test is run.

name
A string name identifying the DocTest. Typically, this is the
name of the object or file that the test was extracted from.

**filename**
The name of the file that this `DocTest` was extracted from; or None if the filename is unknown, or if the `DocTest` was not extracted from a file.

**lineno**
The line number within `filename` where this `DocTest` begins, or None if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**
The string that the test was extracted from, or ‘None’ if the string is unavailable, or if the test was not extracted from a string.

### 26.3.6.2. Example Objects

```python
class doctest.Example(source, want, exc_msg=None, lineno=0, indent=0, options=None)
```

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

`Example` defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**
A string containing the example’s source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.
**want**

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). `want` ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

**exc_msg**

The exception message generated by the example, if the example is expected to generate an exception; or None if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. `exc_msg` ends with a newline unless it's None. The constructor adds a newline if needed.

**lineno**

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**

A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the `DocTestRunner`'s `optionflags`). By default, no options are set.
26.3.6.3. DocTestFinder objects

class doctest.DocTestFinder(verbos\ed=False, parser=DocTestParser(), recurse=True, exclude_empty=True)

A processing class used to extract the DocTests that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTests can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

DocTestFinder defines the following method:

find(obj[, name][, module][, globs][, extraglobs])

Return a list of the DocTests that are defined by obj's docstring, or by any of its contained objects' docstrings.

The optional argument name specifies the object's name; this
name will be used to construct names for the returned DocTests. If name is not specified, then obj.__name__ is used.

The optional parameter module is the module that contains the given object. If the module is not specified or is None, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if globs is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than module are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If module is False, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if module is False, or is None but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each DocTest is formed by combining globs and extraglobs (bindings in extraglobs override bindings in globs). A new shallow copy of the globals dictionary is created for each DocTest. If globs is not specified, then it defaults to the module’s __dict__, if specified, or {} otherwise. If extraglobs is not specified, then it defaults to {}.

26.3.6.4. DocTestParser objects
**class** doctest.**DocTestParser**

A processing class used to extract interactive examples from a string, and use them to create a **DocTest** object.

**DocTestParser** defines the following methods:

**get_doctest**(string, globs, name, filename, lineno)

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

* globs, name, filename, and lineno are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples**(string, name='<string>')

Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse**(string, name='<string>')

Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

---

### 26.3.6.5. DocTestRunner objects

**class** doctest.**DocTestRunner**(checker=None, verbose=None, optionflags=0)

A processing class used to execute and verify the interactive
examples in a DocTest.

The comparison between expected outputs and actual outputs is
done by an OutputChecker. This comparison may be customized
with a number of option flags; see section Option Flags for more
information. If the option flags are insufficient, then the comparison
may also be customized by passing a subclass of OutputChecker to the constructor.

The test runner’s display output can be controlled in two ways.
First, an output function can be passed to TestRunner.run();
this function will be called with strings that should be displayed. It
defaults to sys.stdout.write. If capturing the output is not
sufficient, then the display output can be also customized by
subclassing DocTestRunner, and overriding the methods
report_start(), report_success(), report_unexpected_exception(), and report_failure().

The optional keyword argument checker specifies the
OutputChecker object (or drop-in replacement) that should be
used to compare the expected outputs to the actual outputs of
doctest examples.

The optional keyword argument verbose controls the
DocTestRunner’s verbosity. If verbose is True, then information
is printed about each example, as it is run. If verbose is False,
then only failures are printed. If verbose is unspecified, or None,
then verbose output is used iff the command-line switch -v is used.

The optional keyword argument optionflags can be used to control
how the test runner compares expected output to actual output,
and how it displays failures. For more information, see section
Option Flags.

**DocTestParser** defines the following methods:

**report_start**(out, test, example)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_success**(out, test, example, got)

Report that the given example ran successfully. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**report_failure**(out, test, example, got)

Report that the given example failed. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.
**report_unexpected_exception***(out, test, example, exc_info)***

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *exc_info* is a tuple containing information about the unexpected exception (as returned by **sys.exc_info()**). *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

**run**(test, compileflags=None, out=None, clear_globs=True)

Run the examples in *test* (a **DocTest** object), and display the results using the writer function *out*.

The examples are run in the namespace *test.globs*. If *clear_globs* is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use *clear_globs=False*.

*compileflags* gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to *globs*.

The output of each example is checked using the **DocTestRunner**'s output checker, and the results are formatted by the **DocTestRunner.report_*()** methods.

**summarize**(verbose=None)
Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple 
TestResults(failed, attempted).

The optional verbose argument controls how detailed the summary is. If the verbosity is not specified, then the DocTestRunner's verbosity is used.

26.3.6.6. OutputChecker objects

class doctest.OutputChecker
A class used to check the whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: check_output(), which compares a given pair of outputs, and returns true if they match; and output_difference(), which returns a string describing the differences between two outputs.

OutputChecker defines the following methods:

check_output(want, got, optionflags)
Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags for more information about option flags.

output_difference(example, got, optionflags)
Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare
want and got.
26.3.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```
"
>>> def f(x):
...    g(x*2)
>>> def g(x):
...    print(x+3)
...    import pdb; pdb.set_trace()
>>> f(3)
g
"
```

Then an interactive Python session may look like this:
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
  1   def g(x):
  2       print(x+3)
  3   ->   import pdb; pdb.set_trace()
[EOF]
(Pdb) p x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()->None
-> g(x*2)
(Pdb) list
  1   def f(x):
  2   -> g(x*2)
[EOF]
(Pdb) p x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)
>>>

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

doctest.script_from_examples(s)

Convert text with examples to a script.
Argument `s` is a string containing doctest examples. The string is converted to a Python script, where doctest examples in `s` are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```python
import doctest
print(doctest.script_from_examples(r""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
""))
```

displays:

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

**doctest.testsource**(module, name)

Convert the doctest for an object to a script.

Argument `module` is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument
name is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for script_from_examples() above. For example, if module a.py contains a top-level function f(), then

```python
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function f()'s docstring, with doctests converted to code, and the rest placed in comments.

doctest.debug(module, name, pm=False)

Debug the doctests for an object.

The module and name arguments are the same as for function testsource() above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, pdb.

A shallow copy of module.__dict__ is used for both local and global execution context.

Optional argument pm controls whether post-mortem debugging is used. If pm has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via pdb.post_mortem(), passing the traceback object from the unhandled exception. If pm is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate exec() call to pdb.run().

doctest.debug_src(src, pm=False, globs=None)
Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.

Optional argument `pm` has the same meaning as in function `debug()` above.

Optional argument `globs` gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest.DebugRunner(checker=None, verbose=None, optionflags=0)
```

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section Advanced API.

There are two exceptions that may be raised by `DebugRunner` instances:
exception doctest.**DocTestFailure**(test, example, got)

An exception raised by **DocTestRunner** to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

**DocTestFailure** defines the following attributes:

**DocTestFailure**.**test**

The **DocTest** object that was being run when the example failed.

**DocTestFailure**.**example**

The **Example** that failed.

**DocTestFailure**.**got**

The example's actual output.

exception doctest.**UnexpectedException**(test, example, exc_info)

An exception raised by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

**UnexpectedException** defines the following attributes:

**UnexpectedException**.**test**

The **DocTest** object that was being run when the example failed.

**UnexpectedException**.**example**

The **Example** that failed.

**UnexpectedException**.**exc_info**

A tuple containing information about the unexpected exception, as
returned by `sys.exc_info()`.
26.3.8. Soapbox

As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what’s actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It’s true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper
than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It’s a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```python
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
```
```
obj = globals()[name]

else:
    obj = __test__[name]
doctest.run_docstring_examples(obj, globals(), optionflags=flags)

else:
    fail, total = doctest.testmod(optionflags=flags)
    print("{} failures out of {} tests".format(fail, total))
```

Footnotes

Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

[1]
26.4. **unittest** — Unit testing framework

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The **unittest** unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, **unittest** supports some important concepts in an object-oriented way:

**test fixture**

A *test fixture* represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case**

A *test case* is the individual unit of testing. It checks for a specific response to a particular set of inputs. **unittest** provides a base class, **TestCase**, which may be used to create new test cases.

**test suite**

A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner**

A *test runner* is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a
graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

**Module doctest**
Another test-support module with a very different flavor.

**Simple Smalltalk Testing: With Patterns**
Kent Beck’s original paper on testing frameworks using the pattern shared by `unittest`.

**Nose and py.test**
Third-party unittest frameworks with a lighter-weight syntax for writing tests. For example, `assert func(10) == 42`.

**The Python Testing Tools Taxonomy**
An extensive list of Python testing tools including functional testing frameworks and mock object libraries.

**Testing in Python Mailing List**
A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot, Jenkins or Hudson.
26.4.1. Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```python
import unittest

class TestStringMethods(unittest.TestCase):
    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.
The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more details in the section Organizing test code.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```python
... ---------------------------------------------------------------------- Ran 3 tests in 0.000s OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce the following output:

```python
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok

----------------------------------------------------------------------
Ran 3 tests in 0.001s
OK
```

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
26.4.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the ‘.py’ and converting path separators into ‘.’. If you want to execute a test file that isn’t importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the -v flag:

```
python -m unittest -v test_module
```

When executed without arguments Test Discovery is started:

```
python -m unittest
```
For a list of all the command-line options:

```
python -m unittest -h
```

*Changed in version 3.2:* In earlier versions it was only possible to run individual test methods and not modules or classes.

### 26.4.2.1. Command-line options

`unittest` supports these command-line options:

- **-b, --buffer**
  
  The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

- **-c, --catch**
  
  Control-C during the test run waits for the current test to end and then reports all the results so far. A second Control-C raises the normal `KeyboardInterrupt` exception.

  See [Signal Handling](#) for the functions that provide this functionality.

- **-f, --failfast**
  
  Stop the test run on the first error or failure.

- **--locals**
  
  Show local variables in tracebacks.

*New in version 3.2:* The command-line options `-b`, `-c` and `-f` were added.
New in version 3.5: The command-line option `--locals`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
26.4.3. Test Discovery

New in version 3.2.

unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages (including namespace packages) importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in TestLoader.discover(), but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

**Note:** As a shortcut, python -m unittest is the equivalent of python -m unittest discover. If you want to pass arguments to test discovery the discover sub-command must be used explicitly.

The discover sub-command has the following options:

- **-v, --verbose**
 Verbose output

- **-s, --start-directory directory**
  Directory to start discovery (. default)

- **-p, --pattern pattern**
  Pattern to match test files (test*.py default)
-t, --top-level-directory directory
Top level directory of project (defaults to start directory)

The -s, -p, and -t options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example myproject.subpackage.test, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example foo/bar/baz.py will be imported as foo.bar.baz.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the load_tests protocol.

*Changed in version 3.4:* Test discovery supports namespace
packages.
26.4.4. Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In unittest, test cases are represented by unittest.TestCase instances. To make your own test cases you must write subclasses of TestCase or use FunctionTestCase.

The testing code of a TestCase instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest TestCase subclass will simply implement a test method (i.e. a method whose name starts with test) in order to perform specific testing code:

```python
import unittest
class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the assert*() methods provided by the TestCase base class. If the test fails, an exception will be raised, and unittest will identify the test case as a failure. Any other exceptions will be treated as errors.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called setUp(), which the testing framework will automatically call for every single test we run:
import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

Note: The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the setUp() method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a tearDown() method that tidies up after the test method has been run:

import unittest

class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *fixture*.

Test case instances are grouped together according to the features they test. *unittest* provides a mechanism for this: the *test suite*, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module’s test cases for you, and then execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules
anyway, so why not be consistent?
• If the testing strategy changes, there is no need to change the source code.
26.4.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from unittest, without converting every old test function to a TestCase subclass.

For this reason, unittest provides a FunctionTestCase class. This subclass of TestCase can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```python
testcase = unittest.FunctionTestCase(testSomething, setUp=makeSomethingDB, tearDown=deleteSomethingDB)
```

**Note:** Even though FunctionTestCase can be used to quickly convert an existing test base over to a unittest-based system, this approach is not recommended. Taking the time to set up proper TestCase subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the
doctest module. If so, doctest provides a DocTestSuite class that can automatically build unittest.TestSuite instances from the existing doctest-based tests.
26.4.6. Skipping tests and expected failures

*New in version 3.1.*

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a `TestResult`.

Skipping a test is simply a matter of using the `skip()` decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library")
    def test_format(self):
        # Tests that work for only a certain version
        pass

    @unittest.skipUnless(sys.platform.startswith("win"),
                         "windows specific testing code")
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:
test_format (__main__.MyTestCase) ... skipped 'not supported in this library version'

Ran 3 tests in 0.005s

OK (skipped=3)

Classes can be skipped just like methods:

```python
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator:

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
```
The following decorators implement test skipping and expected failures:

```python
return unittest.skip("{!r} doesn't have {!r}".format(name, error))
```

@unittest.skip(reason)
Unconditionally skip the decorated test. reason should describe why the test is being skipped.

@unittest.skipIf(condition, reason)
Skip the decorated test if condition is true.

@unittest.skipUnless(condition, reason)
Skip the decorated test unless condition is true.

@unittest.expectedFailure
Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

```python
exception unittest.SkipTest(reason)
This exception is raised to skip a test.
```

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run. Skipped modules will not have `setUpModule()` or `tearDownModule()` run.
26.4.7. Distinguishing test iterations using subtests

New in version 3.4.

When some of your tests differ only by a some very small differences, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the `subTest()` context manager.

For example, the following test:

```python
class NumbersTest(unittest.TestCase):
    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even
        """
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
FAIL: test_even (__main__.NumbersTest) (i=1)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

FAIL: test_even (__main__.NumbersTest) (i=3)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

FAIL: test_even (__main__.NumbersTest) (i=5)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of i wouldn’t be displayed:
26.4.8. Classes and functions

This section describes in depth the API of unittest.

26.4.8.1. Test cases

class unittest.TestCase(methodName='runTest')

Instances of the TestCase class represent the logical test units in the unittest universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of TestCase will run a single base method: the method named methodName. In most uses of TestCase, you will neither change the methodName nor reimplement the default runTest() method.

Changed in version 3.2: TestCase can be instantiated successfully without providing a methodName. This makes it easier to experiment with TestCase from the interactive interpreter.

TestCase instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

setUp()
Method called to prepare the test fixture. This is called immediately before calling the test method; other than \texttt{AssertionError} or \texttt{SkipTest}, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

\texttt{tearDown()}

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than \texttt{AssertionError} or \texttt{SkipTest}, raised by this method will be considered an error rather than a test failure. This method will only be called if the \texttt{setUp()} succeeds, regardless of the outcome of the test method. The default implementation does nothing.

\texttt{setUpClass()}

A class method called before tests in an individual class run. \texttt{setUpClass} is called with the class as the only argument and must be decorated as a \texttt{classmethod}:

\begin{verbatim}
@classmethod
def setUpClass(cls):
    ...
\end{verbatim}

See \texttt{Class and Module Fixtures} for more details.

\textit{New in version 3.2.}

\texttt{tearDownClass()}

A class method called after tests in an individual class have run.
tearDownClass is called with the class as the only argument and must be decorated as a `classmethod()`:  

```python
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

_New in version 3.2._

**run**(result=None)

Run the test, collecting the result into the `TestResult` object passed as `result`. If `result` is omitted or None, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

_Changed in version 3.3:_ Previous versions of `run` did not return the result. Neither did calling an instance.

**skipTest**(reason)

Calling this during a test method or `setUp()` skips the current test. See [Skipping tests and expected failures](#) for more information.

_New in version 3.1._

**subTest**(msg=None, **params)

Return a context manager which executes the enclosed code
block as a subtest. msg and params are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See Distinguishing test iterations using subtests for more information.

New in version 3.4.

debug()
Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The TestCase class provides a number of methods to check for and report failures, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td>assertEqual(a, b)</td>
<td>a == b</td>
<td></td>
</tr>
<tr>
<td>assertNotEqual(a, b)</td>
<td>a != b</td>
<td></td>
</tr>
<tr>
<td>assertTrue(x)</td>
<td>bool(x) is True</td>
<td></td>
</tr>
<tr>
<td>assertFalse(x)</td>
<td>bool(x) is False</td>
<td></td>
</tr>
<tr>
<td>assertIs(a, b)</td>
<td>a is b</td>
<td>3.1</td>
</tr>
<tr>
<td>assertIsNot(a, b)</td>
<td>a is not b</td>
<td>3.1</td>
</tr>
<tr>
<td>assertIsNone(x)</td>
<td>x is None</td>
<td>3.1</td>
</tr>
<tr>
<td>assertIsNotNone(x)</td>
<td>x is not None</td>
<td>3.1</td>
</tr>
<tr>
<td>assertIn(a, b)</td>
<td>a in b</td>
<td>3.1</td>
</tr>
</tbody>
</table>
assertNotIn(a, b)

a not in b 3.1

assertIsInstance(a, b)

isinstance(a, b) 3.2

assertNotIsInstance(a, b)

not isinstance(a, b) 3.2

All the assert methods accept a msg argument that, if specified, is used as the error message on failure (see also longMessage). Note that the msg keyword argument can be passed to assertRaises(), assertRaisesRegex(), assertWarns(), assertWarnsRegex() only when they are used as a context manager.

**assertEqual(first, second, msg=None)**

Test that first and second are equal. If the values do not compare equal, the test will fail.

In addition, if first and second are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with addTypeEqualityFunc() the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

*Changed in version 3.1:* Added the automatic calling of type-specific equality function.

*Changed in version 3.2:* assertMultiLineEqual() added as the default type equality function for comparing strings.

**assertNotEqual(first, second, msg=None)**

Test that first and second are not equal. If the values do
compare equal, the test will fail.

**assertTrue**(expr, msg=None)
**assertFalse**(expr, msg=None)

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr)` is True and not to `expr` is True (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

**assertIs**(first, second, msg=None)
**assertIsNot**(first, second, msg=None)

Test that *first* and *second* evaluate (or don’t evaluate) to the same object.

*New in version 3.1.*

**assertIsNone**(expr, msg=None)
**assertIsNotNone**(expr, msg=None)

Test that *expr* is (or is not) None.

*New in version 3.1.*

**assertIn**(first, second, msg=None)
**assertNotIn**(first, second, msg=None)

Test that *first* is (or is not) in *second*.

*New in version 3.1.*

**assertIsInstance**(obj, cls, msg=None)
**assertNotIsInstance**(obj, cls, msg=None)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls)`.

*New in version 3.2.*

It is also possible to check the production of exceptions, warnings and log messages using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertRaises(exc, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRaisesRegexp(exc, r, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc</code> and the message matches regex <em>r</em></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertWarns(warn, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises warn</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertWarnsRegexp(warn, r, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises warn</code> and the message matches regex <em>r</em></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertLogs(logger, level)</code></td>
<td>The with block logs on <em>logger</em> with minimum <em>level</em></td>
<td>3.4</td>
</tr>
</tbody>
</table>

**assertRaises**(exception, callable, *args, **kwds)

**assertRaises**(exception, msg=None)

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to
**assertRaises()**. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, **assertRaises()** accepts the additional keyword argument *msg*.

The context manager will store the caught exception object in its exception attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()
the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 3.1:* Added the ability to use **assertRaises()** as a context manager.

*Changed in version 3.2:* Added the exception attribute.

*Changed in version 3.3:* Added the *msg* keyword argument when used as a context manager.

**assertRaisesRegex**(*exception*, *regex*, *callable*, *args*, *kwargs*, *match*):

.. automethod:: unittest.TestCase.assertRaisesRegex
**kwds)

`assertRaisesRegex(exception, regex, msg=None)`

Like `assertRaises()` but also tests that `regex` matches on the string representation of the raised exception. `regex` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```
self.assertRaisesRegex(ValueError, "invalid literal for \.
int, 'XYZ'")
```

or:

```
with self.assertRaisesRegex(ValueError, 'literal'
int('XYZ')
```

*New in version 3.1:* under the name `assertRaisesRegexp`.

*Changed in version 3.2:* Renamed to `assertRaisesRegex()`.

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

`assertWarns(warning, callable, *args, **kwds)`

`assertWarns(warning, msg=None)`

Test that a warning is triggered when `callable` is called with any positional or keyword arguments that are also passed to `assertWarns()`. The test passes if `warning` is triggered and fails if it isn’t. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as `warnings`.

If only the `warning` and possibly the `msg` arguments are given,
return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, `assertWarns()` accepts the additional keyword argument `msg`.

The context manager will store the caught warning object in its `warning` attribute, and the source line which triggered the warnings in the `filename` and `lineno` attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```python
with self.assertWarns(SomeWarning) as cm:
    do_something()

self.assertIn('myfile.py', cm.filename)
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

```python
assertWarnsRegex(warning, regex, callable, *args, **kwds)
assertWarnsRegex(warning, regex, msg=None)
```

Like `assertWarns()` but also tests that `regex` matches on the message of the triggered warning. `regex` may be a regular expression object or a string containing a regular expression
suitable for use by `re.search()`. Example:

```python
self.assertWarnsRegex(DeprecationWarning, r'legacy_function\([^()]*\) is legacy_function, 'XYZ')
```

or:

```python
with self.assertWarnsRegex(RuntimeWarning, 'unsfrobnicate(\'/etc/passwd\')
```

New in version 3.2.

Changed in version 3.3: Added the `msg` keyword argument when used as a context manager.

**assertLogs**(logger=None, level=None)

A context manager to test that at least one message is logged on the `logger` or one of its children, with at least the given `level`.

If given, `logger` should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages.

If given, `level` should be either a numeric logging level or its string equivalent (for example either "ERROR" or `logging.ERROR`). The default is `logging.INFO`.

The test passes if at least one message emitted inside the with block matches the `logger` and `level` conditions, otherwise it fails.

The object returned by the context manager is a recording
helper which keeps tracks of the matching log messages. It has two attributes:

**records**

A list of `logging.LogRecord` objects of the matching log messages.

**output**

A list of `str` objects with the formatted output of matching messages.

Example:

```python
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message', 'ERROR:foo.bar:second message'])
```

*New in version 3.4.*

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertLess(a, b)</code></td>
<td><code>a &lt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
<td>Python Code</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>assertLess(a, b)</td>
<td>a &lt; b</td>
<td></td>
</tr>
<tr>
<td>assertLessEqual(a, b)</td>
<td>a &lt;= b</td>
<td></td>
</tr>
<tr>
<td>assertRegex(s, r)</td>
<td>r.search(s)</td>
<td></td>
</tr>
<tr>
<td>assertNotRegex(s, r)</td>
<td>not r.search(s)</td>
<td></td>
</tr>
<tr>
<td>assertCountEqual(a, b)</td>
<td>a and b have the same elements in the same number, regardless of their order</td>
<td></td>
</tr>
</tbody>
</table>

| assertAlmostEqual(first, second, places=7, msg=None, delta=None) | Test that first and second are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal places (default 7), and comparing to zero. Note that these methods round the values to the given number of decimal places (i.e. like the `round()` function) and not significant digits. If delta is supplied instead of places then the difference between first and second must be less or equal to (or greater than) delta. Supplying both delta and places raises a TypeError. |
| assertNotAlmostEqual(first, second, places=7, msg=None, delta=None) | Changed in version 3.2: assertAlmostEqual() automatically considers almost equal objects that compare equal. assertNotAlmostEqual() automatically fails if the objects compare equal. Added the delta keyword argument. |

| assertGreater(first, second, msg=None) | |

assertGreaterEqual(first, second, msg=None)
assertLess(first, second, msg=None)
assertLessEqual(first, second, msg=None)

Test that first is respectively >, >=, < or <= than second depending on the method name. If not, the test will fail:

```python
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

New in version 3.1.

assertRegex(text, regex, msg=None)
assertNotRegex(text, regex, msg=None)

Test that a regex search matches (or does not match) text. In case of failure, the error message will include the pattern and the text (or the pattern and the part of text that unexpectedly matched). regex may be a regular expression object or a string containing a regular expression suitable for use by re.search().

New in version 3.1: under the name assertRegexpMatches.

Changed in version 3.2: The method assertRegexpMatches() has been renamed to assertRegex().

New in version 3.2: assertNotRegex().

assertCountEqual(first, second, msg=None)

Test that sequence first contains the same elements as second, regardless of their order. When they don't, an error message listing the differences between the sequences will be
Duplicate elements are not ignored when comparing first and second. It verifies whether each element has the same count in both sequences. Equivalent to:
```
assertEqual(Counter(list(first)), Counter(list(second)))
```
but works with sequences of unhashable objects as well.

*New in version 3.2.*

The `assertEqual()` method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using `addTypeEqualityFunc()`:

```
addTypeEqualityFunc(typeobj, function)
```

Registers a type-specific method called by `assertEqual()` to check if two objects of exactly the same `typeobj` (not subclasses) compare equal. `function` must take two positional arguments and a third `msg=None` keyword argument just as `assertEqual()` does. It must raise `self.failureException(msg)` when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

*New in version 3.1.*

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.
<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td>assertMultiLineEqual(a, b)</td>
<td>strings</td>
<td>3.1</td>
</tr>
<tr>
<td>assertSequenceEqual(a, b)</td>
<td>sequences</td>
<td>3.1</td>
</tr>
<tr>
<td>assertListEqual(a, b)</td>
<td>lists</td>
<td>3.1</td>
</tr>
<tr>
<td>assertTupleEqual(a, b)</td>
<td>tuples</td>
<td>3.1</td>
</tr>
<tr>
<td>assertSetEqual(a, b)</td>
<td>sets or frozensets</td>
<td>3.1</td>
</tr>
<tr>
<td>assertDictEqual(a, b)</td>
<td>dicts</td>
<td>3.1</td>
</tr>
</tbody>
</table>

assertMultiLineEqual(first, second, msg=None)

Test that the multiline string first is equal to the string second. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with assertEqual().

*New in version 3.1.*

assertSequenceEqual(first, second, msg=None, seq_type=None)

Tests that two sequences are equal. If a seq_type is supplied, both first and second must be instances of seq_type or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by assertEqual(), but it's used to implement assertListEqual() and assertTupleEqual().

*New in version 3.1.*
assertListEqual\( (first, second, msg=None) \)

assertTupleEqual\( (first, second, msg=None) \)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 3.1.*

assertSetEqual\( (first, second, msg=None) \)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of `first` or `second` does not have a `set.difference()` method.

*New in version 3.1.*

assertDictEqual\( (first, second, msg=None) \)

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

*New in version 3.1.*

Finally the `TestCase` provides the following methods and attributes:

fail\( (msg=None) \)
Signals a test failure unconditionally, with `msg` or `None` for the error message.

**failureException**

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

If set to `True` then any explicit failure message you pass in to the assert methods will be appended to the end of the normal failure message. The normal messages contain useful information about the objects involved, for example the message from `assertEqual` shows you the repr of the two unequal objects. Setting this attribute to `True` allows you to have a custom error message in addition to the normal one.

This attribute defaults to `True`. If set to `False` then a custom message passed to an assert method will silence the normal message.

The class setting can be overridden in individual tests by assigning an instance attribute to `True` or `False` before calling the assert methods.

*New in version 3.1.*

**maxDiff**

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8
characters. Assert methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

*New in version 3.2.*

Testing frameworks can use the following methods to collect information on the test:

**countTestCases()**

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

**defaultTestResult()**

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

**id()**

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

**shortDescription()**

Returns a description of the test, or `None` if no description has
been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or None.

*Changed in version 3.1:* In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the `TextTestResult` in Python 3.2.

**addCleanup**(function, *args, **kwargs)

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.

If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

*New in version 3.1.*

**doCleanups()**

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.
New in version 3.1.

```python
class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)
```

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### 26.4.8.1.1. Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias</th>
<th>Deprecated since version 3.1</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual()</code></td>
<td><code>failUnlessEqual</code></td>
<td><code>assertEqual</code></td>
</tr>
<tr>
<td><code>assertNotEqual()</code></td>
<td><code>failIfEqual</code></td>
<td><code>assertNotEqual</code></td>
</tr>
<tr>
<td><code>assertTrue()</code></td>
<td><code>failUnless</code></td>
<td><code>assertTrue</code></td>
</tr>
<tr>
<td><code>assertFalse()</code></td>
<td><code>failIf</code></td>
<td><code>assertFalse</code></td>
</tr>
<tr>
<td><code>assertRaises()</code></td>
<td><code>failUnlessRaises</code></td>
<td><code>assertRaises</code></td>
</tr>
<tr>
<td><code>assertAlmostEqual()</code></td>
<td><code>failUnlessAlmostEqual</code></td>
<td><code>assertAlmostEqual</code></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual()</code></td>
<td><code>failIfAlmostEqual</code></td>
<td><code>assertNotAlmostEqual</code></td>
</tr>
<tr>
<td><code>assertRegex()</code></td>
<td></td>
<td><code>assertRegex</code></td>
</tr>
<tr>
<td><code>assertRaisesRegex()</code></td>
<td></td>
<td><code>assertRaisesRegex</code></td>
</tr>
</tbody>
</table>

*Deprecated since version 3.1:* the `fail*` aliases listed in the second column.
Deprecated since version 3.2: the assert* aliases listed in the third column.

Deprecated since version 3.2: assertRegexpMatches and assertRaisesRegexp have been renamed to assertRegex() and assertRaisesRegex()

26.4.8.2. Grouping tests

class unittest.TestSuite(tests=())

This class represents an aggregation of individual tests cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a TestSuite instance is the same as iterating over the suite, running each test individually.

If tests is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

TestSuite objects behave much like TestCase objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to TestSuite instances:

addTest(test)

Add a TestCase or TestSuite to the suite.

addTests(tests)

Add all the tests from an iterable of TestCase and TestSuite
instances to this test suite.

This is equivalent to iterating over tests, calling `addTest()` for each element.

`TestSuite` shares the following methods with `TestCase`:

`run(result)`
Run the tests associated with this suite, collecting the result into the test result object passed as `result`. Note that unlike `TestCase.run()`, `TestSuite.run()` requires the result object to be passed in.

`debug()`
Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

`countTestCases()`
Return the number of tests represented by this test object, including all individual tests and sub-suites.

`__iter__()`
Tests grouped by a `TestSuite` are always accessed by iteration. Subclasses can lazily provide tests by overriding `__iter__()`. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before `TestSuite.run()` must be the same for each call iteration. After `TestSuite.run()`, callers should not rely on the tests returned by this method unless the caller uses
a subclass that overrides TestSuite._removeTestAtIndex() to preserve test references.

*Changed in version 3.2:* In earlier versions the TestSuite accessed tests directly rather than through iteration, so overriding `__iter__()` wasn't sufficient for providing tests.

*Changed in version 3.4:* In earlier versions the TestSuite held references to each TestCase after TestSuite.run(). Subclasses can restore that behavior by overriding TestSuite._removeTestAtIndex().

In the typical usage of a TestSuite object, the run() method is invoked by a TestRunner rather than by the end-user test harness.

### 26.4.8.3. Loading and running tests

class unittest.TestLoader

The TestLoader class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the unittest module provides an instance that can be shared as unittest.defaultTestLoader. Using a subclass or instance, however, allows customization of some configurable properties.

TestLoader objects have the following attributes:

**errors**

A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled
by the relevant a method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

*New in version 3.5.*

**TestLoader** objects have the following methods:

**loadTestsFromTestCase**(**testCaseClass**)  
Return a suite of all tests cases contained in the **TestCase**-derived testCaseClass.

A test case instance is created for each method named by **getTestCaseNames()**. By default these are the method names beginning with test. If **getTestCaseNames()** returns no methods, but the **runTest()** method is implemented, a single test case is created for that method instead.

**loadTestsFromModule**(**module, pattern=None**)  
Return a suite of all tests cases contained in the given module. This method searches **module** for classes derived from **TestCase** and creates an instance of the class for each test method defined for the class.

**Note:** While using a hierarchy of **TestCase**-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a **load_tests** function it will be called to load the tests. This allows modules to customize test loading.
This is the load_tests protocol. The pattern argument is passed as the third argument to load_tests.

*Changed in version 3.2:* Support for load_tests added.

*Changed in version 3.5:* The undocumented and unofficial use_load_tests default argument is deprecated and ignored, although it is still accepted for backward compatibility. The method also now accepts a keyword-only argument pattern which is passed to load_tests as the third argument.

**loadTestsFromName**(name, module=None)

Return a suite of all tests cases given a string specifier.

The specifier name is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a TestSuite instance, or a callable object which returns a TestCase or TestSuite instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module SampleTests containing a TestCase-derived class SampleTestCase with three test methods (test_one(), test_two(), and test_three()), the specifier 'SampleTests.SampleTestCase' would cause this method to return a suite which will run all three test methods. Using the specifier 'SampleTests.SampleTestCase.test_two' would cause it to return a test suite which will run only the test_two() test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-
The method optionally resolves name relative to the given module.

Changed in version 3.5: If an ImportError or AttributeError occurs while traversing name then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by self.errors.

**loadTestsFromNames(names, module=None)**

Similar to loadTestsFromName(), but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames(testCaseClass)**

Return a sorted sequence of method names found within testCaseClass; this should be a subclass of `TestCase`.

**discover(start_dir, pattern='test*.py', top_level_dir=None)**

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match pattern will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will
continue. If the import failure is due to `SkipTest` being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the `load_tests` function itself calls `loader.discover`.

If `load_tests` exists then discovery does not recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. `top_level_dir` is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

`start_dir` can be a dotted module name as well as a directory.

*New in version 3.2.*

*Changed in version 3.4:* Modules that raise `SkipTest` on import are recorded as skips, not errors. Discovery works for *namespace packages*. Paths are sorted before being imported so that execution order is the same even if the underlying file system’s ordering is not dependent on file name.

*Changed in version 3.5:* Found packages are now checked for `load_tests` regardless of whether their path matches `pattern`, because it is impossible for a package name to match the
The following attributes of a TestLoader can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**
String giving the prefix of method names which will be interpreted as test methods. The default value is 'test'.

This affects **getTestCaseNames()** and all the loadTestsFrom*() methods.

**sortTestMethodsUsing**
Function to be used to compare method names when sorting them in getTestCaseNames() and all the loadTestsFrom*() methods.

**suiteClass**
Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the TestSuite class.

This affects all the loadTestsFrom*() methods.

*class* unittest.TestResult
This class is used to compile information about which tests have succeeded and which have failed.

A TestResult object stores the results of a set of tests. The TestCase and TestSuite classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.
Testing frameworks built on top of unittest may want access to the TestResult object generated by running a set of tests for reporting purposes; a TestResult instance is returned by the TestRunner.run() method for this purpose.

TestResult instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

**errors**
A list containing 2-tuples of TestCase instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

**failures**
A list containing 2-tuples of TestCase instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the TestCase.assert*() methods.

**skipped**
A list containing 2-tuples of TestCase instances and strings holding the reason for skipping the test.

*New in version 3.1.*

**expectedFailures**
A list containing 2-tuples of TestCase instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**
A list containing TestCase instances that were marked as expected failures, but succeeded.
**shouldStop**
Set to True when the execution of tests should stop by `stop()`.

**testsRun**
The total number of tests run so far.

**buffer**
If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 3.2.*

**failfast**
If set to true `stop()` will be called on the first failure or error, halting the test run.

*New in version 3.2.*

**tb_locals**
If set to true then local variables will be shown in tracebacks.

*New in version 3.5.*

**wasSuccessful()**
Return True if all tests run so far have passed, otherwise returns False.

*Changed in version 3.4: Returns False if there were any*
unexpectedSuccesses from tests marked with the expectedFailure() decorator.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the shouldStop attribute to True. TestRunner objects should respect this flag and return without running any additional tests.

For example, this feature is used by the TextTestRunner class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide TestRunner implementations can use this in a similar manner.

The following methods of the TestResult class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest**(test)

Called when the test case test is about to be run.

**stopTest**(test)

Called after the test case test has been executed, regardless of the outcome.

**startTestRun()**

Called once before any tests are executed.

*New in version 3.1.*

**stopTestRun()**
Called once after all tests are executed.

New in version 3.1.

addError(test, err)
Called when the test case test raises an unexpected exception. err is a tuple of the form returned by sys.exc_info(): (type, value, traceback).

The default implementation appends a tuple (test, formatted_err) to the instance's errors attribute, where formatted_err is a formatted traceback derived from err.

addFailure(test, err)
Called when the test case test signals a failure. err is a tuple of the form returned by sys.exc_info(): (type, value, traceback).

The default implementation appends a tuple (test, formatted_err) to the instance's failures attribute, where formatted_err is a formatted traceback derived from err.

addSuccess(test)
Called when the test case test succeeds.

The default implementation does nothing.

addSkip(test, reason)
Called when the test case test is skipped. reason is the reason the test gave for skipping.

The default implementation appends a tuple (test, reason) to the instance's skipped attribute.
addExpectedFailure(test, err)
Called when the test case test fails, but was marked with the expectedFailure() decorator.

The default implementation appends a tuple (test, formatted_err) to the instance's expectedFailures attribute, where formatted_err is a formatted traceback derived from err.

addUnexpectedSuccess(test)
Called when the test case test was marked with the expectedFailure() decorator, but succeeded.

The default implementation appends the test to the instance's unexpectedSuccesses attribute.

addSubTest(test, subtest, outcome)
Called when a subtest finishes. test is the test case corresponding to the test method. subtest is a custom TestCase instance describing the subtest.

If outcome is None, the subtest succeeded. Otherwise, it failed with an exception where outcome is a tuple of the form returned by sys.exc_info(): (type, value, traceback).

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

New in version 3.4.

class unittest.TextTestResult(stream, descriptions, verbosity)
A concrete implementation of TestResult used by the
**TextTestRunner.**

*New in version 3.2:* This class was previously named `_TextTestResult`. The old name still exists as an alias but is deprecated.

`unittest.defaultTestLoader`

Instance of the `TestLoader` class intended to be shared. If no customization of the `TestLoader` is needed, this instance can be used instead of repeatedly creating new instances.

```python
class unittest.TextTestRunner(stream=None, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None, warnings=None, *, tb_locals=False)
```

A basic test runner implementation that outputs results to a stream. If `stream` is None, the default, `sys.stderr` is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept **kwargs as the interface to construct runners changes when features are added to unittest.

By default this runner shows `DeprecationWarning`, `PendingDeprecationWarning`, `ResourceWarning` and `ImportWarning` even if they are ignored by default. Deprecation warnings caused by deprecated unittest methods are also special-cased and, when the warning filters are 'default' or 'always', they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using the `-Wd` or `-Wa` options and leaving `warnings` to None.

*Changed in version 3.2:* Added the `warnings` argument.
Changed in version 3.2: The default stream is set to `sys.stderr` at instantiation time rather than import time.

Changed in version 3.5: Added the `tb_locals` parameter.

_makeResult()

This method returns the instance of `TestResult` used by `run()`. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.

_makeResult() instantiates the class or callable passed in the `TextTestRunner` constructor as the `resultclass` argument. It defaults to `TextTestResult` if no `resultclass` is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

run(test)

This method is the main public interface to the `TextTestRunner`. This method takes a `TestSuite` or `TestCase` instance. A `TestResult` is created by calling `_makeResult()` and the test(s) are run and the results printed to stdout.

```
unittest.main(module='__main__', defaultTest=None, argv=None,
testRunner=None, testLoader=unittest.defaultTestLoader, exit=True,
verbosity=1, failfast=None, catchbreak=None, buffer=None,
warnings=None)
```

A command-line program that loads a set of tests from `module` and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:
if __name__ == '__main__':
    unittest.main()

You can run tests with more detailed information by passing in the verbosity argument:

if __name__ == '__main__':
    unittest.main(verbosity=2)

The `defaultTest` argument is either the name of a single test or an iterable of test names to run if no test names are specified via `argv`. If not specified or `None` and no test names are provided via `argv`, all tests found in `module` are run.

The `argv` argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of `sys.argv` are used.

The `testRunner` argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success or failure of the tests run.

The `testLoader` argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```python
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The `failfast`, `catchbreak` and `buffer` parameters have the same
effect as the same-name command-line options.

The warning argument specifies the warning filter that should be used while running the tests. If it's not specified, it will remain None if a -W option is passed to python, otherwise it will be set to 'default'.

Calling main actually returns an instance of the TestProgram class. This stores the result of the tests run as the result attribute.

Changed in version 3.1: The exit parameter was added.

Changed in version 3.2: The verbosity, failfast, catchbreak, buffer and warnings parameters were added.

Changed in version 3.4: The defaultTest parameter was changed to also accept an iterable of test names.

26.4.8.3.1. load_tests Protocol

New in version 3.2.

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called load_tests.

If a test module defines load_tests it will be called by TestLoader.loadTestsFromModule() with the following arguments:

load_tests(loader, standard_tests, pattern)
where \textit{pattern} is passed straight through from \texttt{loadTestsFromModule}. It defaults to \texttt{None}.

It should return a \texttt{TestSuite}.

\texttt{loader} is the instance of \texttt{TestLoader} doing the loading. \texttt{standard_tests} are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical \texttt{load_tests} function that loads tests from a specific set of \texttt{TestCase} classes may look like:

```python
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling \texttt{TestLoader.discover()}, then the package \texttt{__init__.py} will be checked for \texttt{load_tests}. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package's tests will be left up to \texttt{load_tests} which is called with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```
This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:

```python
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir)
    standard_tests.addTests(package_tests)
    return standard_tests
```

*Changed in version 3.5:* Discovery no longer checks package names for matching `pattern` due to the impossibility of package names matching the default pattern.
26.4.9. Class and Module Fixtures

Class and module level fixtures are implemented in `TestSuite`. When the test suite encounters a test from a new class then `tearDownClass()` from the previous class (if there is one) is called, followed by `setUpClass()` from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass / setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no
corresponding test instance an _ErrorHolder object (that has the same interface as a TestCase) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

26.4.9.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest
class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the setUpClass and tearDownClass on base classes called then you must call up to them yourself. The implementations in testCase are empty.

If an exception is raised during a setUpClass then the tests in the class are not run and the tearDownClass is not run. Skipped classes will not have setUpClass or tearDownClass run. If the exception is a SkipTest exception then the class will be reported as having been skipped instead of as an error.

26.4.9.2. setUpModule and tearDownModule
These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a setUpModule then none of the tests in the module will be run and the tearDownModule will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
26.4.10. Signal Handling

*New in version 3.2.*

The `-c/--catch` command-line option to unittest, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but *isn’t* the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need unittest control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

`unittest.registerResult(result)`

Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn’t prevent the
result from being garbage collected.

Registering a TestResult object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

unittest.removeResult(result)
Remove a registered result. Once a result has been removed then stop() will no longer be called on that result object in response to a control-c.

unittest.removeHandler(function=None)
When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```python
@unittest.removeHandler
def test_signal_handling(self):
    ...
```
26.5. `unittest.mock` — mock object library

*New in version 3.3.*

`unittest.mock` is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

`unittest.mock` provides a core `Mock` class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a `patch()` decorator that handles patching module and class level attributes within the scope of a test, along with `sentinel` for creating unique objects. See the quick guide for some examples of how to use `Mock`, `MagicMock` and `patch()`.

Mock is very easy to use and is designed for use with `unittest`. Mock is based on the ‘action -> assertion’ pattern instead of ‘record -> replay’ used by many mocking frameworks.

There is a backport of `unittest.mock` for earlier versions of Python, available as `mock` on PyPI.

**Source code:** `Lib/unittest/mock.py`
26.5.1. Quick Guide

Mock and MagicMock objects create all attributes and methods as you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```python
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

side_effect allows you to perform side effects, including raising an exception when a mock is called:

```python
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
...  
  KeyError: 'foo'
```

```python
>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...   return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```
Mock has many other ways you can configure it and control its behaviour. For example the `spec` argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don’t exist on the spec will fail with an `AttributeError`.

The `patch()` decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```python
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
... >>> test()
```

**Note:** When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal `python` order that decorators are applied). This means from the bottom up, so in the example above the mock for `module.ClassName1` is passed in first.

With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read [where to patch](#).
As well as a decorator `patch()` can be used as a context manager in a with statement:

```python
>>> with patch.object(ProductionClass, 'method', return_value=... thing = ProductionClass()
... thing.method(1, 2, 3)

>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()

>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}

>>> assert foo == original
```

Mock supports the mocking of Python magic methods. The easiest way of using magic methods is with the `MagicMock` class. It allows you to do things like:

```python
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobazbar'
>>> str(mock)
'foobazbar'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The `MagicMock` class is just a Mock variant that has all of the magic methods pre-
created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```python
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='wheeeeee')
>>> str(mock)
'wheeeeee'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use auto-speccing. Auto-speccing can be done through the autospec argument to patch, or the create_autospec() function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```python
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_value='fishy')
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
  File "<lambda>", line 1, in <lambda>
TypeError: <lambda>() takes exactly 3 arguments (1 given)
```
`create_autospec()` can also be used on classes, where it copies the signature of the `__init__` method, and on callable objects where it copies the signature of the `__call__` method.
26.5.2. The Mock Class

Mock is a flexible mock object intended to replace the use of stubs and test doubles throughout your code.Mocks are callable and create attributes as new mocks when you access them [1]. Accessing the same attribute will always return the same mock.Mocks record how you use them, allowing you to make assertions about what your code has done to them.

MagicMock is a subclass of Mock with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren’t callable: NonCallableMock and NonCallableMagicMock.

The patch() decorators makes it easy to temporarily replace classes in a particular module with a Mock object. By default patch() will create a MagicMock for you. You can specify an alternative class of Mock using the new_callable argument to patch().

class unittest.mock.Mock(spec=None, side_effect=None, return_value=DEFAULT, wraps=None, name=None, spec_set=None, unsafe=False, **kwargs)

Create a new Mock object. Mock takes several optional arguments that specify the behaviour of the Mock object:

- spec: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling dir on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an AttributeError.
If `spec` is an object (rather than a list of strings) then `__class__` returns the class of the `spec` object. This allows mocks to pass `isinstance()` tests.

- **`spec_set`:** A stricter variant of `spec`. If used, attempting to set or get an attribute on the mock that isn't on the object passed as `spec_set` will raise an `AttributeError`.

- **`side_effect`:** A function to be called whenever the Mock is called. See the `side_effect` attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns `DEFAULT`, the return value of this function is used as the return value.

  Alternatively `side_effect` can be an exception class or instance. In this case the exception will be raised when the mock is called.

  If `side_effect` is an iterable then each call to the mock will return the next value from the iterable.

  A `side_effect` can be cleared by setting it to `None`.

- **`return_value`:** The value returned when the mock is called. By default this is a new Mock (created on first access). See the `return_value` attribute.

- **`unsafe`:** By default if any attribute starts with `assert` or `assert` will raise an `AttributeError`. Passing `unsafe=True` will allow access to these attributes.

  *New in version 3.5.*
• **wraps**: Item for the mock object to wrap. If *wraps* is not None then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn’t exist will raise an *AttributeError*).

If the mock has an explicit *return_value* set then calls are not passed to the wrapped object and the *return_value* is returned instead.

• **name**: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the *configure_mock()* method for details.

**assert_called_with(***args, **kwargs)**

This method is a convenient way of asserting that calls are made in a particular way:

```python
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_with(1, 2, 3, test='wow')
```

**assert_called_once_with(***args, **kwargs)**

Assert that the mock was called exactly once and with the specified arguments.

```python
>>> mock = Mock(return_value=None)
```
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
Traceback (most recent call last):
...
AssertionError: Expected 'mock' to be called once. Called 2 times.

assert_any_call(*args, **kwargs)
assert the mock has been called with the specified arguments.

The assert passes if the mock has ever been called, unlike
assert_called_with() and
assert_called_once_with() that only pass if the call is
the most recent one.

>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')

assert_has_calls(calls, any_order=False)
assert the mock has been called with the specified calls. The
mock_calls list is checked for the calls.

If any_order is false (the default) then the calls must be
sequential. There can be extra calls before or after the specified
calls.

If any_order is true then the calls can be in any order, but they
must all appear in mock_calls.

>>> mock = Mock(return_value=None)
>>> mock(1)
mock(2)
mock(3)
mock(4)
calls = [call(2), call(3)]
mock.assert_has_calls(calls)
calls = [call(4), call(2), call(3)]
mock.assert_has_calls(calls, any_order=True)
mock.assert_not_called(*args, **kwargs)

assert_not_called(*args, **kwargs)
Assert the mock was never called.

m = Mock()
m.hello.assert_not_called()
obj = m.hello()
m.hello.assert_not_called()
Traceback (most recent call last):
...
AssertionError: Expected 'hello' to not have been called.

New in version 3.5.

reset_mock()
The reset_mock method resets all the call attributes on a mock object:

mock = Mock(return_value=None)
m('hello')
m.called
True
mock.reset_mock()
m.called
False

This can be useful where you want to make a series of
assertions that reuse the same object. Note that `reset_mock()` doesn't clear the return value, `side_effect` or any child attributes you have set using normal assignment. Child mocks and the return value mock (if any) are reset as well.

**mock_add_spec**(spec, spec_set=False)

Add a spec to a mock. `spec` can either be an object or a list of strings. Only attributes on the `spec` can be fetched as attributes from the mock.

If `spec_set` is true then only attributes on the spec can be set.

**attach_mock**(mock, attribute)

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the `method_calls` and `mock_calls` attributes of this one.

**configure_mock**(**kwargs)

Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```python
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.side_effect': 3}
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
  KeyError
```
The same thing can be achieved in the constructor call to mocks:

```python
g>>> attrs = {'method.return_value': 3, 'other.side_effect': }
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
  KeyError
```

configure_mock() exists to make it easier to do configuration after the mock has been created.

__dir__()

Mock objects limit the results of dir(some_mock) to useful results. For mocks with a spec this includes all the permitted attributes for the mock.

See FILTER_DIR for what this filtering does, and how to switch it off.

__get_child_mock__(**kw)

Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of Mock may want to override this to customize the way child mocks are made.

For non-callable mocks the callable variant will be used (rather
than any custom subclass).

**called**
A boolean representing whether or not the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

**call_count**
An integer telling you how many times the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
>>> mock()
>>> mock()
>>> mock.call_count
2
```

**return_value**
Set this to configure the value returned by calling the mock:

```python
>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'
```

The default return value is a mock object and you can configure it in the normal way:
**ReturnValue** can also be set in the constructor:

```python
>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3
```

### side_effect

This can either be a function to be called when the mock is called, an iterable or an exception (class or instance) to be raised.

If you pass in a function, it will be called with the same arguments as the mock and unless the function returns the `DEFAULT` singleton, the call to the mock will then return whatever the function returns. If the function returns `DEFAULT`, then the mock will return its normal value (from the `return_value`).

If you pass in an iterable, it is used to retrieve an iterator which must yield a value on every call. This value can either be an exception instance to be raised, or a value to be returned from the call to the mock (`DEFAULT` handling is identical to the function case).

An example of a mock that raises an exception (to test exception handling of an API):
```python
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

Using `side_effect` to return a sequence of values:

```python
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
>>> mock(), mock(), mock()
(3, 2, 1)
```

Using a callable:

```python
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> mock.side_effect = side_effect
>>> mock()
3
```

`sides_effect` can be set in the constructor. Here’s an example that adds one to the value the mock is called with and returns it:

```python
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
>>> mock(-8)
-7
```

Setting `side_effect` to None clears it:
>>> m = Mock(side_effect=KeyError, return_value=None)
>>> m()
Traceback (most recent call last):
  ...
KeyError

>>> m.side_effect = None
>>> m()
3

**call_args**

This is either None (if the mock hasn’t been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member is any ordered arguments the mock was called with (or an empty tuple) and the second member is any keyword arguments (or an empty dictionary).

```python
>>> mock = Mock(return_value=None)
>>> print(mock.call_args)
None
>>> mock()
>>> mock.call_args
call()
>>> mock.call_args == ()
True
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args
call(3, 4, 5, key='fish', next='w00t!')
```

call_args, along with members of the lists
call_args_list, method_calls and mock_calls are call objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See calls as tuples.

**call_args_list**

This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The call object can be used for conveniently constructing lists of calls to compare with call_args_list.

```python
>>> mock = Mock(return_value=None)
>>> mock()
>>> mock(3, 4)
>>> mock(key='fish', next='w00t!')
>>> mock.call_args_list
[call(), call(3, 4), call(key='fish', next='w00t!')]
>>> expected = [(), ((3, 4),), ({'key': 'fish', 'next': 'w00t!'},)]
>>> mock.call_args_list == expected
True
```

Members of call_args_list are call objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

**method_calls**

As well as tracking calls to themselves, mocks also track calls to methods and attributes, and their methods and attributes:

```python
>>> mock = Mock()
>>> mock.method()  # this is a special method.
<Mock name='mock.method()' id='...'>
```
>>> mock.property.method.attribute()
<Mock name='mock.property.method.attribute()' id='...'>
>>> mock.method_calls
[call.method(), call.property.method.attribute()]

Members of method_calls are call objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

mock_calls

mock_calls records all calls to the mock object, its methods, magic methods and return value mocks.

>>> mock = MagicMock()
>>> result = mock(1, 2, 3)
>>> mock.first(a=3)
<MagicMock name='mock.first()' id='...'>
>>> mock.second()
<MagicMock name='mock.second()' id='...'>
>>> int(mock)
1
>>> result(1)
<MagicMock name='mock()' id='...'>
>>> expected = [call(1, 2, 3), call.first(a=3), ... call.__int__(), call(1)]
>>> mock.mock_calls == expected
True

Members of mock_calls are call objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

__class__
Normally the \_\_class\_\_ attribute of an object will return its type. For a mock object with a spec, \_\_class\_\_ returns the spec class instead. This allows mock objects to pass \_\_isinstance\_\_ tests for the object they are replacing / masquerading as:

```python
>>> mock = Mock(spec=3)
>>> \_\_isinstance\_\_(mock, int)
True
```

\_\_class\_\_ is assignable to, this allows a mock to pass an \_\_isinstance\_\_ check without forcing you to use a spec:

```python
>>> mock = Mock()
>>> mock.\_\_class\_\_ = dict
>>> \_\_isinstance\_\_(mock, dict)
True
```

class unittest.mock.NonCallableMock(spec=None, wraps=None, name=None, spec_set=None, **kwargs)

A non-callable version of Mock. The constructor parameters have the same meaning of Mock, with the exception of \_\_return\_\_value and \_\_side\_\_effect which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a spec or spec\_set are able to pass \_\_isinstance\_\_ tests:

```python
>>> mock = Mock(spec=SomeClass)
>>> \_\_isinstance\_\_(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
>>> \_\_isinstance\_\_(mock, SomeClass)
True
```
The Mock classes have support for mocking magic methods. See magic methods for the full details.

The mock classes and the patch() decorators all take arbitrary keyword arguments for configuration. For the patch() decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```python
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can't use dotted names directly in a call you have to create a dictionary and unpack it using **:

```python
>>> attrs = {'method.return_value': 3, 'other.side_effect': lambda: 'eggs'}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
KeyError
```

A callable mock which was created with a spec (or a spec_set) will introspect the specification object's signature when matching calls to the mock. Therefore, it can match the actual call's arguments regardless of whether they were passed positionally or by name:
```python
def f(a, b, c): pass
...
mock = Mock(spec=f)
mock(1, 2, c=3)
<Mock name='mock()' id='140161580456576'>
mock.assert_called_with(1, 2, 3)
mock.assert_called_with(a=1, b=2, c=3)
```

This applies to `assert_called_with()`, `assert_called_once_with()`, `assert_has_calls()` and `assert_any_call()`. When Autospeccing, it will also apply to method calls on the mock object.

*Changed in version 3.4:* Added signature introspection on specced and autospecced mock objects.

```python
class unittest.mock.PropertyMock(*args, **kwargs)
```

A mock intended to be used as a property, or other descriptor, on a class. `PropertyMock` provides `__get__()` and `__set__()` methods so you can specify a return value when it is fetched.

Fetching a `PropertyMock` instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.

```python
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
...
>>> with patch('__main__.Foo.foo', new_callable=PropertyMock):
...     mock_foo.return_value = 'mockity-mock'
...     this_foo = Foo()
```
Because of the way mock attributes are stored you can’t directly attach a `PropertyMock` to a mock object. Instead you can attach it to the mock type object:

```
>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()
```

### 26.5.2.1. Calling

Mock objects are callable. The call will return the value set as the `return_value` attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like `call_args` and `call_args_list`.

If `side_effect` is set then it will be called after the call has been recorded, so if `side_effect` raises an exception the call is still recorded.
The simplest way to make a mock raise an exception when called is to make `side_effect` an exception class or instance:

```python
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
...  
IndexError
```

```python
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
...  
KeyError: 'Bang!'
```

If `side_effect` is a function then whatever that function returns is what calls to the mock return. The `side_effect` function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```python
>>> def side_effect(value):
...     return value + 1
...
```  

```python
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]
```

If you want the mock to still return the default return value (a new
mock), or any set return value, then there are two ways of doing this. Either return mock.return_value from inside side_effect, or return DEFAULT:

```python
>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
... >>> m.side_effect = side_effect
... >>> m.return_value = 3
... >>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
... >>> m.side_effect = side_effect
... >>> m()
3
```

To remove a side_effect, and return to the default behaviour, set the side_effect to None:

```python
>>> m = MagicMock(return_value=6)
>>> def side_effect(*args, **kwargs):
...     return 3
... >>> m.side_effect = side_effect
... >>> m()
3
>>> m.side_effect = None
>>> m()
6
```

The side_effect can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is
exhausted and a `StopIteration` is raised):

```python
>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
  ... 
StopIteration
```

If any members of the iterable are exceptions they will be raised instead of returned:

```python
>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
  ... 
ValueError
>>> m()
66
```

### 26.5.2.2. Deleting Attributes

Mock objects create attributes on demand. This allows them to pretend to be objects of any type.

You may want a mock object to return False to a `hasattr()` call, or raise an `AttributeError` when an attribute is fetched. You can do
this by providing an object as a spec for a mock, but that isn't always convenient.

You “block” attributes by deleting them. Once deleted, accessing an attribute will raise an `AttributeError`.

```python
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
  ... AttributeError: f
```

26.5.2.3. Mock names and the name attribute

Since “name” is an argument to the `Mock` constructor, if you want your mock object to have a “name” attribute you can’t just pass it in at creation time. There are two alternatives. One option is to use `configure_mock()`:

```python
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```

A simpler option is to simply set the “name” attribute after mock creation:

```python
>>> mock = MagicMock()
```
26.5.2.4. Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a “child” of that mock. Calls to the child are recorded in the `method_calls` and `mock_calls` attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all calls to the children and allows you to make assertions about the order of calls between mocks:

```python
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the “parenting” if for some reason you don’t want it to happen.

```python
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
>>> mock.mock_calls
[]
```

Mocks created for you by `patch()` are automatically given names. To
attach mocks that have names to a parent you use the
attach_mock() method:

```python
>>> thing1 = object()
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None)
...     with patch('__main__.thing2', return_value=None)
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')

>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead raises an `AttributeError`.

[1] This is because the interpreter will often implicitly request these methods, and gets very confused to get a new Mock object when it expects a magic method. If you need magic method support see magic methods.
26.5.3. The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

26.5.3.1. patch

**Note:** `patch()` is straightforward to use. The key is to do the patching in the right namespace. See the section *where to patch.*

```
unittest.mock.patch(target, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)
```

`patch()` acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the `target` is patched with a `new` object. When the function/with statement exits the patch is undone.

If `new` is omitted, then the target is replaced with a `MagicMock`. If `patch()` is used as a decorator and `new` is omitted, the created mock is passed in as an extra argument to the decorated function. If `patch()` is used as a context manager the created mock is returned by the context manager.

`target` should be a string in the form 'package.module.ClassName'. The `target` is imported and the specified object replaced with the `new` object, so the `target` must be importable from the environment you are calling `patch()` from. The target is imported when the decorated function is executed,
not at decoration time.

The `spec` and `spec_set` keyword arguments are passed to the `MagicMock` if patch is creating one for you.

In addition you can pass `spec=True` or `spec_set=True`, which causes patch to pass in the object being mocked as the `spec/spec_set` object.

`new_callable` allows you to specify a different class, or callable object, that will be called to create the `new` object. By default `MagicMock` is used.

A more powerful form of `spec` is `autospec`. If you set `autospec=True` then the mock will be created with a spec from the object being replaced. All attributes of the mock will also have the spec of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a `TypeError` if they are called with the wrong signature. For mocks replacing a class, their return value (the ‘instance’) will have the same spec as the class. See the `create_autospec()` function and Autospeccing.

Instead of `autospec=True` you can pass `autospec=some_object` to use an arbitrary object as the spec instead of the one being replaced.

By default `patch()` will fail to replace attributes that don’t exist. If you pass in `create=True`, and the attribute doesn’t exist, patch will create the attribute for you when the patched function is called, and delete it again afterwards. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you
can write passing tests against APIs that don’t actually exist!

Note:
*Changed in version 3.5:* If you are patching builtins in a module then you don’t need to pass create=True, it will be added by default.

Patch can be used as a TestCase class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. `patch()` finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is 'test', which matches the way `unittest` finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the with statement. Here the patching applies to the indented block after the with statement. If you use “as” then the patched object will be bound to the name after the “as”; very useful if `patch()` is creating a mock object for you.

`patch()` takes arbitrary keyword arguments. These will be passed to the `Mock` (or `new_callable`) on construction.

`patch.dict(...)`, `patch.multiple(...)` and `patch.object(...)` are available for alternate use-cases.

`patch()` as function decorator, creating the mock for you and passing it into the decorated function:

```python
g>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
g```
Patching a class replaces the class with a `MagicMock instance`. If the class is instantiated in the code under test then it will be the `return_value` of the mock that will be used.

If the class is instantiated multiple times you could use `side_effect` to return a new mock each time. Alternatively you can set the `return_value` to be anything you want.

To configure return values on methods of `instances` on the patched class you must do this on the `return_value`. For example:

```python
>>> class Class:
...     def method(self):
...         pass
...>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
```

If you use `spec` or `spec_set` and `patch()` is replacing a `class`, then the return value of the created mock will have the same spec.

```python
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()
```
The `new_callable` argument is useful where you want to use an alternative class to the default `MagicMock` for the created mock. For example, if you wanted a `NonCallableMock` to be used:

```python
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock)
...    assert thing is mock_thing
...    thing()
...
Traceback (most recent call last):
...
TypeError: 'NonCallableMock' object is not callable
```

Another use case might be to replace an object with an `io.StringIO` instance:

```python
>>> from io import StringIO
>>> def foo():
...    print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
...    def test(mock_stdout):
...        foo()
...        assert mock_stdout.getvalue() == 'Something'
...
>>> test()
```

When `patch()` is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to `patch`. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:
As well as attributes on the created mock attributes, like the `return_value` and `side_effect`, of child mocks can also be configured. These aren't syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a `patch()` call using **:

```
>>> config = {'method.return_value': 3, 'other.side_effect': None}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
 ...  
KeyError
```

### 26.5.3.2. `patch.object`

`patch.object(target, attribute, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

patch the named member (`attribute`) on an object (`target`) with a mock object.

`patch.object()` can be used as a decorator, class decorator or
a context manager. Arguments new, spec, create, spec_set, autospec and new_callable have the same meaning as for patch(). Like patch(), patch.object() takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator patch.object() honours patch.TEST_PREFIX for choosing which methods to wrap.

You can either call patch.object() with three arguments or two arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```python
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
... >>> test()
```

spec, create and the other arguments to patch.object() have the same meaning as they do for patch().

26.5.3.3. patch.dict

patch.dict(in_dict, values=(), clear=False, **kwargs)

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

in_dict can be a dictionary or a mapping like container. If it is a
mapping then it must at least support getting, setting and deleting
items plus iterating over keys.

`in_dict` can also be a string specifying the name of the dictionary,
which will then be fetched by importing it.

`values` can be a dictionary of values to set in the dictionary. `values`
can also be an iterable of (key, value) pairs.

If `clear` is true then the dictionary will be cleared before the new
values are set.

`patch.dict()` can also be called with arbitrary keyword
arguments to set values in the dictionary.

`patch.dict()` can be used as a context manager, decorator or
class decorator. When used as a class decorator `patch.dict()`
honours `patch.TEST_PREFIX` for choosing which methods to
wrap.

`patch.dict()` can be used to add members to a dictionary, or
simply let a test change a dictionary, and ensure the dictionary is
restored when the test ends.

```python
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}):
...    assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == {}
```

```python
>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newval'}):
...    print(os.environ['newkey'])
...```

newvalue
>>> assert 'newkey' not in os.environ

Keywords can be used in the `patch.dict()` call to set values in the dictionary:

```python
>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule)
...    import mymodule
...    mymodule.function('some', 'args')
... 'fish'
```

`patch.dict()` can be used with dictionary like objects that aren't actually dictionaries. At the very minimum they must support item getting, setting, deleting and either iteration or membership test. This corresponds to the magic methods `__getitem__`, `__setitem__`, `__delitem__` and either `__iter__` or `__contains__`.

```python
>>> class Container:
...    def __init__(self):
...        self.values = {}
...    def __getitem__(self, name):
...        return self.values[name]
...    def __setitem__(self, name, value):
...        self.values[name] = value
...    def __delitem__(self, name):
...        del self.values[name]
...    def __iter__(self):
...        return iter(self.values)
...    >>> thing = Container()
```
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...   assert thing['one'] == 2
...   assert thing['two'] == 3
...  
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']

26.5.3.4. patch.multiple

`patch.multiple(target, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object by importing) and keyword arguments for the patches:

```python
with patch.multiple(settings, FIRST_PATCH='one', ...
```

Use `DEFAULT` as the value if you want `patch.multiple()` to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when `patch.multiple()` is used as a context manager.

`patch.multiple()` can be used as a decorator, class decorator or a context manager. The arguments `spec`, `spec_set`, `create`, `autospec` and `new_callable` have the same meaning as for `patch()`. These arguments will be applied to all patches done by `patch.multiple()`.

When used as a class decorator `patch.multiple()` honours `patch.TEST_PREFIX` for choosing which methods to wrap.
If you want `patch.multiple()` to create mocks for you, then you can use `DEFAULT` as the value. If you use `patch.multiple()` as a decorator then the created mocks are passed into the decorated function by keyword.

```python
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other)
... def test_function(thing, other):
...    assert isinstance(thing, MagicMock)
...    assert isinstance(other, MagicMock)
...    >>> test_function()
```

`patch.multiple()` can be nested with other patch decorators, but put arguments passed by keyword after any of the standard arguments created by `patch()`:

```python
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other)
... def test_function(mock_exit, other, thing):
...    assert 'other' in repr(other)
...    assert 'thing' in repr(thing)
...    assert 'exit' in repr(mock_exit)
...    >>> test_function()
```

If `patch.multiple()` is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```python
>>> with patch.multiple('__main__', thing=DEFAULT, o
26.5.3.5. patch methods: start and stop

All the patchers have start() and stop() methods. These make it simpler to do patching in setUp methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call patch(), patch.object() or patch.dict() as normal and keep a reference to the returned patcher object. You can then call start() to put the patch in place and stop() to undo it.

If you are using patch() to create a mock for you then it will be returned by the call to patcher.start.

```python
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName is not original
>>> assert module.ClassName is new_mock
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

A typical use case for this might be for doing multiple patches in the setUp method of a TestCase:

```python
>>> class MyTest(TestCase):
```
Caution: If you use this technique you must ensure that the patching is “undone” by calling stop. This can be fiddlier than you might think, because if an exception is raised in the setUp then tearDown is not called. `unittest.TestCase.addCleanup()` makes this easier:

As an added bonus you no longer need to keep a reference to the patcher object.
It is also possible to stop all patches which have been started by using `patch.stopall()`.

`patch.stopall()`  
Stop all active patches. Only stops patches started with `start`.

### 26.5.3.6. patch builtins

You can patch any builtins within a module. The following example patches builtin `ord()`:

```python
>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101
```

### 26.5.3.7. TEST_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with 'test' as being test methods. This is the same way that the `unittest.TestLoader` finds test methods by default.

It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:
>>> patch.TEST_PREFIX = 'foo'
>>> value = 3

>>> @patch('__main__.value', 'not three')
...     class Thing:
...         def foo_one(self):
...             print(value)
...         def foo_two(self):
...             print(value)

>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3

26.5.3.8. Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

>>> @patch.object(SomeClass, 'class_method')
>>> @patch.object(SomeClass, 'static_method')
...     def test(mock1, mock2):
...         assert SomeClass.static_method is mock1
...         assert SomeClass.class_method is mock2
...         SomeClass.static_method('foo')
...         SomeClass.class_method('bar')
...         return mock1, mock2

>>> mock1, mock2 = test()
Note that the decorators are applied from the bottom upwards. This is the standard way that Python applies decorators. The order of the created mocks passed into your test function matches this order.

26.5.3.9. Where to patch

`patch()` works by (temporarily) changing the object that a name points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is looked up, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```
a.py
   -> Defines SomeClass

b.py
   -> from a import SomeClass
   -> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using `patch()`. The problem is that when we import module `b`, which we will have to do then it imports `SomeClass` from module `a`. If we use `patch()` to mock out `a.SomeClass` then it will have no effect on our test; module `b` already has a reference to the
real SomeClass and it looks like our patching had no effect.

The key is to patch out SomeClass where it is used (or where it is looked up). In this case some_function will actually look up SomeClass in module b, where we have imported it. The patching should look like:

```python
@patch('b.SomeClass')
```

However, consider the alternative scenario where instead of from a import SomeClass module b does import a and some_function uses a.SomeClass. Both of these import forms are common. In this case the class we want to patch is being looked up in the module and so we have to patch a.SomeClass instead:

```python
@patch('a.SomeClass')
```

### 26.5.3.10. Patching Descriptors and Proxy Objects

Both `patch` and `patch.object` correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the `class` rather than an instance. They also work with `some` objects that proxy attribute access, like the `django settings object`.
26.5.4. MagicMock and magic method support

26.5.4.1. Mocking Magic Methods

Mock supports mocking the Python protocol methods, also known as “magic methods”. This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods [2], this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes almost all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it must take self as the first argument [3].

```python
>>> def __str__(self):
...     return 'fooble'
...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```python
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'
```
One use case for this is for mocking objects used as context managers in a `with` statement:

```python
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
...    assert m == 'foo'
...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

Calls to magic methods do not appear in `method_calls`, but they are recorded in `mock_calls`.

**Note:** If you use the `spec` keyword argument to create a mock then attempting to set a magic method that isn't in the spec will raise an `AttributeError`.

The full list of supported magic methods is:

- `__hash__`, `__sizeof__`, `__repr__` and `__str__`
- `__dir__`, `__format__` and `__subclasses__`
- `__floor__`, `__trunc__` and `__ceil__`
- Comparisons: `__lt__`, `__gt__`, `__le__`, `__ge__`, `__eq__` and `__ne__`
- Container methods: `__getitem__`, `__setitem__`, `__delitem__`, `__contains__`, `__len__`, `__iter__`,
__reversed__ and __missing__

- Context manager: __enter__ and __exit__
- Unary numeric methods: __neg__, __pos__ and __invert__
- The numeric methods (including right hand and in-place variants): __add__, __sub__, __mul__, __matmul__, __div__, __truediv__, __floordiv__, __mod__, __divmod__, __lshift__, __rshift__, __and__, __xor__, __or__, and __pow__
- Numeric conversion methods: __complex__, __int__, __float__ and __index__
- Descriptor methods: __get__, __set__ and __delete__
- Pickling: __reduce__, __reduce_ex__, __getinitargs__, __getnewargs__, __getstate__ and __setstate__

The following methods exist but are not supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- __getattr__, __setattr__, __init__ and __new__
- __prepare__, __instancecheck__, __subclasscheck__, __del__

### 26.5.4.2. Magic Mock

There are two MagicMock variants: MagicMock and NonCallableMagicMock.

```
class unittest.mock.MagicMock(*args, **kw)
```

MagicMock is a subclass of Mock with default implementations of most of the magic methods. You can use MagicMock without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for Mock.
If you use the `spec` or `spec_set` arguments then only magic methods that exist in the spec will be created.

```python
class unittest.mock.NonCallableMagicMock(*args, **kw)
    A non-callable version of MagicMock.
```

The constructor parameters have the same meaning as for `MagicMock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

The magic methods are setup with `MagicMock` objects, so you can configure them and use them in the usual way:

```python
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren't interested in the return value. You can still set the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: NotImplemented
- `__gt__`: NotImplemented
- `__le__`: NotImplemented
- `__ge__`: NotImplemented
- `__int__`: 1
- `__contains__`: False
• `__len__`: 1
• `__iter__`: `iter([])`
• `__exit__`: `False`
• `__complex__`: `1j`
• `__float__`: `1.0`
• `__bool__`: `True`
• `__index__`: `1`
• `__hash__`: default hash for the mock
• `__str__`: default str for the mock
• `__sizeof__`: default sizeof for the mock

For example:

```python
g>>> mock = MagicMock()
g>>> int(mock)
1
g>>> len(mock)
0
g>>> list(mock)
[]
g>>> object() in mock
False
```

The two equality methods, `__eq__()` and `__ne__()`, are special. They do the default equality comparison on identity, using the `side_effect` attribute, unless you change their return value to return something else:

```python
g>>> MagicMock() == 3
False
g>>> MagicMock() != 3
True
g>>> mock = MagicMock()
g>>> mock.__eq__.return_value = True
```
The return value of `MagicMock.__iter__()` can be any iterable object and isn't required to be an iterator:

```python
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

If the return value is an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```python
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

`MagicMock` has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in `MagicMock` are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__, __set__ and __delete__`
- `__reversed__` and `__missing__`
Magic methods should be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

The function is basically hooked up to the class, but each Mock instance is kept isolated from the others.
26.5.5. Helpers

26.5.5.1. sentinel

The `sentinel` object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible `repr` so that test failure messages are readable.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named `sentinel` objects to test this. `sentinel` provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch method to return `sentinel.some_object`:

```python
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> sentinel.some_object
sentinel.some_object
```

26.5.5.2. DEFAULT
unittest.mock.DEFAULT

The DEFAULT object is a pre-created sentinel (actually sentinel.DEFAULT). It can be used by side_effect functions to indicate that the normal return value should be used.

26.5.5.3. call

unittest.mock.call(*args, **kwargs)

call() is a helper object for making simpler assertions, for comparing with call_args, call_args_list, mock_calls and method_calls. call() can also be used with assert_has_calls().

```python
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar')
True
```

call.call_list()

For a call object that represents multiple calls, call_list() returns a list of all the intermediate calls as well as the final call.

call_list is particularly useful for making assertions on “chained calls”. A chained call is multiple calls on a single line of code. This results in multiple entries in mock_calls on a mock. Manually constructing the sequence of calls can be tedious.

call_list() can construct the sequence of calls from the same chained call:
A call object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn’t particularly interesting, but the call objects that are in the `Mock.call_args`, `Mock.call_args_list` and `Mock.mock_calls` attributes can be introspected to get at the individual arguments they contain.

The call objects in `Mock.call_args` and `Mock.call_args_list` are two-tuples of (positional args, keyword args) whereas the call objects in `Mock.mock_calls`, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their “tupleness” to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:
>>> args
(1, 2, 3)
>>> kwargs
{'arg2': 'two', 'arg': 'one'}
>>> args is kall[0]
True
>>> kwargs is kall[1]
True

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
<MockMock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg2': 'three', 'arg': 'two'}
>>> name is m.mock_calls[0][0]
True

26.5.5.4. create_autospec

unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the spec object as their spec.

Functions or methods being mocked will have their arguments checked to ensure that they are called with the correct signature.
If `spec_set` is `True` then attempting to set attributes that don’t exist on the spec object will raise an `AttributeError`.

If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing `instance=True`. The returned mock will only be callable if instances of the mock are callable.

`create_autospec()` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See `Autospeccing` for examples of how to use auto-speccing with `create_autospec()` and the `autospec` argument to `patch()`.

26.5.5.5. ANY

`unittest.mock.ANY`

Sometimes you may need to make assertions about some of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of `call_args` and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to `everything`. Calls to `assert_called_with()` and `assert_called_once_with()` will then succeed no matter what was passed in.

```python
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)
```
ANY can also be used in comparisons with call lists like mock_calls:

```python
>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True
```

### 26.5.5.6. FILTER_DIR

`unittest.mock.FILTER_DIR`

FILTER_DIR is a module level variable that controls the way mock objects respond to `dir()` (only for Python 2.6 or more recent). The default is True, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set `mock.FILTER_DIR = False`.

With filtering on, `dir(some_mock)` shows only useful attributes and will include any dynamically created attributes that wouldn’t normally be shown. If the mock was created with a `spec` (or `autospec` of course) then all the attributes from the original are shown, even if they haven’t been accessed yet:

```python
>>> dir(Mock())
['assert_any_call',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'attach_mock',
 ...
>>> from urllib import request
>>> dir(Mock(spec=request))
```
Many of the not-very-useful (private to Mock rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling dir() on a Mock. If you dislike this behaviour you can switch it off by setting the module level switch FILTER_DIR:

```python
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['_NonCallableMock__get_return_value',
'_NonCallableMock__get_side_effect',
'_NonCallableMock__return_value_doc',
'_NonCallableMock__set_return_value',
'_NonCallableMock__set_side_effect',
'__call__',
'__class__',
...]
```

Alternatively you can just use vars(my_mock) (instance members) and dir(type(my_mock)) (type members) to bypass the filtering irrespective of mock.FILTER_DIR.

### 26.5.5.7. mock_open

unittest.mock.mock_open(mock=None, read_data=None)

A helper function to create a mock to replace the use of open(). It works for open() called directly or used as a
context manager.

The mock argument is the mock object to configure. If None (the default) then a MagicMock will be created for you, with the API limited to methods or attributes available on standard file handles.

read_data is a string for the read(), readline(), and readlines() methods of the file handle to return. Calls to those methods will take data from read_data until it is depleted. The mock of these methods is pretty simplistic: every time the mock is called, the read_data is rewound to the start. If you need more control over the data that you are feeding to the tested code you will need to customize this mock for yourself. When that is insufficient, one of the in-memory filesystem packages on PyPI can offer a realistic filesystem for testing.

Changed in version 3.4: Added readline() and readlines() support. The mock of read() changed to consume read_data rather than returning it on each call.

Changed in version 3.5: read_data is now reset on each call to the mock.

Using open() as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```python
with open('/some/path', 'w') as f:
    f.write('something')
```

The issue is that even if you mock out the call to open() it is the returned object that is used as a context manager (and has
Mocking context managers with a `MagicMock` is common enough and fiddly enough that a helper function is useful.

```python
def mock_open():
    return io.StringIO()

with patch('__main__.open', mock_open):
    with open('foo', 'w') as h:
        h.write('some stuff')

>>> handle = m()

>>> handle.write.assert_called_once_with('some stuff')
```

And for reading files:

```python
>>> with patch('__main__.open', mock_open(read_data='bibble')):
    with open('foo') as h:
        result = h.read()

>>> m.assert_called_once_with('foo')

>>> assert result == 'bibble'
```

### 26.5.5.8. Autospeccing

Autospeccing is based on the existing spec feature of mock. It limits the api of mocks to the api of an original object (the spec), but it is recursive (implemented lazily) so that attributes of mocks only have
the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a `TypeError` if they are called incorrectly.

Before I explain how auto-speccing works, here's why it is needed.

`Mock` is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the `Mock` api and the other is a more general problem with using mock objects.

First the problem specific to `Mock`. `Mock` has two assert methods that are extremely handy: `assert_called_with()` and `assert_called_once_with()`.

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
...
AssertionError: Expected 'mock' to be called once. Called 2 times.
```

Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(4, 5, 6)
```

Your tests can pass silently and incorrectly because of the typo.
The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the old api but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don’t test how your units are “wired together” there is still lots of room for bugs that tests might have caught.

mock already provides a feature to help with this, called speccing. If you use a class or instance as the spec for a mock then you can only access attributes on the mock that exist on the real class:

```python
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assret_called_with
Traceback (most recent call last):
  ... AttributeError: Mock object has no attribute 'assret
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:

```python
>>> mock.has_data()
<mock.Mock object at 0x...>
>>> mock.has_data.assret_called_with()
```

Auto-speccing solves this problem. You can either pass autospec=True to `patch()` / `patch.object()` or use the `create_autospec()` function to create a mock with a spec. If you use the autospec=True argument to `patch()` then the object that is
being replaced will be used as the spec object. Because the speccing is done “lazily” (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here’s an example of it in use:

```python
golden_tip from urllib import request
golden_tip patcher = patch('__main__.request', autospec=True)
golden_tip mock_request = patcher.start()
golden_tip request is mock_request
golden_tip True
golden_tip mock_request.Request
<MagicMock name='request.Request' spec='Request' id='...'>
```

You can see that request.Request has a spec. request.Request takes two arguments in the constructor (one of which is self). Here’s what happens if we try to call it incorrectly:

```python
golden_tip req = request.Request()
Traceback (most recent call last):
... TypeError: <lambda>() takes at least 2 arguments (1)
```

The spec also applies to instantiated classes (i.e. the return value of specced mocks):

```python
golden_tip req = request.Request('foo')
golden_tip req
<NonCallableMagicMock name='request.Request()' spec=
```
Request objects are not callable, so the return value of instantiating our mocked out request.Request is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```python
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='...'>
>>> req.add_header().assert_called_with
Traceback (most recent call last):
  ... AttributeError: Mock object has no attribute 'assert_called_with'
```  

In many cases you will just be able to add autospec=True to your existing `patch()` calls and then be protected against bugs due to typos and api changes.

As well as using `autospec` through `patch()` there is a `create_autospec()` for creating autospecced mocks directly:

```python
>>> from urllib import request
>>> mock_request = create_autospec(request)
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request'>
```  

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are available on the spec object, autospec has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use autospec. On the other hand it is much better to design your objects
so that introspection is safe [4].

A more serious problem is that it is common for instance attributes to be created in the __init__() method and not to exist on the class at all. autospec can't know about any dynamically created attributes and restricts the api to visible attributes.

```python
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because autospec doesn't allow you to fetch attributes that don't exist on the spec it doesn't prevent you setting them:

```python
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a = 33
...
```

There is a more aggressive version of both spec and autospec that does prevent you setting non-existent attributes. This is useful if you want to ensure your code only sets valid attributes too, but obviously it
prevents this particular scenario:

```python
>>> with patch('__main__.Something', autospec=True,
...             thing = Something()
...             thing.a = 33
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in `__init__()`.

Note that if you are only setting default attributes in `__init__()` then providing them via class attributes (shared between instances of course) is faster too. e.g.

```python
class Something:
    a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn’t let you access any attributes or methods on it. As `None` is never going to be useful as a spec, and probably indicates a member that will normally of some other type, autospec doesn’t use a spec for members that are set to `None`. These will just be ordinary mocks (well - MagicMocks):

```python
>>> class Something:
...     member = None
...
>>> mock = create_autospec(Something)
>>> mock.member.foo.bar.baz()
```
If modifying your production classes to add defaults isn't to your liking then there are more options. One of these is simply to use an instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully `patch()` supports this - you can simply pass the alternative object as the `autospec` argument:

```python
>>> class Something:
    ...   def __init__(self):
    ...     self.a = 33
    ...
>>> class SomethingForTest(Something):
    ...   a = 33
    ...
>>> p = patch('__main__.Something', autospec=SomethingForTest)
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int'
```

This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance *does not* create a real instance. It is only attribute lookups - along with calls to `dir()` - that are done.

[4]
26.6. `unittest.mock` — getting started

*New in version 3.3.*
26.6.1. Using Mock

26.6.1.1. Mock Patching Methods

Common uses for Mock objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```python
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (real.method in this example) it has methods and attributes that allow you to make assertions about how it has been used.

**Note:** In most of these examples the Mock and MagicMock classes are interchangeable. As the MagicMock is the more capable class it makes a sensible one to use by default.

Once the mock has been called its called attribute is set to True. More importantly we can use the assert_called_with() or assert_called_once_with() method to check that it was called with the correct arguments.

This example tests that calling ProductionClass().method results in a call to the something method:
26.6.1.2. Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple `ProductionClass` below has a closer method. If it is called with an object then it calls `close` on it.

```python
>>> class ProductionClass:
    ...
    def closer(self, something):
    ...
        something.close()
    ...
```

So to test it we need to pass in an object with a close method and check that it was called correctly.

```python
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```
We don’t have to do any work to provide the ‘close’ method on our mock. Accessing close creates it. So, if ‘close’ hasn’t already been called then accessing it in the test will create it, but `assert_called_with()` will raise a failure exception.

26.6.1.3. Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by *calling the class*. This means you access the “mock instance” by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to `patch()` replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock `return_value`.

```python
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

26.6.1.4. Naming your mocks

It can be useful to give your mocks a name. The name is shown in the
repr of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or methods of the mock:

```python
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
<MagicMock name='foo.method' id='...'>
```

### 26.6.1.5. Tracking all Calls

Often you want to track more than a single call to a method. The `mock_calls` attribute records all calls to child attributes of the mock - and also to their children.

```python
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```

If you make an assertion about `mock_calls` and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the `call` object to construct lists for comparing with `mock_calls`:

```python
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```
26.6.1.6. Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```python
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```python
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```python
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```python
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for
example mock.connection.cursor().execute("SELECT 1"). If we wanted this call to return a list, then we have to configure the result of the nested call.

We can use call to construct the set of calls in a “chained call” like this for easy assertion afterwards:

```python
>>> mock = Mock()
>>> cursor = mock.connection.cursor.return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT 1")
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().execute("SELECT 1")]
>>> mock.mock_calls == expected
True
```

It is the call to .call_list() that turns our call object into a list of calls representing the chained calls.

26.6.1.7. Raising exceptions with mocks

A useful attribute is side_effect. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```python
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
  ... Exception: Boom!
```
26.6.1.8. Side effect functions and iterables

side_effect can also be set to a function or an iterable. The use case for side_effect as an iterable is where your mock is going to be called several times, and you want each call to return a different value. When you set side_effect to an iterable every call to the mock returns the next value from the iterable:

```python
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, side_effect can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the call returns:

```python
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2
```

26.6.1.9. Creating a Mock from an Existing Object
One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that also provides `some_method`. If later you refactor the first class, so that it no longer has `some_method` - then your tests will continue to pass even though your code is now broken!

**Mock** allows you to provide an object as a specification for the mock, using the `spec` keyword argument. Accessing methods / attributes on the mock that don’t exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```python
>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
 ... AttributeError: object has no attribute 'old_method'
```

Using a specification also enables a smarter matching of calls made to the mock, regardless of whether some parameters were passed as positional or named arguments:

```python
>>> def f(a, b, c): pass
 ... >>> mock = Mock(spec=f)
 ... >>> mock(1, 2, 3)
<Mock name='mock()' id='140161580456576'>
 ... >>> mock.assert_called_with(a=1, b=2, c=3)
```

If you want this smarter matching to also work with method calls on the
mock, you can use **auto-speccing**.

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use `spec_set` instead of `spec`. 
26.6.2. Patch Decorators

**Note:** With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch.*

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

Mock provides three convenient decorators for this: `patch()`, `patch.object()` and `patch.dict()`. `patch` takes a single string, of the form `package.module.Class.attribute` to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with.

`patch.object` takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

```python
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
... def test():
...     assert SomeClass.attribute == sentinel.attribute
... test()
>>> assert SomeClass.attribute == original
>>> @patch('package.module.attribute', sentinel.attribute)
```

```python
```
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
... >>> test()

If you are patching a module (including builtins) then use patch() instead of patch.object():

>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
... >>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle returned"

The module name can be 'dotted', in the form package.module if needed:

>>> @patch('package.module.ClassName.attribute', sentinel)
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.attribute
... >>> test()

A nice pattern is to actually decorate test methods themselves:

>>> class MyTest(unittest2.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel...
If you want to patch with a Mock, you can use `patch()` with only one argument (or `patch.object()` with two arguments). The mock will be created for you and passed into the test function / method:

```python
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

You can stack up multiple patch decorators using this pattern:

```python
>>> class MyTest(unittest2.TestCase):
...     @patch('package.module.ClassName1')
...     @patch('package.module.ClassName2')
...     def test_something(self, MockClass2, MockClass1):
...         self.assertIs(package.module.ClassName1, ...
...         self.assertIs(package.module.ClassName2, ...
... >>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal python order that decorators are applied). This means from the bottom up, so in the example above the mock for test_module.ClassName2 is passed in first.
There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...    assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use `patch()` to create a mock for you, you can get a reference to the mock using the “as” form of the with statement:

```python
>>> class ProductionClass:
...    def method(self):
...        pass
...
>>> with patch.object(ProductionClass, 'method') as mock_method:
...    mock_method.return_value = None
...    real = ProductionClass()
...    real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

As an alternative `patch`, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with “test”.
26.6.3. Further Examples

Here are some more examples for some slightly more advanced scenarios.

26.6.3.1. Mocking chained calls

Mocking chained calls is actually straightforward with mock once you understand the return_value attribute. When a mock is called for the first time, or you fetch its return_value before it has been called, a new Mock is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the return_value mock:

```python
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place...

So, suppose we have some code that looks a little bit like this:

```python
>>> class Something:
...     def __init__(self):
...         self.backend = BackendProvider()
...     def method(self):
...         response = self.backend.get_endpoint('foobar')
```
Assuming that BackendProvider is already well tested, how do we test method()? Specifically, we want to test that the code section # more code uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the backend attribute on a Something instance. In this particular case we are only interested in the return value from the final call to start_call so we don’t have much configuration to do. Let’s assume the object it returns is ‘file-like’, so we’ll ensure that our response object uses the builtin open() as its spec.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final start_call we could do this:

```python
mock_backend.get_endpoint.return_value.create_call.return_value.start_call.return_value
```

We can do that in a slightly nicer way using the configure_mock() method to directly set the return value for us:

```python
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value.start_call.return_value'}
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the “mock backend” in place and can make the real call:

```python
>>> something.backend = mock_backend
```
Using mock_calls we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in mock_calls. We can use call.call_list() to create this list of calls for us:

```python
>>> chained = call.get_endpoint('foobar').create_call
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

### 26.6.3.2. Partial mocking

In some tests I wanted to mock out a call to datetime.date.today() to return a known date, but I didn’t want to prevent the code under test from creating new date objects. Unfortunately datetime.date is written in C, and so I couldn’t just monkey-patch out the static date.today() method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The patch decorator is used here to mock out the date class in the module under test. The side_effect attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by side_effect.

```python
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10
```
Note that we don’t patch `datetime.date` globally, we patch date in the module that uses it. See where to patch.

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (call_count and friends) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other builtin classes, is discussed in this blog entry.

### 26.6.3.3. Mocking a Generator Method

A Python generator is a function or method that uses the `yield` statement to return a series of values when iterated over [1].

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is `__iter__()`, so we can mock this using a `MagicMock`.

Here’s an example class with an “iter” method implemented as a generator:
How would we mock this class, and in particular its “iter” method?

To configure the values returned from the iteration (implicit in the call to `list`), we need to configure the object returned by the call to `foo.iter()`.

```python
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

There are also generator expressions and more advanced uses of generators, but we aren’t concerned about them here. A very good introduction to generators and how powerful they are is: *Generator Tricks for Systems Programmers*.

26.6.3.4. Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. For Python 2.6 or more recent you can use `patch()` (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test method is identified by methods whose names start with `test`:
An alternative way of managing patches is to use the patch methods: start and stop. These allow you to move the patching into your setUp and tearDown methods.
If you use this technique you must ensure that the patching is “undone” by calling stop. This can be fiddlier than you might think, because if an exception is raised in the setUp then tearDown is not called. `unittest.TestCase.addCleanup()` makes this easier:

```python
>>> class MyTest(TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...
...     def test_foo(self):
...         self.assertEqual(mymodule.foo, self.mock_foo)
...     ...;

>>> MyTest('test_foo').run()
```

26.6.3.5. Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed `self` to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can't patch with a mock for this, because if you replace an unbound method with a mock it doesn't become a bound method when fetched from the instance, and so it doesn't get `self` passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to `patch` then it does the patching with a *real* function object. This function object has the same signature as the
one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have self passed in as the first argument, which is exactly what I wanted:

```python
>>> class Foo:
...     def foo(self):
...         pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...     mock_foo.return_value = 'foo'
...     foo = Foo()
...     foo.foo()
... 'foo'
>>> mock_foo.assert_called_once_with(foo)
```

If we don't use autospec=True then the unbound method is patched out with a Mock instance instead, and isn't called with self.

26.6.3.6. Checking multiple calls with mock

mock has a nice API for making assertions about how your mock objects are used.

```python
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

If your mock is only being called once you can use the
assert_called_once_with() method that also asserts that the call_count is one.

```python
>>> mock.foo_bar.assert_called_once_with('baz', spam)
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam)
Traceback (most recent call last):
  ...
AssertionError: Expected to be called once. Called 2
```

Both assert_called_with and assert_called_once_with make assertions about the most recent call. If your mock is going to be called several times, and you want to make assertions about all those calls you can use call_args_list:

```python
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The call helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to call_args_list. This looks remarkably similar to the repr of the call_args_list:

```python
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

26.6.3.7. Coping with mutable arguments
Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store references to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here’s some example code that shows the problem. Imagine the following functions defined in ‘mymodule’:

```python
def frob(val):
    pass

def grob(val):
    "First frob and then clear val"
    frob(val)
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```python
>>> with patch('mymodule.frob') as mock_frob:
...     val = {6}
...     mymodule.grob(val)
... >>> val
set()
>>> mock_frob.assert_called_with({6})
Traceback (most recent call last):
  ... AssertionError: Expected: (({6},), {})
Called with: ((set()), {})```

One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.
Here's one solution that uses the side_effect functionality. If you provide a side_effect function for a mock then side_effect will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I'm using another mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```python
from copy import deepcopy
from unittest.mock import Mock, patch, DEFAULT

def copy_call_args(mock):
    new_mock = Mock()
    def side_effect(*args, **kwars):
        args = deepcopy(args)
        kwars = deepcopy(kwars)
        new_mock(*args, **kwars)
        return DEFAULT
    mock.side_effect = side_effect
    return new_mock

with patch('mymodule.frob') as mock_frob:
    new_mock = copy_call_args(mock_frob)
    val = {6}
    mymodule.grob(val)

e new_mock.assert_called_with({6})
e new_mock.call_args
    call({6})
```

copy_call_args is called with the mock that will be called. It returns a new mock that we do the assertion on. The side_effect function makes a copy of the args and calls our new_mock with the copy.

**Note:** If your mock is only going to be used once there is an easier
way of checking arguments at the point they are called. You can simply do the checking inside a side_effect function.

```python
>>> def side_effect(arg):
...    assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
Traceback (most recent call last):
  ...
AssertionError
```

An alternative approach is to create a subclass of Mock or MagicMock that copies (using copy.deepcopy()) the arguments. Here's an example implementation:

```python
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...    def __call__(self, *args, **kwargs):
...        args = deepcopy(args)
...        kwargs = deepcopy(kwargs)
...        return super(CopyingMock, self).__call__(*args, **kwargs)
...            
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
  ...
AssertionError: Expected call: mock({1})
Actual call: mock(set())
>>> c.foo
```
When you subclass Mock or MagicMock all dynamically created attributes, and the return_value will use your subclass automatically. That means all children of a CopyingMock will also have the type CopyingMock.

26.6.3.8. Nesting Patches

Using patch as a context manager is nice, but if you do multiple patches you can end up with nested with statements indenting further and further to the right:

```python
>>> class MyTest(TestCase):
...     ...
...     def test_foo(self):
...         ...
...         with patch('mymodule.Foo') as mock_foo:
...             ...
...             with patch('mymodule.Bar') as mock_bar:
...                 ...
...                 with patch('mymodule.Spam') as mock_spam:
...                     assert mymodule.Foo is mock_foo
...                     assert mymodule.Bar is mock_bar
...                     assert mymodule.Spam is mock_spam
...     ...
...     original = mymodule.Foo
...     MyTest('test_foo').test_foo()
...     assert mymodule.Foo is original
```

With unittest cleanup functions and the patch methods: start and stop we can achieve the same effect without the nested indentation. A simple helper method, create_patch, puts the patch in place and returns the created mock for us:
>>> class MyTest(TestCase):
...    ...
...    def create_patch(self, name):
...        patcher = patch(name)
...        thing = patcher.start()
...        self.addCleanup(patcher.stop)
...        return thing
...    ...
...    def test_foo(self):
...        mock_foo = self.create_patch('mymodule.Foo'
...        mock_bar = self.create_patch('mymodule.Bar'
...        mock_spam = self.create_patch('mymodule.Spam'
...        ...
...        assert mymodule.Foo is mock_foo
...        assert mymodule.Bar is mock_bar
...        assert mymodule.Spam is mock_spam
...        ...

>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original

### 26.6.3.9. Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object, recording all access to it whilst having it still behave like a dictionary.

We can do this with MagicMock, which will behave like a dictionary, and using side_effect to delegate dictionary access to a real underlying dictionary that is under our control.

When the __getitem__() and __setitem__() methods of our MagicMock are called (normal dictionary access) then side_effect is called with the key (and in the case of __setitem__ the value too). We can also control what is returned.
After the MagicMock has been used we can use attributes like `call_args_list` to assert about how the dictionary was used:

```python
>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
>>> def getitem(name):
...    return my_dict[name]
...
>>> def setitem(name, val):
...    my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

**Note:** An alternative to using MagicMock is to use Mock and *only* provide the magic methods you specifically want:

```python
>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)
```

A *third* option is to use MagicMock but passing in `dict` as the `spec` (or `spec_set`) argument so that the MagicMock created only has dictionary magic methods available:

```python
>>> mock = MagicMock(spec_set=dict)
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

With these side effect functions in place, the mock will behave like a normal dictionary but recording the access. It even raises a `KeyError` if you try to access a key that doesn’t exist.
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
Traceback (most recent call last):
 ... 
  KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
>>> mock['d']
'eggs'

After it has been used you can make assertions about the access using the normal mock methods and attributes:

>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'c': 3, 'b': 'fish', 'd': 'eggs'}

26.6.3.10. Mock subclasses and their attributes

There are various reasons why you might want to subclass Mock. One reason might be to add helper methods. Here’s a silly example:

```python
>>> class MyMock(MagicMock):
...     def has_been_called(self):
...         return self.called

...```
The standard behaviour for Mock instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that Mock attributes are Mocks and Mock attributes are MagicMocks [2]. So if you're subclassing to add helper methods then they'll also be available on the attributes and return value mock of instances of your subclass.

Sometimes this is inconvenient. For example, one user is subclassing mock to created a Twisted adaptor. Having this applied to attributes too actually causes errors.

Mock (in all its flavours) uses a method called _get_child_mock to create these “sub-mocks” for attributes and return values. You can prevent your subclass being used for attributes by overriding this method. The signature is that it takes arbitrary keyword arguments (**kwargs) which are then passed onto the mock constructor:
An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn't have callable methods.

26.6.3.11. Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren’t using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is usually a much better way to solve the problem (refactor the code) or to prevent “up front costs” by delaying the import. This can also be solved in better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use mock to affect the results of an import. Importing fetches an object from the sys.modules dictionary. Note that it fetches an object, which need not be a module. Importing a module for the first time results in a module object being put in sys.modules, so usually when you import something you get a module back. This need not be the case however.
This means you can use `patch.dict()` to temporarily put a mock in place in `sys.modules`. Any imports whilst this patch is active will fetch the mock. When the patch is complete (the decorated function exits, the with statement body is complete or `patcher.stop()` is called) then whatever was there previously will be restored safely.

Here's an example that mocks out the 'fooble' module.

```python
g>>> mock = Mock()  
g>>> with patch.dict('sys.modules', {'fooble': mock}) 
...     import fooble 
...     fooble.blob() 
...<Mock name='mock.blob()' id='...'>
g>>> assert 'fooble' not in sys.modules 
g>>> mock.blob.assert_called_once_with() 
```

As you can see the `import fooble` succeeds, but on exit there is no 'fooble' left in `sys.modules`.

This also works for the `from module import name` form:

```python
g>>> mock = Mock()  
g>>> with patch.dict('sys.modules', {'fooble': mock}) 
...     from fooble import blob 
...     blob.blip() 
...<Mock name='mock.blob.blip()' id='...'>
g>>> mock.blob.blip.assert_called_once_with() 
```

With slightly more work you can also mock package imports:

```python
g>>> mock = Mock()  
```
26.6.3.12. Tracking order of calls and less verbose call assertions

The Mock class allows you to track the order of method calls on your mock objects through the method_calls attribute. This doesn’t allow you to track the order of calls between separate mock objects, however we can use mock_calls to achieve the same effect.

Because mocks track calls to child mocks in mock_calls, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the mock_calls of the parent:

```python
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='...'>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='...'>

>>> manager.mock_calls
```
We can then assert about the calls, including the order, by comparing with the mock_calls attribute on the manager mock:

```python
>>> expected_calls = [call.foo.something(), call.bar.other.thing()]
>>> manager.mock_calls == expected_calls
True
```

If patch is creating, and putting in place, your mocks then you can attach them to a manager mock using the `attach_mock()` method. After attaching calls will be recorded in mock_calls of the manager.

```python
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
...         manager.attach_mock(MockClass1, 'MockClass1')
...         manager.attach_mock(MockClass2, 'MockClass2')
...         MockClass1().foo()
...         MockClass2().bar()
...
<MagicMock name='mock.MockClass1().foo()' id='...'>
<MagicMock name='mock.MockClass2().bar()' id='...'>
>>> manager.mock_calls
[call.MockClass1(),
 call.MockClass1().foo(),
 call.MockClass2(),
 call.MockClass2().bar()]
```

If many calls have been made, but you’re only interested in a particular sequence of them then an alternative is to use the `assert_has_calls()` method. This takes a list of calls (constructed with the `call` object). If that sequence of calls are in `mock_calls`
then the assert succeeds.

```python
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='...'>
>>> m.one().two().three()
<MagicMock name='mock.one().two().three()' id='...'>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)
```

Even though the chained call `m.one().two().three()` aren't the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about some of those calls. You may not even care about the order. In this case you can pass `any_order=True` to `assert_has_calls`:

```python
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7), call(2, 3)]
>>> m.assert_has_calls(calls, any_order=True)
```

26.6.3.13. More complex argument matching

Using the same basic concept as `ANY` we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by default compares equal based on object identity (which is the Python default for user defined classes). To use `assert_called_with()`
we would need to pass in the exact same object. If we are only interested in some of the attributes of this object then we can create a matcher that will check these attributes for us.

You can see in this example how a ‘standard’ call to assert_called_with isn’t sufficient:

```python
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
  ...  
AssertionError: Expected: call(<__main__.Foo object at 0x...>)
Actual call: call(<__main__.Foo object at 0x...>)
```

A comparison function for our Foo class might look something like this:

```python
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
...     return True
...
```

And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```python
>>> class Matcher:
```
Putting all this together:

```python
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The Matcher is instantiated with our compare function and the Foo object we want to compare against. In `assert_called_with` the Matcher equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don't an `AssertionError` is raised:

```python
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
  ...
AssertionError: Expected: ((<Matcher object at 0x...>,), {}) Called with: ((<Foo object at 0x...>,), {})
```

With a bit of tweaking you could have the comparison function raise the `AssertionError` directly and provide a more useful failure message.

As of version 1.5, the Python testing library PyHamcrest provides similar functionality, that may be useful here, in the form of its equality matcher (`hamcrest.library.integration.match_equality`).
26.7. 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library lib2to3 is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. lib2to3 could also be adapted to custom applications in which Python code needs to be edited automatically.
26.7.1. Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the Tools/scripts directory of the Python root.

2to3’s basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, example.py:

```python
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless -n is also given.) Writing the changes back is enabled with the -w flag:

```
$ 2to3 -w example.py
```

After transformation, example.py looks like this:

```python
def greet(name):
    print("Hello, {0}!").format(name))
print("What's your name?")
name = input()
```
greet(name)

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of predefined fixers. The -l flag lists all available fixers. An explicit set of fixers to run can be given with -f. Likewise the -x explicitly disables a fixer. The following example runs only the imports and has_key fixers:

$ 2to3 -f imports -f has_key example.py

This command runs every fixer except the apply fixer:

$ 2to3 -x apply example.py

Some fixers are explicit, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

$ 2to3 -f all -f idioms example.py

Notice how passing all enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the -d flag. Note that only doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.
The -v option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the from __future__ import print_function compiler directive, it modifies its internal grammar to interpret \texttt{print()} as a function. This change can also be enabled manually with the -p flag. Use -p to run fixers on code that already has had its print statements converted.

The -o or --output-dir option allows specification of an alternate directory for processed output files to be written to. The -n flag is required when using this as backup files do not make sense when not overwriting the input files.

\textit{New in version 3.2.3}: The -o option was added.

The -W or --write-unchanged-files flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with -o so that an entire Python source tree is copied with translation from one directory to another. This option implies the -w flag as it would not make sense otherwise.

\textit{New in version 3.2.3}: The -W flag was added.

The --add-suffix option specifies a string to append to all output filenames. The -n flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

\begin{verbatim}
$ 2to3 -n -W --add-suffix=3 example.py
\end{verbatim}

Will cause a converted file named \texttt{example.py3} to be written.
New in version 3.2.3: The `--add-suffix` option was added.

To translate an entire project from one directory tree to another use:

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
```
26.7.2. Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

**apply**

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs).

**asserts**

Replaces deprecated `unittest` method names with the correct ones.

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>failUnlessEqual(a, b)</code></td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td><code>assertEquals(a, b)</code></td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td><code>failIfEqual(a, b)</code></td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td><code>assertNotEquals(a, b)</code></td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td><code>failUnless(a)</code></td>
<td><code>assertTrue(a)</code></td>

<tr>
<td>failIfAlmostEqual(a, b)</td>
<td>assertNotAlmostEqual(a, b)</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>assertNotAlmostEquals(a, b)</td>
<td>assertNotAlmostEqual(a, b)</td>
</tr>
</tbody>
</table>

**basestring**

Converts basestring to str.

**buffer**

Converts buffer to memoryview. This fixer is optional because the memoryview API is similar but not exactly the same as that of buffer.

**callable**

Converts callable(x) to isinstance(x, collections.Callable), adding an import to collections if needed. Note callable(x) has returned in Python 3.2, so if you do not intend to support Python 3.1, you can disable this fixer.

**dict**

Fixes dictionary iteration methods. dict.iteritems() is converted to dict.items(), dict.iterkeys() to dict.keys(), and dict.itervalues() to dict.values(). Similarly, dict.viewitems(), dict.viewkeys() and dict.viewvalues() are converted respectively to dict.items(), dict.keys() and dict.values(). It also wraps existing usages of dict.items(), dict.keys(), and dict.values() in a call to list.

**except**

Converts except X, T to except X as T.
exec
Converts the exec statement to the `exec()` function.

execfile
Removes usage of `execfile()`. The argument to `execfile()` is wrapped in calls to `open()`, `compile()`, and `exec()`.

exitfunc
Changes assignment of `sys.exitfunc` to use of the `atexit` module.

filter
Wraps `filter()` usage in a `list` call.

funcattrs
Fixes function attributes that have been renamed. For example, `my_function.func_closure` is converted to `my_function.__closure__`.

future
Removes from `__future__` import `new_feature` statements.

getcwd
Renames `os.getcwdu()` to `os.getcwd()`.

has_key
Changes `dict.has_key(key)` to `key in dict`.

idioms
This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is`
SomeClass and type(x) == SomeClass are converted to isinstance(x, SomeClass). while 1 becomes while True. This fixer also tries to make use of sorted() in appropriate places. For example, this block

```python
L = list(some_iterable)
L.sort()
```

is changed to

```python
L = sorted(some_iterable)
```

**import**

Detects sibling imports and converts them to relative imports.

**imports**

Handles module renames in the standard library.

**imports2**

Handles other modules renames in the standard library. It is separate from the imports fixer only because of technical limitations.

**input**

Converts input(prompt) to eval(input(prompt)).

**intern**

Converts intern() to sys.intern().

**isinstance**

Fixes duplicate types in the second argument of isinstance(). For example, isinstance(x, (int, int)) is converted to isinstance(x, (int)).
**itertools imports**
Removes imports of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()`. Imports of `itertools.ifilterfalse()` are also changed to `itertools.filterfalse()`.

**itertools**
Changes usage of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()` to their built-in equivalents. `itertools.ifilterfalse()` is changed to `itertools.filterfalse()`.

**long**
Renames `long` to `int`.

**map**
Wraps `map()` in a `list` call. It also changes `map(None, x)` to `list(x)`. Using from `future_builtins` import `map` disables this fixer.

**metaclass**
Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

**methodattrs**
Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

**ne**
Converts the old not-equal syntax, `<>`, to `!=`.

**next**
Converts the use of iterator’s `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

**nonzero**
Renames `__nonzero__()` to `__bool__()`.

**numliterals**
Converts octal literals into the new syntax.

**operator**
Converts calls to various functions in the `operator` module to other, but equivalent, function calls. When needed, the appropriate import statements are added, e.g. `import collections`. The following mapping are made:

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>operator.isCallable(obj)</code></td>
<td><code>hasattr(obj, '__call__')</code></td>
</tr>
<tr>
<td><code>operator.sequenceIncludes(obj)</code></td>
<td><code>operator.contains</code></td>
</tr>
<tr>
<td><code>operator.isSequenceType(obj)</code></td>
<td><code>isinstance(obj, collections.Sequence)</code></td>
</tr>
<tr>
<td><code>operator.isMappingType(obj)</code></td>
<td><code>isinstance(obj, collections.Mapping)</code></td>
</tr>
<tr>
<td><code>operator.isNumberType(obj)</code></td>
<td><code>isinstance(obj, numbers.Number)</code></td>
</tr>
<tr>
<td><code>operator.repeat(obj, n)</code></td>
<td><code>operator.mul(obj, operator.irepeat(obj, n))</code></td>
</tr>
<tr>
<td><code>operator.irepeat(obj, n)</code></td>
<td><code>operator.imul(obj)</code></td>
</tr>
</tbody>
</table>

**paren**
Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2] becomes
[x for x in (1, 2)].

**print**
Converts the print statement to the `print()` function.

**raise**
Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

**raw_input**
Converts `raw_input()` to `input()`.

**reduce**
Handles the move of `reduce()` to `functools.reduce()`.

**reload**
Converts `reload()` to `imp.reload()`.

**renames**
Changes `sys.maxint` to `sys.maxsize`.

**repr**
Replaces backtick `repr` with the `repr()` function.

**set_literal**
Replaces use of the `set` constructor with set literals. This fixer is optional.

**standarderror**
Renames `StandardError` to `Exception`. 
**sys_exc**
Changes the deprecated `sys.exc_value`, `sys.exc_type`, `sys.exc_traceback` to use `sys.exc_info()`.

**throw**
Fixes the API change in generator's `throw()` method.

**tuple_params**
Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

**types**
Fixes code broken from the removal of some members in the `types` module.

**unicode**
Renames `unicode` to `str`.

**urllib**
Handles the rename of `urllib` and `urllib2` to the `urllib` package.

**ws_comma**
Removes excess whitespace from comma separated items. This fixer is optional.

**xrange**
Renames `xrange()` to `range()` and wraps existing `range()` calls with `list`.

**xreadlines**
Changes for `x in file.xreadlines()` to `for x in file`.
zip
Wraps `zip()` usage in a `list` call. This is disabled when from `future_builtins import zip` appears.
26.7.3. **lib2to3** - 2to3’s library

**Note:** The **lib2to3** API should be considered unstable and may change drastically in the future.
26.8. **test** — Regression tests package for Python

**Note:** The **test** package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The **test** package contains all regression tests for Python as well as the modules **test.support** and **test.regrtest**. **test.support** is used to enhance your tests while **test.regrtest** drives the testing suite.

Each module in the **test** package whose name starts with **test_** is a testing suite for a specific module or feature. All new tests should be written using the **unittest** or **doctest** module. Some older tests are written using a “traditional” testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**See also:**

**Module unittest**
   Writing PyUnit regression tests.

**Module doctest**
   Tests embedded in documentation strings.
26.8.1. Writing Unit Tests for the test package

It is preferred that tests that use the unittest module follow a few guidelines. One is to name the test module by starting it with test_ and end it with the name of the module being tested. The test methods in the test module should start with test_ and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as # Tests function returns only True or False) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import support

class MyTestCase1(unittest.TestCase):
    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests

    def tearDown(self):
        ... code to execute to clean up after tests

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...
```
def test_feature_two(self):
    # Test feature two.
    ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...

    ... more test classes ...

if __name__ == '__main__':
    unittest.main()

This code pattern allows the testing suite to be run by test.regrtest, on its own as a script that supports the unittest CLI, or via the python -m unittest CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.

- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.

- Make sure to clean up after your tests (such as close and remove all temporary files).

- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequencesMixin:
    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequencesMixin,
    arg = [1, 2, 3]
```
```python
class AcceptStrings(TestFuncAcceptsSequencesMixin):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequencesMixin):
    arg = (1, 2, 3)
```

When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The Mixin class in the example above does not have any data and so can’t be run by itself, thus it does not inherit from `unittest.TestCase`.

See also:

**Test Driven Development**
A book by Kent Beck on writing tests before code.
26.8.2. Running tests using the command-line interface

The test package can be run as a script to drive Python’s regression test suite, thanks to the -m option: python -m test. Under the hood, it uses test.regrtest; the call python -m test.regrtest used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the test package. It does this by finding all modules in the package whose name starts with test_, importing them, and executing the function test_main() if present or loading the tests via unittest.TestLoader.loadTestsFromModule if test_main does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (python -m test test_spam) will minimize output and only print whether the test passed or failed.

Running test directly allows what resources are available for tests to use to be set. You do this by using the -u command-line option. Specifying all as the value for the -u option enables all possible resources: python -m test -uall. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after all. The command python -m test -uall,-audio,-largefile will run test with all resources except the audio and largefile resources. For a list of all resources and more command-line options, run python -m test -h.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run make test at the top-level directory where Python was built. On Windows, executing rt.bat from your PCBuild directory will run all regression
tests.
26.9. `test.support` — Utilities for the Python test suite

The `test.support` module provides support for Python’s regression test suite.

**Note:** `test.support` is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

This module defines the following exceptions:

- **Exception** `test.support.TestFailed`  
  Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

- **Exception** `test.support.ResourceDenied`  
  Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.support` module defines the following constants:

- **`test.support.verbose`**  
  True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`. 
test.support.is_jython

True if the running interpreter is Jython.

test.support.TESTFN

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The test.support module defines the following functions:

test.support.forget(module_name)

Remove the module named module_name from sys.modules and delete any byte-compiled files of the module.

test.support.is_resource_enabled(resource)

Return True if resource is enabled and available. The list of available resources is only set when test.regrtest is executing the tests.

test.support.requires(resource, msg=None)

Raise ResourceDenied if resource is not available. msg is the argument to ResourceDenied if it is raised. Always returns True if called by a function whose __name__ is '__main__'. Used when tests are executed by test.regrtest.

test.support.findfile(filename, subdir=None)

Return the path to the file named filename. If no match is found filename is returned. This does not equal a failure since it could be the path to the file.

    Setting subdir indicates a relative path to use to find the file rather than looking directly in the path directories.
**run_unittest**(*classes*)

Execute **unittest.TestCase** subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following `test_main()` function:

```python
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

**run_doctest**(module, verbosity=None)

Run `doctest.testmod()` on the given `module`. Return `(failure_count, test_count)`.

If `verbosity` is None, `doctest.testmod()` is run with verbosity set to `verbose`. Otherwise, it is run with verbosity set to None.

**check_warnings**(*filters, quiet=True*)

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form ("message regexp", WarningCategory) as positional arguments. If one
or more filters are provided, or if the optional keyword argument quiet is False, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set quiet to True.

If no arguments are specified, it defaults to:

```python
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a WarningRecorder instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's warnings attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return None.

The recorder object also has a reset() method, which clears the warnings list.

The context manager is designed to be used like this:

```python
with check_warnings(("assertion is always true", "", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning
was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*Changed in version 3.2:* New optional arguments `filters` and `quiet`.

test.support.``captured_stdin``
test.support.``captured_stdout``
test.support.``captured_stderr``

A context managers that temporarily replaces the named stream with `io.StringIO` object.

Example use with output streams:

```
with captured_stdout() as stdout, captured_stderr:
    print("hello")
    print("error", file=sys.stderr)
    stdout.getvalue() == "hello\n"
    stderr.getvalue() == "error\n"
```
Example use with input stream:

```python
with captured_stdin() as stdin:
    stdin.write('hello
')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
captured = input()
self.assertEqual(captured, "hello")
```

test.support.temp_dir(path=None, quiet=False)
A context manager that creates a temporary directory at path and yields the directory.

If path is None, the temporary directory is created using `tempfile.mkdtemp()`. If quiet is False, the context manager raises an exception on error. Otherwise, if path is specified and cannot be created, only a warning is issued.

test.support.change_cwd(path, quiet=False)
A context manager that temporarily changes the current working directory to path and yields the directory.

If quiet is False, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

test.support.temp_cwd(name='tempcwd', quiet=False)
A context manager that temporarly creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name name before temporarily changing the current working directory. If name is None, the temporary directory is
created using `tempfile.mkdtemp()`.

If `quiet` is False and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

test.support.temp_umask(umask)
A context manager that temporarily sets the process umask.

test.support.can_symlink()
Return True if the OS supports symbolic links, False otherwise.

@test.support.skip_unless_symlink
A decorator for running tests that require support for symbolic links.

@test.support.anticipate_failure(condition)
A decorator to conditionally mark tests with unittest.expectedFailure(). Any use of this decorator should have an associated comment identifying the relevant tracker issue.

@test.support.run_with_locale(catstr, *locales)
A decorator for running a function in a different locale, correctly resetting it after it has finished. `catstr` is the locale category as a string (for example "LC_ALL"). The `locales` passed will be tried sequentially, and the first valid locale will be used.

test.support.make_bad_fd()
Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

test.support.import_module(name, deprecated=False)
This function imports and returns the named module. Unlike a
normal import, this function raises unittest.SkipTest if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if deprecated is True.

New in version 3.1.

test.support.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)

This function imports and returns a fresh copy of the named Python module by removing the named module from sys.modules before doing the import. Note that unlike reload(), the original module is not affected by this operation.

fresh is an iterable of additional module names that are also removed from the sys.modules cache before doing the import.

blocked is an iterable of module names that are replaced with None in the module cache during the import to ensure that attempts to import them raise ImportError.

The named module and any modules named in the fresh and blocked parameters are saved before starting the import and then reinserted into sys.modules when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if deprecated is True.

This function will raise ImportError if the named module cannot be imported.

Example use:
# Get copies of the warnings module for testing without affecting the version being used by the rest of the test suite.
# C implementation, the other is forced to use the pure Python fallback implementation
py_warnings = import_fresh_module('warnings', block_warnings=True)
c_warnings = import_fresh_module('warnings', fresh=True)

New in version 3.1.

test.support.bind_port(sock, host=HOST)

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the sock.family is AF_INET and sock.type is SOCK_STREAM, and the socket has SO_REUSEADDR or SO_REUSEPORT set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the SO_EXCLUSIVEADDRUSE socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

test.support.find_unused_port(family=socket.AF_INET, socktype=socket.SOCK_STREAM)

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the sock parameter (default is AF_INET, SOCK_STREAM), and binding it to the specified host address (defaults to 0.0.0.0) with the port set to 0, eliciting an unused ephemeral port from the
OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a python socket, or if an unused port needs to be provided to an constructor or passed to an external program (i.e. the -accept argument to openssl's s_server mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can makes multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

`test.support.load_package_tests(pkg_dir, loader, standard_tests, pattern)`

Generic implementation of the `unittest` load_tests protocol for use in test packages. `pkg_dir` is the root directory of the package; `loader, standard_tests, and pattern` are the arguments expected by load_tests. In simple cases, the test package's `__init__.py` can be the following:

```python
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__))
```

detect_api_mismatch(ref_api, other_api, *,
                     ignore=()):

Returns the set of attributes, functions or methods of `ref_api` not found on `other_api`, except for a defined list of items to be ignored
in this check specified in ignore.

By default this skips private attributes beginning with ‘_’ but includes all magic methods, i.e. those starting and ending in ‘__’.

New in version 3.5.

The test.support module defines the following classes:

class test.support.TransientResource(exc, **kwargs)

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.

class test.support.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying os.environ. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

    Changed in version 3.1: Added dictionary interface.

EnvironmentVarGuard.set(envvar, value)

Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)

Temporarily unset the environment variable envvar.
class test.support.SuppressCrashReport

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using SetErrorMode.

On UNIX, resource.setrlimit() is used to set resource.RLIMIT_CORE's soft limit to 0 to prevent coredump file creation.

On both platforms, the old value is restored by __exit__().

class test.support.WarningsRecorder

Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.
27. Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

27.1. bdb — Debugger framework

Source code: Lib/bdb.py

The bdb module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```
exception bdb.BdbQuit

Exception raised by the Bdb class for quitting the debugger.
```

The bdb module also defines two classes:

```
class bdb.Breakpoint(self, file, line, temporary=0, cond=None, funcname=None)

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called bpbynumber and by (file, line) pairs through bplist. The former points to a single instance of class Breakpoint. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a funcname is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

Breakpoint instances have the following methods:
deleteMe()
Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

enable()
Mark the breakpoint as enabled.

disable()
Mark the breakpoint as disabled.

bpformat()
Return a string with all the information about the breakpoint, nicely formatted:

- The breakpoint number.
- If it is temporary or not.
- Its file,line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

*New in version 3.2.*

bpprint(out=None)
Print the output of `bpformat()` to the file `out`, or if it is None, to standard output.

class bdb.Bdb(skip=None)
The `Bdb` class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (`pdb.Pdb`) is an example.
The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

*New in version 3.1:* The `skip` argument.

The following methods of `Bdb` normally don’t need to be overridden.

**canonic(filename)**

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

**reset()**

Set the botframe, stopframe, returnframe and quitting attributes with values ready to start debugging.

**trace_dispatch(frame, event, arg)**

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. `event` can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to
return.

- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The arg parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to The standard type hierarchy.

**dispatch_line(frame)**

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the Bdb.quitting flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_call(frame, arg)**

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the Bdb.quitting flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return(frame, arg)**

If the debugger should stop on this function return, invoke the
user_return() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_return()). Return a reference to the trace_dispatch() method for further tracing in that scope.

**dispatch_exception(frame, arg)**

If the debugger should stop at this exception, invokes the user_exception() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_exception()). Return a reference to the trace_dispatch() method for further tracing in that scope.

Normally derived classes don’t override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**stop_here(frame)**

This method checks if the frame is somewhere below botframe in the call stack. botframe is the frame in which debugging started.

**break_here(frame)**

This method checks if there is a breakpoint in the filename and line belonging to frame or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**break_anywhere(frame)**

This method checks if there is a breakpoint in the filename of the current frame.
Derived classes should override these methods to gain control over debugger operation.

**user_call(frame, argument_list)**
This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line(frame)**
This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields True.

**user_return(frame, return_value)**
This method is called from `dispatch_return()` when `stop_here()` yields True.

**user_exception(frame, exc_info)**
This method is called from `dispatch_exception()` when `stop_here()` yields True.

**do_clear(arg)**
Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set_step()**
Stop after one line of code.

**set_next(frame)**
Stop on the next line in or below the given frame.

**set_return(frame)**
Stop when returning from the given frame.

**set_until(frame)**
Stop when the line with the line no greater than the current one is reached or when returning from current frame.

**set_trace([frame])**
Start debugging from frame. If frame is not specified, debugging starts from caller's frame.

**set_continue()**
Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

**set_quit()**
Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*( ) methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

**set_break(filename, lineno, temporary=0, cond, funcname)**
Set a new breakpoint. If the lineno line doesn’t exist for the filename passed as argument, return an error message. The filename should be in canonical form, as described in the canonic() method.

**clear_break(filename, lineno)**
Delete the breakpoints in *filename* and *lineno*. If none were set, an error message is returned.

**clear_bpbynumber**(arg)
Delete the breakpoint which has the index *arg* in the Breakpoint.bpbynumber. If *arg* is not numeric or out of range, return an error message.

**clear_all_file_breaks**(filename)
Delete all breakpoints in *filename*. If none were set, an error message is returned.

**clear_all_breaks()**
Delete all existing breakpoints.

**get_bpbynumber**(arg)
Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a *ValueError* is raised.

*New in version 3.2.*

**get_break**(filename, lineno)
Check if there is a breakpoint for *lineno* of *filename*.

**get_breaks**(filename, lineno)
Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

**get_file_breaks**(filename)
Return all breakpoints in *filename*, or an empty list if none are set.
**get_all_breaks()**

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

**get_stack**(*f, t*)

Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

**format_stack_entry**(*frame_lineno, lprefix=':')*

Return a string with information about a stack entry, identified by a (frame, lineno) tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a **statement**, given as a string.

**run**(*cmd, globals=None, locals=None*)

Debug a statement executed via the **exec()** function. **globals** defaults to __main__.__dict__, **locals** defaults to **globals**.

**runeval**(*expr, globals=None, locals=None*)

Debug an expression executed via the **eval()** function. **globals** and **locals** have the same meaning as in **run()**.

**runctx**(*cmd, globals, locals*)
For backwards compatibility. Calls the `run()` method.

**runcall**(*func, *args, **kwds*)

Debug a single function call, and return its result.

Finally, the module defines the following functions:

**bdb.checkfuncname**(*b, frame*)

Check whether we should break here, depending on the way the breakpoint *b* was set.

If it was set via line number, it checks if *b.line* is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

**bdb.effective**(*file, line, frame*)

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return (*None, None*) if there is no matching breakpoint.

**bdb.set_trace()**

Start debugging with a Bdb instance from caller’s frame.
27. Debugging and Profiling
27.2. `faulthandler` — Dump the Python traceback

*New in version 3.3.*

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS, and SIGILL signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X` `faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.
By default, the Python traceback is written to `sys.stderr`. To see
tracebacks, applications must be run in the terminal. A log file can
alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a
crash or when Python is deadlocked.
27.2.1. Dumping the traceback

```
faulthandler.dump_traceback(file=sys.stderr, all_threads=True)
```

Dump the tracebacks of all threads into file. If `all_threads` is False, dump only the current thread.

*Changed in version 3.5:* Added support for passing file descriptor to this function.
27.2.2. Fault handler state

faulthandler.enable(file=sys.stderr, all_threads=True)

Enable the fault handler: install handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS and SIGILL signals to dump the Python traceback. If all_threads is True, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The file must be kept open until the fault handler is disabled: see issue with file descriptors.

Changed in version 3.5: Added support for passing file descriptor to this function.

faulthandler.disable()

Disable the fault handler: uninstall the signal handlers installed by enable().

faulthandler.is_enabled()

Check if the fault handler is enabled.
27.2.3. Dumping the tracebacks after a timeout

```python
faulthandler.dump_traceback_later(timeout, repeat=False, file=sys.stderr, exit=False)
```

Dump the tracebacks of all threads, after a timeout of `timeout` seconds, or every `timeout` seconds if `repeat` is True. If `exit` is True, call `__exit__()` with status=1 after dumping the tracebacks. (Note `__exit__()` exits the process immediately, which means it doesn’t do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The `file` must be kept open until the traceback is dumped or `cancel_dump_traceback_later()` is called: see issue with file descriptors.

This function is implemented using a watchdog thread and therefore is not available if Python is compiled with threads disabled.

*Changed in version 3.5*: Added support for passing file descriptor to this function.

```python
faulthandler.cancel_dump_traceback_later()
```

Cancel the last call to `dump_traceback_later()`.
27.2.4. Dumping the traceback on a user signal

`faulthandler.register(signum, file=sys.stderr, all_threads=True, chain=False)`

Register a user signal: install a handler for the `signum` signal to dump the traceback of all threads, or of the current thread if `all_threads` is False, into `file`. Call the previous handler if `chain` is True.

The `file` must be kept open until the signal is unregistered by `unregister()`: see issue with file descriptors.

Not available on Windows.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

`faulthandler.unregister(signum)`

Unregister a user signal: uninstall the handler of the `signum` signal installed by `register()`. Return True if the signal was registered, False otherwise.

Not available on Windows.
27.2.5. Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their `file` argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.
27.2.6. Example

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python3 -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python3 -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
```

Current thread 0x00007fb899f39700 (most recent call first)
  File "'/home/python/cpython/Lib/ctypes/__init__.py"
  File "<stdin>", line 1 in <module>
Segmentation fault
27.3. pdb — The Python Debugger

Source code: Lib/pdb.py

The module pdb defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible – it is actually defined as the class Pdb. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules bdb and cmd.

The debugger’s prompt is (Pdb). Typical usage to run a program under control of the debugger is:

```python
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

*Changed in version 3.3:* Tab-completion via the readline module is available for commands and command arguments, e.g. the current
global and local names are offered as arguments of the p command.

pdb.py can also be invoked as a script to debug other scripts. For example:

```
python3 -m pdb myscript.py
```

When invoked as a script, pdb will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), pdb will restart the program. Automatic restarting preserves pdb’s state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program’s exit.

*New in version 3.2:* pdb.py now accepts a -c option that executes commands as if given in a .pdbrc file, see Debugger Commands.

The typical usage to break into the debugger from a running program is to insert

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the continue command.

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "./mymodule.py", line 4, in test
```
The module defines the following functions; each enters the debugger in a slightly different way:

```python
import pdb

def test2()
    print(spam)
NameError: name 'spam'
```

```
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print(spam)
(Pdb)
```

**pdb.run**(*statement*, *globals=None*, *locals=None*)

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can step through the statement using `step` or `next` (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module `__main__` is used. (See the explanation of the built-in `exec()` or `eval()` functions.)

**pdb.runeval**(*expression*, *globals=None*, *locals=None*)

Evaluate the *expression* (given as a string or a code object) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`

**pdb.runcall**(*function*, *args*, **kwds*)

Call the *function* (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.
pdb.set_trace()
    Enter the debugger at the calling stack frame. This is useful to
    hard-code a breakpoint at a given point in a program, even if the
    code is not otherwise being debugged (e.g. when an assertion
    fails).

dbd.post_mortem(traceback=None)
    Enter post-mortem debugging of the given traceback object. If no
    traceback is given, it uses the one of the exception that is currently
    being handled (an exception must be being handled if the default is
    to be used).

dbd.pm()
    Enter post-mortem debugging of the traceback found in
    sys.last_traceback.

The run* functions and set_trace() are aliases for instantiating
the Pdb class and calling the method of the same name. If you want to
access further features, you have to do this yourself:

class pdb.Pdb(completekey='tab', stdin=None, stdout=None,
              skip=None, nosigint=False)
    Pdb is the debugger class.

    The completekey, stdin and stdout arguments are passed to the
underlying cmd.Cmd class; see the description there.

    The skip argument, if given, must be an iterable of glob-style
module name patterns. The debugger will not step into frames that
originate in a module that matches one of these patterns. [1]

    By default, Pdb sets a handler for the SIGINT signal (which is sent
when the user presses Ctrl-C on the console) when you give a
continue command. This allows you to break into the debugger again by pressing Ctrl-C. If you want Pdb not to touch the SIGINT handler, set nosigint tot true.

Example call to enable tracing with skip:

```python
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

*New in version 3.1:* The skip argument.

*New in version 3.2:* The nosigint argument. Previously, a SIGINT handler was never set by Pdb.

```python
run(statement, globals=None, locals=None)
runeval(expression, globals=None, locals=None)
runcall(function, *args, **kwds)
set_trace()
```

See the documentation for the functions explained above.
27.3.1. Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. h(e1p) means that either h or help can be used to enter the help command (but not he or hel, nor H or Help or HELP). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ]) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a list command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by ;;. (A single ; is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first ;; pair, even if it is in the middle of a quoted string.
If a file .pdbrc exists in the user’s home directory or in the current directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

*Changed in version 3.2:* .pdbrc can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

**h(elp) [command]**
Without argument, print the list of available commands. With a `command` as argument, print help about that command. `help pdb` displays the full documentation (the docstring of the `pdb` module). Since the `command` argument must be an identifier, `help exec` must be entered to get help on the `!` command.

**w(here)**
Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

**d(own) [count]**
Move the current frame `count` (default one) levels down in the stack trace (to a newer frame).

**u(p) [count]**
Move the current frame `count` (default one) levels up in the stack trace (to an older frame).

**b(reak) [([filename:]lineno | function) [, condition]]**
With a `lineno` argument, set a break there in the current file. With a
function argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn’t been loaded yet). The file is searched on sys.path. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[filename:]lineno | function] [, condition]
Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for break.

clear [filename:lineno | bpnumber [bpnumber ...]]
With a filename:lineno argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber [bpnumber ...]]
Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber [bpnumber ...]]
Enable the breakpoints specified.
**ignore bpnumber [count]**
Set the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

**condition bpnumber [condition]**
Set a new condition for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

**commands [bpnumber]**
Specify a list of commands for breakpoint number bpnumber. The commands themselves appear on the following lines. Type a line containing just end to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with end; that is, give no commands.

With no bpnumber argument, commands refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the continue command, or step, or any other command that resumes execution.
Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

**s(step)**

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

**n(ext)**

Continue execution until the next line in the current function is reached or it returns. (The difference between next and step is that step stops inside a called function, while next executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

**unt(ill) [lineno]**

Without argument, continue execution until the line with a number greater than the current one is reached.

With a line number, continue execution until a line with a number greater or equal to that is reached. In both cases, also stop when the current frame returns.
Changed in version 3.2: Allow giving an explicit line number.

r(eturn)
Continue execution until the current function returns.

c(ont(inue))
Continue execution, only stop when a breakpoint is encountered.

j(ump) lineno
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don’t want to run.

It should be noted that not all jumps are allowed – for instance it is not possible to jump into the middle of a for loop or out of a finally clause.

l(ist) [first[, last]]
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With . as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by ->. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by >>, if it differs from the current line.

New in version 3.2: The >> marker.

l1 l | longlist
List all source code for the current function or frame. Interesting lines are marked as for `list`.

*New in version 3.2.*

**a(rgs)**
Print the argument list of the current function.

**p** expression
Evaluate the `expression` in the current context and print its value.

**Note:** `print()` can also be used, but is not a debugger command — this executes the Python `print()` function.

**pp** expression
Like the `p` command, except the value of the expression is pretty-printed using the `pprint` module.

**whatis** expression
Print the type of the `expression`.

**source** expression
Try to get source code for the given object and display it.

*New in version 3.2.*

**display** `[expression]`
Display the value of the expression if it changed, each time execution stops in the current frame.

Without expression, list all display expressions for the current frame.
New in version 3.2.

**undisplay** [expression]
Do not display the expression any more in the current frame. Without expression, clear all display expressions for the current frame.

New in version 3.2.

**interact**
Start an interative interpreter (using the code module) whose global namespace contains all the (global and local) names found in the current scope.

New in version 3.2.

**alias** [name [command]]
Create an alias called *name* that executes *command*. The command must *not* be enclosed in quotes. Replaceable parameters can be indicated by %1, %2, and so on, while %* is replaced by all the parameters. If no command is given, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the .pdbrc file):
unalias name
  Delete the specified alias.

! statement
  Execute the (one-line) statement in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a global statement on the same line, e.g.:

  (Pdb) global list_options; list_options = ['-l']
  (Pdb)

run [args ...]
restart [args ...]
  Restart the debugged Python program. If an argument is supplied, it is split with shlex and the result is used as the new sys.argv. History, breakpoints, actions and debugger options are preserved. restart is an alias for run.

q(uit)
  Quit from the debugger. The program being executed is aborted.

Footnotes

[1] Whether a frame is considered to originate in a certain module is determined by the __name__ in the frame globals.
27.4. The Python Profilers

Source code: Lib/profile.py and Lib/pstats.py
27.4.1. Introduction to the profilers

cProfile and profile provide deterministic profiling of Python programs. A profile is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the pstats module.

The Python standard library provides two different implementations of the same profiling interface:

1. cProfile is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on lsprof, contributed by Brett Rosen and Ted Czotter.
2. profile, a pure Python module whose interface is imitated by cProfile, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

**Note:** The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is timeit for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.
27.4.2. Instant User’s Manual

This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```python
import cProfile
import re

CProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
197 function calls (192 primitive calls) in 0.
Ordered by: standard name
ncalls tottime percall cumtime percall filename:lineno
 1    0.000    0.000    0.001    0.001 <string>:1
 1    0.000    0.000    0.001    0.001 re.py:212
 1    0.000    0.000    0.001    0.001 re.py:268
 1    0.000    0.000    0.000    0.000 sre_compile:1
 1    0.000    0.000    0.000    0.000 sre_compile:1
 4    0.000    0.000    0.000    0.000 sre_compile:1
 3/1 0.000    0.000    0.000    0.000 sre_compile:1

```

The first line indicates that 197 calls were monitored. Of those calls, 192 were `primitive`, meaning that the call was not induced via
recursion. The next line: Ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls
  for the number of calls,
tottime
  for the total time spent in the given function (and excluding time made in calls to sub-functions)
percall
  is the quotient of tottime divided by ncalls
cumtime
  is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.
percall
  is the quotient of cumtime divided by primitive calls
filename:lineno(function)
  provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the run() function:

```python
import cProfile
import re
```
cProfile.run('re.compile("foo|bar"), 'restats')

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The file `cProfile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order]
```

- `-o` writes the profile results to a file instead of to stdout
- `-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls
to experiment with:

```
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats('time').print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats('time', 'cumulative').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: .5) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could
now (p is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you’re going to have to read the manual, or guess what the following functions do:

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the pstats module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using cmd) and interactive help.
27.4.3. **profile** and **cProfile** Module Reference

Both the **profile** and **cProfile** modules provide the following functions:

**profile.run**(command, filename=None, sort=-1)

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified it is passed to this `Stats` instance to control how the results are sorted.

**profile.runctx**(command, globals, locals, filename=None)

This function is similar to `run()`, with added arguments to supply the globals and locals dictionaries for the `command` string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

**class profile.Profile**(timer=None, timeunit=0.0, subcalls=True, builtins=True)
This class is normally only used if more precise control over profiling is needed than what the \texttt{cProfile.run()} function provides.

A custom timer can be supplied for measuring how long code takes to run via the \texttt{timer} argument. This must be a function that returns a single number representing the current time. If the number is an integer, the \texttt{timeunit} specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be \texttt{.001}.

Directly using the \texttt{Profile} class allows formatting profile results without writing the profile data to a file:

```python
import cProfile, pstats, io
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = 'cumulative'
ps = pstats.Stats(pr, stream=s).sort_stats(sortby
ps.print_stats()
print(s.getvalue())
```

\textbf{enable()}

Start collecting profiling data.

\textbf{disable()}

Stop collecting profiling data.

\textbf{create_stats()}

Stop collecting profiling data and record the results internally as
the current profile.

**print_stats**(sort=-1)
Create a *Stats* object based on the current profile and print the results to stdout.

**dump_stats**(filename)
Write the results of the current profile to *filename*.

**run**(cmd)
Profile the cmd via *exec()*.

**runcxtx**(cmd, globals, locals)
Profile the cmd via *exec()* with the specified global and local environment.

**runcall**(func, *args, **kwargs)
Profile *func*(*args, **kwargs*)
27.4.4. The Stats Class

Analysis of the profiler data is done using the Stats class.

```python
class pstats.Stats(*filenames or profile, stream=sys.stdout)
```

This class constructor creates an instance of a “statistics object” from a filename (or list of filenames) or from a Profile instance. Output will be printed to the stream specified by stream.

The file selected by the above constructor must have been created by the corresponding version of profile or cProfile. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing Stats object, the add() method can be used.

Instead of reading the profile data from a file, a cProfile.Profile or profile.Profile object can be used as the profile data source.

Stats objects have the following methods:

**strip_dirs()**

This method for the Stats class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its
entries in a “random” order, as it was just after object initialization and loading. If \texttt{strip_dirs()} causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

\textbf{add(\texttt{*filenames})}

This method of the \texttt{Stats} class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of \texttt{profile.run()} or \texttt{cProfile.run()}. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

\textbf{dump_stats(\texttt{filename})}

Save the data loaded into the \texttt{Stats} object to a file named \texttt{filename}. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the \texttt{profile.Profile} and \texttt{cProfile.Profile} classes.

\textbf{sort_stats(\texttt{*keys})}

This method modifies the \texttt{Stats} object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example: 'time' or 'name').

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, \texttt{sort_stats('name', 'file')} will sort all the entries according to their function
name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the abbreviation is unambiguous. The following are the keys currently defined:

<table>
<thead>
<tr>
<th>Valid Arg</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'calls'</td>
<td>call count</td>
</tr>
<tr>
<td>'cumulative'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'cumtime'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'file'</td>
<td>file name</td>
</tr>
<tr>
<td>'filename'</td>
<td>file name</td>
</tr>
<tr>
<td>'module'</td>
<td>file name</td>
</tr>
<tr>
<td>'ncalls'</td>
<td>call count</td>
</tr>
<tr>
<td>'pcalls'</td>
<td>primitive call count</td>
</tr>
<tr>
<td>'line'</td>
<td>line number</td>
</tr>
<tr>
<td>'name'</td>
<td>function name</td>
</tr>
<tr>
<td>'nfl'</td>
<td>name/file/line</td>
</tr>
<tr>
<td>'stdname'</td>
<td>standard name</td>
</tr>
<tr>
<td>'time'</td>
<td>internal time</td>
</tr>
<tr>
<td>'tottime'</td>
<td>internal time</td>
</tr>
</tbody>
</table>

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means
that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, sort_stats('nfl') is the same as sort_stats('name', 'file', 'line').

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

**reverse_order()**

This method for the Stats class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

**print_stats(*restrictions)**

This method for the Stats class prints out a report as described in the profile.run() definition.

The order of the printing is based on the last sort_stats() operation done on the object (subject to caveats in add() and strip_dirs()).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction
between 0.0 and 1.0 inclusive (to select a percentage of lines),
or a regular expression (to pattern match the standard name
that is printed. If several restrictions are provided, then they are
applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only
print functions that were part of filename .*foo:. In contrast,
the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names .*foo:,
and then proceed to only print the first 10% of them.

**print_callers(*restrictions)**

This method for the Stats class prints a list of all functions that
called each function in the profiled database. The ordering is
identical to that provided by print_stats(), and the
definition of the restricting argument is also identical. Each
caller is reported on its own line. The format differs slightly
depending on the profiler that produced the stats:

- With profile, a number is shown in parentheses after
each caller to show how many times this specific call was
made. For convenience, a second non-parenthesized
number repeats the cumulative time spent in the function at
the right.
- With cProfile, each caller is preceded by three numbers:
the number of times this specific call was made, and the
total and cumulative times spent in the current function
while it was invoked by this specific caller.
print_callees(*restrictions)

This method for the Stats class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the print_callers() method.
27.4.5. What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
27.4.6. Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it can accumulate and become very significant.

The problem is more important with profile than with the lower-overhead cProfile. For this reason, profile provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do not be alarmed by negative numbers in the profile. They should only appear if you have calibrated your profiler, and the results are actually
better than without calibration.
27.4.7. Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see Limitations).

```python
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running Mac OS X, and using Python’s time.clock() as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is very fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```python
import profile

# 1. Apply computed bias to all Profile instances created thereafter.
profile.Profile.bias = your_computed_bias
```
# 2. Apply computed bias to a specific Profile instance.

```python
pr = profile.Profile()
pr.bias = your_computed_bias
```

# 3. Specify computed bias in instance constructor.

```python
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.
27.4.8. Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the Profile class constructor:

```python
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call your_time_func. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, your_time_func's return value will be interpreted differently:

**profile.Profile**

your_time_func should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see Calibration). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is pretty bad, as it returns a tuple of floating point values). If you want to substitute a a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

**cProfile.Profile**

your_time_func should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For
example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the Profile instance as follows:

```python
cpr = cProfile.Profile(your_integer_time_func, 0.0)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.
27. Debugging and Profiling
27.5. `timeit` — Measure execution time of small code snippets

*Source code: Lib/timeit.py*

This module provides a simple way to time small bits of Python code. It has both a Command-Line Interface as well as a callable one. It avoids a number of common traps for measuring execution times. See also Tim Peters’ introduction to the “Algorithms” chapter in the *Python Cookbook*, published by O'Reilly.
27.5.1. Basic Examples

The following example shows how the Command-Line Interface can be used to compare three different expressions:

```bash
$ python3 -m timeit '"-".join(str(n) for n in range(100))'
10000 loops, best of 3: 30.2 usec per loop
$ python3 -m timeit '"-".join([str(n) for n in range(100)])'
10000 loops, best of 3: 27.5 usec per loop
$ python3 -m timeit '"-".join(map(str, range(100)))'
10000 loops, best of 3: 23.2 usec per loop
```

This can be achieved from the Python Interface with:

```python
>>> import timeit
>>> timeit.timeit('"-".join(str(n) for n in range(100))', 0.3018611848820001
>>> timeit.timeit('"-".join([str(n) for n in range(100)])', 0.2727368790656328
>>> timeit.timeit('"-".join(map(str, range(100)))', 0.23702679807320237
```

Note however that `timeit` will automatically determine the number of repetitions only when the command-line interface is used. In the Examples section you can find more advanced examples.
27.5.2. Python Interface

The module defines three convenience functions and a public class:

```python
import timeit

timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000, globals=None)
```

Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `timeit()` method with `number` executions. The optional `globals` argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional `globals` parameter was added.

```python
import timeit

timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=3, number=1000000, globals=None)
```

Create a `Timer` instance with the given statement, `setup` code and `timer` function and run its `repeat()` method with the given `repeat` count and `number` executions. The optional `globals` argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional `globals` parameter was added.

```python
import timeit

timeit.default_timer()
```

The default timer, which is always `time.perf_counter()`.

*Changed in version 3.3:* `time.perf_counter()` is now the default timer.

```python
class timeit.Timer(stmt='pass', setup='pass', timer=<timer function>, globals=None)
```
Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to 'pass'; the timer function is platform-dependent (see the module doc string). \texttt{stmt} and \texttt{setup} may also contain multiple statements separated by ; or newlines, as long as they don't contain multi-line string literals. The statement will by default be executed within timeit's namespace; this behavior can be controlled by passing a namespace to \texttt{globals}.

To measure the execution time of the first statement, use the \texttt{timeit()} method. The \texttt{repeat()} method is a convenience to call \texttt{timeit()} multiple times and return a list of results.

The execution time of \texttt{setup} is excluded from the overall timed execution run.

The \texttt{stmt} and \texttt{setup} parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by \texttt{timeit()}. Note that the timing overhead is a little larger in this case because of the extra function calls.

\textit{Changed in version 3.5:} The optional \texttt{globals} parameter was added.

\texttt{timeit(number=1000000)}

Time \texttt{number} executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement,
the setup statement and the timer function to be used are passed to the constructor.

**Note:** By default, `timeit()` temporarily turns off garbage collection during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the setup string. For example:

```python
timeit.Timer('for i in range(10): oct(i)', 'gc.enable()')
```

**repeat**(repeat=3, number=1000000)

Call `timeit()` a few times.

This is a convenience function that calls the `timeit()` repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the number argument for `timeit()`.

**Note:** It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python’s speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.
**print_exc**(*file=None*)

Helper to print a traceback from the timed code.

Typical use:

```python
t = Timer(...)  # outside the try/except
try:
    t.timeit(...)  # or t.repeat(...)
except Exception:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional *file* argument directs where the traceback is sent; it defaults to `sys.stderr`.
27.5.3. Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-t] [---]...
```

Where the following options are understood:

- `-n N`, `--number=N`
  how many times to execute 'statement'

- `-r N`, `--repeat=N`
  how many times to repeat the timer (default 3)

- `-s S`, `--setup=S`
  statement to be executed once initially (default pass)

- `-p`, `--process`
  measure process time, not wallclock time, using `time.process_time()` instead of `time.perf_counter()`, which is the default

  *New in version 3.3.*

- `-t`, `--time`
  use `time.time()` (deprecated)

- `-u`, `--unit=U`
  specify a time unit for timer output; can select usec, msec, or sec
New in version 3.5.

- **c, --clock**
  use `time.clock()` (deprecated)

- **v, --verbose**
  print raw timing results; repeat for more digits precision

- **h, --help**
  print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.

If `-n` is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.

`default_timer()` measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 3 repetitions is probably enough in most cases. You can use `time.process_time()` to measure CPU time.

**Note:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn’t try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.
27.5.4. Examples

It is possible to provide a setup statement that is executed only once at the beginning:

```python
$ python -m timeit -s 'text = "sample string"; char = g'
10000000 loops, best of 3: 0.0877 usec per loop
$ python -m timeit -s 'text = "sample string"; char = g'
1000000 loops, best of 3: 0.342 usec per loop

>>> import timeit
timeit.timeit('char in text', setup='text = "sample string"; char = g')
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = g')
1.7246671520006203
```

The same can be done using the `Timer` class and its methods:

```python
>>> import timeit
t = timeit.Timer('char in text', setup='text = "sample string"; char = g')
t.timeit()
0.395516149999312
>>> t.repeat()
[0.40193588800002544, 0.3960157959998014, 0.39594301399984033]
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes:

```python
$ python -m timeit 'try:' str.__bool__ 'except AttributeError'
100000 loops, best of 3: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__bool__")': pass
```
To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement:
```python
def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()"), setup="from __main__ import test")
```

Another option is to pass `globals()` to the `globals` parameter, which will cause the code to be executed within your current global namespace. This can be more convenient than individually specifying imports:

```python
def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]'))
```
27.6. **trace** — Trace or track Python statement execution

**Source code:** [Lib/trace.py](Lib/trace.py)

The **trace** module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.
27.6.1. Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

**--help**
Display usage and exit.

**--version**
Display the version of the module and exit.

27.6.1.1. Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

**-c, --count**
Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

**-t, --trace**
Display lines as they are executed.
-l, --listfuncs
Display the functions executed by running the program.

-r, --report
Produce an annotated list from an earlier program run that used the --count and --file option. This does not execute any code.

-T, --trackcalls
Display the calling relationships exposed by running the program.

27.6.1.2. Modifiers

-f, --file=<file>
Name of a file to accumulate counts over several tracing runs. Should be used with the --count option.

-C, --coverdir=<dir>
Directory where the report files go. The coverage report for package.module is written to file dir/package/module.cover.

-m, --missing
When generating annotated listings, mark lines which were not executed with >>>>>>.

-s, --summary
When using --count or --report, write a brief summary to stdout for each file processed.

-R, --no-report
Do not generate annotated listings. This is useful if you intend to make several runs with --count, and then produce a single set of
annotated listings at the end.

-g, --timings
Prefix each line with the time since the program started. Only used while tracing.

27.6.1.3. Filters

These options may be repeated multiple times.

--ignore-module=<mod>
Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

--ignore-dir=<dir>
Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by \texttt{os.pathsep}.
27.6.2. Programmatic Interface

class Trace(count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(), infile=None, outfile=None, timing=False)

Create an object to trace execution of a single statement or expression. All parameters are optional. count enables counting of line numbers. trace enables line execution tracing. countfuncs enables listing of the functions called during the run. countcallers enables call relationship tracking. ignoremods is a list of modules or packages to ignore. ignoredirs is a list of directories whose modules or packages should be ignored. infile is the name of the file from which to read stored count information. outfile is the name of the file in which to write updated count information. timing enables a timestamp relative to when tracing was started to be displayed.

run(cmd)

Execute the command and gather statistics from the execution with the current tracing parameters. cmd must be a string or code object, suitable for passing into exec().

runcxtx(cmd, globals=None, locals=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, globals and locals default to empty dictionaries.

runfunc(func, *args, **kwds)

Call func with the given arguments under control of the Trace object with the current tracing parameters.
results()

Return a CoverageResults object that contains the cumulative results of all previous calls to run, runctx and runfunc for the given Trace instance. Does not reset the accumulated trace results.

```
class trace.CoverageResults
```

A container for coverage results, created by Trace.results(). Should not be created directly by the user.

```
update(other)
```

Merge in data from another CoverageResults object.

```
write_results(show_missing=True, summary=False, coverdir=None)
```

Write coverage results. Set show_missing to show lines that had no hits. Set summary to include in the output the coverage summary per module. coverdir specifies the directory into which the coverage result files will be output. If None, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, # do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
```
count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")
27.7. `tracemalloc` — Trace memory allocations

*New in version 3.4.*

The tracemalloc module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the `PYTHONTRACEMALLOC` environment variable to 1, or by using `-X tracemalloc` command line option. The `tracemalloc.start()` function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the `PYTHONTRACEMALLOC` environment variable to 25, or use the `-X tracemalloc=25` command line option.
27.7.1. Examples

27.7.1.1. Display the top 10

Display the 10 files allocating the most memory:

```python
import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print('Top 10')
for stat in top_stats[:10]:
    print(stat)
```

Example of output of the Python test suite:

```
[ Top 10 ]
< frozen importlib._bootstrap >: 716: size= 4855 KiB, count=
< frozen importlib._bootstrap >: 284: size= 521 KiB, count=
/usr/lib/python3.4/collections/__init__.py: 368: size=
/usr/lib/python3.4/unittest/case.py: 381: size= 185 KiB, count=
< frozen importlib._bootstrap >: 1446: size= 70.4 KiB, count=
< frozen importlib._bootstrap >: 1454: size= 52.0 KiB, count=
<string>: 5: size= 49.7 KiB, count= 148, average= 344 B
/usr/lib/python3.4/sysconfig.py: 411: size= 48.0 KiB,
```

We can see that Python loaded 4.8 MiB data (bytecode and
constants) from modules and that the collections module allocated 244 KiB to build namedtuple types.

See Snapshot.statistics() for more options.

27.7.1.2. Compute differences

Take two snapshots and display the differences:

```python
import tracemalloc
tracealloc.start()
# ... start your application ...

snapshot1 = tracealloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracealloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output before/after running some tests of the Python test suite:

```
[ Top 10 differences ]
< frozen importlib._bootstrap >: 716: size=8173 KiB (+4
/usr/lib/python3.4/linecache.py: 127: size=940 KiB (+
/usr/lib/python3.4/unittest/case.py: 571: size=298 Ki
< frozen importlib._bootstrap >: 284: size=1005 KiB (+1
/usr/lib/python3.4/mimetypes.py: 217: size=112 KiB (+
/usr/lib/python3.4/http/server.py: 848: size=96.0 KiB
/usr/lib/python3.4(inspect.py: 1465: size=83.5 KiB (+
```
We can see that Python has loaded 8.2 MiB of module data (bytecode and constants), and that this is 4.4 MiB more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the `linecache` module has cached 940 KiB of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the `Snapshot.dump()` method to analyze the snapshot offline. Then use the `Snapshot.load()` method reload the snapshot.

### 27.7.1.3. Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```python
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.size/1024))
for line in stat.traceback.format():
    print(line)
```
Example of output of the Python test suite (traceback limited to 25 frames):

903 memory blocks: 870.1 KiB
File "<frozen importlib._bootstrap>" , line 716
File "<frozen importlib._bootstrap>" , line 1036
File "<frozen importlib._bootstrap>" , line 934
File "<frozen importlib._bootstrap>" , line 1068
File "<frozen importlib._bootstrap>" , line 619
File "<frozen importlib._bootstrap>" , line 1581
File "<frozen importlib._bootstrap>" , line 1614
File "/usr/lib/python3.4/doctest.py" , line 101

    import pdb
File "<frozen importlib._bootstrap>" , line 284
File "<frozen importlib._bootstrap>" , line 938
File "<frozen importlib._bootstrap>" , line 1068
File "<frozen importlib._bootstrap>" , line 619
File "<frozen importlib._bootstrap>" , line 1581
File "<frozen importlib._bootstrap>" , line 1614
File "/usr/lib/python3.4/test/support/__init__.py"

    import doctest
File "/usr/lib/python3.4/test/test_pickletools.py"
support.run_doctest(pickletools)
File "/usr/lib/python3.4/test/regrtest.py" , line 1
test_runner()
File "/usr/lib/python3.4/test/regrtest.py" , line 9
display_failure=not verbose)
File "/usr/lib/python3.4/test/regrtest.py" , line 7
match_tests=ns.match_tests)
File "/usr/lib/python3.4/test/regrtest.py" , line 1
main()
File "/usr/lib/python3.4/test/__main__.py" , line 3
regrtest.main_in_temp_cwd()
File "/usr/lib/python3.4/runpy.py" , line 73
exec(code, run_globals)
File "/usr/lib/python3.4/runpy.py" , line 160
"__main__", fname, loader, pkg_name)
We can see that the most memory was allocated in the importlib
module to load data (bytecode and constants) from modules: 870
KiB. The traceback is where the importlib loaded data most
recently: on the import pdb line of the doctest module. The
traceback may change if a new module is loaded.

27.7.1.4. Pretty top
Code to display the 10 lines allocating the most memory with a pretty
output, ignoring <frozen
importlib._bootstrap> and
<unknown> files:
import linecache
import os
import tracemalloc
def display_top(snapshot, group_by='lineno', limit=10
snapshot = snapshot.filter_traces((
tracemalloc.Filter(False, "<frozen importlib._bootst
tracemalloc.Filter(False, "<unknown>"),
))
top_stats = snapshot.statistics(group_by)
print("Top %s lines" % limit)
for index, stat in enumerate(top_stats[:limit],
frame = stat.traceback[0]
# replace "/path/to/module/file.py" with "module/fil
filename = os.sep.join(frame.filename.split(
print("#%s: %s:%s: %.1f KiB"
% (index, filename, frame.lineno, stat
line = linecache.getline(frame.filename, frame
if line:
print('
%s' % line)


other = top_stats[limit:]
if other:
    size = sum(stat.size for stat in other)
    print("%s other: %.1f KiB" % (len(other), size))
total = sum(stat.size for stat in top_stats)
print("Total allocated size: %.1f KiB" % (total))

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)

Example of output of the Python test suite:

Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
    _b85chars2 = [(a + b) for a in _b85chars for b in _b85chars]
#2: Lib/base64.py:306: 419.8 KiB
    _a85chars2 = [(a + b) for a in _a85chars for b in _a85chars]
#3: collections/__init__.py:368: 293.6 KiB
    exec(class_definition, namespace)
#4: Lib/abc.py:133: 115.2 KiB
    cls = super().__new__(mcls, name, bases, namespace)
#5: unittest/case.py:574: 103.1 KiB

27.7.2. API

27.7.2.1. Functions

tracemalloc.\texttt{clear\_traces}()

Clear traces of memory blocks allocated by Python.

See also \texttt{stop}().

tracemalloc.\texttt{get\_object\_traceback}(\texttt{obj})

Get the traceback where the Python object \texttt{obj} was allocated. Return a \texttt{Traceback} instance, or None if the \texttt{tracemalloc} module is not tracing memory allocations or did not trace the allocation of the object.

See also \texttt{gc.get\_referrers}() and \texttt{sys.getsizeof}() functions.

tracemalloc.\texttt{get\_traceback\_limit}()

Get the maximum number of frames stored in the traceback of a trace.

The \texttt{tracemalloc} module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the \texttt{start}() function.

tracemalloc.\texttt{get\_traced\_memory}()

Get the current size and peak size of memory blocks traced by the \texttt{tracemalloc} module as a tuple: (current: int, peak: int).
tracemalloc.get_tracemalloc_memory()

Get the memory usage in bytes of the tracemalloc module used to store traces of memory blocks. Return an int.

tracemalloc.is_tracing()

True if the tracemalloc module is tracing Python memory allocations, False otherwise.

See also start() and stop() functions.

tracemalloc.start(nframe: int=1)

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to nframe frames. By default, a trace of a memory block only stores the most recent frame: the limit is 1. nframe must be greater or equal to 1.

Storing more than 1 frame is only useful to compute statistics grouped by 'traceback' or to compute cumulative statistics: see the Snapshot.compare_to() and Snapshot.statistics() methods.

Storing more frames increases the memory and CPU overhead of the tracemalloc module. Use the get_tracemalloc_memory() function to measure how much memory is used by the tracemalloc module.

The PYTHONTRACEMALLOC environment variable (PYTHONTRACEMALLOC=NFRAME) and the -X tracemalloc=NFRAME command line option can be used to start tracing at startup.
See also `stop()`, `is_tracing()` and `get_traceback_limit()` functions.

```python
tracemalloc.stop()
```

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call `take_snapshot()` function to take a snapshot of traces before clearing them.

See also `start()`, `is_tracing()` and `clear_traces()` functions.

```python
tracemalloc.take_snapshot()
```

Take a snapshot of traces of memory blocks allocated by Python. Return a new `Snapshot` instance.

The snapshot does not include memory blocks allocated before the `tracemalloc` module started to trace memory allocations.

Tracebacks of traces are limited to `get_traceback_limit()` frames. Use the `nframe` parameter of the `start()` function to store more frames.

The `tracemalloc` module must be tracing memory allocations to take a snapshot, see the `start()` function.

See also the `get_object_traceback()` function.

### 27.7.2.2. Filter

```python
class tracemalloc.Filter(inclusive: bool, filename_pattern: str,
```
Filter on traces of memory blocks.

See the `fnmatch.fnmatch()` function for the syntax of `filename_pattern`. The '.pyc' file extension is replaced with '.py'.

Examples:

- Filter(True, subprocess.__file__) only includes traces of the `subprocess` module
- Filter(False, tracemalloc.__file__) excludes traces of the `tracemalloc` module
- Filter(False, "<unknown>") excludes empty tracebacks

*Changed in version 3.5:* The '.pyo' file extension is no longer replaced with '.py'.

**inclusive**

If `inclusive` is True (include), only trace memory blocks allocated in a file with a name matching `filename_pattern` at line number `lineno`.

If `inclusive` is False (exclude), ignore memory blocks allocated in a file with a name matching `filename_pattern` at line number `lineno`.

**lineno**

Line number (int) of the filter. If `lineno` is None, the filter matches any line number.

**filename_pattern**
Filename pattern of the filter (str).

all_frames
If `all_frames` is True, all frames of the traceback are checked. If `all_frames` is False, only the most recent frame is checked.

This attribute has no effect if the traceback limit is 1. See the `get_traceback_limit()` function and `Snapshot.traceback_limit` attribute.

27.7.2.3. Frame

`class` `tracemalloc.Frame`
Frame of a traceback.

The `Traceback` class is a sequence of `Frame` instances.

filename
Filename (str).

lineno
Line number (int).

27.7.2.4. Snapshot

`class` `tracemalloc.Snapshot`
Snapshot of traces of memory blocks allocated by Python.

The `take_snapshot()` function creates a snapshot instance.

`compare_to(old_snapshot: Snapshot, group_by: str, cumulative: bool=False)`
Compute the differences with an old snapshot. Get statistics as a sorted list of `StatisticDiff` instances grouped by `group_by`.

See the `Snapshot.statistics()` method for `group_by` and `cumulative` parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `Statistic.count` and then by `StatisticDiff.traceback`.

**dump(filename)**
Write the snapshot into a file.

Use `load()` to reload the snapshot.

**filter_traces(filters)**
Create a new `Snapshot` instance with a filtered `traces` sequence, `filters` is a list of `Filter` instances. If `filters` is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

**classmethod load(filename)**
Load a snapshot from a file.

See also `dump()`.
**statistics** *(group_by: str, cumulative: bool=False)*

Get statistics as a sorted list of *Statistic* instances grouped by *group_by*:

<table>
<thead>
<tr>
<th>group_by</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'filename'</td>
<td>filename</td>
</tr>
<tr>
<td>'lineno'</td>
<td>filename and line number</td>
</tr>
<tr>
<td>'traceback'</td>
<td>traceback</td>
</tr>
</tbody>
</table>

If *cumulative* is True, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with *group_by* equals to 'filename' and 'lineno'.

The result is sorted from the biggest to the smallest by: *Statistic.size*, *Statistic.count* and then by *Statistic.traceback*.

**traceback_limit**

Maximum number of frames stored in the traceback of *traces*: result of the *get_traceback_limit()* when the snapshot was taken.

**traces**

Traces of all memory blocks allocated by Python: sequence of *Trace* instances.

The sequence has an undefined order. Use the *Snapshot.statistics()* method to get a sorted list of statistics.
27.7.2.5. Statistic

```python
class tracemalloc.Statistic
    Statistic on memory allocations.

Snapshot.statistics() returns a list of Statistic instances.
```

See also the StatisticDiff class.

- **count**
  Number of memory blocks (int).

- **size**
  Total size of memory blocks in bytes (int).

- **traceback**
  Traceback where the memory block was allocated, Traceback instance.

27.7.2.6. StatisticDiff

```python
class tracemalloc.StatisticDiff
    Statistic difference on memory allocations between an old and a new Snapshot instance.

Snapshot.compare_to() returns a list of StatisticDiff instances. See also the Statistic class.
```

- **count**
  Number of memory blocks in the new snapshot (int): 0 if the memory blocks have been released in the new snapshot.
**count_diff**
Difference of number of memory blocks between the old and the new snapshots (int): 0 if the memory blocks have been allocated in the new snapshot.

**size**
Total size of memory blocks in bytes in the new snapshot (int): 0 if the memory blocks have been released in the new snapshot.

**size_diff**
Difference of total size of memory blocks in bytes between the old and the new snapshots (int): 0 if the memory blocks have been allocated in the new snapshot.

**traceback**
Traceback where the memory blocks were allocated, `Traceback` instance.

### 27.7.2.7. Trace

**class** `tracemalloc.Trace`
Trace of a memory block.

The `Snapshot.traces` attribute is a sequence of `Trace` instances.

**size**
Size of the memory block in bytes (int).

**traceback**
Traceback where the memory block was allocated, `Traceback` instance.
27.7.2.8. Traceback

```python
class tracemalloc.Traceback
    Sequence of Frame instances sorted from the most recent frame to the oldest frame.
```

A traceback contains at least 1 frame. If the tracemalloc module failed to get a frame, the filename "<unknown>" at line number 0 is used.

When a snapshot is taken, tracebacks of traces are limited to `get_traceback_limit()` frames. See the `take_snapshot()` function.

The `Trace.traceback` attribute is an instance of `Traceback` instance.

```python
format(limit=None)
    Format the traceback as a list of lines with newlines. Use the linecache module to retrieve lines from the source code. If `limit` is set, only format the `limit` most recent frames.
```

Similar to the `traceback.format_tb()` function, except that `format()` does not include newlines.

Example:

```python
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```
Traceback (most recent call first):
  File "test.py", line 9
    obj = Object()
  File "test.py", line 12
    tb = tracemalloc.get_object_traceback(f())
28. Software Packaging and Distribution

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the Python Package Index, they can also be used with a local index server, or without any index server at all.

28.1. `distutils` — Building and installing Python modules

The `distutils` package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

Most Python users will not want to use this module directly, but instead use the cross-version tools maintained by the Python Packaging Authority. In particular, `setuptools` is an enhanced alternative to `distutils` that provides:

- support for declaring project dependencies
- additional mechanisms for configuring which files to include in source releases (including plugins for integration with version control systems)
- the ability to declare project “entry points”, which can be used as the basis for application plugin systems
- the ability to automatically generate Windows command line executables at installation time rather than needing to prebuild them
- consistent behaviour across all supported Python versions

The recommended `pip` installer runs all `setup.py` scripts with `setuptools`, even if the script itself only imports `distutils`. Refer to the [Python Packaging User Guide](https://docs.python.org/3/tutorials/distutils/) for more information.

For the benefits of packaging tool authors and users seeking a deeper understanding of the details of the current packaging and distribution
system, the legacy distutils based user documentation and API reference remain available:

- Installing Python Modules (Legacy version)
- Distributing Python Modules (Legacy version)
28.2. **ensurepip** — Bootstrapping the pip installer

*New in version 3.4.*

The **ensurepip** package provides support for bootstrapping the **pip** installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that **pip** is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn’t need to invoke this module directly (as **pip** should be bootstrapped by default), but it may be needed if installing **pip** was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling **pip**.

**Note:** This module *does not* access the internet. All of the components needed to bootstrap **pip** are included as internal parts of the package.

**See also:**

- **Installing Python Modules**
  - The end user guide for installing Python packages
- **PEP 453**: Explicit bootstrapping of **pip** in Python installations
  - The original rationale and specification for this module.
28.2.1. Command line interface

The command line interface is invoked using the interpreter’s -m switch.

The simplest possible invocation is:

```
python -m ensurepip
```

This invocation will install pip if it is not already installed, but otherwise does nothing. To ensure the installed version of pip is at least as recent as the one bundled with ensurepip, pass the --upgrade option:

```
python -m ensurepip --upgrade
```

By default, pip is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options:

- **--root <dir>**: Installs pip relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- **--user**: Installs pip into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts pipX and pipX.Y will be installed (where X.Y stands for the version of Python used to invoke ensurepip). The scripts installed can be controlled through two additional command line options:
- `--altinstall`: if an alternate installation is requested, the `pipX` script will *not* be installed.

- `--default-pip`: if a “default pip” installation is requested, the `pip` script will be installed in addition to the two regular scripts.

Providing both of the script selection options will trigger an exception.
28.2.2. Module API

`ensurepip` exposes two functions for programmatic use:

`ensurepip.version()`

Returns a string specifying the bundled version of pip that will be installed when bootstrapping an environment.

`ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=False, verbosity=0)`

Bootstraps pip into the current or designated environment.

`root` specifies an alternative root directory to install relative to. If `root` is None, then installation uses the default install location for the current environment.

`upgrade` indicates whether or not to upgrade an existing installation of an earlier version of pip to the bundled version.

`user` indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pipX` and `pipX.Y` will be installed (where `X.Y` stands for the current version of Python).

If `altinstall` is set, then `pipX` will not be installed.

If `default_pip` is set, then `pip` will be installed in addition to the two regular scripts.

Setting both `altinstall` and `default_pip` will trigger `ValueError`.

`verbosity` controls the level of output to `sys.stdout` from the
bootstrapping operation.

**Note:** The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

**Note:** The bootstrapping process may install additional modules required by `pip`, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of `pip`).
28.3. **venv** — Creation of virtual environments

*New in version 3.3.*

**Source code:** Lib/venv

The *venv* module provides support for creating lightweight “virtual environments” with their own site directories, optionally isolated from system site directories. Each virtual environment has its own Python binary (allowing creation of environments with various Python versions) and can have its own independent set of installed Python packages in its site directories.

See **PEP 405** for more information about Python virtual environments.
28.3.1. Creating virtual environments

Creation of virtual environments is done by executing the pyvenv script:

```
pyvenv /path/to/new/virtual/environment
```

Running this command creates the target directory (creating any parent directories that don’t exist already) and places a pyvenv.cfg file in it with a home key pointing to the Python installation the command was run from. It also creates a bin (or Scripts on Windows) subdirectory containing a copy of the python binary (or binaries, in the case of Windows). It also creates an (initially empty) lib/pythonX.Y/site-packages subdirectory (on Windows, this is Lib\site-packages).

**See also:** Python Packaging User Guide: Creating and using virtual environments

On Windows, you may have to invoke the pyvenv script as follows, if you don’t have the relevant PATH and PATHEXT settings:

```
c:\Temp>c:\Python35\python c:\Python35\Tools\Scripts\pyvenv.py myenv
```

or equivalently:

```
c:\Temp>c:\Python35\python -m venv myenv
```

The command, if run with -h, will show the available options:

```
usage: venv [-h] [--system-site-packages] [--symlink
```
[--upgrade] [--without-pip] ENV_DIR

Creates virtual Python environments in one or more target directories.

Positional arguments:
  ENV_DIR A directory to create the environment in.

Optional arguments:
  -h, --help show this help message and exit
  --system-site-packages Give access to the global site-packages dir of the virtual environment.
  --symlinks Try to use symlinks rather than copies, when symlinks are the default for the platform.
  --copies Try to use copies rather than symlinks, even when symlinks are the default for the platform.
  --clear Delete the environment directory if it already exists. If not specified and the directory exists, an error is raised.
  --upgrade Upgrade the environment directory to use this version of Python, assuming Python has been upgraded in-place.
  --without-pip Skips installing or upgrading pip in the virtual environment (pip is bootstrapped by default).

Depending on how the venv functionality has been invoked, the usage message may vary slightly, e.g. referencing pyvenv rather than venv.

*Changed in version 3.4:* Installs pip by default, added the --without-pip and --copies options

*Changed in version 3.4:* In earlier versions, if the target directory already existed, an error was raised, unless the --clear or --upgrade option was provided. Now, if an existing directory is specified, its contents are removed and the directory is processed as if it had been newly created.
The created pyvenv.cfg file also includes the include-system-site-packages key, set to true if venv is run with the --system-site-packages option, false otherwise.

Unless the --without-pip option is given, ensurepip will be invoked to bootstrap pip into the virtual environment.

Multiple paths can be given to pyvenv, in which case an identical virtualenv will be created, according to the given options, at each provided path.

Once a venv has been created, it can be “activated” using a script in the venv's binary directory. The invocation of the script is platform-specific:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Shell</th>
<th>Command to activate virtual environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Posix</td>
<td>bash/zsh</td>
<td>$ source &lt;venv&gt;/bin/activate</td>
</tr>
<tr>
<td></td>
<td>fish</td>
<td>$. &lt;venv&gt;/bin/activate.fish</td>
</tr>
<tr>
<td></td>
<td>csh/tcsh</td>
<td>$ source &lt;venv&gt;/bin/activate.csh</td>
</tr>
<tr>
<td>Windows</td>
<td>cmd.exe</td>
<td>C:&gt; &lt;venv&gt;/Scripts/activate.bat</td>
</tr>
<tr>
<td></td>
<td>PowerShell</td>
<td>PS C:&gt; &lt;venv&gt;/Scripts/Activate.ps1</td>
</tr>
</tbody>
</table>

You don’t specifically need to activate an environment; activation just prepends the venv’s binary directory to your path, so that “python” invokes the venv’s Python interpreter and you can run installed scripts without having to use their full path. However, all scripts installed in a venv should be runnable without activating it, and run with the venv’s Python automatically.

You can deactivate a venv by typing “deactivate” in your shell. The
exact mechanism is platform-specific: for example, the Bash activation script defines a “deactivate” function, whereas on Windows there are separate scripts called deactivate.bat and Deactivate.ps1 which are installed when the venv is created.

New in version 3.4: fish and csh activation scripts.

**Note:** A virtual environment (also called a venv) is a Python environment such that the Python interpreter, libraries and scripts installed into it are isolated from those installed in other virtual environments, and (by default) any libraries installed in a “system” Python, i.e. one which is installed as part of your operating system.

A venv is a directory tree which contains Python executable files and other files which indicate that it is a venv.

Common installation tools such as Setuptools and pip work as expected with venvs - i.e. when a venv is active, they install Python packages into the venv without needing to be told to do so explicitly. Of course, you need to install them into the venv first: this could be done by running ez_setup.py with the venv activated, followed by running easy_install pip. Alternatively, you could download the source tarballs and run python setup.py install after unpacking, with the venv activated.

When a venv is active (i.e. the venv’s Python interpreter is running), the attributes `sys.prefix` and `sys.exec_prefix` point to the base directory of the venv, whereas `sys.base_prefix` and `sys.base_exec_prefix` point to the non-venv Python installation which was used to create the venv. If a venv is not active, then `sys.prefix` is the same as `sys.base_prefix` and `sys.exec_prefix` is the same as `sys.base_exec_prefix` (they
all point to a non-venv Python installation).

When a venv is active, any options that change the installation path will be ignored from all distutils configuration files to prevent projects being inadvertently installed outside of the virtual environment.

When working in a command shell, users can make a venv active by running an activate script in the venv’s executables directory (the precise filename is shell-dependent), which prepends the venv’s directory for executables to the PATH environment variable for the running shell. There should be no need in other circumstances to activate a venv – scripts installed into venvs have a shebang line which points to the venv’s Python interpreter. This means that the script will run with that interpreter regardless of the value of PATH.

On Windows, shebang line processing is supported if you have the Python Launcher for Windows installed (this was added to Python in 3.3 - see PEP 397 for more details). Thus, double-clicking an installed script in a Windows Explorer window should run the script with the correct interpreter without there needing to be any reference to its venv in PATH.
28.3.2. API

The high-level method described above makes use of a simple API which provides mechanisms for third-party virtual environment creators to customize environment creation according to their needs, the EnvBuilder class.

```python
class venv.EnvBuilder(system_site_packages=False, clear=False, symlinks=False, upgrade=False, with_pip=False)

The EnvBuilder class accepts the following keyword arguments on instantiation:

- system_site_packages – a Boolean value indicating that the system Python site-packages should be available to the environment (defaults to False).
- clear – a Boolean value which, if true, will delete the contents of any existing target directory, before creating the environment.
- symlinks – a Boolean value indicating whether to attempt to symlink the Python binary (and any necessary DLLs or other binaries, e.g. pythonw.exe), rather than copying. Defaults to True on Linux and Unix systems, but False on Windows.
- upgrade – a Boolean value which, if true, will upgrade an existing environment with the running Python - for use when that Python has been upgraded in-place (defaults to False).
- with_pip – a Boolean value which, if true, ensures pip is installed in the virtual environment. This uses ensurepip with the --default-pip option.

Changed in version 3.4: Added the with_pip parameter
```

Creators of third-party virtual environment tools will be free to use
the provided EnvBuilder class as a base class.

The returned env-builder is an object which has a method, create:

\texttt{create(env\_dir)}

This method takes as required argument the path (absolute or relative to the current directory) of the target directory which is to contain the virtual environment. The create method will either create the environment in the specified directory, or raise an appropriate exception.

The create method of the EnvBuilder class illustrates the hooks available for subclass customization:

\begin{verbatim}
def create(self, env_dir):
    """
    Create a virtualized Python environment in env_dir is the target directory to create a """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
\end{verbatim}

Each of the methods ensure\_directories(), create\_configuration(), setup\_python(), setup\_scripts() and post\_setup() can be overridden.

\texttt{ensure\_directories(env\_dir)}

Creates the environment directory and all necessary directories,
and returns a context object. This is just a holder for attributes (such as paths), for use by the other methods. The directories are allowed to exist already, as long as either clear or upgrade were specified to allow operating on an existing environment directory.

**create_configuration(context)**

Creates the pyvenv.cfg configuration file in the environment.

**setup_python(context)**

Creates a copy of the Python executable (and, under Windows, DLLs) in the environment. On a POSIX system, if a specific executable python3.x was used, symlinks to python and python3 will be created pointing to that executable, unless files with those names already exist.

**setup_scripts(context)**

Installs activation scripts appropriate to the platform into the virtual environment.

**post_setup(context)**

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

In addition, `EnvBuilder` provides this utility method that can be called from `setup_scripts()` or `post_setup()` in subclasses to assist in installing custom scripts into the virtual environment.

**install_scripts(context, path)**

`path` is the path to a directory that should contain subdirectories “common”, “posix”, “nt”, each containing scripts destined for the
bin directory in the environment. The contents of “common” and the directory corresponding to `os.name` are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of environment directory).
- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment’s executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

There is also a module-level convenience function:

```python
venv.create(env_dir, system_site_packages=False, clear=False, symlinks=False, with_pip=False)
```

Create an `EnvBuilder` with the given keyword arguments, and call its `create()` method with the `env_dir` argument.

*Changed in version 3.4:* Added the `with_pip` parameter
28.3.3. An example of extending EnvBuilder

The following script shows how to extend `EnvBuilder` by implementing a subclass which installs setuptools and pip into a created venv:

```python
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    """
    This builder installs setuptools and pip so that easy_install other packages into the created env.

    :param nodist: If True, setuptools and pip are not installed into the created environment.
    :param nopip: If True, pip is not installed into the created environment.
    :param progress: If setuptools or pip are installed, the progress can be monitored by passing a progress callable. If specified, it is called with two arguments: a string indicating where the setup is occurring, and a context indicating where the setup is occurring. The context argument can have one of three values: 'main', indicating that it is being called from the main thread, or 'stdout' and 'stderr', which are obtained by reading lines from the output streams of a subprocess.
    """
```
which is used to install the app.

If a callable is not specified, information is output to sys.stderr.

```python
def __init__(self, *args, **kwargs):
    self.nodist = kwargs.pop('nodist', False)
    self.nopip = kwargs.pop('nopip', False)
    self.progress = kwargs.pop('progress', None)
    self.verbose = kwargs.pop('verbose', False)
    super().__init__(*args, **kwargs)

def post_setup(self, context):
    ""
    Set up any packages which need to be pre-installed into the environment being created.
    
    :param context: The information for the environment being processed.
    ""
    os.environ['VIRTUAL_ENV'] = context.env_dir
    if not self.nodist:

28.4. **zipapp** — Manage executable python zip archives

*New in version 3.5.*  

**Source code:** Lib/zipapp.py

This module provides tools to manage the creation of zip files containing Python code, which can be executed directly by the Python interpreter. The module provides both a Command-Line Interface and a Python API.
28.4.1. Basic Example

The following example shows how the Command-Line Interface can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the main function from the module myapp in the archive.

```
$ python -m zipapp myapp -m "myapp:main"
$ python myapp.pyz
<output from myapp>
```
28.4.2. Command-Line Interface

When called as a program from the command line, the following form is used:

```
$ python -m zipapp source [options]
```

If `source` is a directory, this will create an archive from the contents of `source`. If `source` is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will be displayed if the –info option is specified).

The following options are understood:

- **-o <output>, --output=<output>**
  Write the output to a file named `output`. If this option is not specified, the output filename will be the same as the input `source`, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

  An output filename must be specified if the `source` is an archive (and in that case, `output` must not be the same as `source`).

- **-p <interpreter>, --python=<interpreter>**
  Add a `#!` line to the archive specifying `interpreter` as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

- **-m <mainfn>, --main=<mainfn>**
  Write a `__main__.py` file to the archive that executes `mainfn`. The `mainfn` argument should have the form “pkg.mod:fn”, where “pkg.mod” is a package/module in the archive, and “fn” is a callable
in the given module. The __main__.py file will execute that callable.

--main cannot be specified when copying an archive.

--info
Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and SOURCE must be an archive, not a directory.

-h, --help
Print a short usage message and exit.
28.4.3. Python API

The module defines two convenience functions:

\texttt{zipapp.create_archive(source, target=\texttt{None}, interpreter=\texttt{None}, main=\texttt{None})}

Create an application archive from \texttt{source}. The source can be any of the following:

- The name of a directory, or a \texttt{pathlib\_Path} object referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a \texttt{pathlib\_Path} object referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the \texttt{interpreter} argument). The file name should include the \texttt{.pyz} extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The \texttt{target} argument determines where the resulting archive will be written:

- If it is the name of a file, or a \texttt{pathlib\_Path} object, the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or \texttt{None}), the source must be a directory and the target will be a file with the same name as the source, with a \texttt{.pyz} extension added.

The \texttt{interpreter} argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a
“shebang” line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the interpreter results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The main argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a __main__.py file. The main argument should take the form “pkg.module:callable” and the archive will be run by importing “pkg.module” and executing the given callable with no arguments. It is an error to omit main if the source is a directory and does not contain a __main__.py file, as otherwise the resulting archive would not be executable.

If a file object is specified for source or target, it is the caller's responsibility to close it after calling create_archive.

When copying an existing archive, file objects supplied only need read and readline, or write methods. When creating an archive from a directory, if the target is a file object it will be passed to the zipfile.ZipFile class, and must supply the methods needed by that class.

zipapp.get_interpreter(archive)

Return the interpreter specified in the #! line at the start of the archive. If there is no #! line, return None. The archive argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.
28.4.4. Examples

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp.pyz', 'myapp')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archive.pyz')
```

To update the file in place, do the replacement in memory using a `BytesIO` object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/python2')
>>> with open('myapp.pyz', 'wb') as f:
...     f.write(temp.getvalue())

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use `"/usr/bin/env python"` (or other forms of the "python" command, such as `"/usr/bin/python"`), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example `"/usr/bin/env python3"` your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say "python X.Y or later", so be careful of using an exact version like `"/usr/bin/env python3.4"` as you will need to change your shebang line for users of Python 3.5, for example.
28.4.5. The Python Zip Application Archive Format

Python has been able to execute zip files which contain a __main__.py file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a __main__.py file which will be run as the entry point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on sys.path and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX “shebang” line to the file (#!/path/to/interpreter).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters b'#!' followed by an interpreter name, and then a newline (b'\n') character. The interpreter name can be anything acceptable to the OS “shebang” processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in sys.getfilesystemencoding() on POSIX.

2. Standard zipfile data, as generated by the zipfile module. The zipfile content must include a file called __main__.py (which must be in the “root” of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the executable bit set on POSIX systems, to allow it to be executed directly.
There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.
29. Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

- **29.1. sys** — System-specific parameters and functions
- **29.2. sysconfig** — Provide access to Python's configuration information
  - 29.2.1. Configuration variables
  - 29.2.2. Installation paths
  - 29.2.3. Other functions
  - 29.2.4. Using sysconfig as a script
- **29.3. builtins** — Built-in objects
- **29.4. __main__** — Top-level script environment
- **29.5. warnings** — Warning control
  - 29.5.1. Warning Categories
  - 29.5.2. The Warnings Filter
    - 29.5.2.1. Default Warning Filters
  - 29.5.3. Temporarily Suppressing Warnings
  - 29.5.4. Testing Warnings
  - 29.5.5. Updating Code For New Versions of Python
  - 29.5.6. Available Functions
  - 29.5.7. Available Context Managers
- **29.6. contextlib** — Utilities for with-statement contexts
  - 29.6.1. Utilities
  - 29.6.2. Examples and Recipes
    - 29.6.2.1. Supporting a variable number of context managers
    - 29.6.2.2. Simplifying support for single optional context managers
    - 29.6.2.3. Catching exceptions from __enter__ methods
• 29.6.2.4. Cleaning up in an __enter__ implementation
• 29.6.2.5. Replacing any use of try-finally and flag variables
• 29.6.2.6. Using a context manager as a function decorator
  • 29.6.3. Single use, reusable and reentrant context managers
    • 29.6.3.1. Reentrant context managers
    • 29.6.3.2. Reusable context managers
• 29.7. abc — Abstract Base Classes
• 29.8. atexit — Exit handlers
  • 29.8.1. atexit Example
• 29.9. traceback — Print or retrieve a stack traceback
  • 29.9.1. TracebackException Objects
  • 29.9.2. StackSummary Objects
  • 29.9.3. FrameSummary Objects
  • 29.9.4. Traceback Examples
• 29.10. __future__ — Future statement definitions
• 29.11. gc — Garbage Collector interface
• 29.12. inspect — Inspect live objects
  • 29.12.1. Types and members
  • 29.12.2. Retrieving source code
  • 29.12.3. Introspecting callables with the Signature object
  • 29.12.4. Classes and functions
  • 29.12.5. The interpreter stack
  • 29.12.6. Fetching attributes statically
  • 29.12.7. Current State of Generators and Coroutines
  • 29.12.8. Command Line Interface
• 29.13. site — Site-specific configuration hook
  • 29.13.1. Readline configuration
  • 29.13.2. Module contents
• 29.14. fpectl — Floating point exception control
  • 29.14.1. Example
  • 29.14.2. Limitations and other considerations
29.1. **sys** — System-specific parameters and functions

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

**sys.abiflags**
On POSIX systems where Python was built with the standard configure script, this contains the ABI flags as specified by PEP 3149.

*New in version 3.2.*

**sys.argv**
The list of command line arguments passed to a Python script. argv[0] is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the -c command line option to the interpreter, argv[0] is set to the string '-c'. If no script name was passed to the Python interpreter, argv[0] is the empty string.

To loop over the standard input, or the list of files given on the command line, see the fileinput module.

**sys.base_exec_prefix**
Set during Python startup, before site.py is run, to the same value as exec_prefix. If not running in a virtual environment, the values will stay the same; if site.py finds that a virtual environment is in use, the values of prefix and exec_prefix
will be changed to point to the virtual environment, whereas
base_prefix and base_exec_prefix will remain pointing to
the base Python installation (the one which the virtual environment
was created from).

New in version 3.3.

sys.base_prefix
Set during Python startup, before site.py is run, to the same
value as prefix. If not running in a virtual environment, the values
will stay the same; if site.py finds that a virtual environment is in
use, the values of prefix and exec_prefix will be changed to
point to the virtual environment, whereas base_prefix and
base_exec_prefix will remain pointing to the base Python
installation (the one which the virtual environment was created
from).

New in version 3.3.

sys.byteorder
An indicator of the native byte order. This will have the value
'big' on big-endian (most-significant byte first) platforms, and
'little' on little-endian (least-significant byte first) platforms.

sys.builtin_module_names
A tuple of strings giving the names of all modules that are compiled
into this Python interpreter. (This information is not available in any
other way — modules.keys() only lists the imported modules.)

sys.call_tracing(func, args)
Call func(*args), while tracing is enabled. The tracing state is
saved, and restored afterwards. This is intended to be called from
a debugger from a checkpoint, to recursively debug some other code.

sys.\texttt{copyright}
A string containing the copyright pertaining to the Python interpreter.

sys.\texttt{\_clear\_type\_cache()}
Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function \textit{only} to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

sys.\texttt{\_current\_frames()}
Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the \texttt{traceback} module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

sys.\texttt{\_debugmallocstats()}
Print low-level information to stderr about the state of CPython's
memory allocator.

If Python is configured –with-pydebug, it also performs some expensive internal consistency checks.

*New in version 3.3.*

**CPython implementation detail:** This function is specific to CPython. The exact output format is not defined here, and may change.

**sys.dllhandle**

Integer specifying the handle of the Python DLL. Availability: Windows.

**sys.displayhook(value)**

If `value` is not None, this function prints `repr(value)` to `sys.stdout`, and saves `value` in builtins._. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably 'strict'), encode it to `sys.stdout.encoding` with 'backslashreplace' error handler.

`sys.displayhook` is called on the result of evaluating an expression entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```python
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
```
```python
builtins._ = None
text = repr(value)
try:
    sys.stdout.write(text)
except UnicodeEncodeError:
    bytes = text.encode(sys.stdout.encoding,
    if hasattr(sys.stdout, 'buffer'):
        sys.stdout.buffer.write(bytes)
    else:
        text = bytes.decode(sys.stdout.encodi
    sys.stdout.write(text)
sys.stdout.write("\n")
builtins._ = value
```

*Changed in version 3.2:* Use 'backslashreplace' error handler on `UnicodeEncodeError`.

**sys.dont_write_bytecode**

If this is true, Python won’t try to write .pyc files on the import of source modules. This value is initially set to True or False depending on the `-B` command line option and the `PYTHONDONTWRITEBYTECODE` environment variable, but you can set it yourself to control bytecode file generation.

**sys.excepthook(type, value, traceback)**

This function prints out a given traceback and exception to `sys.stderr`.

When an exception is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits.
The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

```
sys.__displayhook__
sys.__excepthook__
```

These objects contain the original values of `displayhook` and `excepthook` at the start of the program. They are saved so that `displayhook` and `excepthook` can be restored in case they happen to get replaced with broken objects.

```
sys.exc_info()
```

This function returns a tuple of three values that give information about the exception that is currently being handled. The information returned is specific both to the current thread and to the current stack frame. If the current stack frame is not handling an exception, the information is taken from the calling stack frame, or its caller, and so on until a stack frame is found that is handling an exception. Here, “handling an exception” is defined as “executing an except clause.” For any stack frame, only information about the exception being currently handled is accessible.

If no exception is being handled anywhere on the stack, a tuple containing three `None` values is returned. Otherwise, the values returned are `(type, value, traceback)`. Their meaning is:

- `type` gets the type of the exception being handled (a subclass of `BaseException`);
- `value` gets the exception instance (an instance of the exception type);
- `traceback` gets a traceback object (see the Reference Manual) which encapsulates the call stack at the point where the exception originally occurred.

```
sys.exec_prefix
```

A string giving the site-specific directory prefix where the platform-
dependent Python files are installed; by default, this is also '/usr/local'. This can be set at build time with the --exec-prefix argument to the configure script. Specifically, all configuration files (e.g. the pyconfig.h header file) are installed in the directory exec_prefix/lib/pythonX.Y/config, and shared library modules are installed in exec_prefix/lib/pythonX.Y/lib-dynload, where X.Y is the version number of Python, for example 3.2.

**Note:** If a virtual environment is in effect, this value will be changed in site.py to point to the virtual environment. The value for the Python installation will still be available, via base_exec_prefix.

**sys.executable**

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, sys.executable will be an empty string or None.

**sys.exit([arg])**

Exit from Python. This is implemented by raising the SystemExit exception, so cleanup actions specified by finally clauses of try statements are honored, and it is possible to intercept the exit attempt at an outer level.

The optional argument arg can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and the like. Most systems require it to be in the range 0-127, and produce undefined
results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, None is equivalent to passing zero, and any other object is printed to `stderr` and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately “only” raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted.

**sys.**flags

The struct sequence `flags` exposes the status of command line flags. The attributes are read only.

<table>
<thead>
<tr>
<th>attribute</th>
<th>flag</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

sys.float_info

A struct sequence holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file float.h for the ‘C’ programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], ‘Characteristics of floating types’, for details.
<table>
<thead>
<tr>
<th>max_exp</th>
<th>DBL_MAX_EXP</th>
<th>that ( \text{radix}^{(e-1)} ) is a representable finite float</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_10_exp</td>
<td>DBL_MAX_10_EXP</td>
<td>maximum integer ( e ) such that ( 10^{e} ) is in the range of representable finite floats</td>
</tr>
<tr>

</tr>
<tr>
<td>rounds</td>
<td>FLT_ROUNDS</td>
<td>integer constant representing the rounding mode used for arithmetic operations. This reflects the value of the system FLT_ROUNDS macro at interpreter startup time. See section 5.2.4.2.2 of the C99 standard for an explanation of the possible values and their meanings.</td>
</tr>
</tbody>
</table>

The attribute `sys.float_info.dig` needs further explanation. If `s` is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting `s` to a float and back again will recover a string representing the same decimal value:
But for strings with more than `sys.float_info.dig` significant digits, this isn’t always true:

```
>>> s = '9876543211234567'  # 16 significant digits
>>> format(float(s), '.16g')  # conversion changes value
'9876543211234568'
```

`sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value 'short' then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value 'legacy' and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

*New in version 3.1.*

`sys.getallocatedblocks()`

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter’s internal caches, the result can vary from call to call; you may have to call `_clear_type_cache()` and `gc.collect()` to get more predictable results.
If a Python build or implementation cannot reasonably compute this information, `getallocatedblocks()` is allowed to return 0 instead.

*New in version 3.4.*

**sys.getcheckinterval()**
Return the interpreter's "check interval"; see `setcheckinterval()`.

*Deprecated since version 3.2:* Use `getswitchinterval()` instead.

**sys.getdefaultencoding()**
Return the name of the current default string encoding used by the Unicode implementation.

**sys.getdlopenflags()**
Return the current value of the flags that are used for `dlopen()` calls. Symbolic names for the flag values can be found in the `os` module (RTLD_xxx constants, e.g. `os.RTLD_LAZY`). Availability: Unix.

**sys.getfilesystemencoding()**
Return the name of the encoding used to convert Unicode filenames into system file names. The result value depends on the operating system:

- On Mac OS X, the encoding is 'utf-8'.
- On Unix, the encoding is the user's preference according to the result of `nl_langinfo(CODESET)`. On Windows NT+, file names are Unicode natively, so no conversion is performed. `getfilesystemencoding()` still
returns 'mbcs', as this is the encoding that applications should use when they explicitly want to convert Unicode strings to byte strings that are equivalent when used as file names.

- On Windows 9x, the encoding is 'mbcs'.

  *Changed in version 3.2: getfilesystemencoding() result cannot be None anymore.*

**sys.getrefcount(object)**

Return the reference count of the object. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to getrefcount().

**sys.getrecursionlimit()**

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by setrecursionlimit().

**sys.getsizeof(object[, default])**

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, default will be returned if the object does not provide means to retrieve the size. Otherwise a TypeError will be raised.

getsizeof() calls the object's __sizeof__ method and adds
an additional garbage collector overhead if the object is managed by the garbage collector.

See recursive sizeof recipe for an example of using getsizeof() recursively to find the size of containers and all their contents.

**sys.getswitchinterval()**

Return the interpreter’s “thread switch interval”; see setswitchinterval().

*New in version 3.2.*

**sys._getframe([depth])**

Return a frame object from the call stack. If optional integer depth is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, ValueError is raised. The default for depth is zero, returning the frame at the top of the call stack.

**CPython implementation detail:** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

**sys.getprofile()**

Get the profiler function as set by setprofile().

**sys.gettrace()**

Get the trace function as set by settrace().

**CPython implementation detail:** The gettrace() function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be
available in all Python implementations.

**sys.getwindowsversion()**

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service_pack*, *service_pack_minor*, *service_pack_major*, *suite_mask*, and *product_type*. *service_pack* contains a string while all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

*platform* may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (VER_PLATFORM_WIN32s)</td>
<td>Win32s on Windows 3.1</td>
</tr>
<tr>
<td>1 (VER_PLATFORM_WIN32_WINDOWS)</td>
<td>Windows 95/98/ME</td>
</tr>
<tr>
<td>2 (VER_PLATFORM_WIN32_NT)</td>
<td>Windows NT/2000/XP/x64</td>
</tr>
<tr>
<td>3 (VER_PLATFORM_WIN32_CE)</td>
<td>Windows CE</td>
</tr>
</tbody>
</table>

*product_type* may be one of the following values:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (VER_NT_WORKSTATION)</td>
<td>The system is a workstation.</td>
</tr>
<tr>
<td>2 (VER_NT_DOMAIN_CONTROLLER)</td>
<td>The system is a domain controller.</td>
</tr>
<tr>
<td></td>
<td>The system is a server, but</td>
</tr>
</tbody>
</table>
This function wraps the Win32 GetVersionEx() function; see the Microsoft documentation on OSVERSIONINFOEX() for more information about these fields.

Availability: Windows.

*Changed in version 3.2:* Changed to a named tuple and added *service_pack_minor*, *service_pack_major*, *suite_mask*, and *product_type*.

**sys.get_coroutine_wrapper()**

Returns None, or a wrapper set by `set_coroutine_wrapper()`.

*New in version 3.5:* See PEP 492 for more details.

**Note:** This function has been added on a provisional basis (see PEP 411 for details.) Use it only for debugging purposes.

**sys.hash_info**

A `struct sequence` giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see Hashing of numeric types.

<table>
<thead>
<tr>
<th>attribute</th>
<th>explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>width in bits used for hash values</td>
</tr>
<tr>
<td>modulus</td>
<td>prime modulus P used for numeric hash scheme</td>
</tr>
<tr>
<td>inf</td>
<td>hash value returned for a positive infinity</td>
</tr>
<tr>
<td>nan</td>
<td>hash value returned for a nan</td>
</tr>
<tr>
<td>imag</td>
<td>multiplier used for the imaginary part of a complex number</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>algorithm</td>
<td>name of the algorithm for hashing of str, bytes, and memoryview</td>
</tr>
<tr>
<td>hash_bits</td>
<td>internal output size of the hash algorithm</td>
</tr>
<tr>
<td>seed_bits</td>
<td>size of the seed key of the hash algorithm</td>
</tr>
</tbody>
</table>

*New in version 3.2.*

*Changed in version 3.4: Added* `algorithm`, `hash_bits` *and* `seed_bits`

### `sys.hexversion`

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```python
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
...
else:
    # use an alternative implementation or warn the user
...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The `struct` sequence `sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at API and ABI Versioning.

### `sys.implementation`

```python
if sys.implementation:
    # do something
else:
    # do something else
```
An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

*name* is the implementation's identifier, e.g. 'cpython'. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

*version* is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python implementation. This has a distinct meaning from the specific version of the Python language to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

*hexversion* is the implementation version in hexadecimal format, like `sys.hexversion`.

*cache_tag* is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like 'cpython-33'. However, a Python implementation may use some other value if appropriate. If `cache_tag` is set to None, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless
of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See [PEP 421](https://www.python.org/dev/peps/pep-0421/) for more information.

*New in version 3.3.*

**sys.int_info**

A *struct sequence* that holds information about Python’s internal representation of integers. The attributes are read only.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>bits_per_digit</td>
<td>number of bits held in each digit. Python integers are stored internally in base $2^{\text{int_info.bits_per_digit}}$</td>
</tr>
<tr>
<td>sizeof_digit</td>
<td>size in bytes of the C type used to represent a digit</td>
</tr>
</tbody>
</table>

*New in version 3.1.*

**sys.__interactivehook__**

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in interactive mode. This is done after the `PYTHONSTARTUP` file is read, so that you can set this hook there. The `site` module sets this.

*New in version 3.4.*

**sys.intern(string)**

Enter *string* in the table of “interned” strings and return the interned string – which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup – if the keys in a dictionary are interned, and the lookup key is interned, the key
comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not immortal; you must keep a reference to the return value of `intern()` around to benefit from it.

```python
sys.is_finalizing()
```
Return `True` if the Python interpreter is shutting down, `False` otherwise.

*New in version 3.5.*

```python
sys.last_type
sys.last_value
sys.last_traceback
```
These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see `pdb` module for more information.)

The meaning of the variables is the same as that of the return values from `exc_info()` above.

```python
sys.maxsize
```
An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually $2^{31} - 1$ on a 32-bit platform and $2^{63} - 1$ on a 64-bit platform.
sys.**maxunicode**

An integer giving the value of the largest Unicode code point, i.e. 1114111 (0x10FFFF in hexadecimal).

*Changed in version 3.3:* Before **PEP 393**, `sys.maxunicode` used to be either 0xFFFF or 0x10FFFF, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

**sys.meta_path**

A list of finder objects that have their `find_module()` methods called to see if one of the objects can find the module to be imported. The `find_module()` method is called at least with the absolute name of the module being imported. If the module to be imported is contained in a package then the parent package's `__path__` attribute is passed in as a second argument. The method returns None if the module cannot be found, else returns a loader.

`sys.meta_path` is searched before any implicit default finders or `sys.path`.

See **PEP 302** for the original specification.

**sys.modules**

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail.

**sys.path**
A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

As initialized upon program startup, the first item of this list, `path[0]`, is the directory containing the script that was used to invoke the Python interpreter. If the script directory is not available (e.g. if the interpreter is invoked interactively or if the script is read from standard input), `path[0]` is the empty string, which directs Python to search modules in the current directory first. Notice that the script directory is inserted before the entries inserted as a result of `PYTHONPATH`.

A program is free to modify this list for its own purposes. Only strings and bytes should be added to `sys.path`; all other data types are ignored during import.

**See also:** Module `site` This describes how to use .pth files to extend `sys.path`.

**sys.path_hooks**
A list of callables that take a path argument to try to create a finder for the path. If a finder can be created, it is to be returned by the callable, else raise `ImportError`.

Originally specified in **PEP 302**.

**sys.path_importer_cache**
A dictionary acting as a cache for finder objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no finder is found on `sys.path_hooks` then None is stored.
Originally specified in **PEP 302**.

*Changed in version 3.3:* None is stored instead of `imp.NullImporter` when no finder is found.

**sys.platform**

This string contains a platform identifier that can be used to append platform-specific components to `sys.path`, for instance.

For Unix systems, except on Linux, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5' or 'freebsd8', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```python
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
```

For other systems, the values are:

<table>
<thead>
<tr>
<th>System</th>
<th>platform value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>'linux'</td>
</tr>
<tr>
<td>Windows</td>
<td>'win32'</td>
</tr>
<tr>
<td>Windows/Cygwin</td>
<td>'cygwin'</td>
</tr>
<tr>
<td>Mac OS X</td>
<td>'darwin'</td>
</tr>
</tbody>
</table>

*Changed in version 3.3:* On Linux, `sys.platform` doesn't contain the major version anymore. It is always 'linux', instead of 'linux2' or 'linux3'. Since older Python versions include the
version number, it is recommended to always use the `startswith` idiom presented above.

**See also:** `os.name` has a coarser granularity. `os.uname()` gives system-dependent version information. The `platform` module provides detailed checks for the system's identity.

### `sys.prefix`
A string giving the site-specific directory prefix where the platform independent Python files are installed; by default, this is the string `/usr/local`. This can be set at build time with the `--prefix` argument to the `configure` script. The main collection of Python library modules is installed in the directory `prefix/lib/pythonX.Y` while the platform independent header files (all except `pyconfig.h`) are stored in `prefix/include/pythonX.Y`, where `X.Y` is the version number of Python, for example 3.2.

**Note:** If a virtual environment is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_prefix`.

### `sys.ps1`  
### `sys.ps2`
Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `''` and `''`. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new
interactive command; this can be used to implement a dynamic prompt.

**sys.setcheckinterval(interval)**

Set the interpreter’s “check interval”. This integer value determines how often the interpreter checks for periodic things such as thread switches and signal handlers. The default is 100, meaning the check is performed every 100 Python virtual instructions. Setting it to a larger value may increase performance for programs using threads. Setting it to a value <= 0 checks every virtual instruction, maximizing responsiveness as well as overhead.

*Deprecated since version 3.2:* This function doesn’t have an effect anymore, as the internal logic for thread switching and asynchronous tasks has been rewritten. Use `setswitchinterval()` instead.

**sys.setdlopenflags(n)**

Set the flags used by the interpreter for dlopen() calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the `os` module (RTLD_xxx constants, e.g. `os.RTLD_LAZY`).

Availability: Unix.

**sys.setprofile(profilefunc)**

Set the system’s profile function, which allows you to implement a Python source code profiler in Python. See chapter *The Python
Profilers for more information on the Python profiler. The system’s profile function is called similarly to the system’s trace function (see `settrace()`), but it isn’t called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return None.

```
sys.setrecursionlimit(limit)
```

Set the maximum depth of the Python interpreter stack to `limit`. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

If the new limit is too low at the current recursion depth, a `RecursionError` exception is raised.

*Changed in version 3.5.1:* A `RecursionError` exception is now raised if the new limit is too low at the current recursion depth.

```
sys.setswitchinterval(interval)
```

Set the interpreter’s thread switch interval (in seconds). This floating-point value determines the ideal duration of the “timeslices” allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system’s
decision. The interpreter doesn’t have its own scheduler.

_New in version 3.2._

```
sys.settrace(tracefunc)
```

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must be registered using `settrace()` for each thread being debugged.

Trace functions should have three arguments: `frame`, `event`, and `arg`. `frame` is the current stack frame. `event` is a string: 'call', 'line', 'return', 'exception', 'c_call', 'c_return', or 'c_exception'. `arg` depends on the event type.

The trace function is invoked (with `event` set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used that scope, or None if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or None to turn off tracing in that scope.

The events have the following meaning:

'field'

A function is called (or some other code block entered). The global trace function is called; `arg` is None; the return value specifies the local trace function.

'field'

The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is
called; `arg` is None; the return value specifies the new local trace function. See Objects/lnotab_notes.txt for a detailed explanation of how this works.

'return'
A function (or other code block) is about to return. The local trace function is called; `arg` is the value that will be returned, or None if the event is caused by an exception being raised. The trace function’s return value is ignored.

'exception'
An exception has occurred. The local trace function is called; `arg` is a tuple `(exception, value, traceback);` the return value specifies the new local trace function.

'c_call'
A C function is about to be called. This may be an extension function or a built-in. `arg` is the C function object.

'c_return'
A C function has returned. `arg` is the C function object.

'c_exception'
A C function has raised an exception. `arg` is the C function object.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more information on code and frame objects, refer to The standard type hierarchy.

**CPython implementation detail:** The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be
available in all Python implementations.

```python
sys.set_tsc_dump(on_flag)
```
Activate dumping of VM measurements using the Pentium timestamp counter, if `on_flag` is true. Deactivate these dumps if `on_flag` is off. The function is available only if Python was compiled with `--with-tsc`. To understand the output of this dump, read `Python/ceval.c` in the Python sources.

**CPython implementation detail:** This function is intimately bound to CPython implementation details and thus not likely to be implemented elsewhere.

```python
sys.set_coroutine_wrapper(wrapper)
```
Allows intercepting creation of `coroutine` objects (only ones that are created by an `async def` function; generators decorated with `types.coroutine()` or `asyncio.coroutine()` will not be intercepted).

The `wrapper` argument must be either:

- a callable that accepts one argument (a coroutine object);
- None, to reset the wrapper.

If called twice, the new wrapper replaces the previous one. The function is thread-specific.

The `wrapper` callable cannot define new coroutines directly or indirectly:

```python
def wrapper(coro):
    async def wrap(coro):
        return await coro
    return wrap(coro)
```
sys.set_coroutine_wrapper(wrapper)

async def foo():
    pass

# The following line will fail with a RuntimeError,
# ``wrapper`` creates a ``wrap(coro)`` coroutine:
foo()

See also get_coroutine_wrapper().

*New in version 3.5:* See PEP 492 for more details.

**Note:** This function has been added on a provisional basis (see PEP 411 for details.) Use it only for debugging purposes.

```python
sys.stdin
sys.stdout
sys.stderr
```

File objects used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);
- `stdout` is used for the output of `print()` and expression statements and for the prompts of `input()`;
- The interpreter's own prompts and its error messages go to `stderr`.

These streams are regular text files like those returned by the `open()` function. Their parameters are chosen as follows:

- The character encoding is platform-dependent. Under Windows, if the stream is interactive (that is, if its `isatty()`
method returns True), the console codepage is used, otherwise the ANSI code page. Under other platforms, the locale encoding is used (see `locale.getpreferredencoding()`).

Under all platforms though, you can override this value by setting the `PYTHONIOENCODING` environment variable before starting Python.

- When interactive, standard streams are line-buffered. Otherwise, they are block-buffered like regular text files. You can override this value with the `-u` command-line option.

**Note:** To write or read binary data from/to the standard streams, use the underlying binary `buffer` object. For example, to write bytes to `stdout`, use `sys.stdout.buffer.write(b'abc')`. However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like `io.StringIO` which do not support the buffer attribute.

```python
sys.__stdin__
sys.__stdout__
sys.__stderr__
```

These objects contain the original values of stdin, stderr and stdout at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the
previous stream before replacing it, and restore the saved object.

Note: Under some conditions stdin, stdout and stderr as well as the original values __stdin__, __stdout__ and __stderr__ can be None. It is usually the case for Windows GUI apps that aren’t connected to a console and Python apps started with `pythonw`.

**sys.thread_info**

A struct sequence holding information about the thread implementation.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| name      | Name of the thread implementation:  
  - 'nt': Windows threads  
  - 'pthread': POSIX threads  
  - 'solaris': Solaris threads |
| lock      | Name of the lock implementation:  
  - 'semaphore': a lock uses a semaphore  
  - 'mutex+cond': a lock uses a mutex and a condition variable  
  - None if this information is unknown |
| version   | Name and version of the thread library. It is a string, or None if these informations are unknown. |

*New in version 3.3.*
sys.tracebacklimit
When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

sys.version
A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use version_info and the functions provided by the platform module.

sys.api_version
The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

sys.version_info
A tuple containing the five components of the version number: major, minor, micro, releaselevel, and serial. All values except releaselevel are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The version_info value corresponding to the Python version 2.0 is (2, 0, 0, 'final', 0). The components can also be accessed by name, so sys.version_info[0] is equivalent to sys.version_info.major and so on.

Changed in version 3.1: Added named component attributes.
sys.**warnoptions**
This is an implementation detail of the warnings framework; do not modify this value. Refer to the `warnings` module for more information on the warnings framework.

sys.**winver**
The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of `version`. It is provided in the `sys` module for informational purposes; modifying this value has no effect on the registry keys used by Python. Availability: Windows.

sys.**_xoptions**
A dictionary of the various implementation-specific flags passed through the `-X` command-line option. Option names are either mapped to their values, if given explicitly, or to `True`. Example:

```bash
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license"
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

**CPython implementation detail**: This is a CPython-specific way of accessing options passed through `-X`. Other implementations may export them through other means, or not at all. 
*New in version 3.2.*
29.2. `sysconfig` — Provide access to Python’s configuration information

*New in version 3.2.*

**Source code:** `Lib/sysconfig.py`  

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.
29.2.1. Configuration variables

A Python distribution contains a Makefile and a pyconfig.h header file that are necessary to build both the Python binary itself and third-party C extensions compiled using distutils.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

`sysconfig.get_config_vars(*args)`

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return None.

`sysconfig.get_config_var(name)`

Return the value of a single variable `name`. Equivalent to `get_config_vars().get(name)`.

If `name` is not found, return None.

Example of usage:

```python
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
```
'/usr/local/lib'

```python
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```
29.2.2. Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`.

Every new component that is installed using `distutils` or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports seven schemes:

- `posix_prefix`: scheme for Posix platforms like Linux or Mac OS X. This is the default scheme used when Python or a component is installed.
- `posix_home`: scheme for Posix platforms used when a `home` option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- `posix_user`: scheme for Posix platforms used when a component is installed through Distutils and the `user` option is used. This scheme defines paths located under the user home directory.
- `nt`: scheme for NT platforms like Windows.
- `nt_user`: scheme for NT platforms, when the `user` option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- `stdlib`: directory containing the standard Python library files that are not platform-specific.
- `platstdlib`: directory containing the standard Python library files that are platform-specific.
- **platlib**: directory for site-specific, platform-specific files.
- **purelib**: directory for site-specific, non-platform-specific files.
- **include**: directory for non-platform-specific header files.
- **platinclude**: directory for platform-specific header files.
- **scripts**: directory for script files.
- **data**: directory for data files.

**sysconfig** provides some functions to determine these paths.

**sysconfig.get_scheme_names()**

Return a tuple containing all schemes currently supported in **sysconfig**.

**sysconfig.get_path_names()**

Return a tuple containing all path names currently supported in **sysconfig**.

**sysconfig.get_path(name[, scheme[, vars[, expand]]])**

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

*name* has to be a value from the list returned by **get_path_names()**.

**sysconfig** stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is: `{base}/Lib`.

**get_path()** will use the variables returned by **get_config_vars()** to expand the path. All variables have default values for each platform so one may call this function and get the default value.
If `scheme` is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary returned by `get_config_vars()`.

If `expand` is set to False, the path will not be expanded using the variables.

If `name` is not found, return None.

```python
sysconfig.get_paths([scheme, vars, expand])
```

Returns a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If `scheme` is not provided, will use the default scheme for the current platform.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If `expand` is set to False, the paths will not be expanded.

If `scheme` is not an existing scheme, `get_paths()` will raise a `KeyError`. 

```python
```
29.2.3. Other functions

sysconfig.get_python_version()
Return the MAJOR.MINOR Python version number as a string. Similar to sys.version[:3].

sysconfig.get_platform()
Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by os.uname()), although the exact information included depends on the OS; e.g. for IRIX the architecture isn’t particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn’t particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u
- irix-5.3
- irix64-6.2

Windows will return one of:

- win-amd64 (64bit Windows on AMD64 (aka x86_64, Intel64, EM64T, etc)
- win-ia64 (64bit Windows on Itanium)
- win32 (all others - specifically, sys.platform is returned)

Mac OS X can return:
• macosx-10.6-ppc
• macosx-10.4-ppc64
• macosx-10.3-i386
• macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`  
Return True if the current Python installation was built from source.

`sysconfig.parse_config_h(fp[, vars])`  
Parse a config.h-style file.

`fp` is a file-like object pointing to the config.h-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`  
Return the path of pyconfig.h.

`sysconfig.get_makefile_filename()`  
Return the path of Makefile.
29.2.4. Using `sysconfig` as a script

You can use `sysconfig` as a script with Python’s `-m` option:

```
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"

Paths:
  data = "/usr/local"
  include = "/Users/tarek/Dev/svn.python.org/py3k/Include"
  platincludedir = "."
  platlib = "/usr/local/lib/python3.2/site-packages"
  platstdlibdir = "/usr/local/lib/python3.2"  
  purelib = "/usr/local/lib/python3.2/site-packages"
  scripts = "/usr/local/bin"
  stdlib = "/usr/local/lib/python3.2"

Variables:
  AC_APPLE_UNIVERSAL_BUILD = "0"
  AIX_GENUINE_CPLUSPLUS = "0"
  AR = "ar"
  ARFLAGS = "rc"
  ASDLGEN = "/Parser/astl_c.py"
  ...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.
29.3. **builtins** — Built-in objects

This module provides direct access to all ‘built-in’ identifiers of Python; for example, `builtins.open` is the full name for the built-in function `open()`. See Built-in Functions and Built-in Constants for documentation.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an `open()` function that wraps the built-in `open()`, this module can be used directly:

```python
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upper-case.'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

As an implementation detail, most modules have the name
__builtins__ made available as part of their globals. The value of __builtins__ is normally either this module or the value of this module's __dict__ attribute. Since this is an implementation detail, it may not be used by alternate implementations of Python.
29.4. __main__ — Top-level script environment

'__main__' is the name of the scope in which top-level code executes. A module's __name__ is set equal to '__main__' when read from standard input, a script, or from an interactive prompt.

A module can discover whether or not it is running in the main scope by checking its own __name__, which allows a common idiom for conditionally executing code in a module when it is run as a script or with python -m but not when it is imported:

```python
if __name__ == '__main__':
    # execute only if run as a script
    main()
```

For a package, the same effect can be achieved by including a __main__.py module, the contents of which will be executed when the module is run with -m.
29.5. **warnings** — Warning control

**Source code:** Lib/warnings.py

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see *Exception Handling* for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category (see below), the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and
actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

**See also:** `logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.
29.5.1. Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings. The following warnings category classes are currently defined:

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>This is the base class of all warning category classes. It is a subclass of Exception.</td>
</tr>
<tr>
<td>UserWarning</td>
<td>The default category for warn().</td>
</tr>
<tr>
<td>DeprecationWarning</td>
<td>Base category for warnings about deprecated features (ignored by default).</td>
</tr>
<tr>
<td>SyntaxWarning</td>
<td>Base category for warnings about dubious syntactic features.</td>
</tr>
<tr>
<td>RuntimeWarning</td>
<td>Base category for warnings about dubious runtime features.</td>
</tr>
<tr>
<td>FutureWarning</td>
<td>Base category for warnings about constructs that will change semantically in the future.</td>
</tr>
<tr>
<td>PendingDeprecationWarning</td>
<td>Base category for warnings about features that will be deprecated in the future (ignored by default).</td>
</tr>
<tr>
<td>ImportWarning</td>
<td>Base category for warnings triggered during the process of importing a module (ignored by</td>
</tr>
</tbody>
</table>
While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.
29.5.2. The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the match determines the disposition of the match. Each entry is a tuple of the form \((action, message, category, module, lineno)\), where:

- **action** is one of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Disposition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;error&quot;</td>
<td>turn matching warnings into exceptions</td>
</tr>
<tr>
<td>&quot;ignore&quot;</td>
<td>never print matching warnings</td>
</tr>
<tr>
<td>&quot;always&quot;</td>
<td>always print matching warnings</td>
</tr>
<tr>
<td>&quot;default&quot;</td>
<td>print the first occurrence of matching warnings for each location where the warning is issued</td>
</tr>
<tr>
<td>&quot;module&quot;</td>
<td>print the first occurrence of matching warnings for each module where the warning is issued</td>
</tr>
<tr>
<td>&quot;once&quot;</td>
<td>print only the first occurrence of matching warnings, regardless of location</td>
</tr>
</tbody>
</table>

- **message** is a string containing a regular expression that the warning message must match (the match is compiled to always be case-insensitive).

- **category** is a class (a subclass of `Warning`) of which the warning category must be a subclass in order to match.
• *module* is a string containing a regular expression that the module name must match (the match is compiled to be case-sensitive).

• *lineno* is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the **Warning** class is derived from the built-in **Exception** class, to turn a warning into an error we simply raise `category(message)`.

The warnings filter is initialized by `-W` options passed to the Python interpreter command line. The interpreter saves the arguments for all `-W` options without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

### 29.5.2.1. Default Warning Filters

By default, Python installs several warning filters, which can be overridden by the command-line options passed to `-W` and calls to `filterwarnings()`.

- **DeprecationWarning** and **PendingDeprecationWarning**, and **ImportWarning** are ignored.
- **BytesWarning** is ignored unless the `-b` option is given once or twice; in this case this warning is either printed (`-b`) or turned into an exception (`-bb`).
- **ResourceWarning** is ignored unless Python was built in debug mode.

*Changed in version 3.2: **DeprecationWarning** is now ignored by default in addition to **PendingDeprecationWarning**.*
29.5.3. Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning, then it is possible to suppress the warning using the `catch_warnings` context manager:

```python
import warnings
def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.
29.5.4. Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```python
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert issubclass(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a once/default rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the
module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).
29.5.5. Updating Code For New Versions of Python

Warnings that are only of interest to the developer are ignored by default. As such you should make sure to test your code with typically ignored warnings made visible. You can do this from the command-line by passing `-wd` to the interpreter (this is shorthand for `-W default`). This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you simply change what argument is passed to `-W`, e.g. `-W error`. See the `-W` flag for more details on what is possible.

To programmatically do the same as `-wd`, use:

```
warnings.simplefilter('default')
```

Make sure to execute this code as soon as possible. This prevents the registering of what warnings have been raised from unexpectedly influencing how future warnings are treated.

Having certain warnings ignored by default is done to prevent a user from seeing warnings that are only of interest to the developer. As you do not necessarily have control over what interpreter a user uses to run their code, it is possible that a new version of Python will be released between your release cycles. The new interpreter release could trigger new warnings in your code that were not there in an older interpreter, e.g. `DeprecationWarning` for a module that you are using. While you as a developer want to be notified that your code is using a deprecated module, to a user this information is essentially noise and provides no benefit to them.
The `unittest` module has been also updated to use the 'default' filter while running tests.
### 29.5.6. Available Functions

**warnings.warn**(message, category=None, stacklevel=1)

Issue a warning, or maybe ignore it or raise an exception. The `category` argument, if given, must be a warning category class (see above); it defaults to `UserWarning`. Alternatively `message` can be a `Warning` instance, in which case `category` will be ignored and `message.__class__` will be used. In this case the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the warnings filter see above. The `stacklevel` argument can be used by wrapper functions written in Python, like this:

```python
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecation()`'s caller, rather than to the source of `deprecation()` itself (since the latter would defeat the purpose of the warning message).

**warnings.warn_explicit**(message, category, filename, lineno, module=None, registry=None, module_globals=None)

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. `message` must be a string and `category` a subclass of `Warning` or `message` may be a `Warning` instance, in which case `category` will be ignored.
module_globals, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

```
warnings.showwarning(message, category, filename, lineno, 
file=None, line=None)
```

Write a warning to a file. The default implementation calls formatwarning(message, category, filename, lineno, line) and writes the resulting string to file, which defaults to sys.stderr. You may replace this function with any callable by assigning to warnings.showwarning. line is a line of source code to be included in the warning message; if line is not supplied, showwarning() will try to read the line specified by filename and lineno.

```
warnings.formatwarning(message, category, filename, lineno, 
line=None)
```

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. line is a line of source code to be included in the warning message; if line is not supplied, formatwarning() will try to read the line specified by filename and lineno.

```
warnings.filterwarnings(action, message="", 
category=Warning, module="", lineno=0, append=False)
```

Insert an entry into the list of warnings filter specifications. The entry is inserted at the front by default; if append is true, it is inserted at the end. This checks the types of the arguments, compiles the message and module regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a
particular warning. Omitted arguments default to a value that matches everything.

```
warnings.simplefilter(action=category=Warning, lineno=0, append=False)
```

Insert a simple entry into the list of warnings filter specifications. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

```
warnings.resetwarnings()
```

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.
29.5.7. Available Context Managers

```python
class warnings.catch_warnings(*, record=False, module=None)
```

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the `record` argument is `False` (the default) the context manager returns `None` on entry. If `record` is `True`, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The `module` argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

**Note:** The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.
29.6. `contextlib` — Utilities for `with`-statement contexts

Source code: `Lib/contextlib.py`

This module provides utilities for common tasks involving the `with` statement. For more information see also Context Manager Types and With Statement Context Managers.
29.6.1. Utilities

Functions and classes provided:

@contextlib.contextmanager

This function is a decorator that can be used to define a factory function for with statement context managers, without needing to create a class or separate __enter__() and __exit__() methods.

A simple example (this is not recommended as a real way of generating HTML!):

```python
from contextlib import contextmanager

class contextmanager:
    def __enter__(self):
        return self

    def __exit__(self, exc_type, exc_val, exc_tb):
        if exc_val:
            print(exc_val)

def tag(name):
    print("<%s>") % name
    yield
    print("</%s>") % name

>>> with tag("h1"):
    ...   print("foo")
    ...
<h1>
foo
</h1>
```

The function being decorated must return a generator-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the with statement's as clause, if any.

At the point where the generator yields, the block nested in the
The `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise “one-shot” context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

*Changed in version 3.2:* Use of `ContextDecorator`.

`contextlib.closing(thing)`

Return a context manager that closes `thing` upon completion of the block. This is basically equivalent to:

```python
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
```
And lets you write code like this:

```python
from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('http://www.python.org')) as page:
    for line in page:
        print(line)
```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

```python
contextlib.suppress(*exceptions)
```

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a `with` statement and then resumes execution with the first statement following the end of the `with` statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program execution is known to be the right thing to do.

For example:

```python
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')

with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```
This code is equivalent to:

```python
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is **reentrant**.

*New in version 3.4.*

```python
contextlib.redirect_stdout(new_target)
```

Context manager for temporarily redirecting `sys.stdout` to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to stdout.

For example, the output of `help()` normally is sent to `sys.stdout`. You can capture that output in a string by redirecting the output to an `io.StringIO` object:

```python
f = io.StringIO()
with redirect_stdout(f):
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:
```python
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to `sys.stderr`:

```python
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is reentrant.

*New in version 3.4.*

```
contextlib.redirect_stderr(new_target)
```

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is reentrant.

*New in version 3.5.*

```
class contextlib.ContextDecorator
```

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a
ContextDecorator is used by `contextmanager()`, so you get this functionality automatically.

Example of ContextDecorator:

```python
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self

    def __exit__(self, *exc):
        print('Finishing')
        return False

>>> @mycontext()
... def function():
...     print('The bit in the middle')
... >>> function()
Starting
The bit in the middle
Finishing

>>> with mycontext():
...     print('The bit in the middle')
... Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:
```python
def f():
    with cm():
        # Do stuff
```

ContextDecorator lets you instead write:

```python
@cm()
def f():
    # Do stuff
```

It makes it clear that the cm applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can be extended by using ContextDecorator as a mixin class:

```python
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
        return False
```

**Note:** As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple `with` statements. If this is not the case, then the original construct with the explicit `with` statement inside the function should be used.

*New in version 3.2.*

```python
class contextlib.ExitStack
```
A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single with statement as follows:

```python
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for
    # All opened files will automatically be closed
    # the with statement, even if attempts to open
    # in the list raise an exception
```

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are not invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a
suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

*New in version 3.3.*

**enter_context(cm)**

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager's own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.

**push(exit)**

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.
**callback**(*callback*, *args*, **kwds*)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

**pop_all()**

Transfers the callback stack to a fresh `ExitStack` instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a `with` statement).

For example, a group of files can be opened as an “all or nothing” operation as follows:

```python
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname]
    # Hold onto the close method, but don't call it yet.
    close_files = stack.pop_all().close
    # If opening any file fails, all previously closed automatically. If all files are open,
    # they will remain open even after the with block.
    # close_files() can then be invoked explicitly.
```

**close()**

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate
that no exception occurred.
29.6.2. Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by contextlib.

29.6.2.1. Supporting a variable number of context managers

The primary use case for ExitStack is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single with statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```python
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
# Perform operations that use the acquired resource
```

As shown, ExitStack also makes it quite easy to use with statements to manage arbitrary resources that don’t natively support the context management protocol.

29.6.2.2. Simplifying support for single optional context managers
In the specific case of a single optional context manager, `ExitStack` instances can be used as a “do nothing” context manager, allowing a context manager to easily be omitted without affecting the overall structure of the source code:

```python
def debug_trace(details):
    if __debug__:
        return TraceContext(details)
        # Don't do anything special with the context in
    return ExitStack()

with debug_trace():
    # Suite is traced in debug mode, but runs normal
```

29.6.2.3. Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, `without` inadvertently catching exceptions from the `with` statement body or the context manager’s `__exit__` method. By using `ExitStack` the steps in the context management protocol can be separated slightly in order to allow this:

```python
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API
should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then `ExitStack` can make it easier to handle various situations that can't be handled directly in a `with` statement.

29.6.2.4. Cleaning up in an `__enter__` implementation

As noted in the documentation of `ExitStack.push()`, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```python
from contextlib import contextmanager, ExitStack

class ResourceManager:
    def __init__(self, acquire_resource, release_resource):
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
            self.check_resource_ok = check_resource_ok

@contextmanager
def _cleanup_on_error(self):
```
with ExitStack() as stack:
    stack.push(self)
    yield
    # The validation check passed and didn't raise an exception
    # Accordingly, we want to keep the resource and pass it back to our caller
    stack.pop_all()

def __enter__(self):
    resource = self.acquire_resource()
    with self._cleanup_on_error():
        if not self.check_resource_ok(resource):
            msg = "Failed validation for {!r}"
            raise RuntimeError(msg.format(resource))
    return resource

def __exit__(self, *exc_details):
    # We don't need to duplicate any of our resource release logic
    self.release_resource()

29.6.2.5. Replacing any use of try-finally and flag variables

A pattern you will sometimes see is a try-finally statement with a flag variable to indicate whether or not the body of the finally clause should be executed. In its simplest form (that can't already be handled just by using an except clause instead), it looks something like this:

cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()

As with any try statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

ExitStack makes it possible to instead register a callback for execution at the end of a with statement, and then later decide to skip executing that callback:

```python
from contextlib import ExitStack
with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()
```

This allows the intended cleanup up behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```python
from contextlib import ExitStack
class Callback(ExitStack):
    def __init__(self, callback, *args, **kwds):
        super(Callback, self).__init__()
        self.callback(callback, *args, **kwds)

    def cancel(self):
        self.pop_all()
```
with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```python
from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
def cleanup_resources():
        ...
        result = perform_operation()
        if result:
            stack.pop_all()
```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

**29.6.2.6. Using a context manager as a function decorator**

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context
manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```python
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
        self.name = name

    def __enter__(self):
        logging.info('Entering: {}'.format(self.name))

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: {}'.format(self.name))

Instances of this class can be used as both a context manager:

```python
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```  

And also as a function decorator:

```python
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of `__enter__()`. If that value is needed, then it is still
necessary to use an explicit `with` statement.

See also:

**PEP 0343 - The “with” statement**
The specification, background, and examples for the Python `with` statement.
29.6.3. Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a `with` statement once. These single use context managers must be created afresh each time they’re used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the `with` statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first `with` statement will close the file, preventing any further IO operations using that file object.

Context managers created using `contextmanager()` are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```python
>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...
>>> cm = singleuse()
>>> with cm:
...     pass
```
29.6.3.1. Reentrant context managers

More sophisticated context managers may be “reentrant”. These context managers can not only be used in multiple `with` statements, but may also be used `inside` a `with` statement that is already using the same context manager.

`threading.RLock` is an example of a reentrant context manager, as are `suppress()` and `redirect_stdout()`. Here's a very simple example of reentrant use:

```python
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...    print("This is written to the stream rather than stdout")
...    with write_to_stream:
...        print("This is also written to the stream rather than stdout")
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```
Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is not the same thing as being thread safe. `redirect_stdout()`, for example, is definitely not thread safe, as it makes a global modification to the system state by binding `sys.stdout` to a different stream.

### 29.6.3.2. Reusable context managers

Distinct from both single use and reentrant context managers are “reusable” context managers (or, to be completely explicit, “reusable, but not reentrant” context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not work correctly) if the specific context manager instance has already been used in a containing with statement.

`threading.Lock` is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use `threading.RLock` instead).

Another example of a reusable, but not reentrant, context manager is `ExitStack`, as it invokes all currently registered callbacks when leaving any with statement, regardless of where those callbacks were added:

```python
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...    stack.callback(print, "Callback: from first context")
...    print("Leaving first context")
```
Leaving first context
Callback: from first context

```python
>>> with stack:
...    stack.callback(print, "Callback: from second context")
...    print("Leaving second context")

Leaving second context
Callback: from second context

>>> with stack:
...    stack.callback(print, "Callback: from outer context")
...    with stack:
...        stack.callback(print, "Callback: from inner context")
...        print("Leaving inner context")
...        print("Leaving outer context")

Leaving inner context
Callback: from inner context
Callback: from outer context
Leaving outer context
```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate `ExitStack` instances instead of reusing a single instance avoids that problem:

```python
>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...    outer_stack.callback(print, "Callback: from first context")
...    with ExitStack() as inner_stack:
...        inner_stack.callback(print, "Callback: from second context")
...        print("Leaving inner context")
```
... print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context
29.7. abc — Abstract Base Classes

Source code: Lib/abc.py

This module provides the infrastructure for defining abstract base classes (ABCs) in Python, as outlined in PEP 3119; see the PEP for why this was added to Python. (See also PEP 3141 and the numbers module regarding a type hierarchy for numbers based on ABCs.)

The collections module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition the collections.abc submodule has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, is it hashable or a mapping.

This module provides the following classes:

class abc.ABCMeta

Metaclass for defining Abstract Base Classes (ABCs).

Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as “virtual subclasses” – these and their descendants will be considered subclasses of the registering ABC by the built-in issubclass() function, but the registering ABC won’t show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via super()). [1]
Classes created with a metaclass of `ABCMeta` have the following method:

**register(subclass)**

Register `subclass` as a “virtual subclass” of this ABC. For example:

```python
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

*Changed in version 3.3:* Returns the registered subclass, to allow usage as a class decorator.

*Changed in version 3.4:* To detect calls to `register()`, you can use the `get_cache_token()` function.

You can also override this method in an abstract base class:

**__subclasshook__(subclass)**

(Must be defined as a class method.)

Check whether `subclass` is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call `register()` on every class you want to consider a subclass of the ABC. (This class method is called from the `__subclasscheck__()` method of the ABC.)
This method should return True, False or NotImplemented. If it returns True, the subclass is considered a subclass of this ABC. If it returns False, the subclass is not considered a subclass of this ABC, even if it would normally be one. If it returns NotImplemented, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:

```python
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(metaclass=ABCMeta):
    @abstractmethod
    def __iter__(self):  # This method is defined here
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

@classmethod
def __subclasshook__(cls, C):
    if cls is MyIterable:
        if any("__iter__" in B.__dict__ for B
            return True
    return NotImplemented
```
The ABC MyIterable defines the standard iterable method, \_\_iter\_\_(), as an abstract method. The implementation given here can still be called from subclasses. The get\_iterator() method is also part of the MyIterable abstract base class, but it does not have to be overridden in non-abstract derived classes.

The \_\_subclasshook\_\_() class method defined here says that any class that has an \_\_iter\_\_() method in its \_\_dict\_\_ (or in that of one of its base classes, accessed via the \_\_mro\_\_ list) is considered a MyIterable too.

Finally, the last line makes Foo a virtual subclass of MyIterable, even though it does not define an \_\_iter\_\_() method (it uses the old-style iterable protocol, defined in terms of \_\_len\_\_() and \_\_getitem\_\_()). Note that this will not make get\_iterator available as a method of Foo, so it is provided separately.

class abc.**ABC**

A helper class that has **ABCMeta** as its metaclass. With this class, an abstract base class can be created by simply deriving from **ABC**, avoiding sometimes confusing metaclass usage.

Note that the type of **ABC** is still **ABCMeta**, therefore inheriting from **ABC** requires the usual precautions regarding metaclass usage, as multiple inheritance may lead to metaclass conflicts.

*New in version 3.4.*

The **abc** module also provides the following decorators:
@abc.abstractmethod
A decorator indicating abstract methods.

Using this decorator requires that the class's metaclass is ABCMeta or is derived from it. A class that has a metaclass derived from ABCMeta cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal ‘super’ call mechanisms. abstractmethod() may be used to declare abstract methods for properties and descriptors.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are not supported. The abstractmethod() only affects subclasses derived using regular inheritance; “virtual subclasses” registered with the ABC's register() method are not affected.

When abstractmethod() is applied in combination with other method descriptors, it should be applied as the innermost decorator, as shown in the following usage examples:

class C(metaclass=ABCMeta):
    @abstractmethod
    def my_abstract_method(self, ...):
        ...

    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, ...):
        ...

    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(...):
        ...
@property
@abstractmethod
def my_abstract_property(self):
...

@my_abstract_property.setter
@abstractmethod
def my_abstract_property(self, val):
...

@abstractmethod
def _get_x(self):
...

@abstractmethod
def _set_x(self, val):
...

x = property(_get_x, _set_x)

In order to correctly interoperate with the abstract base class machinery, the descriptor must identify itself as abstract using __isabstractmethod__. In general, this attribute should be True if any of the methods used to compose the descriptor are abstract. For example, Python’s built-in property does the equivalent of:

class Descriptor:
...

@property
def __isabstractmethod__(self):
    return any(getattr(f, '__isabstractmethod__')
                f in (self._fget, self._fset,

Note: Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the super() mechanism from the class that overrides it. This
could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.

@abc.abstractclassmethod
A subclass of the built-in `classmethod()`, indicating an abstract classmethod. Otherwise it is similar to `abstractmethod()`.

This special case is deprecated, as the `classmethod()` decorator is now correctly identified as abstract when applied to an abstract method:

```python
class C(metaclass=ABCMeta):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, ...):
        ...
```

*New in version 3.2.*

*Deprecated since version 3.3:* It is now possible to use `classmethod` with `abstractmethod()`, making this decorator redundant.

@abc.abstractstaticmethod
A subclass of the built-in `staticmethod()`, indicating an abstract staticmethod. Otherwise it is similar to `abstractmethod()`.

This special case is deprecated, as the `staticmethod()` decorator is now correctly identified as abstract when applied to an abstract method:

```python
class C(metaclass=ABCMeta):
    @staticmethod
    @abstractmethod
```

New in version 3.2.

*Deprecated since version 3.3:* It is now possible to use `staticmethod` with `abstractmethod()`, making this decorator redundant.

```python
@abc.abstractproperty(fget=None, fset=None, fdel=None, doc=None)
```

A subclass of the built-in `property()`, indicating an abstract property.

Using this function requires that the class’s metaclass is `ABCMeta` or is derived from it. A class that has a metaclass derived from `ABCMeta` cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract properties can be called using any of the normal ‘super’ call mechanisms.

This special case is deprecated, as the `property()` decorator is now correctly identified as abstract when applied to an abstract method:

```python
class C(metaclass=ABCMeta):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

The above example defines a read-only property; you can also define a read-write abstract property by appropriately marking one or more of the underlying methods as abstract:
```python
class C(metaclass=ABCMeta):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

If only some components are abstract, only those components need to be updated to create a concrete property in a subclass:

```python
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

*Deprecated since version 3.3:* It is now possible to use `property`, `property.getter()`, `property.setter()` and `property.deleter()` with `abstractmethod()`, making this decorator redundant.

The `abc` module also provides the following functions:

- `abc.get_cache_token()`
  Returns the current abstract base class cache token.

  The token is an opaque object (that supports equality testing) identifying the current version of the abstract base class cache for virtual subclasses. The token changes with every call to `ABCMeta.register()` on any ABC.

  *New in version 3.4.*
C++ programmers should note that Python's virtual base class concept is not the same as C++'s.
29.8. **atexit** — Exit handlers

The `atexit` module defines functions to register and unregister cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the reverse order in which they were registered; if you register A, B, and C, at interpreter termination time they will be run in the order C, B, A.

**Note:** The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

```python
atexit.register(func, *args, **kargs)
```

Register `func` as a function to be executed at termination. Any optional arguments that are to be passed to `func` must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run the last exception to be raised is re-raised.

This function returns `func`, which makes it possible to use it as a
decorator.

**atexit_unregister(func)**

Remove *func* from the list of functions to be run at interpreter shutdown. After calling `unregister()`, *func* is guaranteed not to be called when the interpreter shuts down, even if it was registered more than once. `unregister()` silently does nothing if *func* was not previously registered.

**See also:**

**Module readline**

Useful example of `atexit` to read and write `readline` history files.
29.8.1. **atexit** Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter’s updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```python
try:
    with open("counterfile") as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open("counterfile", "w") as outfile:
        outfile.write("%d" % _count)

import atexit
atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to `register()` to be passed along to the registered function when it is called:

```python
def goodbye(name, adjective):
    print('Goodbye, %s, it was %s to meet you.' % (name, adjective))

import atexit
atexit.register(goodbye, 'Donny', 'nice')
```
Usage as a decorator:

```python
import atexit
def goodbye():
    print("You are now leaving the Python sector.")
```

This only works with functions that can be called without arguments.
29.9. `traceback` — Print or retrieve a stack traceback

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a “wrapper” around the interpreter.

The module uses traceback objects — this is the object type that is stored in the `sys.last_traceback` variable and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

`traceback.print_tb(traceback, limit=None, file=None)`

Print up to `limit` stack trace entries from `traceback` (starting from the caller’s frame) if `limit` is positive. Otherwise, print the last `abs(limit)` entries. If `limit` is omitted or None, all entries are printed. If `file` is omitted or None, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

*Changed in version 3.5:* Added negative limit support.

`traceback.print_exception(type, value, traceback, limit=None, file=None, chain=True)`

Print exception information and stack trace entries from `traceback` to `file`. This differs from `print_tb()` in the following ways:

- if `traceback` is not None, it prints a header Traceback (most
recent call last):

- it prints the exception type and value after the stack trace
- if type is SyntaxError and value has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

The optional limit argument has the same meaning as for print_tb(). If chain is true (the default), then chained exceptions (the __cause__ or __context__ attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

```
traceback.print_exc(limit=None, file=None, chain=True)
```

This is a shorthand for print_exception(*sys.exc_info(), limit, file, chain).

```
traceback.print_last(limit=None, file=None, chain=True)
```

This is a shorthand for print_exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file, chain). In general it will work only after an exception has reached an interactive prompt (see sys.last_type).

```
traceback.print_stack(f=None, limit=None, file=None)
```

Print up to limit stack trace entries (starting from the invocation point) if limit is positive. Otherwise, print the last abs(limit) entries. If limit is omitted or None, all entries are printed. The optional f argument can be used to specify an alternate stack frame to start. The optional file argument has the same meaning as for print_tb().

*Changed in version 3.5: Added negative limit support.*

```
traceback.extract_tb(traceback, limit=None)
```
Return a list of “pre-processed” stack trace entries extracted from the traceback object traceback. It is useful for alternate formatting of stack traces. The optional limit argument has the same meaning as for print_tb(). A “pre-processed” stack trace entry is a 4-tuple (filename, line number, function name, text) representing the information that is usually printed for a stack trace. The text is a string with leading and trailing whitespace stripped; if the source is not available it is None.

```
traceback.extract_stack(f=None, limit=None)
```

Extract the raw traceback from the current stack frame. The return value has the same format as for extract_tb(). The optional f and limit arguments have the same meaning as for print_stack().

```
traceback.format_list(list)
```

Given a list of tuples as returned by extract_tb() or extract_stack(), return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not None.

```
traceback.format_exception_only(type, value)
```

Format the exception part of a traceback. The arguments are the exception type and value such as given by sys.last_type and sys.last_value. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for SyntaxError exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception
occurred is the always last string in the list.

```
traceback.format_exception(type, value, tb, limit=None, chain=True)
```

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to `print_exception()`. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does `print_exception()`.

```
traceback.format_exc(limit=None, chain=True)
```

This is like `print_exc(limit)` but returns a string instead of printing to a file.

```
traceback.format_tb(tb, limit=None)
```

A shorthand for `format_list(extract_tb(tb, limit))`.

```
traceback.format_stack(f=None, limit=None)
```

A shorthand for `format_list(extract_stack(f, limit))`.

```
traceback.clear_frames(tb)
```

Clears the local variables of all the stack frames in a traceback `tb` by calling the `clear()` method of each frame object.

*New in version 3.4.*

```
traceback.walk_stack(f)
```

Walk a stack following `f.f_back` from the given frame, yielding the frame and line number for each frame. If `f` is `None`, the current stack is used. This helper is used with `StackSummary.extract()`.
New in version 3.5.

traceback.walk_tb(tb)

Walk a traceback following tb_next yielding the frame and line number for each frame. This helper is used with StackSummary.extract().

New in version 3.5.

The module also defines the following classes:
29.9.1. `TracebackException` Objects

*New in version 3.5.*

`TracebackException` objects are created from actual exceptions to capture data for later printing in a lightweight fashion.

```python
class traceback.TracebackException(exc_type, exc_value, exc_traceback, *, limit=None, lookup_lines=True, capture_locals=False)
```

Capture an exception for later rendering. `limit`, `lookup_lines` and `capture_locals` are as for the `StackSummary` class.

Note that when locals are captured, they are also shown in the traceback.

```python
__cause__
A `TracebackException` of the original `__cause__`.

__context__
A `TracebackException` of the original `__context__`.

__suppress_context__
The `__suppress_context__` value from the original exception.

stack
A `StackSummary` representing the traceback.

exc_type
The class of the original traceback.

filename
For syntax errors - the file name where the error occurred.

**lineno**
For syntax errors - the line number where the error occurred.

**text**
For syntax errors - the text where the error occurred.

**offset**
For syntax errors - the offset into the text where the error occurred.

**msg**
For syntax errors - the compiler error message.

```python
classmethod from_exception(exc, *, limit=None, lookup_lines=True, capture_locals=False)
```
Capture an exception for later rendering. `limit, lookup_lines` and `capture_locals` are as for the `StackSummary` class.

Note that when locals are captured, they are also shown in the traceback.

```python
format(*, chain=True)
```
Format the exception.

If `chain` is not True, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines. `print_exception()` is a wrapper around this method which just prints the lines to a file.
The message indicating which exception occurred is always the last string in the output.

**format_exception_only()**

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

Normally, the generator emits a single string; however, for SyntaxError exceptions, it emits several lines that (when printed) display detailed information about where the syntax error occurred.

The message indicating which exception occurred is always the last string in the output.
29.9.2. **StackSummary** Objects

*New in version 3.5.*

**StackSummary** objects represent a call stack ready for formatting.

```python
class traceback.StackSummary
    @classmethod
    def extract(cls, frame_gen, *, limit=None, lookup_lines=True, capture_locals=False)

    Construct a StackSummary object from a frame generator (such as is returned by walk_stack() or walk_tb()).

    If `limit` is supplied, only this many frames are taken from `frame_gen`. If `lookup_lines` is False, the returned FrameSummary objects will not have read their lines in yet, making the cost of creating the StackSummary cheaper (which may be valuable if it may not actually get formatted). If `capture_locals` is True the local variables in each FrameSummary are captured as object representations.

    @classmethod
    def from_list(cls, a_list)

    Construct a StackSummary object from a supplied old-style list of tuples. Each tuple should be a 4-tuple with filename, lineno, name, line as the elements.
```
29.9.3. FrameSummary Objects

*New in version 3.5.*

FrameSummary objects represent a single frame in a traceback.

```python
class traceback.FrameSummary(filename, lineno, name, lookup_line=True, locals=None, line=None)
```

Represent a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frames locals included in it. If `lookup_line` is `False`, the source code is not looked up until the FrameSummary has the line attribute accessed (which also happens when casting it to a tuple). `line` may be directly provided, and will prevent line lookups happening at all. `locals` is an optional local variable dictionary, and if supplied the variable representations are stored in the summary for later display.
29.9.4. Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the code module.

```python
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except Exception:
        print("Exception in user code:")
        print("-"*60)
        traceback.print_exc(file=sys.stdout)
        print("-"*60)

envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```python
import sys, traceback

def lumberjack():
    bright_side_of_death()

def bright_side_of_death():
    return tuple()[0]
```
try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
    print("*** print_tb:")
    traceback.print_tb(exc_traceback, limit=1, file=sys.stderr)
    print("*** print_exception:")
    traceback.print_exception(exc_type, exc_value, exc_traceback, limit=2, file=sys.stdout)
    print("*** print_exc:")
    traceback.print_exc()
    print("*** format_exc, first and last line:")
    formatted_lines = traceback.format_exc().splitlines()
    print(formatted_lines[0])
    print(formatted_lines[-1])
    print("*** format_exception:")
    print(repr(traceback.format_exception(exc_type, exc_value, exc_traceback)))
    print("*** extract_tb:")
    print(repr(traceback.extract_tb(exc_traceback)))
    print("*** format_tb:")
    print(repr(traceback.format_tb(exc_traceback)))
    print("*** tb_lineno:", exc_traceback.tb_lineno)

The output for the example would look similar to this:

*** print_tb:
    File "<doctest...>", line 10, in <module>
        lumberjack()
*** print_exception:
Traceback (most recent call last):
    File "<doctest...>", line 10, in <module>
        lumberjack()
    File "<doctest...>", line 4, in lumberjack
        bright_side_of_death()
IndexError: tuple index out of range
The following example shows the different ways to print and format the stack:

```python
>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
```
...     print(repr(traceback.format_stack()))
...

>>> another_function()
    File "<doctest>", line 10, in <module>
        another_function()
    File "<doctest>", line 3, in another_function
        lumberstack()
    File "<doctest>", line 6, in lumberstack
        traceback.print_stack()
[("<doctest>", 10, "<module>", 'another_function()')
 ("<doctest>", 3, 'another_function', 'lumberstack()')
 ("<doctest>", 7, 'lumberstack', 'print(repr(traceback.extract_stack()))')
 [  File "<doctest>", line 10, in <module>
    another_function()
    File "<doctest>", line 3, in another_function
    lumberstack()
    File "<doctest>", line 6, in lumberstack
        traceback.print_stack()
]

This last example demonstrates the final few formatting functions:

>>> import traceback

>>> traceback.format_list([("spam.py", 3, "<module>"),
                          ("eggs.py", 42, "eggs"),
                          ("<doctest>", 10, "<module>"),
                          ("<doctest>", 3, 'another_function', 'lumberstack()')
                        ])
['File "spam.py", line 3, in <module>
 spam.eggs()
', 'File "eggs.py", line 42, in eggs
 return "bacon"
', 'File "<doctest>", line 10, in <module>
 another_function()
', 'File "<doctest>", line 3, in another_function
 lumberstack()
', 'File "<doctest>", line 6, in lumberstack
 traceback.print_stack()
']

>>> an_error = IndexError('tuple index out of range')

>>> traceback.format_exception_only(type(an_error), an_error)
['IndexError: tuple index out of range\n']
29.10. __future__ — Future statement definitions

Source code: Lib/__future__.py

__future__ is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they’re importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of __future__ will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing __future__ and examining its contents.

Each statement in __future__.py is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease, CompilerFlag)
```

where, normally, OptionalRelease is less than MandatoryRelease, and both are 5-tuples of the same form as sys.version_info:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or
 PY_RELEASE_SERIAL # the 3; an int
```
OptionalRelease records the first release in which the feature was accepted.

In the case of a MandatoryRelease that has not yet occurred, MandatoryRelease predicts the release in which the feature will become part of the language.

Else MandatoryRelease records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

MandatoryRelease may also be None, meaning that a planned feature got dropped.

Instances of class _Feature have two corresponding methods, getOptionalRelease() and getMandatoryRelease().

CompilerFlag is the (bitfield) flag that should be passed in the fourth argument to the built-in function compile() to enable the feature in dynamically compiled code. This flag is stored in the compiler_flag attribute on _Feature instances.

No feature description will ever be deleted from __future__. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

<table>
<thead>
<tr>
<th>feature</th>
<th>optional in</th>
<th>mandatory in</th>
<th>effect</th>
</tr>
</thead>
<tbody>

</table>

**See also:**

**Future statements**
How the compiler treats future imports.
This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in `gc.garbage` for inspection.

The `gc` module provides the following functions:

- `gc.enable()`  
  Enable automatic garbage collection.

- `gc.disable()`  
  Disable automatic garbage collection.

- `gc.isenabled()`  
  Returns true if automatic collection is enabled.

- `gc.collect(generations=2)`  
  With no arguments, run a full collection. The optional argument `generation` may be an integer specifying which generation to collect (from 0 to 2). A `ValueError` is raised if the generation number is
invalid. The number of unreachable objects found is returned.

The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular float.

\texttt{gc.set\_debug(flags)}

Set the garbage collection debugging flags. Debugging information will be written to \texttt{sys.stderr}. See below for a list of debugging flags which can be combined using bit operations to control debugging.

\texttt{gc.get\_debug()}

Return the debugging flags currently set.

\texttt{gc.get\_objects()}

Returns a list of all objects tracked by the collector, excluding the list returned.

\texttt{gc.get\_stats()}

Return a list of three per-generation dictionaries containing collection statistics since interpreter start. The number of keys may change in the future, but currently each dictionary will contain the following items:

- \texttt{collections} is the number of times this generation was collected;
- \texttt{collected} is the total number of objects collected inside this generation;
- \texttt{uncollectable} is the total number of objects which were found to be uncollectable (and were therefore moved to the \texttt{garbage} list) inside this generation.
New in version 3.4.

```python
gc.set_threshold(threshold0, threshold1, threshold2)
```
Set the garbage collection thresholds (the collection frequency). Setting threshold0 to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation 0). If an object survives a collection it is moved into the next older generation. Since generation 2 is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds threshold0, collection starts. Initially only generation 0 is examined. If generation 0 has been examined more than threshold1 times since generation 1 has been examined, then generation 1 is examined as well. Similarly, threshold2 controls the number of collections of generation 1 before collecting generation 2.

```python
gc.get_count()
```
Return the current collection counts as a tuple of (count0, count1, count2).

```python
gc.get_threshold()
```
Return the current collection thresholds as a tuple of (threshold0, threshold1, threshold2).

```python
gc.get_referrers(*objs)
```
Return the list of objects that directly refer to any of objs. This function will only locate those containers which support garbage
collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call `collect()` before calling `get_referrers()`.

Care must be taken when using objects returned by `get_referrers()` because some of them could still be under construction and hence in a temporarily invalid state. Avoid using `get_referrers()` for any purpose other than debugging.

```python
gc.get_referents(*objs)
```

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments’ C-level `tp_traverse` methods (if any), and may not be all objects actually directly reachable. `tp_traverse` methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

```python
gc.is_tracked(obj)
```

Returns True if the object is currently tracked by the garbage collector, False otherwise. As a general rule, instances of atomic types aren’t tracked and instances of non-atomic types (containers, user-defined objects...) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):
New in version 3.1.

The following variables are provided for read-only access (you can mutate the values but should not rebind them):

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

```
gc.garbage
```

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). Starting with Python 3.4, this list should be empty most of the time, except when using instances of C extension types with a non-NULL `tp_del` slot.

If `DEBUG_SAVEALL` is set, then all unreachable objects will be added to this list rather than freed.

Changed in version 3.2: If this list is non-empty at interpreter shutdown, a `ResourceWarning` is emitted, which is silent by default. If `DEBUG_UNCOLLECTABLE` is set, in addition all uncollectable objects are printed.

Changed in version 3.4: Following PEP 442, objects with a `__del__()` method don’t end up in `gc.garbage` anymore.
**gc.callbacks**

A list of callbacks that will be invoked by the garbage collector before and after collection. The callbacks will be called with two arguments, *phase* and *info*.

*phase* can be one of two values:

- “start”: The garbage collection is about to start.
- “stop”: The garbage collection has finished.

*info* is a dict providing more information for the callback. The following keys are currently defined:

- “generation”: The oldest generation being collected.
- “collected”: When *phase* is “stop”, the number of objects successfully collected.
- “uncollectable”: When *phase* is “stop”, the number of objects that could not be collected and were put in garbage.

Applications can add their own callbacks to this list. The primary use cases are:

- Gathering statistics about garbage collection, such as how often various generations are collected, and how long the collection takes.
- Allowing applications to identify and clear their own uncollectable types when they appear in garbage.

*New in version 3.3.*

The following constants are provided for use with *set_debug()*:
gc. **DEBUG_STATS**

Print statistics during collection. This information can be useful when tuning the collection frequency.

gc. **DEBUG_COLLECTABLE**

Print information on collectable objects found.

gc. **DEBUG_UNCOLLECTABLE**

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the garbage list.

*Changed in version 3.2:* Also print the contents of the garbage list at interpreter shutdown, if it isn't empty.

gc. **DEBUG_SAVEALL**

When set, all unreachable objects found will be appended to garbage rather than being freed. This can be useful for debugging a leaking program.

gc. **DEBUG_LEAK**

The debugging flags necessary for the collector to print information about a leaking program (equal to DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL).
29.12. **inspect** — Inspect live objects

**Source code:** Lib/inspect.py

The `inspect` module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.
29.12.1. Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The functions whose names begin with “is” are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes:

<table>
<thead>
<tr>
<th>Type</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>file</strong></td>
<td>filename (missing for built-in modules)</td>
</tr>
<tr>
<td>class</td>
<td><strong>doc</strong></td>
<td>documentation string</td>
</tr>
<tr>
<td></td>
<td><strong>name</strong></td>
<td>name with which this class was defined</td>
</tr>
<tr>
<td></td>

</tbody>
</table>

*Changed in version 3.5:* Add `__qualname__` and `gi_yieldfrom` attributes to generators.

The `__name__` attribute of generators is now set from the function
name, instead of the code name, and it can now be modified.

**inspect.getmembers**(object[, predicate])

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional *predicate* argument is supplied, only members for which the predicate returns a true value are included.

**Note:** *getmembers()* will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass’ custom __dir__().

**inspect.getmoduleinfo**(path)

Returns a named tuple ModuleInfo(name, suffix, mode, module_type) of values that describe how Python will interpret the file identified by *path* if it is a module, or None if it would not be identified as a module. In that tuple, *name* is the name of the module without the name of any enclosing package, *suffix* is the trailing part of the file name (which may not be a dot-delimited extension), *mode* is the open() mode that would be used ('r' or 'rb'), and *module_type* is an integer giving the type of the module. *module_type* will have a value which can be compared to the constants defined in the imp module; see the documentation for that module for more information on module types.

*Deprecated since version 3.3:* You may check the file path’s suffix against the supported suffixes listed in *importlib.machinery* to infer the same information.

**inspect.getmodulename**(path)

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is
checked against all of the entries in \texttt{importlib.machinery.all_suffixes()}. If it matches, the final path component is returned with the extension removed. Otherwise, \texttt{None} is returned.

Note that this function \textit{only} returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return \texttt{None}.

\textit{Changed in version 3.3:} This function is now based directly on \texttt{importlib} rather than the deprecated \texttt{getmoduleinfo()}. 

\begin{description}
\item[\texttt{inspect.ismodule(object)}] Return true if the object is a module.
\item[\texttt{inspect.isclass(object)}] Return true if the object is a class, whether built-in or created in Python code.
\item[\texttt{inspect.ismethod(object)}] Return true if the object is a bound method written in Python.
\item[\texttt{inspect.isfunction(object)}] Return true if the object is a Python function, which includes functions created by a \texttt{lambda} expression.
\item[\texttt{inspect.isgeneratorfunction(object)}] Return true if the object is a Python generator function.
\item[\texttt{inspect.isgenerator(object)}] Return true if the object is a generator.
\item[\texttt{inspect.iscoroutinefunction(object)}]
Return true if the object is a coroutine function (a function defined with an `async def` syntax).

*New in version 3.5.*

`inspect.iscoroutine(object)`

Return true if the object is a coroutine created by an `async def` function.

*New in version 3.5.*

`inspect.isawaitable(object)`

Return true if the object can be used in `await` expression. Can also be used to distinguish generator-based coroutines from regular generators:

```python
def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
assert isawaitable(gen_coro())
```

*New in version 3.5.*

`inspect.istraceback(object)`

Return true if the object is a traceback.

`inspect.isframe(object)`

Return true if the object is a frame.
inspect. **iscode**(object)
Return true if the object is a code.

inspect. **isbuiltin**(object)
Return true if the object is a built-in function or a bound built-in method.

inspect. **isroutine**(object)
Return true if the object is a user-defined or built-in function or method.

inspect. **isabstract**(object)
Return true if the object is an abstract base class.

inspect. **ismethoddescriptor**(object)
Return true if the object is a method descriptor, but not if
ismethod(), isclass(), isfunction() or isbuiltin() are true.

This, for example, is true of int.__add__. An object passing this
test has a __get__ attribute but not a __set__ attribute, but
beyond that the set of attributes varies. __name__ is usually
sensible, and __doc__ often is.

Methods implemented via descriptors that also pass one of the
other tests return false from the ismethoddescriptor() test,
simply because the other tests promise more – you can, e.g., count
on having the __func__ attribute (etc) when an object passes
ismethod().

inspect. **isdatadescriptor**(object)
Return true if the object is a data descriptor.
Data descriptors have both a `__get__` and a `__set__` attribute. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

```
inspect.isgetsetdescriptor(object)
```

Return true if the object is a getset descriptor.

**CPython implementation detail:** getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return `False`.

```
inspect.ismemberdescriptor(object)
```

Return true if the object is a member descriptor.

**CPython implementation detail:** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return `False`. 
29.12.2. Retrieving source code

inspect.getdoc(object)
Get the documentation string for an object, cleaned up with cleandoc(). If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy.

*Changed in version 3.5:* Documentation strings are now inherited if not overridden.

inspect.getcomments(object)
Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module).

inspect.getfile(object)
Return the name of the (text or binary) file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

inspect.getmodule(object)
Try to guess which module an object was defined in.

inspect.getsourcefile(object)
Return the name of the Python source file in which an object was defined. This will fail with a TypeError if the object is a built-in module, class, or function.

inspect.getsourcelines(object)
Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An OSError is raised if the source code cannot be retrieved.

*Changed in version 3.3:* OSError is raised instead of IOError, now an alias of the former.

**inspect.getsource** *(object)*

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An OSError is raised if the source code cannot be retrieved.

*Changed in version 3.3:* OSError is raised instead of IOError, now an alias of the former.

**inspect.cleandoc** *(doc)*

Clean up indentation from docstrings that are indented to line up with blocks of code. Any whitespace that can be uniformly removed from the second line onwards is removed. Also, all tabs are expanded to spaces.
29.12.3. Introspecting callables with the Signature object

*New in version 3.3.*

The Signature object represents the call signature of a callable object and its return annotation. To retrieve a Signature object, use the `signature()` function.

```
inspect.signature(callable, *, follow_wrapped=True)
```

Return a Signature object for the given callable:

```python
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b:int, **kwargs)'

>>> str(sig.parameters['b'])
'b:int'

>>> sig.parameters['b'].annotation
<class 'int'>
```

Accepts a wide range of python callables, from plain functions and classes to `functools.partial()` objects.

Raises `ValueError` if no signature can be provided, and `TypeError` if that type of object is not supported.
New in version 3.5: follow_wrapped parameter. Pass False to get a signature of callable specifically (callable.__wrapped__ will not be used to unwrap decorated callables.)

Note: Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

class inspect.Signature(parameters=None, *,
return_annotation=Signature.empty)

A Signature object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a Parameter object in its parameters collection.

The optional parameters argument is a sequence of Parameter objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional return_annotation argument, can be an arbitrary Python object, is the “return” annotation of the callable.

Signature objects are immutable. Use Signature.replace() to make a modified copy.

Changed in version 3.5: Signature objects are picklable and hashable.

empty
A special class-level marker to specify absence of a return annotation.

parameters
An ordered mapping of parameters’ names to the corresponding Parameter objects.

return_annotation
The “return” annotation for the callable. If the callable has no “return” annotation, this attribute is set to Signature.empty.

bind(*args, **kwargs)
Create a mapping from positional and keyword arguments to parameters. Returns BoundArguments if *args and **kwargs match the signature, or raises a TypeError.

bind_partial(*args, **kwargs)
Works the same way as Signature.bind(), but allows the omission of some required arguments (mimics functools.partial() behavior.) Returns BoundArguments, or raises a TypeError if the passed arguments do not match the signature.

replace(*[, parameters][, return_annotation])
Create a new Signature instance based on the instance replace was invoked on. It is possible to pass different parameters and/or return_annotation to override the corresponding properties of the base signature. To remove return_annotation from the copied Signature, pass in Signature.empty.

>>> def test(a, b):
...     pass
```python
global sig = signature(test)
global new_sig = sig.replace(return_annotation="new")
global str(new_sig)
"(a, b) -> 'new return anno'"
```
The name of the parameter as a string. The name must be a valid Python identifier.

**default**

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

**annotation**

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

**kind**

Describes how argument values are bound to the parameter. Possible values (accessible via `Parameter`, like `Parameter.KEYWORD_ONLY`):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>POSITIONAL_ONLY</code></td>
<td>Value must be supplied as a positional argument.</td>
</tr>
<tr>
<td></td>
<td>Python has no explicit syntax for defining positional-only parameters,</td>
</tr>
<tr>
<td></td>
<td>but many built-in and extension module functions (especially those</td>
</tr>
<tr>
<td></td>
<td>that accept only one or two parameters) accept them.</td>
</tr>
<tr>
<td><code>POSITIONAL_OR_KEYWORD</code></td>
<td>Value may be supplied as either a keyword or positional argument (this</td>
</tr>
<tr>
<td></td>
<td>is the standard binding</td>
</tr>
<tr>
<td><strong>VAR_POSITIONAL</strong></td>
<td>A tuple of positional arguments that aren’t bound to any other parameter. This corresponds to a *args parameter in a Python function definition.</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>KEYWORD_ONLY</strong></td>
<td>Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a * or *args entry in a Python function definition.</td>
</tr>
<tr>
<td><strong>VAR_KEYWORD</strong></td>
<td>A dict of keyword arguments that aren’t bound to any other parameter. This corresponds to a **kwargs parameter in a Python function definition.</td>
</tr>
</tbody>
</table>

Example: print all keyword-only arguments without default values:

```python
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and param.default is parameter)
...         print('Parameter:', param)
Parameter: c
```
replace(*[, name][, kind][, default][, annotation])

Create a new Parameter instance based on the instance replaced was invoked on. To override a Parameter attribute, pass the corresponding argument. To remove a default value or/and an annotation from a Parameter, pass Parameter.empty.

```python
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY)
>>> str(param)
'foo=42'

>>> str(param.replace())  # Will create a shallow copy of 'param'
'foo=42'

>>> str(param.replace(default=Parameter.empty, kind='POSITIONAL_ONLY'))
'foo:'spam'
```

*Changed in version 3.4:* In Python 3.3 Parameter objects were allowed to have name set to None if their kind was set to POSITIONAL_ONLY. This is no longer permitted.

class inspect.BoundArguments

Result of a Signature.bind() or Signature.bind_partial() call. Holds the mapping of arguments to the function's parameters.

**arguments**

An ordered, mutable mapping (collections.OrderedDict) of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in arguments will reflect
in \texttt{args} and \texttt{kwargs}.

Should be used in conjunction with \texttt{Signature.parameters} for any argument processing purposes.

\begin{tcolorbox}[colback=white]
\textbf{Note:} Arguments for which \texttt{Signature.bind()} or \texttt{Signature.bind_partial()} relied on a default value are skipped. However, if needed, use \texttt{BoundArguments.apply_defaults()} to add them.
\end{tcolorbox}

\textbf{args}

A tuple of positional arguments values. Dynamically computed from the \texttt{arguments} attribute.

\textbf{kwargs}

A dict of keyword arguments values. Dynamically computed from the \texttt{arguments} attribute.

\textbf{signature}

A reference to the parent \texttt{Signature} object.

\textbf{apply_defaults()}

Set default values for missing arguments.

For variable-positional arguments (*args) the default is an empty tuple.

For variable-keyword arguments (**kwargs) the default is an empty dict.

\begin{Verbatim}
>>> \texttt{def foo(a, b='ham', *args): pass}
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
\end{Verbatim}
New in version 3.5.

The `args` and `kwargs` properties can be used to invoke functions:

```python
def test(a, *, b):
    ...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwargs)
```

See also:

**PEP 362 - Function Signature Object.**

The detailed specification, implementation details and examples.
29.12.4. Classes and functions

inspect.getclasstree(classes, unique=False)

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the unique argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

inspect.getargspec(func)

Get the names and default values of a Python function's arguments. A named tuple ArgSpec(args, varargs, keywords, defaults) is returned. args is a list of the argument names. varargs and keywords are the names of the * and ** arguments or None. defaults is a tuple of default argument values or None if there are no default arguments; if this tuple has n elements, they correspond to the last n elements listed in args.

Deprecated since version 3.0: Use signature() and Signature Object, which provide a better introspecting API for callables. This function will be removed in Python 3.6.

inspect.getfullargspec(func)

Get the names and default values of a Python function's arguments. A named tuple is returned:

FullArgSpec(args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations)
args is a list of the argument names. varargs and varkw are the names of the * and ** arguments or None. defaults is an n-tuple of the default values of the last n arguments, or None if there are no default arguments. kwonlyargs is a list of keyword-only argument names. kwonlydefaults is a dictionary mapping names from kwonlyargs to defaults. annotations is a dictionary mapping argument names to annotations.

The first four items in the tuple correspond to getargspec().

*Changed in version 3.4:* This function is now based on signature(), but still ignores __wrapped__ attributes and includes the already bound first parameter in the signature output for bound methods.

*Deprecated since version 3.5:* Use signature() and Signature Object, which provide a better introspecting API for callables.

inspect.getargvalues(frame)

Get information about arguments passed into a particular frame. A named tuple ArgInfo(args, varargs, keywords, locals) is returned. args is a list of the argument names. varargs and keywords are the names of the * and ** arguments or None. locals is the locals dictionary of the given frame.

*Deprecated since version 3.5:* Use signature() and Signature Object, which provide a better introspecting API for callables.

inspect.formatargspec(args[, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations[, formatarg, formatvarargs, formatvarkw, formatvalue, formatreturns, formatannotations]])

Format a pretty argument spec from the values returned by
getargspec() or getfullargspec().

The first seven arguments are (args, varargs, varkw, defaults, kwonlyargs, kwonlydefaults, annotations).

The other six arguments are functions that are called to turn argument names, * argument name, ** argument name, default values, return annotation and individual annotations into strings, respectively.

For example:

```python
>>> from inspect import formatargspec, getfullargspec
>>> def f(a: int, b: float):
...     pass
...
>>> formatargspec(*getfullargspec(f))
'(a: int, b: float)'
```

*Deprecated since version 3.5:* Use signature() and Signature Object, which provide a better introspecting API for callables.

inspect.formatargvalues(args[, varargs, varkw, locals, formatarg, formatvarargs, formatvarkw, formatvalue])

Format a pretty argument spec from the four values returned by getargvalues(). The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

*Deprecated since version 3.5:* Use signature() and Signature Object, which provide a better introspecting API for callables.

inspect.getmro(cls)
Return a tuple of class cls's base classes, including cls, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on cls's type. Unless a very peculiar user-defined metatype is in use, cls will be the first element of the tuple.

`inspect.getcallargs(func, *args, **kwds)`

Bind the `args` and `kwds` to the argument names of the Python function or method `func`, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the `*` and `**` arguments, if any) to their values from `args` and `kwds`. In case of invoking `func` incorrectly, i.e. whenever `func(*args, **kwds)` would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example:

```python
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}}, True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': True}
>>> getcallargs(f)
Traceback (most recent call last):
  ...
TypeError: f() missing 1 required positional argument
```

*New in version 3.2.*

*Deprecated since version 3.5:* Use `Signature.bind()` and
Signature.bind_partial() instead.

inspect.getclosurevars(func)
Get the mapping of external name references in a Python function or method func to their current values. A named tuple ClosureVars(nonlocals, globals, builtins, unbound) is returned. nonlocals maps referenced names to lexical closure variables, globals to the function's module globals and builtins to the builtins visible from the function body. unbound is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

TypeError is raised if func is not a Python function or method.

New in version 3.3.

inspect.unwrap(func, *, stop=None)
Get the object wrapped by func. It follows the chain of __wrapped__ attributes returning the last object in the chain.

stop is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, signature() uses this to stop unwrapping if any object in the chain has a __signature__ attribute defined.

ValueError is raised if a cycle is encountered.

New in version 3.4.
29.12.5. The interpreter stack

When the following functions return “frame records,” each record is a named tuple `FrameInfo(frame, filename, lineno, function, code_context, index)`. The tuple contains the frame object, the filename, the line number of the current line, the function name, a list of lines of context from the source code, and the index of the current line within that list.

*Changed in version 3.5:* Return a named tuple instead of a tuple.

**Note:** Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python’s optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```python
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
```
If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the `frame.clear()` method.

The optional `context` argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

```python
inspect.getframeinfo(frame, context=1)
```

Get information about a frame or traceback object. A named tuple `Traceback(filename, lineno, function, code_context, index)` is returned.

```python
inspect.getouterframes(frame, context=1)
```

Get a list of frame records for a frame and all outer frames. These frames represent the calls that lead to the creation of `frame`. The first entry in the returned list represents `frame`; the last entry represents the outermost call on `frame`'s stack.

*Changed in version 3.5:* A list of named tuples `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

```python
inspect.getinnerframes(traceback, context=1)
```

Get a list of frame records for a traceback's frame and all inner frames. These frames represent calls made as a consequence of `frame`. The first entry in the list represents `traceback`; the last entry represents where the exception was raised.

*Changed in version 3.5:* A list of named tuples
FrameInfo(frame, filename, lineno, function, code_context, index) is returned.

inspect.currentframe()

Return the frame object for the caller's stack frame.

**CPython implementation detail:** This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns None.

inspect.stack(context=1)

Return a list of frame records for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

*Changed in version 3.5:* A list of named tuples FrameInfo(frame, filename, lineno, function, code_context, index) is returned.

inspect.trace(context=1)

Return a list of frame records for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

*Changed in version 3.5:* A list of named tuples FrameInfo(frame, filename, lineno, function, code_context, index) is returned.
29.12.6. Fetching attributes statically

Both `getattr()` and `hasattr()` can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and `__getattr__()` and `__getattribute__()` may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. `getattr_static()` has the same signature as `getattr()` but avoids executing code when it fetches attributes.

```
inspect.getattr_static(obj, attr, default=None)
```

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, `__getattr__()` or `__getattribute__()`.

Note: this function may not be able to retrieve all attributes that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can’t (like descriptors that raise AttributeError). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

New in version 3.2.

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.
You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```python
# example code for resolving the builtin descriptor
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor)

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```
29.12.7. Current State of Generators and Coroutines

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

```python
inspect.getgeneratorstate(generator)
```
Get current state of a generator-iterator.

Possible states are:
- GEN_CREATED: Waiting to start execution.
- GEN_RUNNING: Currently being executed by the interpreter.
- GEN_SUSPENDED: Currently suspended at a yield expression.
- GEN_CLOSED: Execution has completed.

*New in version 3.2.*

```python
inspect.getcoroutinestate(coroutine)
```
Get current state of a coroutine object. The function is intended to be used with coroutine objects created by `async def` functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

Possible states are:
- CORO_CREATED: Waiting to start execution.
- CORO_RUNNING: Currently being executed by the interpreter.
- CORO_SUSPENDED: Currently suspended at an await expression.
- CORO_CLOSED: Execution has completed.

New in version 3.5.

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

```python
inspect.getgeneratorlocals(generator)
```

Get the mapping of live local variables in `generator` to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If `generator` is a `generator` with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if `generator` is not a Python generator object.

**CPython implementation detail:** This function relies on the generator exposing a Python stack frame for introspection, which isn’t guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary. New in version 3.3.

```python
inspect.getcoroutinelocals(coroutine)
```

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

New in version 3.5.
29.12.8. Command Line Interface

The `inspect` module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

```bash
--details
Print information about the specified object rather than the source code
```

29.13. **site** — Site-specific configuration hook

**Source code:** Lib/site.py

This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter’s `-S` option.

Importing this module will append site-specific paths to the module search path and add a few builtins, unless `-S` was used. In that case, this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the `site.main()` function.

*Changed in version 3.3:* Importing the module used to trigger paths manipulation even when using `-S`.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y/site-packages` (on Unix and Macintosh). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

*Changed in version 3.5:* Support for the “site-python” directory has been removed.

If a file named “pyvenv.cfg” exists one directory above `sys.executable`,
sys.prefix and sys.exec_prefix are set to that directory and it is also checked for site-packages (sys.base_prefix and sys.base_exec_prefix will always be the “real” prefixes of the Python installation). If “pyvenv.cfg” (a bootstrap configuration file) contains the key “includem system-site-packages” set to anything other than “false” (case-insensitive), the system-level prefixes will still also be searched for site-packages; otherwise they won’t.

A path configuration file is a file whose name has the form name.pth and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to sys.path. Non-existing items are never added to sys.path, and no check is made that the item refers to a directory rather than a file. No item is added to sys.path more than once. Blank lines and lines beginning with # are skipped. Lines starting with import (followed by space or tab) are executed.

For example, suppose sys.prefix and sys.exec_prefix are set to /usr/local. The Python X.Y library is then installed in /usr/local/lib/pythonX.Y. Suppose this has a subdirectory /usr/local/lib/pythonX.Y/site-packages with three subsubdirectories, foo, bar and spam, and two path configuration files, foo.pth and bar.pth. Assume foo.pth contains the following:

```
# foo package configuration
foo
bar
bletch
```

and bar.pth contains:
# bar package configuration

bar

Then the following version-specific directories are added to sys.path, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that bletch is omitted because it doesn’t exist; the bar directory precedes the foo directory because bar.pth comes alphabetically before foo.pth; and spam is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named sitecustomize, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the site-packages directory. If this import fails with an ImportError exception, it is silently ignored. If Python is started without output streams available, as with pythonw.exe on Windows (which is used by default to start IDLE), attempted output from sitecustomize is ignored. Any exception other than ImportError causes a silent and perhaps mysterious failure of the process.

After this, an attempt is made to import a module named usercustomize, which can perform arbitrary user-specific customizations, if ENABLE_USER_SITE is true. This file is intended to be created in the user site-packages directory (see below), which is part of sys.path unless disabled by -s. An ImportError will be silently ignored.
Note that for some non-Unix systems, sys.prefix and sys.exec_prefix are empty, and the path manipulations are skipped; however the import of sitecustomize and usercustomize is still attempted.
29.13.1. Readline configuration

On systems that support `readline`, this module will also import and configure the `rlcompleter` module, if Python is started in interactive mode and without the `-S` option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the `sys.__interactivehook__` attribute in your `sitecustomize` or `usercustomize` module or your `PYTHONSTARTUP` file.

*Changed in version 3.4:* Activation of rlcompleter and history was made automatic.
29.13.2. Module contents

**site.PREFIXES**

A list of prefixes for site-packages directories.

**site.ENABLE_USER_SITE**

Flag showing the status of the user site-packages directory. True means that it is enabled and was added to sys.path. False means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). None means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

**site.USER_SITE**

Path to the user site-packages for the running Python. Can be None if `getusersitepackages()` hasn’t been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework Mac OS X builds, `~/Library/Python/X.Y/lib/python/site-packages` for Mac framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that .pth files in it will be processed.

**site.USER_BASE**

Path to the base directory for the user site-packages. Can be None if `getuserbase()` hasn’t been called yet. Default value is `~/.local` for UNIX and Mac OS X non-framework builds, `~/Library/Python/X.Y` for Mac framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils
to compute the installation directories for scripts, data files, Python modules, etc. for the user installation scheme. See also PYTHONUSERBASE.

site.main()
Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the -S flag.

*Changed in version 3.3:* This function used to be called unconditionally.

site.addsitedir(sitedir, known_paths=None)
Add a directory to sys.path and process its .pth files. Typically used in sitecustomize or usercustomize (see above).

site.getsitepackages()
Return a list containing all global site-packages directories.

*New in version 3.2.*

site.getuserbase()
Return the path of the user base directory, USER_BASE. If it is not initialized yet, this function will also set it, respecting PYTHONUSERBASE.

*New in version 3.2.*

site.getusersitepackages()
Return the path of the user-specific site-packages directory, USER_SITE. If it is not initialized yet, this function will also set it, respecting PYTHONNOUSERSITE and USER_BASE.
New in version 3.2.

The site module also provides a way to get the user directories from the command line:

```
$ python3 -m site --user-site
/home/user/.local/lib/python3.3/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

--user-base

Print the path to the user base directory.

--user-site

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

See also: PEP 370 – Per user site-packages directory
29.14. \texttt{fpectl} — Floating point exception control

\textbf{Note:} The \texttt{fpectl} module is not built by default, and its usage is discouraged and may be dangerous except in the hands of experts. See also the section Limitations and other considerations on limitations for more details.

Most computers carry out floating point operations in conformance with the so-called IEEE-754 standard. On any real computer, some floating point operations produce results that cannot be expressed as a normal floating point value. For example, try

\begin{verbatim}
>>> import math
>>> math.exp(1000)
inf
>>> math.exp(1000) / math.exp(1000)
nan
\end{verbatim}

(The example above will work on many platforms. DEC Alpha may be one exception.) “Inf” is a special, non-numeric value in IEEE-754 that stands for “infinity”, and “nan” means “not a number.” Note that, other than the non-numeric results, nothing special happened when you asked Python to carry out those calculations. That is in fact the default behaviour prescribed in the IEEE-754 standard, and if it works for you, stop reading now.

In some circumstances, it would be better to raise an exception and stop processing at the point where the faulty operation was attempted. The \texttt{fpectl} module is for use in that situation. It provides control over floating point units from several hardware manufacturers, allowing the
user to turn on the generation of SIGFPE whenever any of the IEEE-754 exceptions Division by Zero, Overflow, or Invalid Operation occurs. In tandem with a pair of wrapper macros that are inserted into the C code comprising your python system, SIGFPE is trapped and converted into the Python `FloatingPointError` exception.

The `fpectl` module defines the following functions and may raise the given exception:

```python
def turnon_sigfpe():
    # Turn on the generation of SIGFPE, and set up an appropriate
    # signal handler.

def turnoff_sigfpe():
    # Reset default handling of floating point exceptions.

exception FloatingPointError
    # After `turnon_sigfpe()` has been executed, a floating point
    # operation that raises one of the IEEE-754 exceptions Division by
    # Zero, Overflow, or Invalid operation will in turn raise this standard
    # Python exception.
```
29.14.1. Example

The following example demonstrates how to start up and test operation of the `fpectl` module.

```python
>>> import fpectl
>>> import fpetest
>>> fpectl.turnon_sigfpe()
>>> fpetest.test()
overflow PASS
FloatingPointError: Overflow

div by 0 PASS
FloatingPointError: Division by zero
   [ more output from test elided ]
>>> import math
>>> math.exp(1000)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
FloatingPointError: in math_1
```
29.14.2. Limitations and other considerations

Setting up a given processor to trap IEEE-754 floating point errors currently requires custom code on a per-architecture basis. You may have to modify `fpectl` to control your particular hardware.

Conversion of an IEEE-754 exception to a Python exception requires that the wrapper macros `PyFPE_START_PROTECT` and `PyFPE_END_PROTECT` be inserted into your code in an appropriate fashion. Python itself has been modified to support the `fpectl` module, but many other codes of interest to numerical analysts have not.

The `fpectl` module is not thread-safe.

**See also:** Some files in the source distribution may be interesting in learning more about how this module operates. The include file `Include/pyfpe.h` discusses the implementation of this module at some length. Modules/fpetestmodule.c gives several examples of use. Many additional examples can be found in Objects/floatobject.c.
30. Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python’s interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the code module. (The codeop module is lower-level, used to support compiling a possibly-incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- **30.1. code — Interpreter base classes**
  - 30.1.1. Interactive Interpreter Objects
  - 30.1.2. Interactive Console Objects
- **30.2. codeop — Compile Python code**
30.1. **code** — Interpreter base classes

**Source code:** Lib/code.py

The code module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

```python
class code.InteractiveInterpreter(locals=None)
    This class deals with parsing and interpreter state (the user’s namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional `locals` argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key '__name__' set to '__console__' and key '__doc__' set to None.
```

```python
class code.InteractiveConsole(locals=None, filename="<console>")
    Closely emulate the behavior of the interactive Python interpreter. This class builds on `InteractiveInterpreter` and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.
```

```python
code.interact(banner=None, readfunc=None, local=None)
    Convenience function to run a read-eval-print loop. This creates a new instance of `InteractiveConsole` and sets `readfunc` to be used as the `InteractiveConsole.raw_input()` method, if
```
provided. If `local` is provided, it is passed to the `InteractiveConsole` constructor for use as the default namespace for the interpreter loop. The `interact()` method of the instance is then run with `banner` passed as the banner to use, if provided. The console object is discarded after use.

code`compile_command(source, filename="<input>", symbol="single")

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function `almost` always makes the same decision as the real interpreter main loop.

`source` is the source string; `filename` is the optional filename from which source was read, defaulting to '<input>'; and `symbol` is the optional grammar start symbol, which should be either 'single' (the default) or 'eval'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; None if the command is incomplete; raises `SyntaxError` if the command is complete and contains a syntax error, or raises `OverflowError` or `ValueError` if the command contains an invalid literal.
30.1.1. Interactive Interpreter Objects

InteractiveInterpreter.runsource(source, filename="<input>", symbol="single")

Compile and run some source in the interpreter. Arguments are the same as for compile_command(); the default for filename is '<input>', and for symbol is 'single'. One several things can happen:

- The input is incorrect; compile_command() raised an exception (SyntaxError or OverflowError). A syntax traceback will be printed by calling the showsyntaxerror() method. runsource() returns False.
- The input is incomplete, and more input is required; compile_command() returned None. runsource() returns True.
- The input is complete; compile_command() returned a code object. The code is executed by calling the runcode() (which also handles run-time exceptions, except for SystemExit). runsource() returns False.

The return value can be used to decide whether to use sys.ps1 or sys.ps2 to prompt the next line.

InteractiveInterpreter.runcode(code)

Execute a code object. When an exception occurs, showtraceback() is called to display a traceback. All exceptions are caught except SystemExit, which is allowed to propagate.

A note about KeyboardInterrupt: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.
InteractiveInterpreter.\texttt{showsyntaxerror}(\textit{filename}=None)

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If \textit{filename} is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses '⟨string⟩' when reading from a string. The output is written by the \texttt{write()} method.

InteractiveInterpreter.\texttt{showtraceback}()

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the \texttt{write()} method.

\textit{Changed in version 3.5}: The full chained traceback is displayed instead of just the primary traceback.

InteractiveInterpreter.\texttt{write}(\textit{data})

Write a string to the standard error stream (\texttt{sys.stderr}). Derived classes should override this to provide the appropriate output handling as needed.
30.1.2. Interactive Console Objects

The  `InteractiveConsole`  class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

**`InteractiveConsole.interact(banner=None)`**

Closely emulate the interactive Python console. The optional `banner` argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it’s so close!).

*Changed in version 3.4:* To suppress printing any banner, pass an empty string.

**`InteractiveConsole.push(line)`**

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter’s `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

**`InteractiveConsole.resetbuffer()`**

Remove any unhandled source text from the input buffer.
`InteractiveConsole.raw_input(prompt='')`

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.
30.2. codeop — Compile Python code

The codeop module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the code module. As a result, you probably don’t want to use the module directly; if you want to include such a loop in your program you probably want to use the code module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print ‘>>>’ or ‘...‘ next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The codeop module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

```python
codeop.compile_command(source, filename="<input>", symbol="single")
```

Tries to compile source, which should be a string of Python code and return a code object if source is valid Python code. In that case, the filename attribute of the code object will be filename, which defaults to '<input>'. Returns None if source is not valid Python code, but is a prefix of valid Python code.

If there is a problem with source, an exception will be raised. `SyntaxError` is raised if there is invalid Python syntax, and
**OverflowError** or **ValueError** if there is an invalid literal.

The **symbol** argument determines whether **source** is compiled as a statement ('single', the default) or as an **expression** ('eval'). Any other value will cause **ValueError** to be raised.

**Note:** It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

**class codeop.Compile**

Instances of this class have **__call__()** methods identical in signature to the built-in function **compile()**, but with the difference that if the instance compiles program text containing a **__future__** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.

**class codeop.CommandCompiler**

Instances of this class have **__call__()** methods identical in signature to **compile_command()**; the difference is that if the instance compiles program text containing a **__future__** statement, the instance ‘remembers’ and compiles all subsequent program texts with the statement in force.
31. Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- **31.1. zipimport** — Import modules from Zip archives
  - 31.1.1. zipimporter Objects
  - 31.1.2. Examples
- **31.2. pkgutil** — Package extension utility
- **31.3. modulefinder** — Find modules used by a script
  - 31.3.1. Example usage of ModuleFinder
- **31.4. runpy** — Locating and executing Python modules
- **31.5. importlib** — The implementation of import
  - 31.5.1. Introduction
  - 31.5.2. Functions
  - 31.5.3. importlib.abc — Abstract base classes related to import
  - 31.5.4. importlib.machinery — Importers and path hooks
  - 31.5.5. importlib.util — Utility code for importers
31.1. zipimport — Import modules from Zip archives

This module adds the ability to import Python modules (*.py, *.py[co]) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but only files .py and .pyc are available for import. ZIP import of dynamic modules (.pyd, .so) is disallowed. Note that if an archive only contains .py files, Python will not attempt to modify the archive by adding the corresponding .pyc file, meaning that if a ZIP archive doesn't contain .pyc files, importing may be rather slow.

ZIP archives with an archive comment are currently not supported.

See also:

**PKZIP Application Note**

Documentation on the ZIP file format by Phil Katz, the creator of
the format and algorithms used.

**PEP 273 - Import Modules from Zip Archives**
Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302.

**PEP 302 - New Import Hooks**
The PEP to add the import hooks that help this module work.

This module defines an exception:

```python
exception zipimport.ZipImportError
    Exception raised by zipimporter objects. It's a subclass of ImportError, so it can be caught as ImportError, too.
```
31.1.1. zipimporter Objects

`zipimporter` is the class for importing ZIP files.

```python
class zipimport.zipimporter(archivepath)
```

Create a new zipimporter instance. `archivepath` must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an `archivepath` of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

`ZipImportError` is raised if `archivepath` doesn't point to a valid ZIP archive.

```python
find_module(fullname[, path])
```

Search for a module specified by `fullname`. `fullname` must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or `None` if it wasn't. The optional `path` argument is ignored—it's there for compatibility with the importer protocol.

```python
get_code(fullname)
```

Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be found.

```python
get_data(pathname)
```

Return the data associated with `pathname`. Raise `OSError` if the file wasn’t found.

*Changed in version 3.3:* `IOError` used to be raised instead of `OSError`.
get_filename(fullname)
    Return the value __file__ would be set to if the specified module was imported. Raise ZipImportError if the module couldn't be found.

    New in version 3.1.

get_source(fullname)
    Return the source code for the specified module. Raise ZipImportError if the module couldn't be found, return None if the archive does contain the module, but has no source for it.

is_package(fullname)
    Return True if the module specified by fullname is a package. Raise ZipImportError if the module couldn't be found.

load_module(fullname)
    Load the module specified by fullname. fullname must be the fully qualified (dotted) module name. It returns the imported module, or raises ZipImportError if it wasn't found.

archive
    The file name of the importer's associated ZIP file, without a possible subpath.

prefix
    The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

    The archive and prefix attributes, when combined with a slash, equal the original archivepath argument given to the
zipimporter constructor.
31.1.2. Examples

Here is an example that imports a module from a ZIP archive - note that the `zipimport` module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
         Length  Date     Time    Name
          ------  ----      ----    ----
          8467  11-26-02 22:30  jwzthreading.py
          ------  ------    ------
          8467
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```
This module provides utilities for the import system, in particular package support.

`pkgutil.extend_path(path, name)`

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's `__path__` all subdirectories of directories on `sys.path` named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for `*.pkg` files beginning where `*` matches the `name` argument. This feature is similar to `*.pth` files (see the `site` module for more information), except that it doesn’t special-case lines starting with `import`. A `*.pkg` file is trusted at face value: apart from checking for duplicates, all entries found in a `*.pkg` file are added to the path, regardless of whether they exist on the filesystem. (This is a feature.)

If the input path is not a list (as is the case for frozen packages) it is
returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that `sys.path` is a sequence. Items of `sys.path` that are not strings referring to existing directories are ignored. Unicode items on `sys.path` that cause errors when used as filenames may cause this function to raise an exception (in line with `os.path.isdir()` behavior).

```python
class pkgutil.ImpImporter(dirname=None)

PEP 302 Importer that wraps Python’s “classic” import algorithm.
```

If `dirname` is a string, a **PEP 302** importer is created that searches that directory. If `dirname` is None, a **PEP 302** importer is created that searches the current `sys.path`, plus any modules that are frozen or built-in.

Note that `ImpImporter` does not currently support being used by placement on `sys.meta_path`.

**Deprecated since version 3.3:** This emulation is no longer needed, as the standard import mechanism is now fully PEP 302 compliant and available in `importlib`.

```python
class pkgutil.ImpLoader(fullname, file, filename, etc)

PEP 302 Loader that wraps Python’s “classic” import algorithm.
```

**Deprecated since version 3.3:** This emulation is no longer needed, as the standard import mechanism is now fully PEP 302 compliant and available in `importlib`.

```python
pkgutil.find_loader(fullname)

Retrieve a **PEP 302** module loader for the given `fullname`.
This is a backwards compatibility wrapper around `importlib.util.find_spec()` that converts most failures to `ImportError` and only returns the loader rather than the full ModuleSpec.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

*Changed in version 3.4:* Updated to be based on PEP 451

`pkgutil.get_importer(path_item)`

Retrieve a PEP 302 importer for the given `path_item`.

The returned importer is cached in `sys.path_importer_cache` if it was newly created by a path hook.

The cache (or part of it) can be cleared manually if a rescan of `sys.path_hooks` is necessary.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

`pkgutil.get_loader(module_or_name)`

Get a PEP 302 “loader” object for `module_or_name`.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns None if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package __path__. 
Changed in version 3.3: Updated to be based directly on *importlib* rather than relying on the package internal PEP 302 import emulation.

*Changed in version 3.4:* Updated to be based on **PEP 451**

```python
cpkgutil.iter_importers(fullname="")
```

Yield **PEP 302** importers for the given module name.

If `fullname` contains a `.'`, the importers will be for the package containing `fullname`, otherwise they will be all registered top level importers (i.e. those on both `sys.meta_path` and `sys.path_hooks`).

If the named module is in a package, that package is imported as a side effect of invoking this function.

If no module name is specified, all top level importers are produced.

*Changed in version 3.3:* Updated to be based directly on *importlib* rather than relying on the package internal PEP 302 import emulation.

```python
cpkgutil.iter_modules(path=None, prefix="")
```

Yields `(module_finder, name, ispkg)` for all submodules on `path`, or, if `path` is `None`, all top-level modules on `sys.path`.

`path` should be either `None` or a list of paths to look for modules in.

`prefix` is a string to output on the front of every module name on output.

**Note:** Only works for a `finder` which defines an `iter_modules()` method. This interface is non-standard, so the
module also provides implementations for
importlib.machinery.FileFinder
and
zipimport.zipimporter.

*Changed in version 3.3:* Updated to be based directly on
importlib rather than relying on the package internal PEP 302
import emulation.

pkgutil.walk_packages(path=None, prefix='', onerror=None)
Yields (module_finder, name, ispkg) for all modules
recursively on path, or, if path is None, all accessible modules.

*path* should be either None or a list of paths to look for modules in.

*prefix* is a string to output on the front of every module name on
output.

Note that this function must import all *packages* (*not* all modules!)
on the given *path*, in order to access the __path__ attribute to find
submodules.

*onerror* is a function which gets called with one argument (the
name of the package which was being imported) if any exception
occurs while trying to import a package. If no *onerror* function is
supplied, *ImportErrors* are caught and ignored, while all other
exceptions are propagated, terminating the search.

Examples:

```python
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ +
```
Note: Only works for a finder which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for `importlib.machinery.FileFinder` and `zipimport.zipimporter`.

*Changed in version 3.3:* Updated to be based directly on `importlib` rather than relying on the package internal PEP 302 import emulation.

`pkgutil.get_data(package, resource)`

Get a resource from a package.

This is a wrapper for the **PEP 302** loader `get_data()` API. The `package` argument should be the name of a package, in standard module format (`foo.bar`). The `resource` argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```python
d = os.path.dirname(sys.modules[package].__file__)  
data = open(os.path.join(d, resource), 'rb').read
```

If the package cannot be located or loaded, or it uses a **PEP 302** loader which does not support `get_data()`, then `None` is
returned.
31.3. modulefinder — Find modules used by a script

Source code: Lib/modulefinder.py

This module provides a ModuleFinder class that can be used to determine the set of modules imported by a script. modulefinder.py can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

modulefinder.\texttt{AddPackagePath}(pkg\_name, path)

Record that the package named \texttt{pkg\_name} can be found in the specified \texttt{path}.

modulefinder.\texttt{ReplacePackage}(oldname, newname)

Allows specifying that the module named \texttt{oldname} is in fact the package named \texttt{newname}.

class modulefinder.\texttt{ModuleFinder}(path=None, debug=0, excludes=[], replace\_paths=[])

This class provides \texttt{run\_script()} and \texttt{report()} methods to determine the set of modules imported by a script. \texttt{path} can be a list of directories to search for modules; if not specified, \texttt{sys.path} is used. \texttt{debug} sets the debugging level; higher values make the class print debugging messages about what it's doing. \texttt{excludes} is a list of module names to exclude from the analysis. \texttt{replace\_paths} is a list of (oldpath, newpath) tuples that will be replaced in module paths.
report()
    Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

run_script(pathname)
    Analyze the contents of the pathname file, which must contain Python code.

modules
    A dictionary mapping module names to modules. See Example usage of ModuleFinder.
31.3.1. Example usage of ModuleFinder

The script that is going to get analyzed later on (bacon.py):

```python
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```python
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
    print(',', ''.join(list(mod.globalnames.keys()))[:3])

print('-'*50)
print('Modules not imported: ')
print('\n'.join(finder.badmodules.keys()))
```

Sample output (may vary depending on the architecture):
Loaded modules:
_types:
copyreg: _inverted_registry, _slotnames, __all__
sre_compile: isstring, _sre, _optimize_unicode
_sre:
sre_constants: REPEAT_ONE, makedict, AT_END_LINE
sys:
re: __module__, finditer, _expand
itertools:
__main__: re, itertools, baconhameggs
sre_parse: _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types: __module__, IntType, TypeType

---------------------------------------------------

Modules not imported:
guido.python.ham
baconhameggs
The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is not a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

```
runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)
```

Execute the code of the specified module and return the resulting module globals dictionary. The module’s code is first located using the standard import mechanism (refer to PEP 302 for details) and then executed in a fresh module namespace.

If the supplied module name refers to a package rather than a normal module, then that package is imported and the `__main__`
submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by `run_module()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to `run_name` if this optional argument is not `None`, to `mod_name + '.__main__'` if the named module is a package and to the `mod_name` argument otherwise.

`__spec__` will be set appropriately for the actually imported module (that is, `__spec__.name` will always be `mod_name` or `mod_name + '.__main__`, never `run_name`).

`__file__`, `__cached__`, `__loader__` and `__package__` are set as normal based on the module spec.

If the argument `alter_sys` is supplied and evaluates to `True`, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.
Note that this manipulation of `sys` is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the `sys` module be left alone when invoking this function from threaded code.

**See also:** The `-m` option offering equivalent functionality from the command line.

*Changed in version 3.1:* Added ability to execute packages by looking for a `__main__` submodule.

*Changed in version 3.2:* Added `__cached__` global variable (see PEP 3147).

*Changed in version 3.4:* Updated to take advantage of the module spec feature added by PEP 451. This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

```python
runpy.run_path(file_path, init_globals=None, run_name=None)
```

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid `sys.path` entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid `sys.path` entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection
against invoking an existing __main__ entry located elsewhere on sys.path if there is no such module at the specified location.

The optional dictionary argument init_globals may be used to pre-populate the module’s globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by run_path().

The special global variables __name__, __spec__, __file__, __cached__, __loader__ and __package__ are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

__name__ is set to run_name if this optional argument is not None and to '<run_path>' otherwise.

If the supplied path directly references a script file (whether as source or as precompiled byte code), then __file__ will be set to the supplied path, and __spec__, __cached__, __loader__ and __package__ will all be set to None.

If the supplied path is a reference to a valid sys.path entry, then __spec__ will be set appropriately for the imported __main__ module (that is, __spec__.name will always be __main__). __file__, __cached__, __loader__ and __package__ will be set as normal based on the module spec.

A number of alterations are also made to the sys module. Firstly, sys.path may be altered as described above. sys.argv[0] is updated with the value of file_path and
sys.modules[\_\_\_name\_\_\_] is updated with a temporary module object for the module being executed. All modifications to items in sys are reverted before the function returns.

Note that, unlike run_module(), the alterations made to sys are not optional in this function as these adjustments are essential to allowing the execution of sys.path entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

See also: Interface options for equivalent functionality on the command line (python path/to/script).

New in version 3.2.

Changed in version 3.4: Updated to take advantage of the module spec feature added by PEP 451. This allows \_\_cached\_\_ to be set correctly in the case where \_\_main\_\_ is imported from a valid sys.path entry rather than being executed directly.

The importlib.import_module() function
31.5. `importlib` – The implementation of `import`

*New in version 3.1.*
31.5.1. Introduction

The purpose of the importlib package is two-fold. One is to provide the implementation of the import statement (and thus, by extension, the __import__() function) in Python source code. This provides an implementation of import which is portable to any Python interpreter. This also provides an implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement import are exposed in this package, making it easier for users to create their own custom objects (known generically as an importer) to participate in the import process.

See also:

The import statement
The language reference for the import statement.

Packages specification
Original specification of packages. Some semantics have changed since the writing of this document (e.g. redirecting based on None in sys.modules).

The __import__() function
The import statement is syntactic sugar for this function.

31.5.2. Functions

importlib.__import__(name, globals=None, locals=None, fromlist=(), level=0)

An implementation of the built-in __import__() function.

**Note:** Programmatic importing of modules should use import_module() instead of this function.

importlib.import_module(name, package=None)

Import a module. The name argument specifies what module to import in absolute or relative terms (e.g. either pkg.mod or ..mod). If the name is specified in relative terms, then the package argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. import_module('..mod', 'pkg.subpkg') will import pkg.mod).

The import_module() function acts as a simplifying wrapper around importlib.__import__(). This means all semantics of the function are derived from importlib.__import__(). The most important difference between these two functions is that import_module() returns the specified package or module (e.g. pkg.mod), while __import__() returns the top-level package or module (e.g. pkg).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call invalidate_caches() in order for the new module to be noticed by the import system.
Changed in version 3.3: Parent packages are automatically imported.

importlib.find_loader(name, path=None)

Find the loader for a module, optionally within the specified path. If the module is in sys.modules, then sys.modules[name].__loader__ is returned (unless the loader would be None or is not set, in which case ValueError is raised). Otherwise a search using sys.meta_path is done. None is returned if no loader is found.

A dotted name does not have its parent's implicitly imported as that requires loading them and that may not be desired. To properly import a submodule you will need to import all parent packages of the submodule and use the correct argument to path.

New in version 3.3.

Changed in version 3.4: If __loader__ is not set, raise ValueError, just like when the attribute is set to None.

Deprecated since version 3.4: Use importlib.util.find_spec() instead.

importlib.invalidate_caches()

Invalidate the internal caches of finders stored at sys.meta_path. If a finder implements invalidate_caches() then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

New in version 3.3.
importlib.reload(module)

Reload a previously imported module. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in sys.modules).

When reload() is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the loader which originally loaded the module. The init function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects — with a try statement it can test for the table's presence
and skip its initialization if desired:

```python
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it — one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (`module.name`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

*New in version 3.4.*
31.5.3. `importlib.abc` – Abstract base classes related to import

The `importlib.abc` module contains all of the core abstract base classes used by `import`. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
    +-- Finder (deprecated)
    |    +-- MetaPathFinder
    |    +-- PathEntryFinder
    +-- Loader
        +-- ResourceLoader ---------+
        +-- InspectLoader         |
        |    +-- ExecutionLoader   --+
        |                       +-- FileLoader
        |                       +-- SourceLoader
```

**class importlib.abc.Finder**

An abstract base class representing a `finder`.

*Deprecated since version 3.3:* Use `MetaPathFinder` or `PathEntryFinder` instead.

**find_module**(fullname, path=None)

An abstract method for finding a `loader` for the specified module. Originally specified in PEP 302, this method was meant for use in `sys.meta_path` and in the path-based import subsystem.

*Changed in version 3.4:* Returns None when called instead of
class importlib.abc.MetaPathFinder

An abstract base class representing a meta path finder. For compatibility, this is a subclass of Finder.

New in version 3.3.

find_spec(fullname, path, target=None)

An abstract method for finding a spec for the specified module. If this is a top-level import, path will be None. Otherwise, this is a search for a subpackage or module and path will be the value of __path__ from the parent package. If a spec cannot be found, None is returned. When passed in, target is a module object that the finder may use to make a more educated about what spec to return.

New in version 3.4.

find_module(fullname, path)

A legacy method for finding a loader for the specified module. If this is a top-level import, path will be None. Otherwise, this is a search for a subpackage or module and path will be the value of __path__ from the parent package. If a loader cannot be found, None is returned.

If find_spec() is defined, backwards-compatible functionality is provided.

Changed in version 3.4: Returns None when called instead of raising NotImplementedException. Can use find_spec() to provide functionality.
Deprecated since version 3.4: Use `find_spec()` instead.

**invalidate_caches()**

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `importlib.invalidate_caches()` when invalidating the caches of all finders on `sys.meta_path`.

*Changed in version 3.4:* Returns `None` when called instead of `NotImplemented`.

**class importlib.abc.PathEntryFinder**

An abstract base class representing a path entry finder. Though it bears some similarities to `MetaPathFinder`, `PathEntryFinder` is meant for use only within the path-based import subsystem provided by `PathFinder`. This ABC is a subclass of `Finder` for compatibility reasons only.

*New in version 3.3.*

**find_spec(fullname, target=None)**

An abstract method for finding a spec for the specified module. The finder will search for the module only within the path entry to which it is assigned. If a spec cannot be found, `None` is returned. When passed in, `target` is a module object that the finder may use to make a more educated about what spec to return.

*New in version 3.4.*

**find_loader(fullname)**

A legacy method for finding a loader for the specified module.
Returns a 2-tuple of (loader, portion) where portion is a sequence of file system locations contributing to part of a namespace package. The loader may be None while specifying portion to signify the contribution of the file system locations to a namespace package. An empty list can be used for portion to signify the loader is not part of a namespace package. If loader is None and portion is the empty list then no loader or location for a namespace package were found (i.e. failure to find anything for the module).

If find_spec() is defined then backwards-compatible functionality is provided.

*Changed in version 3.4:* Returns (None, []) instead of raising NotImplementedError. Uses find_spec() when available to provide functionality.

*Deprecated since version 3.4:* Use find_spec() instead.

**find_module** *(fullname)*

A concrete implementation of Finder.find_module() which is equivalent to self.find_loader(fullname)[0].

*Deprecated since version 3.4:* Use find_spec() instead.

**invalidate_caches** *

An optional method which, when called, should invalidate any internal cache used by the finder. Used by PathFinder.invalidate_caches() when invalidating the caches of all cached finders.

```python
class importlib.abc.Loader
```
An abstract base class for a loader. See PEP 302 for the exact definition for a loader.

**create_module**(spec)
A method that returns the module object to use when importing a module. This method may return None, indicating that default module creation semantics should take place.

*New in version 3.4.*

*Changed in version 3.5:* Starting in Python 3.6, this method will not be optional when **exec_module()** is defined.

**exec_module**(module)
An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when **exec_module()** is called.

*New in version 3.4.*

**load_module**(fullname)
A legacy method for loading a module. If the module cannot be loaded, **ImportError** is raised, otherwise the loaded module is returned.

If the requested module already exists in **sys.modules**, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into **sys.modules** before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from **sys.modules**; modules already in **sys.modules** before the loader began execution should be left
alone (see `importlib.util.module_for_loader()`).

The loader should set several attributes on the module. (Note that some of these attributes can change when a module is reloaded):

- **__name__**
  The name of the module.

- **__file__**
  The path to where the module data is stored (not set for built-in modules).

- **__cached__**
  The path to where a compiled version of the module is/should be stored (not set when the attribute would be inappropriate).

- **__path__**
  A list of strings specifying the search path within a package. This attribute is not set on modules.

- **__package__**
  The parent package for the module/package. If the module is top-level then it has a value of the empty string. The `importlib.util.module_for_loader()` decorator can handle the details for **__package__**.

- **__loader__**
  The loader used to load the module. The `importlib.util.module_for_loader()` decorator can handle the details for **__package__**.
When `exec_module()` is available then backwards-compatible functionality is provided.

*Changed in version 3.4:* Raise `ImportError` when called instead of `NotImplementedError`. Functionality provided when `exec_module()` is available.

*Deprecated since version 3.4:* The recommended API for loading a module is `exec_module()` (and `create_module()`). Loaders should implement it instead of `load_module()`. The import machinery takes care of all the other responsibilities of `load_module()` when `exec_module()` is implemented.

```
module_repr(module)
```

A legacy method which when implemented calculates and returns the given module’s repr, as a string. The module type’s default repr() will use the result of this method as appropriate.

*New in version 3.3.*

*Changed in version 3.4:* Made optional instead of an abstractmethod.

*Deprecated since version 3.4:* The import machinery now takes care of this automatically.

```
class importlib.abc.ResourceLoader
```

An abstract base class for a `loader` which implements the optional PEP 302 protocol for loading arbitrary resources from the storage back-end.

```
get_data(path)
```
An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. *OSError* is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's __file__ attribute or an item from a package's __path__.

*Changed in version 3.4:* Raises *OSError* instead of *NotImplementedError*.

class importlib.abc.InspectLoader

An abstract base class for a loader which implements the optional PEP 302 protocol for loaders that inspect modules.

**get_code**(fullname)

Return the code object for a module, or None if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an *ImportError* if loader cannot find the requested module.

**Note:** While the method has a default implementation, it is suggested that it be overridden if possible for performance.

*Changed in version 3.4:* No longer abstract and a concrete implementation is provided.

**get_source**(fullname)

An abstract method to return the source of a module. It is returned as a text string using universal newlines, translating all recognized line separators into '*
' characters. Returns None if no source is available (e.g. a built-in module). Raises
**ImportError** if the loader cannot find the module specified.

*Changed in version 3.4:* Raises **ImportError** instead of **NotImplementedError**.

**is_package(fullname)**

An abstract method to return a true value if the module is a package, a false value otherwise. **ImportError** is raised if the **loader** cannot find the module.

*Changed in version 3.4:* Raises **ImportError** instead of **NotImplementedError**.

**static source_to_code(data, path='<string>')**

Create a code object from Python source.

The *data* argument can be whatever the `compile()` function supports (i.e. string or bytes). The *path* argument should be the “path” to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

*New in version 3.4.*

*Changed in version 3.5:* Made the method static.

**exec_module(module)**

Implementation of **Loader.exec_module()**.

*New in version 3.4.*

**load_module(fullname)**
Implementation of `Loader.load_module()`.

*Deprecated since version 3.4:* use `exec_module()` instead.

**class importlib.abc.ExecutionLoader**

An abstract base class which inherits from `InspectLoader` that, when implemented, helps a module to be executed as a script. The ABC represents an optional PEP 302 protocol.

**get_filename(fullname)**

An abstract method that is to return the value of `__file__` for the specified module. If no path is available, `ImportError` is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

*Changed in version 3.4:* Raises `ImportError` instead of `NotImplementedError`.

**class importlib.abc.FileLoader(fullname, path)**

An abstract base class which inherits from `ResourceLoader` and `ExecutionLoader`, providing concrete implementations of `ResourceLoader.get_data()` and `ExecutionLoader.get_filename()`.

The `fullname` argument is a fully resolved name of the module the loader is to handle. The `path` argument is the path to the file for the module.

*New in version 3.3.*
name
The name of the module the loader can handle.

path
Path to the file of the module.

load_module(fullname)
Calls super’s load_module().

Deprecated since version 3.4: Use Loader.exec_module() instead.

get_filename(fullname)
Returns path.

get_data(path)
Reads path as a binary file and returns the bytes from it.

class importlib.abc.SourceLoader
An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both ResourceLoader and ExecutionLoader, requiring the implementation of:

- ResourceLoader.get_data()
- ExecutionLoader.get_filename()
  Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise NotImplementedError) causes the loader
to only work with source code. Implementing the methods allows the loader to work with source and bytecode files; it does not allow for sourceless loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python’s compiler, and so no bytecode-specific API is exposed.

**path_stats(path)**

Optional abstract method which returns a `dict` containing metadata about the specified path. Supported dictionary keys are:

- `'mtime'` (mandatory): an integer or floating-point number representing the modification time of the source code;
- `'size'` (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, `OSError` is raised.

*New in version 3.3.*

*Changed in version 3.4:* Raise `OSError` instead of `NotImplementedError`.

**path_mtime(path)**

Optional abstract method which returns the modification time for the specified path.

*Deprecated since version 3.3:* This method is deprecated in favour of `path_stats()`. You don’t have to implement it, but it is still available for compatibility purposes. Raise `OSError` if the path cannot be handled.

*Changed in version 3.4:* Raise `OSError` instead of
set_data(path, data)
Optional abstract method which writes the specified bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (errno.EACCES/PermissionError), do not propagate the exception.

Changed in version 3.4: No longer raises NotImplementedError when called.

get_code(fullname)
Concrete implementation of InspectLoader.get_code().

exec_module(module)
Concrete implementation of Loader.exec_module().

New in version 3.4.

load_module(fullname)
Concrete implementation of Loader.load_module().

Deprecated since version 3.4: Use exec_module() instead.

get_source(fullname)
Concrete implementation of InspectLoader.get_source().

is_package(fullname)
Concrete implementation of
InspectLoader.is_package(). A module is determined to be a package if its file path (as provided by ExecutionLoader.get_filename()) is a file named __init__ when the file extension is removed and the module name itself does not end in __init__. 
31.5.4. **importlib.machinery** – Importers and path hooks

This module contains the various objects that help `import` find and load modules.

**importlib.machinery.SOURCE_SUFFIXES**
A list of strings representing the recognized file suffixes for source modules.

*New in version 3.3.*

**importlib.machinery.DEBUG_BYTECODE_SUFFIXES**
A list of strings representing the file suffixes for non-optimized bytecode modules.

*New in version 3.3.*

*Deprecated since version 3.5:* Use `BYTECODE_SUFFIXES` instead.

**importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES**
A list of strings representing the file suffixes for optimized bytecode modules.

*New in version 3.3.*

*Deprecated since version 3.5:* Use `BYTECODE_SUFFIXES` instead.

**importlib.machinery.BYTECODE_SUFFIXES**
A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

*New in version 3.3.*
Changed in version 3.5: The value is no longer dependent on \_\_debug\_.

importlib.machinery.\texttt{EXTENSION\_SUFFIXES}
A list of strings representing the recognized file suffixes for extension modules.

New in version 3.3.

importlib.machinery.\texttt{all\_suffixes()}
Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, \texttt{inspect.getmodulename()}).

New in version 3.3.

class importlib.machinery.\texttt{BuiltinImporter}
An importer for built-in modules. All known built-in modules are listed in \texttt{sys.builtin\_module\_names}. This class implements the \texttt{importlib.abc.MetaPathFinder} and \texttt{importlib.abc.InspectLoader} ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

Changed in version 3.5: As part of PEP 489, the builtin importer now implements \texttt{Loader.create\_module()} and \texttt{Loader.exec\_module()}

class importlib.machinery.\texttt{FrozenImporter}
An importer for frozen modules. This class implements the
importlib.abc.MetaPathFinder and importlib.abc.InspectLoader ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

class importlib.machinery.WindowsRegistryFinder
Finder for modules declared in the Windows registry. This class implements the importlib.abc.Finder ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

New in version 3.3.

class importlib.machinery.PathFinder
A Finder for sys.path and package __path__ attributes. This class implements the importlib.abc.MetaPathFinder ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

classmethod find_spec(fullname, path=None, target=None)
Class method that attempts to find a spec for the module specified by fullname on sys.path or, if defined, on path. For each path entry that is searched, sys.path_importer_cache is checked. If a non-false object is found then it is used as the path entry finder to look for the module being searched for. If no entry is found in sys.path_importer_cache, then sys.path_hooks is searched for a finder for the path entry and, if found, is stored in sys.path_importer_cache along with being queried about the module. If no finder is ever found then None is both stored
in the cache and returned.

*New in version 3.4.*

*Changed in version 3.5:* If the current working directory – represented by an empty string – is no longer valid then `None` is returned but no value is cached in `sys.path_importer_cache`.

*classmethod* `find_module(fullname, path=None)`

A legacy wrapper around `find_spec()`.

*Deprecated since version 3.4:* Use `find_spec()` instead.

*classmethod* `invalidate_caches()`

Calls

`importlib.abc.PathEntryFinder.invalidate_caches()` on all finders stored in `sys.path_importer_cache`.

*Changed in version 3.4:* Calls objects in `sys.path_hooks` with the current working directory for '' (i.e. the empty string).

`class importlib.machinery.FileFinder(path, *loader_details)`

A concrete implementation of `importlib.abc.PathEntryFinder` which caches results from the file system.

The `path` argument is the directory for which the finder is in charge of searching.

The `loader_details` argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader
recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call `importlib.invalidate_caches()`.

*New in version 3.3.*

**path**

The path the finder will search in.

**find_spec**(fullname, target=None)

Attempt to find the spec to handle `fullname` within `path`.

*New in version 3.4.*

**find_loader**(fullname)

Attempt to find the loader to handle `fullname` within `path`.

**invalidate_caches()**

Clear out the internal cache.

*classmethod path_hook*(*loader_details*)

A class method which returns a closure for use on `sys.path_hooks`. An instance of `FileFinder` is returned by
the closure using the path argument given to the closure directly and \textit{loader_details} indirectly.

If the argument to the closure is not an existing directory, \texttt{ImportError} is raised.

\begin{verbatim}
class importlib.machinery.SourceFileLoader(fullname, path)
    A concrete implementation of \texttt{importlib.abc.SourceLoader} by subclassing \texttt{importlib.abc.FileLoader} and providing some concrete implementations of other methods.

    \textit{New in version 3.3.}

    \texttt{name}
    The name of the module that this loader will handle.

    \texttt{path}
    The path to the source file.

    \texttt{is_package(fullname)}
    Return true if \texttt{path} appears to be for a package.

    \texttt{path_stats(path)}
    Concrete implementation of \texttt{importlib.abc.SourceLoader.path_stats()}.  

    \texttt{set_data(path, data)}
    Concrete implementation of \texttt{importlib.abc.SourceLoader.set_data()}.  

    \texttt{load_module(name=None)}
    Concrete implementation of
importlib.abc.Loader.load_module() where specifying the name of the module to load is optional.

class importlib.machinery.SourcelessFileLoader(fullname, path)
    A concrete implementation of importlib.abc.FileLoader which can import bytecode files (i.e. no source code files exist).

    Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

    New in version 3.3.

name
    The name of the module the loader will handle.

path
    The path to the bytecode file.

is_package(fullname)
    Determines if the module is a package based on path.

get_code(fullname)
    Returns the code object for name created from path.

get_source(fullname)
    Returns None as bytecode files have no source when this loader is used.

load_module(name=None)
Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

```python
class importlib.machinery.ExtensionFileLoader(fullname, path)
    A concrete implementation of `importlib.abc.ExecutionLoader` for extension modules.
```

The `fullname` argument specifies the name of the module the loader is to support. The `path` argument is the path to the extension module's file.

*New in version 3.3.*

**name**

Name of the module the loader supports.

**path**

Path to the extension module.

**create_module**(spec)

Creates the module object from the given specification in accordance with [PEP 489](https://www.python.org/dev/peps/pep-0489/).

*New in version 3.5.*

**exec_module**(module)

Initializes the given module object in accordance with [PEP 489](https://www.python.org/dev/peps/pep-0489/).

*New in version 3.5.*

**is_package**(fullname)
Returns True if the file path points to a package's __init__ module based on EXTENSION_SUFFIXES.

get_code(fullname)
Returns None as extension modules lack a code object.

get_source(fullname)
Returns None as extension modules do not have source code.

get_filename(fullname)
Returns path.

New in version 3.4.

class importlib.machinery.ModuleSpec(name, loader, *,
origin=None, loader_state=None, is_package=None)
A specification for a module's import-system-related state.

New in version 3.4.

name
(__name__)
A string for the fully-qualified name of the module.

loader
(__loader__)
The loader to use for loading. For namespace packages this should be set to None.

origin
(\_\_file\_\_)

Name of the place from which the module is loaded, e.g. “builtin” for built-in modules and the filename for modules loaded from source. Normally “origin” should be set, but it may be None (the default) which indicates it is unspecified.

**submodule_search_locations**

(\_\_path\_\_)

List of strings for where to find submodules, if a package (None otherwise).

**loader_state**

Container of extra module-specific data for use during loading (or None).

**cached**

(\_\_cached\_\_)

String for where the compiled module should be stored (or None).

**parent**

(\_\_package\_\_)

(Read-only) Fully-qualified name of the package to which the module belongs as a submodule (or None).

**has_location**

Boolean indicating whether or not the module’s “origin” attribute refers to a loadable location.
31.5.5. **importlib.util** – Utility code for importers

This module contains the various objects that help in the construction of an importer.

**importlib.util.MAGIC_NUMBER**

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider `importlib.abc.SourceLoader`.

*New in version 3.4.*

**importlib.util.cache_from_source**(path, debug_override=None, *, optimization=None)

Return the PEP 3147/PEP 488 path to the byte-compiled file associated with the source path. For example, if path is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The cpython-32 string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `' '` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. None causes the interpreter's optimization level to be used. Any other value's string representation being used, so `/foo/bar/baz.py` with an *optimization* of 2 will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-`
The string representation of `optimization` can only be alphanumeric, else `ValueError` is raised.

The `debug_override` parameter is deprecated and can be used to override the system's value for `__debug__`. A True value is the equivalent of setting `optimization` to the empty string. A False value is the same as setting `optimization` to 1. If both `debug_override` an `optimization` are not None then `TypeError` is raised.

*New in version 3.4.*

`importlib.util.source_from_cache(path)`

Given the `path` to a [PEP 3147](https://www.python.org/dev/peps/pep-03147/) file name, return the associated source code file path. For example, if `path` is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. `path` need not exist, however if it does not conform to [PEP 3147](https://www.python.org/dev/peps/pep-03147/) or [PEP 488](https://www.python.org/dev/peps/pep-0488/) format, a `ValueError` is raised. If `sys.implementation.cache_tag` is not defined, `NotImplementedError` is raised.

*New in version 3.4.*

`importlib.util.decode_source(source_bytes)`

Decode the given bytes representing source code and return it as a string with universal newlines (as required by `importlib.abc.InspectLoader.get_source()`).

*New in version 3.4.*

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.
If `name` has no leading dots, then `name` is simply returned. This allows for usage such as `importlib.util.resolve_name('sys', __package__)` without doing a check to see if the `package` argument is needed.

`ValueError` is raised if `name` is a relative module name but `package` is a false value (e.g. None or the empty string). `ValueError` is also raised a relative name would escape its containing package (e.g. requesting ..bacon from within the spam package).

*New in version 3.3.*

`importlib.util.find_spec(name, package=None)`

Find the `spec` for a module, optionally relative to the specified `package` name. If the module is in `sys.modules`, then `sys.modules[name].__spec__` is returned (unless the spec would be None or is not set, in which case `ValueError` is raised). Otherwise a search using `sys.meta_path` is done. None is returned if no spec is found.

If `name` is for a submodule (contains a dot), the parent module is automatically imported.

`name` and `package` work the same as for `import_module()`.

*New in version 3.4.*

`importlib.util.module_from_spec(spec)`

Create a new module based on `spec` and `spec.loader.create_module()`.

If `spec.loader.create_module()` does not return None, then
any pre-existing attributes will not be reset. Also, no AttributeError will be raised if triggered while accessing spec or setting an attribute on the module.

This function is preferred over using types.ModuleType to create a new module as spec is used to set as many import-controlled attributes on the module as possible.

New in version 3.5.

@importlib.util.module_for_loader
A decorator for importlib.abc.Loader.load_module() to handle selecting the proper module object to load with. The decorated method is expected to have a call signature taking two positional arguments (e.g. load_module(self, module)) for which the second argument will be the module object to be used by the loader. Note that the decorator will not work on static methods because of the assumption of two arguments.

The decorated method will take in the name of the module to be loaded as expected for a loader. If the module is not found in sys.modules then a new one is constructed. Regardless of where the module came from, __loader__ set to self and __package__ is set based on what importlib.abc.InspectLoader.is_package() returns (if available). These attributes are set unconditionally to support reloading.

If an exception is raised by the decorated method and a module was added to sys.modules, then the module will be removed to prevent a partially initialized module from being in left in sys.modules. If the module was already in sys.modules then it
is left alone.

*Changed in version 3.3:* __loader__ and __package__ are automatically set (when possible).

*Changed in version 3.4:* Set __name__, __loader__, __package__ unconditionally to support reloading.

*Deprecated since version 3.4:* The import machinery now directly performs all the functionality provided by this function.

@importlib.util.set_loader
A decorator for importlib.abc.Loader.load_module() to set the __loader__ attribute on the returned module. If the attribute is already set the decorator does nothing. It is assumed that the first positional argument to the wrapped method (i.e. self) is what __loader__ should be set to.

*Changed in version 3.4:* Set __loader__ if set to None, as if the attribute does not exist.

*Deprecated since version 3.4:* The import machinery takes care of this automatically.

@importlib.util.set_package
A decorator for importlib.abc.Loader.load_module() to set the __package__ attribute on the returned module. If __package__ is set and has a value other than None it will not be changed.

*Deprecated since version 3.4:* The import machinery takes care of this automatically.
importlib.util.spec_from_loader(name, loader, *, origin=None, is_package=None)

A factory function for creating a ModuleSpec instance based on a loader. The parameters have the same meaning as they do for ModuleSpec. The function uses available loader APIs, such as InspectLoader.is_package(), to fill in any missing information on the spec.

*New in version 3.4.*

importlib.util.spec_from_file_location(name, location, *, loader=None, submodule_search_locations=None)

A factory function for creating a ModuleSpec instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

*New in version 3.4.*

class importlib.util.LazyLoader(loader)

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define exec_module() as control over what module type is used for the module is required. For those same reasons, the loader’s create_module() method will be ignored (i.e., the loader’s method should only return None). Finally, modules which substitute the object placed into sys.modules will not work as there is no way to properly replace the module references throughout the interpreter safely; **ValueError** is raised if such a substitution is detected.
**Note:** For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is heavily discouraged due to error messages created during loading being postponed and thus occurring out of context.

*New in version 3.5.*

**classmethod `factory(loader)`**

A static method which returns a callable that creates a lazy loader. This is meant to be used in situations where the loader is passed by class instead of by instance.

```python
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory
finder = importlib.machinery.FileFinder(path, [...])
```
32. Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **32.1. parser — Access Python parse trees**
  - 32.1.1. Creating ST Objects
  - 32.1.2. Converting ST Objects
  - 32.1.3. Queries on ST Objects
  - 32.1.4. Exceptions and Error Handling
  - 32.1.5. ST Objects
  - 32.1.6. Example: Emulation of compile()

- **32.2. ast — Abstract Syntax Trees**
  - 32.2.1. Node classes
  - 32.2.2. Abstract Grammar
  - 32.2.3. ast Helpers

- **32.3. symtable — Access to the compiler’s symbol tables**
  - 32.3.1. Generating Symbol Tables
  - 32.3.2. Examining Symbol Tables

- **32.4. symbol — Constants used with Python parse trees**
- **32.5. token — Constants used with Python parse trees**
- **32.6. keyword — Testing for Python keywords**
- **32.7. tokenize — Tokenizer for Python source**
  - 32.7.1. Tokenizing Input
  - 32.7.2. Command-Line Usage
  - 32.7.3. Examples

- **32.8. tabnanny — Detection of ambiguous indentation**

- **32.9. pyclbr — Python class browser support**
  - 32.9.1. Class Objects
- 32.9.2. Function Objects
- 32.10. `py_compile` — Compile Python source files
- 32.11. `compileall` — Byte-compile Python libraries
  - 32.11.1. Command-line use
  - 32.11.2. Public functions
- 32.12. `dis` — Disassembler for Python bytecode
  - 32.12.1. Bytecode analysis
  - 32.12.2. Analysis functions
  - 32.12.3. Python Bytecode Instructions
  - 32.12.4. Opcode collections
- 32.13. `pickletools` — Tools for pickle developers
  - 32.13.1. Command line usage
    - 32.13.1.1. Command line options
  - 32.13.2. Programmatic Interface
32.1. **parser** — Access Python parse trees

The **parser** module provides an interface to Python’s internal parser and byte-code compiler. The primary purpose for this interface is to allow Python code to edit the parse tree of a Python expression and create executable code from this. This is better than trying to parse and modify an arbitrary Python code fragment as a string because parsing is performed in a manner identical to the code forming the application. It is also faster.

**Note:** From Python 2.5 onward, it’s much more convenient to cut in at the Abstract Syntax Tree (AST) generation and compilation stage, using the **ast** module.

There are a few things to note about this module which are important to making use of the data structures created. This is not a tutorial on editing the parse trees for Python code, but some examples of using the **parser** module are presented.

Most importantly, a good understanding of the Python grammar processed by the internal parser is required. For full information on the language syntax, refer to *The Python Language Reference*. The parser itself is created from a grammar specification defined in the file Grammar/Grammar in the standard Python distribution. The parse trees stored in the ST objects created by this module are the actual output from the internal parser when created by the **expr()** or **suite()** functions, described below. The ST objects created by **sequence2st()** faithfully simulate those structures. Be aware that
the values of the sequences which are considered “correct” will vary from one version of Python to another as the formal grammar for the language is revised. However, transporting code from one Python version to another as source text will always allow correct parse trees to be created in the target version, with the only restriction being that migrating to an older version of the interpreter will not support more recent language constructs. The parse trees are not typically compatible from one version to another, whereas source code has always been forward-compatible.

Each element of the sequences returned by `st2list()` or `st2tuple()` has a simple form. Sequences representing non-terminal elements in the grammar always have a length greater than one. The first element is an integer which identifies a production in the grammar. These integers are given symbolic names in the C header file `Include/graminit.h` and the Python module `symbol`. Each additional element of the sequence represents a component of the production as recognized in the input string: these are always sequences which have the same form as the parent. An important aspect of this structure which should be noted is that keywords used to identify the parent node type, such as the keyword `if` in an `if_stmt`, are included in the node tree without any special treatment. For example, the `if` keyword is represented by the tuple `(1, 'if')`, where 1 is the numeric value associated with all NAME tokens, including variable and function names defined by the user. In an alternate form returned when line number information is requested, the same token might be represented as `(1, 'if', 12)`, where the 12 represents the line number at which the terminal symbol was found.

Terminal elements are represented in much the same way, but without any child elements and the addition of the source text which was identified. The example of the `if` keyword above is representative.
The various types of terminal symbols are defined in the C header file `Include/token.h` and the Python module `token`.

The ST objects are not required to support the functionality of this module, but are provided for three purposes: to allow an application to amortize the cost of processing complex parse trees, to provide a parse tree representation which conserves memory space when compared to the Python list or tuple representation, and to ease the creation of additional modules in C which manipulate parse trees. A simple “wrapper” class may be created in Python to hide the use of ST objects.

The `parser` module defines functions for a few distinct purposes. The most important purposes are to create ST objects and to convert ST objects to other representations such as parse trees and compiled code objects, but there are also functions which serve to query the type of parse tree represented by an ST object.

**See also:**

**Module symbol**

Useful constants representing internal nodes of the parse tree.

**Module token**

Useful constants representing leaf nodes of the parse tree and functions for testing node values.
32.1.1. Creating ST Objects

ST objects may be created from source code or from a parse tree. When creating an ST object from source, different functions are used to create the 'eval' and 'exec' forms.

parser.expr(source)

The expr() function parses the parameter source as if it were an input to compile(source, 'file.py', 'eval'). If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

parser.suite(source)

The suite() function parses the parameter source as if it were an input to compile(source, 'file.py', 'exec'). If the parse succeeds, an ST object is created to hold the internal parse tree representation, otherwise an appropriate exception is raised.

parser.sequence2st(sequence)

This function accepts a parse tree represented as a sequence and builds an internal representation if possible. If it can validate that the tree conforms to the Python grammar and all nodes are valid node types in the host version of Python, an ST object is created from the internal representation and returned to the called. If there is a problem creating the internal representation, or if the tree cannot be validated, a ParserError exception is raised. An ST object created this way should not be assumed to compile correctly; normal exceptions raised by compilation may still be initiated when the ST object is passed to compilest(). This may indicate problems not related to syntax (such as a MemoryError exception), but may also be due to constructs such as the result of
parsing del f(0), which escapes the Python parser but is checked by the bytecode compiler.

Sequences representing terminal tokens may be represented as either two-element lists of the form \((1, \ 'name'\)\) or as three-element lists of the form \((1, \ 'name', \ 56)\). If the third element is present, it is assumed to be a valid line number. The line number may be specified for any subset of the terminal symbols in the input tree.

```python
tuple2st(sequence)
```
This is the same function as `sequence2st()` . This entry point is maintained for backward compatibility.
32.1.2. Converting ST Objects

ST objects, regardless of the input used to create them, may be converted to parse trees represented as list- or tuple- trees, or may be compiled into executable code objects. Parse trees may be extracted with or without line numbering information.

\texttt{parser.st2list(st, line\_info=False, col\_info=False)}

This function accepts an ST object from the caller in \texttt{st} and returns a Python list representing the equivalent parse tree. The resulting list representation can be used for inspection or the creation of a new parse tree in list form. This function does not fail so long as memory is available to build the list representation. If the parse tree will only be used for inspection, \texttt{st2tuple()} should be used instead to reduce memory consumption and fragmentation. When the list representation is required, this function is significantly faster than retrieving a tuple representation and converting that to nested lists.

If \texttt{line\_info} is true, line number information will be included for all terminal tokens as a third element of the list representing the token. Note that the line number provided specifies the line on which the token \textit{ends}. This information is omitted if the flag is false or omitted.

\texttt{parser.st2tuple(st, line\_info=False, col\_info=False)}

This function accepts an ST object from the caller in \texttt{st} and returns a Python tuple representing the equivalent parse tree. Other than returning a tuple instead of a list, this function is identical to \texttt{st2list()}.

If \texttt{line\_info} is true, line number information will be included for all
terminal tokens as a third element of the list representing the token. This information is omitted if the flag is false or omitted.

```
parser.compilest(st, filename='<syntax-tree>')
```

The Python byte compiler can be invoked on an ST object to produce code objects which can be used as part of a call to the built-in `exec()` or `eval()` functions. This function provides the interface to the compiler, passing the internal parse tree from `st` to the parser, using the source file name specified by the `filename` parameter. The default value supplied for `filename` indicates that the source was an ST object.

Compiling an ST object may result in exceptions related to compilation; an example would be a `SyntaxError` caused by the parse tree for `del f(0)`: this statement is considered legal within the formal grammar for Python but is not a legal language construct. The `SyntaxError` raised for this condition is actually generated by the Python byte-compiler normally, which is why it can be raised at this point by the `parser` module. Most causes of compilation failure can be diagnosed programmatically by inspection of the parse tree.
32.1.3. Queries on ST Objects

Two functions are provided which allow an application to determine if an ST was created as an expression or a suite. Neither of these functions can be used to determine if an ST was created from source code via `expr()` or `suite()` or from a parse tree via `sequence2st()`.

`parser.isexpr(st)`
When `st` represents an 'eval' form, this function returns true, otherwise it returns false. This is useful, since code objects normally cannot be queried for this information using existing built-in functions. Note that the code objects created by `compilest()` cannot be queried like this either, and are identical to those created by the built-in `compile()` function.

`parser.issuite(st)`
This function mirrors `isexpr()` in that it reports whether an ST object represents an 'exec' form, commonly known as a “suite.” It is not safe to assume that this function is equivalent to not `isexpr(st)`, as additional syntactic fragments may be supported in the future.
32.1.4. Exceptions and Error Handling

The parser module defines a single exception, but may also pass other built-in exceptions from other portions of the Python runtime environment. See each function for information about the exceptions it can raise.

*exception* parser.*ParserError*

Exception raised when a failure occurs within the parser module. This is generally produced for validation failures rather than the built-in *SyntaxError* raised during normal parsing. The exception argument is either a string describing the reason of the failure or a tuple containing a sequence causing the failure from a parse tree passed to *sequence2st()* and an explanatory string. Calls to *sequence2st()* need to be able to handle either type of exception, while calls to other functions in the module will only need to be aware of the simple string values.

Note that the functions *compilest(), expr(),* and *suite()* may raise exceptions which are normally raised by the parsing and compilation process. These include the built in exceptions *MemoryError, OverflowError, SyntaxError,* and *SystemError.* In these cases, these exceptions carry all the meaning normally associated with them. Refer to the descriptions of each function for detailed information.
32.1.5. ST Objects

Ordered and equality comparisons are supported between ST objects. Pickling of ST objects (using the pickle module) is also supported.

parser.**STType**

The type of the objects returned by `expr()`, `suite()` and `sequence2st()`.

ST objects have the following methods:

**ST.compile**(filename='<syntax-tree>')</n>

Same as `compilest(st, filename)`.

**ST.isexpr()**

Same as `isexpr(st)`.

**ST.issuite()**

Same as `issuite(st)`.

**ST.tolist**(line_info=False, col_info=False)

Same as `st2list(st, line_info, col_info)`.

**ST.totuple**(line_info=False, col_info=False)

Same as `st2tuple(st, line_info, col_info)`.
32.1.6. Example: Emulation of `compile()`

While many useful operations may take place between parsing and bytecode generation, the simplest operation is to do nothing. For this purpose, using the `parser` module to produce an intermediate data structure is equivalent to the code

```python
>>> code = compile('a + 5', 'file.py', 'eval')
>>> a = 5
>>> eval(code)
10
```

The equivalent operation using the `parser` module is somewhat longer, and allows the intermediate internal parse tree to be retained as an ST object:

```python
>>> import parser
>>> st = parser.expr('a + 5')
>>> code = st.compile('file.py')
>>> a = 5
>>> eval(code)
10
```

An application which needs both ST and code objects can package this code into readily available functions:

```python
import parser

def load_suite(source_string):
    st = parser.suite(source_string)
    return st, st.compile()
```
```python
def load_expression(source_string):
    st = parser.expr(source_string)
    return st, st.compile()
```
32.2. ast — Abstract Syntax Trees

Source code: Lib/ast.py

The ast module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programmatically what the current grammar looks like.

An abstract syntax tree can be generated by passing ast.PyCF_ONLY_AST as a flag to the compile() built-in function, or using the parse() helper provided in this module. The result will be a tree of objects whose classes all inherit from ast.AST. An abstract syntax tree can be compiled into a Python code object using the built-in compile() function.
32.2.1. Node classes

class ast.AST

This is the base of all AST node classes. The actual node classes are derived from the Parser/Python.asdl file, which is reproduced below. They are defined in the _ast C module and re-exported in ast.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, ast.stmt or ast.expr). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, ast.BinOp inherits from ast.expr. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

_fields

Each concrete class has an attribute _fields which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, ast.BinOp instances have an attribute left of type ast.expr.

If these attributes are marked as optional in the grammar (using a question mark), the value might be None. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with
compile().

**lineno**

**col_offset**

Instances of `ast.expr` and `ast.stmt` subclasses have `lineno` and `col_offset` attributes. The `lineno` is the line number of source text (1-indexed so the first line is line 1) and the `col_offset` is the UTF-8 byte offset of the first token that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

The constructor of a class `ast.T` parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in `T._fields`; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an `ast.UnaryOp` node, you could use

```python
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Num()
node.operand.n = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

or the more compact

```python
node = ast.UnaryOp(ast.USub(), ast.Num(5, lineno=0, col_offset=0))
```
32.2.2. Abstract Grammar

The abstract grammar is currently defined as follows:

```python
module Python {
    mod = Module(stmt* body)
    | Interactive(stmt* body)
    | Expression(expr body)

    -- not really an actual node but useful in Jython's typesystem.
    | Suite(stmt* body)

    stmt = FunctionDef(identifier name, arguments arg, stmt* body, expr* decorator_list)
    | AsyncFunctionDef(identifier name, arguments arg, stmt* body, expr* decorator_list)
    | ClassDef(identifier name, expr* bases, keyword* keywords, stmt* body, expr* decorator_list)
    | Return(expr? value)
    | Delete(expr* targets)
    | Assign(expr* targets, expr value)
    | AugAssign(expr target, operator op, expr value)

    -- use 'orelse' because else is a keyword
    | For(expr target, expr iter, stmt* body, stmt* orelse)
    | AsyncFor(expr target, expr iter, stmt* body, stmt* orelse)
    | While(expr test, stmt* body, stmt* orelse)
}
```
If(expr test, stmt* body, stmt* orelse)
With(withitem* items, stmt* body)
AsyncWith(withitem* items, stmt* body)
Raise(expr? exc, expr? cause)
Try(stmt* body, excepthandler* handlers, stmt* orelse, stmt* finalbody)
Assert(expr test, expr? msg)
Import(alias* names)
ImportFrom(identifier? module, alias* names)
Global(identifier* names)
Nonlocal(identifier* names)
Expr(expr value)
Pass | Break | Continue

-- XXX Jython will be different
-- col_offset is the byte offset in the utf8 string the parser uses
attributes (int lineno, int col_offset)

-- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
BinOp(expr left, operator op, expr right)
UnaryOp(unaryop op, expr operand)
Lambda(arguments args, expr body)
IfExp(expr test, expr body, expr orelse)
Dict(expr* keys, expr* values)
Set(expr* elts)
ListComp(expr elt, comprehension* generators)
SetComp(expr elt, comprehension* generators)
DictComp(expr key, expr value, comprehension* generators)
GeneratorExp(expr elt, comprehension* generators)
-- the grammar constrains where yield expressions can occur
Await(expr value)
Yield(expr? value)
YieldFrom(expr value)
-- need sequences for compare to distinguish
-- x < 4 < 3 and (x < 4) < 3
| Compare(expr left, cmpop* ops, expr* comparators)
| Call(expr func, expr* args, keyword* keywords)
| Num(object n) -- a number as a PyObject.
| Str(string s) -- need to specify raw, unicode, etc?
| Bytes(bytes s)
| NameConstant(singleton value)
| Ellipsis

-- the following expression can appear in an assignment context
| Attribute(expr value, identifier attr, expr_context ctx)
| Subscript(expr value, slice slice, expr_context ctx)
| Starred(expr value, expr_context ctx)
| Name(identifier id, expr_context ctx)
| List(expr* els, expr_context ctx)
| Tuple(expr* els, expr_context ctx)

-- col_offset is the byte offset in the utf8 string the parser uses
attributes (int lineno, int col_offset)

equiv_context = Load | Store | Del | AugLoad | AugStore

slice = Slice(expr? lower, expr? upper, expr? step)
| ExtSlice(slice* dims)
| Index(expr value)

boolop = And | Or

operator = Add | Sub | Mult | MatMult | Div | Mod | Pow | LShift | RShift | BitOr | BitXor | BitAnd

unaryop = Invert | Not | UAdd | USub

cmpop = Eq | NotEq | Lt | LtE | Gt | GtE | Is | IsNot | In | NotIn

comprehension = (expr target, expr iter, expr* ifs)
excepthandler = ExceptHandler(expr? type, identifier? name, stmt* body)

attributes (int lineno, int col_offset)

arguments = (arg* args, arg? vararg, arg* kwonly
arg? kwarg, expr* defaults)

arg = (identifier arg, expr? annotation)

attributes (int lineno, int col_offset)

-- keyword arguments supplied to call (NULL identifier for **kwargs)
keyword = (identifier? arg, expr value)

-- import name with optional 'as' alias.
alias = (identifier name, identifier? asname)

withitem = (expr context_expr, expr? optional_vars)

}
32.2.3. ast Helpers

Apart from the node classes, the ast module defines these utility functions and classes for traversing abstract syntax trees:

```python
ast.parse(source, filename='<unknown>', mode='exec')
```
Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

```python
ast.literal_eval(node_or_string)
```
Safely evaluate an expression node or a string containing a Python literal or container display. The string or node provided may only consist of the following Python literal structures: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, and None.

This can be used for safely evaluating strings containing Python values from untrusted sources without the need to parse the values oneself. It is not capable of evaluating arbitrarily complex expressions, for example involving operators or indexing.

*Changed in version 3.2:* Now allows bytes and set literals.

```python
ast.get_docstring(node, clean=True)
```
Return the docstring of the given node (which must be a FunctionDef, ClassDef or Module node), or None if it has no docstring. If clean is true, clean up the docstring’s indentation with `inspect.cleandoc()`.

```python
ast.fix_missing_locations(node)
```
When you compile a node tree with `compile()`, the compiler
expects lineno and col_offset attributes for every node that supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at node.

```
ast.increment_lineno(node, n=1)
```
Increment the line number of each node in the tree starting at node by \( n \). This is useful to “move code” to a different location in a file.

```
ast.copy_location(new_node, old_node)
```
Copy source location (lineno and col_offset) from old_node to new_node if possible, and return new_node.

```
ast.iter_fields(node)
```
Yield a tuple of (fieldname, value) for each field in node._fields that is present on node.

```
ast.iter_child_nodes(node)
```
Yield all direct child nodes of node, that is, all fields that are nodes and all items of fields that are lists of nodes.

```
ast.walk(node)
```
Recursively yield all descendant nodes in the tree starting at node (including node itself), in no specified order. This is useful if you only want to modify nodes in place and don’t care about the context.

```
class ast.NodeVisitor
```
A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This function may return a value which is forwarded by the visit() method.
This class is meant to be subclassed, with the subclass adding visitor methods.

**visit(node)**
Visit a node. The default implementation calls the method called `self.visit_classname` where `classname` is the name of the node class, or `generic_visit()` if that method doesn’t exist.

**generic_visit(node)**
This visitor calls `visit()` on all children of the node.

Note that child nodes of nodes that have a custom visitor method won’t be visited unless the visitor calls `generic_visit()` or visits them itself.

Don’t use the `NodeVisitor` if you want to apply changes to nodes during traversal. For this a special visitor exists (NodeTransformer) that allows modifications.

**class ast.NodeTransformer**
A `NodeVisitor` subclass that walks the abstract syntax tree and allows modification of nodes.

The `NodeTransformer` will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is `None`, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (foo) to `data['foo']:`
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return copy_location(Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Index(value=Str(s=node.id)),
            ctx=node.ctx), node)

Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the generic_visit() method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

Usually you use the transformer like this:

    node = YourTransformer().visit(node)

ast.dump(node, annotate_fields=True, include_attributes=False)

Return a formatted dump of the tree in node. This is mainly useful for debugging purposes. The returned string will show the names and the values for fields. This makes the code impossible to evaluate, so if evaluation is wanted annotate_fields must be set to False. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, include_attributes can be set to True.
32.3. `symtable` — Access to the compiler’s symbol tables

**Source code:** Lib/symtable.py

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. `symtable` provides an interface to examine these tables.
32.3.1. Generating Symbol Tables

`symtable.symtable(code, filename, compile_type)`

Return the toplevel SymbolTable for the Python source code. `filename` is the name of the file containing the code. `compile_type` is like the mode argument to `compile()`.
32.3.2. Examining Symbol Tables

```python
class symtable.SymbolTable
    A namespace table for a block. The constructor is not public.

    get_type()
    Return the type of the symbol table. Possible values are 'class', 'module', and 'function'.

    get_id()
    Return the table's identifier.

    get_name()
    Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or 'top' if the table is global (get_type() returns 'module').

    get_lineno()
    Return the number of the first line in the block this table represents.

    is_optimized()
    Return True if the locals in this table can be optimized.

    is_nested()
    Return True if the block is a nested class or function.

    has_children()
    Return True if the block has nested namespaces within it. These can be obtained with get_children().
```
has_exec()
    Return True if the block uses exec.

get_identifiers()
    Return a list of names of symbols in this table.

lookup(name)
    Lookup name in the table and return a Symbol instance.

get_symbols()
    Return a list of Symbol instances for names in the table.

get_children()
    Return a list of the nested symbol tables.

class symtable.Function
    A namespace for a function or method. This class inherits SymbolTable.

get_parameters()
    Return a tuple containing names of parameters to this function.

getlocals()
    Return a tuple containing names of locals in this function.

get_globals()
    Return a tuple containing names of globals in this function.

get_frees()
    Return a tuple containing names of free variables in this function.

class symtable.Class
A namespace of a class. This class inherits `SymbolTable`.

`get_methods()`  
Return a tuple containing the names of methods declared in the class.

`class symtable.Symbol`  
An entry in a `SymbolTable` corresponding to an identifier in the source. The constructor is not public.

`get_name()`  
Return the symbol's name.

`is_referenced()`  
Return True if the symbol is used in its block.

`is_imported()`  
Return True if the symbol is created from an import statement.

`is_parameter()`  
Return True if the symbol is a parameter.

`is_global()`  
Return True if the symbol is global.

`is_declared_global()`  
Return True if the symbol is declared global with a `global` statement.

`is_local()`  
Return True if the symbol is local to its block.

`is_free()`
Return True if the symbol is referenced in its block, but not assigned to.

**is_assigned()**
Return True if the symbol is assigned to in its block.

**is_namespace()**
Return True if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

For example:

```python
>>> table = symtable.symtable("def some_func():
>>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is True, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

**get_namespaces()**
Return a list of namespaces bound to this name.

**get_namespace()**
Return the namespace bound to this name. If more than one namespace is bound, `ValueError` is raised.

Created using Sphinx 1.3.1.
32.4. symbol — Constants used with Python parse trees

Source code: Lib/symbol.py

This module provides constants which represent the numeric values of internal nodes of the parse tree. Unlike most Python constants, these use lower-case names. Refer to the file Grammar/Grammar in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

This module also provides one additional data object:

```
symbol.sym_name
```

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.
32.5. **token** — Constants used with Python parse trees

**Source code: Lib/token.py**

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file Grammar/Grammar in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

**token.** *tok_name*

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

**token.** *ISTERMINAL*(x)

Return true for terminal token values.

**token.** *ISNONTERMINAL*(x)

Return true for non-terminal token values.

**token.** *ISEOF*(x)

Return true if x is the marker indicating the end of input.
The token constants are:

token.ENDMARKER
token.NAME
token.NUMBER
token.STRING
token.NEWLINE
token.INDENT
token.DEDENT
token.LPAR
token.RPAR
token.LSQB
token.RSQB
token.COLON
token.COMMA
token.SEMI
token.PLUS
token.MINUS
token.STAR
token.SLASH
token.VBAR
token.AMPER
token.LESS
token.GREATER
token.EQUAL
token.DOT
token.PERCENT
token.LBRACE
token.RBRACE
token.EQEQUAL
token.NOTEQUAL
token.LESSEQUAL
token.GREATEREQUAL
See also:

**Module** parser

The second example for the parser module shows how to use the symbol module.
This module allows a Python program to determine if a string is a keyword.

**keyword**.iskeyword(s)

Return true if s is a Python keyword.

**keyword**.kwlist

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular __future__ statements are in effect, these will be included as well.
32.7. `tokenize` — Tokenizer for Python source

**Source code:** Lib/tokenize.py

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers,” including colorizers for on-screen displays.

To simplify token stream handling, all `Operators` and `Delimiters` tokens are returned using the generic `token.OP` token type. The exact type can be determined by checking the `exact_type` property on the `named tuple` returned from `tokenize.tokenize()`.
32.7.1. Tokenizing Input

The primary entry point is a generator:

tokenize(tokenize(readline))

The `tokenize()` generator requires one argument, `readline`, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple (`srow, scol`) of ints specifying the row and column where the token begins in the source; a 2-tuple (`erow, ecol`) of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the logical line; continuation lines are included. The 5 tuple is returned as a named tuple with the field names: `type`, `string`, `start`, `end`, `line`.

The returned named tuple has an additional property named `exact_type` that contains the exact operator type for `token.OP` tokens. For all other token types `exact_type` equals the named tuple `type` field.

*Changed in version 3.1:* Added support for named tuples.

*Changed in version 3.3:* Added support for `exact_type`.

`tokenize()` determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to PEP 263.

All constants from the `token` module are also exported from
The `tokenize` function includes the following token type values:

- **tokenize.COMMENT**: Token value used to indicate a comment.
- **tokenize.NL**: Token value used to indicate a non-terminating newline. The NEWLINE token indicates the end of a logical line of Python code; NL tokens are generated when a logical line of code is continued over multiple physical lines.
- **tokenize.ENCODING**: Token value that indicates the encoding used to decode the source bytes into text. The first token returned by `tokenize()` will always be an ENCODING token.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

**tokenize.untokenize(iterable)**

Converts tokens back into Python source code. The `iterable` must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the ENCODING token, which is the first token sequence output by `tokenize()`.
**tokenize()** needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

**tokenize.** detect_encoding(readline)

The **detect_encoding()** function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, readline, in the same way as the **tokenize()** generator.

It will call readline a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in **PEP 263**. If both a BOM and a cookie are present, but disagree, a SyntaxError will be raised. Note that if the BOM is found, 'utf-8-sig' will be returned as an encoding.

If no encoding is specified, then the default of 'utf-8' will be returned.

Use **open()** to open Python source files: it uses **detect_encoding()** to detect the file encoding.

**tokenize.** open(filename)

Open a file in read only mode using the encoding detected by **detect_encoding()**.

*New in version 3.2.*

**exception** tokenize.**TokenError**

Raised when either a docstring or expression that may be split over
several lines is not completed anywhere in the file, for example:

```
"""Beginning of docstring
```

or:

```
[1,
  2,
  3
```

Note that unclosed single-quoted strings do not cause an error to be raised. They are tokenized as `ERRORTOKEN`, followed by the tokenization of their contents.
32.7.2. Command-Line Usage

*New in version 3.3.*

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

- **-h, --help**
  - show this help message and exit

- **-e, --exact**
  - display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.
32.7.3. Examples

Example of a script rewriter that transforms float literals into Decimal objects:

```python
from tokenize import tokenize, untokenize, NUMBER, STRING
from io import BytesIO

def decistmt(s):
    """Substitute Decimals for floats in a string of statements."

    >>> from decimal import Decimal
    >>> s = 'print(+21.3e-5*-.1234/81.7)'
    >>> decistmt(s)
    "print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7'))"

    The format of the exponent is inherited from the platform C library. Known cases are "e-007" (Windows) and "e-07" (not Windows). Since we're only showing 12 digits, and the 13th isn't close to 5, the rest of the output should be platform-independent.

    >>> exec(s) # doctest: +ELLIPSIS
    -3.21716034272e-0...7

    Output from calculations with Decimal should be identical across all platforms.

    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7

    ""

    result = []
g = tokenize(BytesIO(s.encode('utf-8')).readline)
for toknum, tokval, _, _, _ in g:
    if toknum == NUMBER and '.' in tokval:  # replace NUMBER tokens
        result.extend([...]
```
Example of tokenizing from the command line. The script:

```python
def say_hello():
    print("Hello, World!")
say_hello()
```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```
$ python -m tokenize hello.py
0,0-0,0: ENCODING 'utf-8'
1,0-1,3: NAME 'def'
1,4-1,13: NAME 'say_hello'
1,13-1,14: OP '('
1,14-1,15: OP ')
1,15-1,16: OP ':'
1,16-1,17: NEWLINE '\n'
2,0-2,4: INDENT '    '
2,4-2,9: NAME 'print'
2,9-2,10: OP '('
2,10-2,25: STRING '"Hello, World!"'
2,25-2,26: OP ')
2,26-2,27: NEWLINE '\n'
```
The exact token type names can be displayed using the -e option:

```bash
$ python -m tokenize -e hello.py
```

```
0,0-0,0: ENCODING 'utf-8'
1,0-1,3: NAME 'def'
1,4-1,13: NAME 'say_hello'
1,13-1,14: LPAR '
1,14-1,15: RPAR ')
1,15-1,16: COLON ':'
1,16-1,17: NEWLINE '
2,0-2,4: INDENT '
2,4-2,9: NAME 'print'
2,9-2,10: LPAR '
2,10-2,25: STRING "Hello, World!"
2,25-2,26: RPAR ')
2,26-2,27: NEWLINE '
3,0-3,1: NL '
4,0-4,0: DEDENT '
4,0-4,9: NAME 'say_hello'
4,9-4,10: LPAR '
4,10-4,11: RPAR ')
4,11-4,12: NEWLINE '
5,0-5,0: ENDMARKER '''
```
32.8. **tabnanny** — Detection of ambiguous indentation

**Source code:** Lib/tabnanny.py

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

**Note:** The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

`tabnanny.check(file_or_dir)`

If `file_or_dir` is a directory and not a symbolic link, then recursively descend the directory tree named by `file_or_dir`, checking all `.py` files along the way. If `file_or_dir` is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the `print()` function.

`tabnanny.verbose`

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

`tabnanny.filename_only`

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.
exception tabnanny. **NannyNag**

Raised by *tokeneater()* if detecting an ambiguous indent. Captured and handled in *check()*.

tabnanny. **tokeneater**(type, token, start, end, line)

This function is used by *check()* as a callback parameter to the function *tokenize.tokenize()*.

**See also:**

**Module tokenize**

Lexical scanner for Python source code.
The `pyclbr` module can be used to determine some limited information about the classes, methods and top-level functions defined in a module. The information provided is sufficient to implement a traditional three-pane class browser. The information is extracted from the source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyclbr.readmodule(module, path=None)`

Read a module and return a dictionary mapping class names to class descriptor objects. The parameter `module` should be the name of a module as a string; it may be the name of a module within a package. The `path` parameter should be a sequence, and is used to augment the value of `sys.path`, which is used to locate module source code.

`pyclbr.readmodule_ex(module, path=None)`

Like `readmodule()`, but the returned dictionary, in addition to mapping class names to class descriptor objects, also maps top-level function names to function descriptor objects. Moreover, if the module being read is a package, the key '__path__' in the returned dictionary has as its value a list which contains the package search path.
32.9.1. Class Objects

The Class objects used as values in the dictionary returned by \texttt{readmodule()} and \texttt{readmodule\_ex()} provide the following data attributes:

\textbf{Class.\texttt{module}}

The name of the module defining the class described by the class descriptor.

\textbf{Class.\texttt{name}}

The name of the class.

\textbf{Class.\texttt{super}}

A list of Class objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by \texttt{readmodule()} are listed as a string with the class name instead of as Class objects.

\textbf{Class.\texttt{methods}}

A dictionary mapping method names to line numbers.

\textbf{Class.\texttt{file}}

Name of the file containing the class statement defining the class.

\textbf{Class.\texttt{lineno}}

The line number of the class statement within the file named by \texttt{file}.
32.9.2. Function Objects

The Function objects used as values in the dictionary returned by `readmodule_ex()` provide the following attributes:

**Function.module**

The name of the module defining the function described by the function descriptor.

**Function.name**

The name of the function.

**Function.file**

Name of the file containing the `def` statement defining the function.

**Function.lineno**

The line number of the `def` statement within the file named by `file`.
32.10. **py_compile** — Compile Python source files

**Source code:** Lib/py_compile.py

The **py_compile** module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

**exception py_compile.PyCompileError**

Exception raised when an error occurs while attempting to compile the file.

**py_compile.compile(file, cfile=None, dfile=None, dorrase=False, optimize=-1)**

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file name `file`. The byte-code is written to `cfile`, which defaults to the PEP 3147/PEP 488 path, ending in `.pyc`. For example, if `file` is `/foo/bar/baz.py` `cfile` will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If `dfile` is specified, it is used as the name of the source file in error messages when instead of `file`. If `dorrase` is true, a **PyCompileError** is raised when an error is encountered while
compiling *file*. If *doraise* is false (the default), an error string is written to `sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever *cfile* value was used.

If the path that *cfile* becomes (either explicitly specified or computed) is a symlink or non-regular file, *FileExistsError* will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

*optimize* controls the optimization level and is passed to the built-in `compile()` function. The default of -1 selects the optimization level of the current interpreter.

*Changed in version 3.2:* Changed default value of *cfile* to be PEP 3147-compliant. Previous default was *file* + 'c' ('o' if optimization was enabled). Also added the *optimize* parameter.

*Changed in version 3.4:* Changed code to use *importlib* for the byte-code cache file writing. This means file creation/writing semantics now match what *importlib* does, e.g. permissions, write-and-move semantics, etc. Also added the caveat that *FileExistsError* is raised if *cfile* is a symlink or non-regular file.

**py_compile.main**(args=None)

Compile several source files. The files named in *args* (or on the command line, if *args* is None) are compiled and the resulting byte-code is cached in the normal manner. This function does not search a directory structure to locate source files; it only compiles
files named explicitly. If ' - ' is the only parameter in args, the list of files is taken from standard input.

*Changed in version 3.2:* Added support for ' - '.

When this module is run as a script, the `main()` is used to compile all the files named on the command line. The exit status is nonzero if one of the files could not be compiled.

**See also:**

**Module** **compileall**

Utilities to compile all Python source files in a directory tree.
32.11. `compileall` — Byte-compile Python libraries

**Source code:** `Lib/compileall.py`

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached bytecode files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.
32.11.1. Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

directory ...
file ...

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

-\l

Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

-\f

Force rebuild even if timestamps are up-to-date.

-\q

Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (-qq), all output is suppressed.

-\d destdir

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled into the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

-\x regex
regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

-\texttt{\textbf{i}} list
Read the file list and add each line that it contains to the list of files and directories to compile. If list is -, read lines from stdin.

-\texttt{\textbf{b}}
Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their \texttt{PEP 3147} locations and names, which allows byte-code files from multiple versions of Python to coexist.

-\texttt{\textbf{r}}
Control the maximum recursion level for subdirectories. If this is given, then -\texttt{l} option will not be taken into account. \texttt{python \textminus m compileall <directory> -r 0} is equivalent to \texttt{python \textminus m compileall <directory> -l}.

-\texttt{\textbf{j}} \texttt{N}
Use \texttt{N} workers to compile the files within the given directory. If 0 is used, then the result of \texttt{os.cpu_count()} will be used.

\textit{Changed in version 3.2:} Added the -\texttt{i}, -\texttt{b} and -\texttt{h} options.

\textit{Changed in version 3.5:} Added the -\texttt{j}, -\texttt{r}, and -\texttt{qq} options. -\texttt{q} option was changed to a multilevel value. -\texttt{b} will always produce a byte-code file ending in .\texttt{pyc}, never .\texttt{pyo}.

There is no command-line option to control the optimization level used by the \texttt{compile()} function, because the Python interpreter itself
already provides the option: `python -O -m compileall`. 
32.11.2. Public functions

```
compileall.compile_dir(dir, maxlevels=10, ddir=None, force=False, rx=None, quiet=0, legacy=False, optimize=-1, workers=1)
```

Recursively descend the directory tree named by `dir`, compiling all `.py` files along the way.

The `maxlevels` parameter is used to limit the depth of the recursion; it defaults to 10.

If `ddir` is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `force` is true, modules are re-compiled even if the timestamps are up to date.

If `rx` is given, its search method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped.

If `quiet` is False or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If `legacy` is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their PEP 3147 locations and names, which allows byte-code files from multiple versions of Python to coexist.
optimize specifies the optimization level for the compiler. It is passed to the built-in compile() function.

The argument workers specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can’t use multiple workers and workers argument is given, then sequential compilation will be used as a fallback. If workers is lower than 0, a `ValueError` will be raised.

*Changed in version 3.2:* Added the legacy and optimize parameter.

*Changed in version 3.5:* Added the workers parameter.

*Changed in version 3.5:* quiet parameter was changed to a multilevel value.

*Changed in version 3.5:* The legacy parameter only writes out .pyc files, not .pyo files no matter what the value of optimize is.

`compileall.compile_file(fullname, ddir=None, force=False, rx=None, quiet=0, legacy=False, optimize=-1)`

Compile the file with path `fullname`.

If `ddir` is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If `rx` is given, its search method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and True is returned.

If `quiet` is False or 0 (the default), the filenames and other
information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If legacy is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their PEP 3147 locations and names, which allows byte-code files from multiple versions of Python to coexist.

optimize specifies the optimization level for the compiler. It is passed to the built-in compile() function.

*New in version 3.2.*

*Changed in version 3.5: quiet parameter was changed to a multilevel value.*

*Changed in version 3.5: The legacy parameter only writes out .pyc files, not .pyo files no matter what the value of optimize is.*

**compileall.compile_path**

```python
compileall.compile_path(skip_curdir=True, maxlevels=0, force=False, quiet=0, legacy=False, optimize=-1)
```  
Byte-compile all the .py files found along sys.path. If skip_curdir is true (the default), the current directory is not included in the search. All other parameters are passed to the compile_dir() function. Note that unlike the other compile functions, maxlevels defaults to 0.

*Changed in version 3.2: Added the legacy and optimize parameter.*

*Changed in version 3.5: quiet parameter was changed to a multilevel value.*

*Changed in version 3.5: The legacy parameter only writes out...*
.pyc files, not .pyo files no matter what the value of optimize is.

To force a recompile of all the .py files in the Lib/ subdirectory and all its subdirectories:

```python
import compileall
closeall.compile_dir('Lib/', force=True)
```

```python
# Perform same compilation, excluding files in .svn
don't need.
import re
closeall.compile_dir('Lib/', rx=re.compile(r'[\/]\.svn'))
```

See also:

**Module py_compile**

Byte-compile a single source file.
32.12. **dis** — Disassembler for Python bytecode

**Source code:** Lib/dis.py

The *dis* module supports the analysis of CPython bytecode by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

**CPython implementation detail:** Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Example: Given the function `myfunc()`:

```python
def myfunc(alist):
    return len(alist)
```

the following command can be used to display the disassembly of `myfunc()`:

```bash
>>> dis.dis(myfunc)
   2           0 LOAD_GLOBAL    0 (len)
   3 LOAD_FAST    0 (alist)
   6 CALL_FUNCTION 1
   9 RETURN_VALUE
```

(The “2” is a line number).
32.12.1. Bytecode analysis

*New in version 3.4.*

The bytecode analysis API allows pieces of Python code to be wrapped in a `Bytecode` object that provides easy access to details of the compiled code.

```python
class dis.Bytecode(x, *, first_line=None, current_offset=None)
```

Analyse the bytecode corresponding to a function, generator, method, string of source code, or a code object (as returned by `compile()`).

This is a convenience wrapper around many of the functions listed below, most notably `get_instructions()`, as iterating over a `Bytecode` instance yields the bytecode operations as `Instruction` instances.

If `first_line` is not None, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If `current_offset` is not None, it refers to an instruction offset in the disassembled code. Setting this means `dis()` will display a “current instruction” marker against the specified opcode.

```python
classmethod from_traceback(tb)
```

Construct a `Bytecode` instance from the given traceback, setting `current_offset` to the instruction responsible for the exception.
**codeobj**

The compiled code object.

**first_line**

The first source line of the code object (if available)

**dis()**

Return a formatted view of the bytecode operations (the same as printed by `dis.dis()`, but returned as a multi-line string).

**info()**

Return a formatted multi-line string with detailed information about the code object, like `code_info()`.

Example:

```python
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
LOAD_GLOBAL
LOAD_FAST
CALL_FUNCTION
RETURN_VALUE
```
32.12.2. Analysis functions

The `dis` module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn’t useful:

`dis.code_info(x)`
Return a formatted multi-line string with detailed code object information for the supplied function, generator, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

*New in version 3.2.*

`dis.show_code(x, *, file=None)`
Print detailed code object information for the supplied function, method, source code string or code object to `file` (or `sys.stdout` if `file` is not specified).

This is a convenient shorthand for `print(code_info(x), file=file)`, intended for interactive exploration at the interpreter prompt.

*New in version 3.2.*

*Changed in version 3.4: Added `file` parameter.*

`dis.dis(x=None, *, file=None)`
Disassemble the \( x \) object. \( x \) can denote either a module, a class, a method, a function, a generator, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods. For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. Strings are first compiled to code objects with the \texttt{compile()}\ built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied \texttt{file} argument if provided and to \texttt{sys.stdout} otherwise.

\textit{Changed in version 3.4: Added \texttt{file} parameter.}

\texttt{dis.distb(tb=None, *, file=None)}

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied \texttt{file} argument if provided and to \texttt{sys.stdout} otherwise.

\textit{Changed in version 3.4: Added \texttt{file} parameter.}

\texttt{dis.disassemble(code, lasti=-1, *, file=None)}
\texttt{dis.disco(code, lasti=-1, *, file=None)}

Disassemble a code object, indicating the last instruction if \texttt{lasti} was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as \texttt{ -->},
3. a labelled instruction, indicated with \texttt{>>},
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied file argument if provided and to sys.stdout otherwise.

*Changed in version 3.4:* Added file parameter.

```python
dis.get_instructions(x, *, first_line=None)
```

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of Instruction named tuples giving the details of each operation in the supplied code.

If first_line is not None, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

*New in version 3.4.*

```python
dis.findlinestarts(code)
```

This generator function uses the co_firstlineno and co_lnotab attributes of the code object code to find the offsets which are starts of lines in the source code. They are generated as (offset, lineno) pairs.

```python
dis.findlabels(code)
```
Detect all offsets in the code object `code` which are jump targets, and return a list of these offsets.

```

dis.stack_effect(opcode[, oparg])
```

Compute the stack effect of `opcode` with argument `oparg`.

*New in version 3.4.*
32.12.3. Python Bytecode Instructions

The `get_instructions()` function and `Bytecode` class provide details of bytecode instructions as `Instruction` instances:

```python
class dis/Instruction

Details for a bytecode operation

opcode
numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the Opcode collections.

opname
human readable name for operation

arg
numeric argument to operation (if any), otherwise None

argval
resolved arg value (if known), otherwise same as arg

argrepr
human readable description of operation argument

offset
start index of operation within bytecode sequence

starts_line
line started by this opcode (if any), otherwise None

is_jump_target
True if other code jumps to here, otherwise False
```
New in version 3.4.

The Python compiler currently generates the following bytecode instructions.

**General instructions**

**NOP**

Do nothing code. Used as a placeholder by the bytecode optimizer.

**POP_TOP**

Removes the top-of-stack (TOS) item.

**ROT_TWO**

Swaps the two top-most stack items.

**ROT_THREE**

Lifts second and third stack item one position up, moves top down to position three.

**DUP_TOP**

Duplicates the reference on top of the stack.

**DUP_TOP_TWO**

Duplicates the two references on top of the stack, leaving them in the same order.

**Unary operations**

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY_POSITIVE**

Implements TOS = +TOS.
**UNARY_NEGATIVE**
Implements TOS = -TOS.

**UNARY_NOT**
Implements TOS = not TOS.

**UNARY_INVERT**
Implements TOS = ~TOS.

**GET_ITER**
Implements TOS = iter(TOS).

**GET_YIELD_FROM_ITER**
If TOS is a generator iterator or coroutine object it is left as is. Otherwise, implements TOS = iter(TOS).

*New in version 3.5.*

**Binary operations**

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

**BINARY_POWER**
Implements TOS = TOS1 ** TOS.

**BINARY_MULTIPLY**
Implements TOS = TOS1 * TOS.

**BINARY_MATRIX_MULTIPLY**
Implements TOS = TOS1 @ TOS.

*New in version 3.5.*
**BINARY_FLOOR_DIVIDE**

Implements TOS = TOS1 // TOS.

**BINARY_TRUE_DIVIDE**

Implements TOS = TOS1 / TOS.

**BINARY_MODULO**

Implements TOS = TOS1 % TOS.

**BINARY_ADD**

Implements TOS = TOS1 + TOS.

**BINARY_SUBTRACT**

Implements TOS = TOS1 - TOS.

**BINARY_SUBSCR**

Implements TOS = TOS1[TOS].

**BINARY_LSHIFT**

Implements TOS = TOS1 << TOS.

**BINARY_RSHIFT**

Implements TOS = TOS1 >> TOS.

**BINARY_AND**

Implements TOS = TOS1 & TOS.

**BINARY_XOR**

Implements TOS = TOS1 ^ TOS.

**BINARY_OR**

Implements TOS = TOS1 | TOS.
In-place operations

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

**INPLACE_POWER**
Implements in-place $TOS = TOS1 \times TOS$.

**INPLACE_MULTIPLY**
Implements in-place $TOS = TOS1 \times TOS$.

**INPLACE_MATRIX_MULTIPLY**
Implements in-place $TOS = TOS1 \times TOS$.

*New in version 3.5.*

**INPLACE_FLOOR_DIVIDE**
Implements in-place $TOS = TOS1 \div TOS$.

**INPLACE_TRUE_DIVIDE**
Implements in-place $TOS = TOS1 \div TOS$.

**INPLACE_MODULO**
Implements in-place $TOS = TOS1 \mod TOS$.

**INPLACE_ADD**
Implements in-place $TOS = TOS1 + TOS$.

**INPLACE_SUBTRACT**
Implements in-place $TOS = TOS1 - TOS$.

**INPLACE_LSHIFT**
Implements in-place TOS = TOS1 << TOS.

**INPLACE_RSHIFT**
Implements in-place TOS = TOS1 >> TOS.

**INPLACE_AND**
Implements in-place TOS = TOS1 & TOS.

**INPLACE_XOR**
Implements in-place TOS = TOS1 ^ TOS.

**INPLACE_OR**
Implements in-place TOS = TOS1 | TOS.

**STORE_SUBSCR**
Implements TOS1[TOS] = TOS2.

**DELETE_SUBSCR**
Implements del TOS1[TOS].

**Coroutine opcodes**

**GET_AWAITABLE**
Implements TOS = get_awaitable(TOS), where get_awaitable(o) returns o if o is a coroutine object or a generator object with the CO_ITERABLE_COROUTINE flag, or resolves o.__await__.

**GET_AITER**
Implements TOS = get_awaitable(TOS.__aiter__()). See GET_AWAITABLE for details about get_awaitable

**GET_ANEXT**
Implements `PUSH(get_awaitable(TOS.__anext__()))`. See `GET_AWAITABLE` for details about `get_awaitable`.

**BEFORE_ASYNC_WITH**
Resolves `__aenter__` and `__aexit__` from the object on top of the stack. Pushes `__aexit__` and result of `__aenter__()` to the stack.

**SETUP_ASYNC_WITH**
Creates a new frame object.

**Miscellaneous opcodes**

**PRINT_EXPR**
Implements the expression statement for the interactive mode. TOS is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with `POP_TOP`.

**BREAK_LOOP**
Terminates a loop due to a `break` statement.

**CONTINUE_LOOP**(target)
Continues a loop due to a `continue` statement. `target` is the address to jump to (which should be a `FOR_ITER` instruction).

**SET_ADD**(i)
Calls `set.add(TOS1[-i], TOS)`. Used to implement set comprehensions.

**LIST_APPEND**(i)
Calls `list.append(TOS[-i], TOS)`. Used to implement list comprehensions.
**MAP_ADD(i)**

Calls `dict.setitem(TOS1[-i], TOS, TOS1)`. Used to implement dict comprehensions.

For all of the **SET_ADD**, **LIST_APPEND** and **MAP_ADD** instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

**RETURN_VALUE**

Returns with TOS to the caller of the function.

**YIELD_VALUE**

Pops TOS and yields it from a generator.

**YIELD_FROM**

Pops TOS and delegates to it as a subiterator from a generator.

*New in version 3.3.*

**IMPORT_STAR**

Loads all symbols not starting with '_' directly from the module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

**POP_BLOCK**

Removes one block from the block stack. Per frame, there is a stack of blocks, denoting nested loops, try statements, and such.

**POP_EXCEPT**

Removes one block from the block stack. The popped block must be an exception handler block, as implicitly created when entering an except handler. In addition to popping extraneous values from
the frame stack, the last three popped values are used to restore
the exception state.

**END FINALLY**

Terminates a *finally* clause. The interpreter recalls whether the
exception has to be re-raised, or whether the function returns, and
continues with the outer-next block.

**LOAD_BUILD_CLASS**

Pushes `builtins.__build_class__()` onto the stack. It is
later called by `CALL_FUNCTION` to construct a class.

**SETUP_WITH**(*delta*)

This opcode performs several operations before a with block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_CLEANUP`. Then, `__enter__()` is called, and a finally block pointing to *delta* is pushed. Finally, the result of calling the enter method is pushed onto the stack. The next opcode will either ignore it (`POP_TOP`), or store it in (a) variable(s) (`STORE_FAST`, `STORE_NAME`, or `UNPACK_SEQUENCE`).

**WITH_CLEANUP_START**

 Cleans up the stack when a *with* statement block exits. TOS is the context manager’s `__exit__()` bound method. Below TOS are 1–3 values indicating how/why the finally clause was entered:

- SECOND = None
- (SECOND, THIRD) = (WHY_{{RETURN, CONTINUE}}), retval
- SECOND = WHY_*; no retval below it
- (SECOND, THIRD, FOURTH) = exc_info()

In the last case, TOS(SECOND, THIRD, FOURTH) is called,
otherwise TOS(None, None, None). Pushes SECOND and result of the call to the stack.

**WITH_CLEANUP_FINISH**

Pops exception type and result of ‘exit’ function call from the stack.

If the stack represents an exception, *and* the function call returns a ‘true’ value, this information is “zapped” and replaced with a single WHY_SILENCED to prevent **END_FINALLY** from re-raising the exception. (But non-local gotos will still be resumed.)

All of the following opcodes expect arguments. An argument is two bytes, with the more significant byte last.

**STORE_NAME**(namei)

Implements name = TOS. namei is the index of name in the attribute co_names of the code object. The compiler tries to use **STORE_FAST** or **STORE_GLOBAL** if possible.

**DELETE_NAME**(namei)

Implements del name, where namei is the index into co_names attribute of the code object.

**UNPACK_SEQUENCE**(count)

Unpacks TOS into count individual values, which are put onto the stack right-to-left.

**UNPACK_EX**(counts)

Implements assignment with a starred target: Unpacks an iterable in TOS into individual values, where the total number of values can be smaller than the number of items in the iterable: one the new values will be a list of all leftover items.
The low byte of \textit{counts} is the number of values before the list value, the high byte of \textit{counts} the number of values after it. The resulting values are put onto the stack right-to-left.

\textbf{STORE\_ATTR}(namei)
Implementes TOS.name = TOS1, where namei is the index of name in co_names.

\textbf{DELETE\_ATTR}(namei)
Implementes del TOS.name, using namei as index into co_names.

\textbf{STORE\_GLOBAL}(namei)
Works as \textbf{STORE\_NAME}, but stores the name as a global.

\textbf{DELETE\_GLOBAL}(namei)
Works as \textbf{DELETE\_NAME}, but deletes a global name.

\textbf{LOAD\_CONST}(consti)
Pushes co_consts[consti] onto the stack.

\textbf{LOAD\_NAME}(namei)
Pushes the value associated with co_names[namei] onto the stack.

\textbf{BUILD\_TUPLE}(count)
Creates a tuple consuming \textit{count} items from the stack, and pushes the resulting tuple onto the stack.

\textbf{BUILD\_LIST}(count)
Works as \textbf{BUILD\_TUPLE}, but creates a list.
**BUILD_SET**(count)

Works as **BUILD_TUPLE**, but creates a set.

**BUILD_MAP**(count)

Pushes a new dictionary object onto the stack. The dictionary is pre-sized to hold *count* entries.

**LOAD_ATTR**(namei)

Replaces TOS with `getattr(TOS, co_names[namei])`.

**COMPARE_OP**(opname)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

**IMPORT_NAME**(namei)

Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the `fromlist` and `level` arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent **STORE_FAST** instruction modifies the namespace.

**IMPORT_FROM**(namei)

Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a **STORE_FAST** instruction.

**JUMP_FORWARD**(delta)

Increments bytecode counter by *delta*.

**POP_JUMP_IF_TRUE**(target)

If TOS is true, sets the bytecode counter to *target*. TOS is popped.
**POP_JUMP_IF_FALSE**(*target*)

If TOS is false, sets the bytecode counter to *target*. TOS is popped.

**JUMP_IF_TRUE_OR_POP**(*target*)

If TOS is true, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

**JUMP_IF_FALSE_OR_POP**(*target*)

If TOS is false, sets the bytecode counter to *target* and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

**JUMP_ABSOLUTE**(*target*)

Set bytecode counter to *target*.

**FOR_ITER**(*delta*)

TOS is an *iterator*. Call its **_next_** method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted TOS is popped, and the byte code counter is incremented by *delta*.

**LOAD_GLOBAL**(*namei*)

Loads the global named co_names[*namei*] onto the stack.

**SETUP_LOOP**(*delta*)

Pushes a block for a loop onto the block stack. The block spans from the current instruction with a size of *delta* bytes.

**SETUP_EXCEPT**(*delta*)

Pushes a try block from a try-except clause onto the block stack. *delta* points to the first except block.

**SETUP_FINALLY**(*delta*)

Pushes a try block from a try-except clause onto the block stack.
\(\text{delta}\) points to the finally block.

**LOAD\_FAST(var\_num)**

Pushes a reference to the local co\_varnames[var\_num] onto the stack.

**STORE\_FAST(var\_num)**

Stores TOS into the local co\_varnames[var\_num].

**DELETE\_FAST(var\_num)**

Deletes local co\_varnames[var\_num].

**LOAD\_CLOSURE(i)**

Pushes a reference to the cell contained in slot \(i\) of the cell and free variable storage. The name of the variable is co\_cellvars[i] if \(i\) is less than the length of co\_cellvars. Otherwise it is co\_freevars[i - len(co\_cellvars)].

**LOAD\_DEREF(i)**

Loads the cell contained in slot \(i\) of the cell and free variable storage. Pushes a reference to the object the cell contains on the stack.

**LOAD\_CLASSDEREF(i)**

Much like **LOAD\_DEREF** but first checks the locals dictionary before consulting the cell. This is used for loading free variables in class bodies.

**STORE\_DEREF(i)**

Stores TOS into the cell contained in slot \(i\) of the cell and free variable storage.
DELETE_DEREF(i)

Empties the cell contained in slot i of the cell and free variable storage. Used by the `del` statement.

RAISE_VARARGS(argc)

Raises an exception. `argc` indicates the number of parameters to the raise statement, ranging from 0 to 3. The handler will find the traceback as TOS2, the parameter as TOS1, and the exception as TOS.

CALL_FUNCTION(argc)

Calls a function. The low byte of `argc` indicates the number of positional parameters, the high byte the number of keyword parameters. On the stack, the opcode finds the keyword parameters first. For each keyword argument, the value is on top of the key. Below the keyword parameters, the positional parameters are on the stack, with the right-most parameter on top. Below the parameters, the function object to call is on the stack. Pops all function arguments, and the function itself off the stack, and pushes the return value.

MAKE_FUNCTION(argc)

Pushes a new function object on the stack. From bottom to top, the consumed stack must consist of

- `argc & 0xFF` default argument objects in positional order
- `(argc >> 8) & 0xFF` pairs of name and default argument, with the name just below the object on the stack, for keyword-only parameters
- `(argc >> 16) & 0x7FFF` parameter annotation objects
- a tuple listing the parameter names for the annotations (only if there are any annotation objects)
- the code associated with the function (at TOS1)
• the qualified name of the function (at TOS)

MAKE_CLOSURE(argc)

Creates a new function object, sets its __closure__ slot, and pushes it on the stack. TOS is the qualified name of the function, TOS1 is the code associated with the function, and TOS2 is the tuple containing cells for the closure’s free variables. argc is interpreted as in MAKE_FUNCTION; the annotations and defaults are also in the same order below TOS2.

BUILD_SLICE(argc)

Pushes a slice object on the stack. argc must be 2 or 3. If it is 2, slice(TOS1, TOS) is pushed; if it is 3, slice(TOS2, TOS1, TOS) is pushed. See the slice() built-in function for more information.

EXTENDED_ARG(ext)

Prefixes any opcode which has an argument too big to fit into the default two bytes. ext holds two additional bytes which, taken together with the subsequent opcode’s argument, comprise a four-byte argument, ext being the two most-significant bytes.

CALL_FUNCTION_VAR(argc)

Calls a function. argc is interpreted as in CALL_FUNCTION. The top element on the stack contains the variable argument list, followed by keyword and positional arguments.

CALL_FUNCTION_KW(argc)

Calls a function. argc is interpreted as in CALL_FUNCTION. The top element on the stack contains the keyword arguments dictionary, followed by explicit keyword and positional arguments.
**CALL_FUNCTION_VAR_KW**(argc)

Calls a function. *argc* is interpreted as in **CALL_FUNCTION**. The top element on the stack contains the keyword arguments dictionary, followed by the variable-arguments tuple, followed by explicit keyword and positional arguments.

**HAVE_ARGUMENT**

This is not really an opcode. It identifies the dividing line between opcodes which don’t take arguments < HAVE_ARGUMENT and those which do >= HAVE_ARGUMENT.
32.12.4. Opcode collections

These collections are provided for automatic introspection of bytecode instructions:

**dis.opname**
Sequence of operation names, indexable using the bytecode.

**dis.opmap**
Dictionary mapping operation names to bytecodes.

**dis.cmp_op**
Sequence of all compare operation names.

**dis.hasconst**
Sequence of bytecodes that have a constant parameter.

**dis.hasfree**
Sequence of bytecodes that access a free variable (note that ‘free’ in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes).

**dis.hasname**
Sequence of bytecodes that access an attribute by name.

**dis.hasjrel**
Sequence of bytecodes that have a relative jump target.

**dis.hasjabs**
Sequence of bytecodes that have an absolute jump target.
dis.**haslocal**
Sequence of bytecodes that access a local variable.

dis.**hascompare**
Sequence of bytecodes of Boolean operations.
32.13. pickletools — Tools for pickle developers

Source code: Lib/pickletools.py

This module contains various constants relating to the intimate details of the pickle module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the pickle; ordinary users of the pickle module probably won't find the pickletools module relevant.
32.13.1. Command line usage

New in version 3.2.

When invoked from the command line, python -m pickletools will disassemble the contents of one or more pickle files. Note that if you want to see the Python object stored in the pickle rather than the details of pickle format, you may want to use -m pickle instead. However, when the pickle file that you want to examine comes from an untrusted source, -m pickletools is a safer option because it does not execute pickle bytecode.

For example, with a tuple (1, 2) pickled in file x.pickle:

```
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
  0: \x80 PROTO 3
  2: K BININT1 1
  4: K BININT1 2
  6: \x86 TUPLE2
  7: q BININPUT 0
  9: . STOP
highest protocol among opcodes = 2
```
Name of a file where the output should be written.

- **l**, **--indentlevel**=<num>
  The number of blanks by which to indent a new MARK level.

- **m**, **--memo**
  When multiple objects are disassembled, preserve memo between disassemblies.

- **p**, **--preamble**=<preamble>
  When more than one pickle file are specified, print given preamble before each disassembly.
32.13.2. Programmatic Interface

```python
define pickletools.dis(pickle, out=None, memo=None, indentlevel=4, annotate=0)
```

Outputs a symbolic disassembly of the pickle to the file-like object `out`, defaulting to `sys.stdout`. `pickle` can be a string or a file-like object. `memo` can be a Python dictionary that will be used as the pickle’s memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by MARK opcodes in the stream, are indented by `indentlevel` spaces. If a nonzero value is given to `annotate`, each opcode in the output is annotated with a short description. The value of `annotate` is used as a hint for the column where annotation should start.

*New in version 3.2:* The `annotate` argument.

```python
define pickletools.genops(pickle)
```

Provides an iterator over all of the opcodes in a pickle, returning a sequence of `(opcode, arg, pos)` triples. `opcode` is an instance of an OpcodeInfo class; `arg` is the decoded value, as a Python object, of the opcode’s argument; `pos` is the position at which this opcode is located. `pickle` can be a string or a file-like object.

```python
define pickletools.optimize(picklestring)
```

Returns a new equivalent pickle string after eliminating unused PUT opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.
33. Miscellaneous Services

The modules described in this chapter provide miscellaneous services that are available in all Python versions. Here's an overview:

- **33.1. formatter — Generic output formatting**
  - 33.1.1. The Formatter Interface
  - 33.1.2. Formatter Implementations
  - 33.1.3. The Writer Interface
  - 33.1.4. Writer Implementations
33.1. **formatter** — Generic output formatting

*Deprecated since version 3.4:* Due to lack of usage, the formatter module has been deprecated.

This module supports two interface definitions, each with multiple implementations: The *formatter* interface, and the *writer* interface which is required by the formatter interface.

Formatter objects transform an abstract flow of formatting events into specific output events on writer objects. Formatters manage several stack structures to allow various properties of a writer object to be changed and restored; writers need not be able to handle relative changes nor any sort of “change back” operation. Specific writer properties which may be controlled via formatter objects are horizontal alignment, font, and left margin indentations. A mechanism is provided which supports providing arbitrary, non-exclusive style settings to a writer as well. Additional interfaces facilitate formatting events which are not reversible, such as paragraph separation.

Writer objects encapsulate device interfaces. Abstract devices, such as file formats, are supported as well as physical devices. The provided implementations all work with abstract devices. The interface makes available mechanisms for setting the properties which formatter objects manage and inserting data into the output.
33.1.1. The Formatter Interface

Interfaces to create formatters are dependent on the specific formatter class being instantiated. The interfaces described below are the required interfaces which all formatters must support once initialized.

One data element is defined at the module level:

formatter.AS_IS

Value which can be used in the font specification passed to the push_font() method described below, or as the new value to any other push_property() method. Pushing the AS_IS value allows the corresponding pop_property() method to be called without having to track whether the property was changed.

The following attributes are defined for formatter instance objects:

formatter.writer

The writer instance with which the formatter interacts.

formatter.end_paragraph(blanklines)

Close any open paragraphs and insert at least blanklines before the next paragraph.

formatter.add_line_break()

Add a hard line break if one does not already exist. This does not break the logical paragraph.

formatter.add_hor_rule(*args, **kw)

Insert a horizontal rule in the output. A hard break is inserted if there is data in the current paragraph, but the logical paragraph is not broken. The arguments and keywords are passed on to the
writer's `send_line_break()` method.

**formatter.add_flowing_data(data)**

Provide data which should be formatted with collapsed whitespace. Whitespace from preceding and successive calls to `add_flowing_data()` is considered as well when the whitespace collapse is performed. The data which is passed to this method is expected to be word-wrapped by the output device. Note that any word-wrapping still must be performed by the writer object due to the need to rely on device and font information.

**formatter.add_literal_data(data)**

Provide data which should be passed to the writer unchanged. Whitespace, including newline and tab characters, are considered legal in the value of `data`.

**formatter.add_label_data(format, counter)**

Insert a label which should be placed to the left of the current left margin. This should be used for constructing bulleted or numbered lists. If the `format` value is a string, it is interpreted as a format specification for `counter`, which should be an integer. The result of this formatting becomes the value of the label; if `format` is not a string it is used as the label value directly. The label value is passed as the only argument to the writer’s `send_label_data()` method. Interpretation of non-string label values is dependent on the associated writer.

Format specifications are strings which, in combination with a counter value, are used to compute label values. Each character in the format string is copied to the label value, with some characters recognized to indicate a transform on the counter value. Specifically, the character '1' represents the counter value...
formatter as an Arabic number, the characters 'A' and 'a' represent alphabetic representations of the counter value in upper and lower case, respectively, and 'I' and 'i' represent the counter value in Roman numerals, in upper and lower case. Note that the alphabetic and roman transforms require that the counter value be greater than zero.

**formatter.flush_softspace()**
Send any pending whitespace buffered from a previous call to **add_flowing_data()** to the associated writer object. This should be called before any direct manipulation of the writer object.

**formatter.push_alignment(align)**
Push a new alignment setting onto the alignment stack. This may be **AS_IS** if no change is desired. If the alignment value is changed from the previous setting, the writer's **new_alignment()** method is called with the **align** value.

**formatter.pop_alignment()**
Restore the previous alignment.

**formatter.push_font((size, italic, bold, teletype))**
Change some or all font properties of the writer object. Properties which are not set to **AS_IS** are set to the values passed in while others are maintained at their current settings. The writer’s **new_font()** method is called with the fully resolved font specification.

**formatter.pop_font()**
Restore the previous font.

**formatter.push_margin(margin)**
Increase the number of left margin indentations by one, associating the logical tag `margin` with the new indentation. The initial margin level is 0. Changed values of the logical tag must be true values; false values other than `AS_IS` are not sufficient to change the margin.

```python
formatter.pop_margin()
Restore the previous margin.
```

```python
formatter.push_style(*styles)
Push any number of arbitrary style specifications. All styles are pushed onto the styles stack in order. A tuple representing the entire stack, including `AS_IS` values, is passed to the writer's `new_styles()` method.
```

```python
formatter.pop_style(n=1)
Pop the last `n` style specifications passed to `push_style()`. A tuple representing the revised stack, including `AS_IS` values, is passed to the writer's `new_styles()` method.
```

```python
formatter.set_spacing(spacing)
Set the spacing style for the writer.
```

```python
formatter.assert_line_data(flag=1)
Inform the formatter that data has been added to the current paragraph out-of-band. This should be used when the writer has been manipulated directly. The optional `flag` argument can be set to false if the writer manipulations produced a hard line break at the end of the output.
```
33.1.2. Formatter Implementations

Two implementations of formatter objects are provided by this module. Most applications may use one of these classes without modification or subclassing.

```python
class formatter.NullFormatter(writer=None)
    A formatter which does nothing. If writer is omitted, a NullWriter instance is created. No methods of the writer are called by NullFormatter instances. Implementations should inherit from this class if implementing a writer interface but don't need to inherit any implementation.
```

```python
class formatter(AbstractFormatter(writer)
    The standard formatter. This implementation has demonstrated wide applicability to many writers, and may be used directly in most circumstances. It has been used to implement a full-featured World Wide Web browser.
```
33.1.3. The Writer Interface

Interfaces to create writers are dependent on the specific writer class being instantiated. The interfaces described below are the required interfaces which all writers must support once initialized. Note that while most applications can use the AbstractFormatter class as a formatter, the writer must typically be provided by the application.

writer.flush()
Flush any buffered output or device control events.

writer.new_alignment(align)
Set the alignment style. The align value can be any object, but by convention is a string or None, where None indicates that the writer’s “preferred” alignment should be used. Conventional align values are 'left', 'center', 'right', and 'justify'.

writer.new_font(font)
Set the font style. The value of font will be None, indicating that the device’s default font should be used, or a tuple of the form (size, italic, bold, teletype). Size will be a string indicating the size of font that should be used; specific strings and their interpretation must be defined by the application. The italic, bold, and teletype values are Boolean values specifying which of those font attributes should be used.

writer.new_margin(margin, level)
Set the margin level to the integer level and the logical tag to margin. Interpretation of the logical tag is at the writer’s discretion; the only restriction on the value of the logical tag is that it not be a false value for non-zero values of level.
writer.new_spacing(spacing)
    Set the spacing style to spacing.

writer.new_styles(styles)
    Set additional styles. The styles value is a tuple of arbitrary values; the value AS_IS should be ignored. The styles tuple may be interpreted either as a set or as a stack depending on the requirements of the application and writer implementation.

writer.send_line_break()
    Break the current line.

writer.send_paragraph(blankline)
    Produce a paragraph separation of at least blankline blank lines, or the equivalent. The blankline value will be an integer. Note that the implementation will receive a call to send_line_break() before this call if a line break is needed; this method should not include ending the last line of the paragraph. It is only responsible for vertical spacing between paragraphs.

writer.send_hor_rule(*args, **kw)
    Display a horizontal rule on the output device. The arguments to this method are entirely application- and writer-specific, and should be interpreted with care. The method implementation may assume that a line break has already been issued via send_line_break().

writer.send_flowing_data(data)
    Output character data which may be word-wrapped and re-flowed as needed. Within any sequence of calls to this method, the writer may assume that spans of multiple whitespace characters have been collapsed to single space characters.
**writer.send_literal_data(data)**

Output character data which has already been formatted for display. Generally, this should be interpreted to mean that line breaks indicated by newline characters should be preserved and no new line breaks should be introduced. The data may contain embedded newline and tab characters, unlike data provided to the send_formatted_data() interface.

**writer.send_label_data(data)**

Set data to the left of the current left margin, if possible. The value of data is not restricted; treatment of non-string values is entirely application- and writer-dependent. This method will only be called at the beginning of a line.
33.1.4. Writer Implementations

Three implementations of the writer object interface are provided as examples by this module. Most applications will need to derive new writer classes from the NullWriter class.

class formatter.NullWriter
    A writer which only provides the interface definition; no actions are taken on any methods. This should be the base class for all writers which do not need to inherit any implementation methods.

class formatter.AbstractWriter
    A writer which can be used in debugging formatters, but not much else. Each method simply announces itself by printing its name and arguments on standard output.

class formatter.DumbWriter(file=None, maxcol=72)
    Simple writer class which writes output on the file object passed in as file or, if file is omitted, on standard output. The output is simply word-wrapped to the number of columns specified by maxcol. This class is suitable for reflowing a sequence of paragraphs.
34. MS Windows Specific Services

This chapter describes modules that are only available on MS Windows platforms.

- **34.1. msilib** — Read and write Microsoft Installer files
  - 34.1.1. Database Objects
  - 34.1.2. View Objects
  - 34.1.3. Summary Information Objects
  - 34.1.4. Record Objects
  - 34.1.5. Errors
  - 34.1.6. CAB Objects
  - 34.1.7. Directory Objects
  - 34.1.8. Features
  - 34.1.9. GUI classes
  - 34.1.10. Precomputed tables

- **34.2. msvcr** — Useful routines from the MS VC++ runtime
  - 34.2.1. File Operations
  - 34.2.2. Console I/O
  - 34.2.3. Other Functions

- **34.3. winreg** — Windows registry access
  - 34.3.1. Functions
  - 34.3.2. Constants
    - 34.3.2.1. HKEY_* Constants
    - 34.3.2.2. Access Rights
      - 34.3.2.2.1. 64-bit Specific
    - 34.3.2.3. Value Types
  - 34.3.3. Registry Handle Objects

- **34.4. winsound** — Sound-playing interface for Windows
34.1. *msilib* — Read and write Microsoft Installer files

The *msilib* supports the creation of Microsoft Installer (.msi) files. Because these files often contain an embedded “cabinet” file (.cab), it also exposes an API to create CAB files. Support for reading .cab files is currently not implemented; read support for the .msi database is possible.

This package aims to provide complete access to all tables in an .msi file, therefore, it is a fairly low-level API. Two primary applications of this package are the *distutils* command *bdist_msi*, and the creation of Python installer package itself (although that currently uses a different version of *msilib*).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

**msilib.FCICreate(cabname, files)**

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.
msilib.UuidCreate()

Return the string representation of a new unique identifier. This wraps the Windows API functions UuidCreate() and UuidToString().

msilib.OpenDatabase(path, persist)

Return a new database object by calling MsiOpenDatabase. path is the file name of the MSI file; persist can be one of the constants MSIDBOPEN_CREATEDIRECT, MSIDBOPEN_CREATE, MSIDBOPEN_DIRECT, MSIDBOPEN_READONLY, or MSIDBOPEN_TRANSACT, and may include the flag MSIDBOPEN_PATCHFILE. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

msilib.CreateRecord(count)

Return a new record object by calling MSICreateRecord(). count is the number of fields of the record.

msilib.init_database(name, schema, ProductName, ProductCode, ProductVersion, Manufacturer)

Create and return a new database name, initialize it with schema, and set the properties ProductName, ProductCode, ProductVersion, and Manufacturer.

schema must be a module object containing tables and _Validation_records attributes; typically, msilib.schema should be used.

The database will contain just the schema and the validation records when this function returns.
msilib.add_data(database, table, records)
Add all records to the table named table in database.

The table argument must be one of the predefined tables in the MSI schema, e.g. 'Feature', 'File', 'Component', 'Dialog', 'Control', etc.

records should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, None can be passed.

Field values can be ints, strings, or instances of the Binary class.

class msilib.Binary(filename)
 Represents entries in the Binary table; inserting such an object using add_data() reads the file named filename into the table.

msilib.add_tables(database, module)
Add all table content from module to database. module must contain an attribute tables listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

msilib.add_stream(database, name, path)
Add the file path into the _Stream table of database, with the stream name name.

msilib.gen_uuid()
Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in upper-case).

See also: FCICreateFile UuidCreate UuidToString
34.1.1. Database Objects

Database.**OpenView**(sql)

Return a view object, by calling MSIDatabaseOpenView(). *sql* is the SQL statement to execute.

Database.**Commit**()

Commit the changes pending in the current transaction, by calling MSIDatabaseCommit().

Database.**GetSummaryInformation**(count)

Return a new summary information object, by calling MsiGetSummaryInformation(). *count* is the maximum number of updated values.

**See also:** MSIDatabaseOpenView MSIDatabaseCommit MsiGetSummaryInformation
34.1.2. View Objects

View.**Execute**(params)
Execute the SQL query of the view, through MSIViewExecute(). If *params* is not None, it is a record describing actual values of the parameter tokens in the query.

View.**GetColumnInfo**(kind)
Return a record describing the columns of the view, through calling MsiViewGetColumnInfo(). *kind* can be either MSICOLINFO_NAMES or MSICOLINFO_TYPES.

View.**Fetch**()
Return a result record of the query, through calling MsiViewFetch().

View.**Modify**(kind, data)
Modify the view, by calling MsiViewModify(). *kind* can be one of MSIMODIFY_SEEK, MSIMODIFY_REFRESH, MSIMODIFY_INSERT, MSIMODIFY_UPDATE, MSIMODIFY_ASSIGN, MSIMODIFY_REPLACE, MSIMODIFY_MERGE, MSIMODIFY_DELETE, MSIMODIFY_INSERT_TEMPORARY, MSIMODIFY_VALIDATE, MSIMODIFY_VALIDATE_NEW, MSIMODIFY_VALIDATE_FIELD, or MSIMODIFY_VALIDATE_DELETE.

*data* must be a record describing the new data.

View.**Close**()
Close the view, through MsiViewClose().
See also:  MsiViewExecute MSIViewGetColumnInfo MsiViewFetch MsiViewModify MsiViewClose
34.1.3. Summary Information Objects

SummaryInformation.GetProperty(field)

Return a property of the summary, through MsiSummaryInfoGetProperty(). field is the name of the property, and can be one of the constants PID_CODEPAGE, PID_TITLE, PID_SUBJECT, PID_AUTHOR, PID_KEYWORDS, PID_COMMENTS, PID_TEMPLATE, PID_LASTAUTHOR, PID_REVNNUMBER, PID_LASTPRINTED, PID_CREATE_DTM, PID_LASTSAVE_DTM, PID_PAGECOUNT, PID_WORDCOUNT, PID_CHARCOUNT, PID_APPNAME, or PID_SECURITY.

SummaryInformation.GetPropertyCount()

Return the number of summary properties, through MsiSummaryInfoGetPropertyCount().

SummaryInformation.SetProperty(field, value)

Set a property through MsiSummaryInfoSetProperty(). field can have the same values as in GetProperty(), value is the new value of the property. Possible value types are integer and string.

SummaryInformation.Persistent()

Write the modified properties to the summary information stream, using MsiSummaryInfoPersist().

See also: MsiSummaryInfoGetProperty
MsiSummaryInfoGetPropertyCount MsiSummaryInfoSetProperty
MsiSummaryInfoPersist
34.1.4. Record Objects

Record.\texttt{GetFieldCount}()
Return the number of fields of the record, through MsiRecordGetFieldCount().

Record.\texttt{GetInteger}(field)
Return the value of \texttt{field} as an integer where possible. \texttt{field} must be an integer.

Record.\texttt{GetString}(field)
Return the value of \texttt{field} as a string where possible. \texttt{field} must be an integer.

Record.\texttt{SetString}(field, value)
Set \texttt{field} to \texttt{value} through MsiRecordSetString(). \texttt{field} must be an integer; \texttt{value} a string.

Record.\texttt{SetStream}(field, value)
Set \texttt{field} to the contents of the file named \texttt{value}, through MsiRecordSetStream(). \texttt{field} must be an integer; \texttt{value} a string.

Record.\texttt{SetInteger}(field, value)
Set \texttt{field} to \texttt{value} through MsiRecordSetInteger(). Both \texttt{field} and \texttt{value} must be an integer.

Record.\texttt{ClearData}()
Set all fields of the record to 0, through MsiRecordClearData().

\textbf{See also: } MsiRecordGetFieldCount MsiRecordSetString MsiRecordSetStream MsiRecordSetInteger MsiRecordClear
34.1.5. Errors

All wrappers around MSI functions raise MsiError; the string inside the exception will contain more detail.
34.1.6. CAB Objects

class msilib.CAB(name)

The class CAB represents a CAB file. During MSI construction, files will be added simultaneously to the Files table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

name is the name of the CAB file in the MSI file.

append(full, file, logical)

Add the file with the pathname full to the CAB file, under the name logical. If there is already a file named logical, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

commit(database)

Generate a CAB file, add it as a stream to the MSI file, put it into the Media table, and remove the generated file from the disk.
34.1.7. Directory Objects

class msilib.Directory(database, cab, basedir, physical, logical, default[, componentflags])

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through start_component(), or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be None), the path to the physical directory, and a logical directory name. default specifies the DefaultDir slot in the directory table. componentflags specifies the default flags that new components get.

start_component(component=None, feature=None, flags=None, keyfile=None, uuid=None)

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no feature is given, the current feature is used. If no flags are given, the directory’s default flags are used. If no keyfile is given, the KeyPath is left null in the Component table.

add_file(file, src=None, version=None, language=None)

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the src file is specified, it is interpreted relative to the current directory. Optionally, a version and a language can be specified for the entry in the File table.
**glob**(pattern, exclude=None)

Add a list of files to the current component as specified in the glob pattern. Individual files can be excluded in the exclude list.

**remove_pyc()**

Remove .pyc/.pyo files on uninstall.

**See also:** Directory Table File Table Component Table FeatureComponents Table
34.1.8. Features

```python
class msilib.Feature(db, id, title, desc, display, level=1, 
parent=None, directory= None, attributes=0)
```

Add a new record to the Feature table, using the values `id`, 
`parent.id`, `title`, `desc`, `display`, `level`, `directory`, and `attributes`. The 
resulting feature object can be passed to the 
`start_component()` method of `Directory`.

**set_current()**

Make this feature the current feature of `msilib`. New 
components are automatically added to the default feature, 
unless a feature is explicitly specified.

**See also:** Feature Table
msilib provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided; use bdist_msi to create MSI files with a user-interface for installing Python packages.

```python
class msilib.Control(dlg, name)
    Base class of the dialog controls. `dlg` is the dialog object the control belongs to, and `name` is the control's name.

    event(event, argument, condition=1, ordering=None)
        Make an entry into the ControlEvent table for this control.

    mapping(event, attribute)
        Make an entry into the EventMapping table for this control.

    condition(action, condition)
        Make an entry into the ControlCondition table for this control.
```

```python
class msilib.RadioButtonGroup(dlg, name, property)
    Create a radio button control named `name`. `property` is the installer property that gets set when a radio button is selected.

    add(name, x, y, width, height, text, value=None)
        Add a radio button named `name` to the group, at the coordinates `x, y, width, height`, and with the label `text`. If `value` is None, it defaults to `name`.
```

```python
class msilib.Dialog(db, name, x, y, w, h, attr, title, first, default, cancel)
```
Return a new Dialog object. An entry in the Dialog table is made, with the specified coordinates, dialog attributes, title, name of the first, default, and cancel controls.

control\(\text{name}, \text{type}, x, y, width, height, attributes, property, text, control\_next, help\)

Return a new Control object. An entry in the Control table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

text\(\text{name}, x, y, width, height, attributes, text\)

Add and return a Text control.

bitmap\(\text{name}, x, y, width, height, text\)

Add and return a Bitmap control.

line\(\text{name}, x, y, width, height\)

Add and return a Line control.

pushbutton\(\text{name}, x, y, width, height, attributes, text, next\_control\)

Add and return a PushButton control.

radiogroup\(\text{name}, x, y, width, height, attributes, property, text, next\_control\)

Add and return a RadioButtonGroup control.

checkbox\(\text{name}, x, y, width, height, attributes, property, text, next\_control\)

Add and return a CheckBox control.

ControlCondition Table ControlEvent Table EventMapping Table
RadioButton Table
34.1.10. Precomputed tables

`msilib` provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

`msilib.schema`

This is the standard MSI schema for MSI 2.0, with the `tables` variable providing a list of table definitions, and `_Validation_records` providing the data for MSI validation.

`msilib.sequence`

This module contains table contents for the standard sequence tables: `AdminExecuteSequence`, `AdminUISequence`, `AdvtExecuteSequence`, `InstallExecuteSequence`, and `InstallUISequence`.

`msilib.text`

This module contains definitions for the UIText and ActionText tables, for the standard installer actions.
34.2. msvcr1 – Useful routines from the MS VC++ runtime

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the getpass module uses this in the implementation of the getpass() function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used wherever possible.

*Changed in version 3.3:* Operations in this module now raise OSError where IOError was raised.
34.2.1. File Operations

**`msvcrtd.locking(fd, mode, nbytes)`**

Lock part of a file based on file descriptor `fd` from the C runtime. Raises `OSError` on failure. The locked region of the file extends from the current file position for `nbytes` bytes, and may continue beyond the end of the file. `mode` must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

**`msvcrtd.LK_LOCK`**

**`msvcrtd.LK_RLCK`**

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, `OSError` is raised.

**`msvcrtd.LK_NBLCK`**

**`msvcrtd.LK_NBRLCK`**

Locks the specified bytes. If the bytes cannot be locked, `OSError` is raised.

**`msvcrtd.LK_UNLCK`**

Unlocks the specified bytes, which must have been previously locked.

**`msvcrtd.setmode(fd, flags)`**

Set the line-end translation mode for the file descriptor `fd`. To set it to text mode, `flags` should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`. 
msvcrt.\texttt{open\_osfhandle}(\textit{handle}, \textit{flags})

Create a C runtime file descriptor from the file handle \textit{handle}. The \textit{flags} parameter should be a bitwise OR of \texttt{os.0\_APPEND}, \texttt{os.0\_RDONLY}, and \texttt{os.0\_TEXT}. The returned file descriptor may be used as a parameter to \texttt{os.fdopen()} to create a file object.

msvcrt.\texttt{get\_osfhandle}(\textit{fd})

Return the file handle for the file descriptor \textit{fd}. Raises \texttt{OSError} if \textit{fd} is not recognized.
34.2.2. Console I/O

**msvcrth.kbhit()**
Return true if a keypress is waiting to be read.

**msvcrth.getch()**
Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for Enter to be pressed. If the pressed key was a special function key, this will return '\000' or '\xe0'; the next call will return the keycode. The Control-C keypress cannot be read with this function.

**msvcrth.getwch()**
Wide char variant of **getch()**, returning a Unicode value.

**msvcrth.getche()**
Similar to **getch()**, but the keypress will be echoed if it represents a printable character.

**msvcrth.getwche()**
Wide char variant of **getche()**, returning a Unicode value.

**msvcrth.putch(char)**
Print the byte string **char** to the console without buffering.

**msvcrth.putwch(unicode_char)**
Wide char variant of **putch()**, accepting a Unicode value.

**msvcrth.ungetchar(char)**
Cause the byte string **char** to be “pushed back” into the console
buffer; it will be the next character read by \texttt{getch()} or \texttt{getche()}.

\texttt{msvcrt.ungetwch(unicode\_char)}

Wide char variant of \texttt{ungetch()}, accepting a Unicode value.
34.2.3. Other Functions

**msvcrt.heapmin()**

Force the malloc() heap to clean itself up and return unused blocks to the operating system. On failure, this raises **OSError**.
34.3. **winreg** – Windows registry access

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a handle object is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

*Changed in version 3.3:* Several functions in this module used to raise a `WindowsError`, which is now an alias of `OSError`.
34.3.1. Functions

This module offers the following functions:

**winreg.CloseKey(hkey)**

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

*Note:* If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

**winreg.ConnectRegistry(computer_name, key)**

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

*computer_name* is the name of the remote computer, of the form *r"\\computername"*. If *None*, the local computer is used.

*key* is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

*Changed in version 3.3:* See *above*.

**winreg.CreateKey(key, sub_key)**

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY_* constants.
sub_key is a string that names the key this method opens or creates.

If key is one of the predefined keys, sub_key may be None. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an OSError exception is raised.

*Changed in version 3.3:* See above.

winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)

Creates or opens the specified key, returning a handle object.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the key this method opens or creates.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is KEY_WRITE. See Access Rights for other allowed values.

If key is one of the predefined keys, sub_key may be None. In that case, the handle returned is the same key handle passed in to the function.
If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an OSError exception is raised.

*New in version 3.2.*

*Changed in version 3.3:* See above.

```
winreg.DeleteKey(key, sub_key)
```

Deletes the specified key.

`key` is an already open key, or one of the predefined HKEY_* constants.

`sub_key` is a string that must be a subkey of the key identified by the `key` parameter. This value must not be None, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an OSError exception is raised.

*Changed in version 3.3:* See above.

```
winreg.DeleteKeyEx(key, sub_key, access=KEY_WOW64_64KEY, reserved=0)
```

Deletes the specified key.
